Legal Disclaimer

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics. With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation, warranties of non-infringement of intellectual property rights of any third party.

Information

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (**www.infineon.com**).

Warnings

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office.

Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

TC21x/TC22x/TC23x User's Manual

Revision History: V1.1 2014-12

Significant changes since previous version: TC22x/TC23x Family User's Manual V1.0, 2014-01

Chapter	Subjects (major changes since last revision)
–	• "TC21x" added to headlines and title.
Introduction	Introduction, Table "Overview of TC22x/TC23x Family Devices": • Added LFBGA-292 package option to TC23x-ADAS. • Added TQFP-144 package option to TC21x. • Added SAL package option to all devices.
SCU/CCU	• Removed documentation of internal oscillator load caps ("adjustable Load Caps") as these are not implemented.
SCU/SCU	• Corrected DTSCON.CAL width. • Removed design related register reference from "OCDS Behavior of WDTs".
MTU	• MCONTROL.Res4 field (bits 14:12) marked as "Must be written with 0x4" in to maintain redundancy. • Sections "Reading a Single Memory Location" and "Writing a Single Memory Location" should always write MCONTROL with the MS nibble 0x4 instead of 0x0. • Design related register reference "RDR" removed.

TC21x/TC22x/TC23x User's Manual

Revision History: V1.1 2014-12

SMU	• Corrected register long name of SMU_RTC to "Recovery Timer Configuration". • DMA alarm ALM2[24] is now reserved. Alarm implemented by DMA SRI error detection alarms. • Improved description of alarm ALM3[27]. • SCU alarm ALM3[28] is now reserved. Feature not implemented. • Pre-alarms PreAlarm[129=DMA.(Safety FF Error Detection)] and PreAlarm[130=PMU.(Safety FF Error Detection)] removed because DMA and PMU do not implement Safety FF. • Added configuration hints to SMU_AG<n>CF<m> Registers: reserved alarms shall be configured as "No Action". • Enhanced description of register SMU_RMEF and SMU_RMSTS. • Enhanced description of register SMU_PCTL with advice how to operate it in the application. • Changed section "SMU Integration Guidelines". • Explained "Register Monitor" = "Safety Flip-Flop". • Improved Figure "SMU State Machine". • Improved section "FSP Fault State".

TC21x/TC22x/TC23x User's Manual

Revision History: V1.1 2014-12

PMU/Flash	• Repeated the advice to handle PVER as signal to jump to the next word-line in the receipe for the Robust EEPROM emulation. Previously this advice was only contained in the section "Handling Errors During Operation". • Showed the ECC decoder of the BootROM in the block diagram and described its SEC-DED capability. • Highlighted in the description of FCON and the wait cycle description that after System Resets and Power-On Resets the wait cycles are only sufficient for 100 MHz. • Noted in the "Application Hints" that the recommended sequence for issuing "Verify Erased Logical Sector Range" is analog to "Erase". • Changed recommendations in the "Application Hints" for ECC test patterns. Made the all-0/all-1 and address error patterns optional. Recommended to store 2 of the 4 pattern sets inverse to the other 2. • Improved description of "Load Page" to make the offsets used for 32-bit transfers more explicit. • Added to the description of "Write Page" the clear statement that each page shall be programmed only once. • Noted that "Verify Erased Logical Sector Range" is not blocked on password containing UCBs when the protection is disabled. • Removed confusing statement that unavailable DFlash ranges can be programmed to all-1. • Noted explicitly that the UCBs 8 to 11 are read-only. • Clarified that both "Write Page" and "Write Burst" can be used to program UCBs. • Removed statement about restricted FAR capabilities. • Removed note from "Erase Logical Sector Range" that warned from erasing more than 256 KByte because of increased suspend times. The suspend times are not increasing. • Changed note for "Erase Logical Sector Range" that described that erase time can be much shorter than maximum times documented in the Data Sheet. The reason was removed as there are more dependencies. • Documented "Test Pass Marker" in UCB_IFX. • Removed term "Reset Class" and replaced by named resets. • Stated explicitly that a failed HSM boot prevents device boot.
DMA	• Added address alignment rules to address registers.

TC21x/TC22x/TC23x User's Manual

Revision History: V1.1 2014-12

IR	• Added clarification: a pending Service Request is cleared in the Service Request Node with the Acknowledge from the Service Provider. The Acknowledge does not mean that the Service Request is serviced at that time (e.g. disabled or not implemented DMA channel, Trap on CPU prevents execution of Service Request). • Added description of the ECC algorithm used for the IR internal Error Detection.
OCDS	• Replaced detailed OCDS chapter with overview chapter. OCDS and Emulation functionality is described in separate documentation.
ASCLIN	• Block "Auto Baud Rate Operation" added. • Description of register field "BRD.MEASURED" improved.
QSPI	• Removed maximum baud rates from feature list as these depend on pad speeds and PCB implementation.
MultiCAN+	• Added additional text on Section Transmitter Delay Compensation to describe more details on secondary sample point implementation. • Added on footnote of Table Minimum Operating Frequencies for CAN FD "When message objects are configured as transmit or receive FIFO structures i.e MOFCRn.MMC = 0001/0010, only the base object of 1 is counted towards the minimum frequency requirement, all other slave objects on the FIFO do not count towards the minimum frequency requirement. • Under Section "Data Frames" abbreviation added for FDF, BRS, ESI bit. • Under Section "Transceiver Delay Compensation", amended from "measured Transmitter Delay" to "measured loop delay". • All reference to EDL is renamed to FDF, register bit MOFCR.EDL is renamed to MOFCR.FDF, functionality remains the same. • Changed CAN FD descriptions to customer relevant information. • Fixed pad naming for all devices. • CRC issue of CAN FD standard documented and recommended additional software CRC.
SENT	• Changed minimum tick timer to 0.2 µs. • Changed "Extended Serial Data Frame" to "Enhanced Serial Message Frame". Updated its description.

TC21x/TC22x/TC23x User's Manual

Revision History: V1.1 2014-12

GTM	• Corrected/added wiring tables for QFP-80. • Corrected description of CLK_SEL field of GTM_DTMx_CTRL registers.
CCU6	• Changed signal name "VADC_G0BFL3" to "VADCG0BFL3" for consistency with VADC chapter (no functional change).

About this Document

This User's Manual describes the Infineon TC21x/TC22x/TC23x family, a family of 32-bit microcontroller DSPs based on the Infineon TriCore Architecture.

The term "TC21x/TC22x/TC23x" generally refers to the following devices:

- TC21x
- TC22x
- TC23x
- TC23x ADAS

This document is designed to be read primarily by design engineers and software engineers who need a detailed description of the interactions of the TC21x/TC22x/TC23x functional units, registers, instructions, and exceptions.

This TC21x/TC22x/TC23x User's Manual describes the features of the TC21x/TC22x/TC23x with respect to the TriCore Architecture. Where the TC21x/TC22x/TC23x directly implements TriCore architectural functions, this manual simply refers to those functions as features of the TC21x/TC22x/TC23x. In all cases where this manual describes a TC21x/TC22x/TC23x feature without referring to the TriCore Architecture, this means that the TC21x/TC22x/TC23x is a direct implementation of the TriCore Architecture.

Where the TC21x/TC22x/TC23x implements a subset of TriCore architectural features, this manual describes the TC21x/TC22x/TC23x implementation, and then describes how it differs from the TriCore Architecture. Such differences between the TC21x/TC22x/TC23x and the TriCore Architecture are documented in the section covering each such subject.

Note: This document describes the maximum feature set of the TC21x/TC22x/TC23x family. Some features or characteristics may not be available in each device version. For an overview of common and key differentiating features see ***Table 1****.*

Related Documentation

A complete description of the TriCore architecture is found in the document entitled "TriCore Architecture Manual". The architecture of the TC21x/TC22x/TC23x is described separately this way because of the configurable nature of the TriCore specification: Different versions of the architecture may contain a different mix of systems components. The TriCore architecture, however, remains constant across all derivative designs in order to preserve compatibility.

This TC21x/TC22x/TC23x Target Specification together with the "TriCore Architecture Manual" is required to understand the complete TC21x/TC22x/TC23x microcontroller functionality.

Text Conventions

This document uses the following text conventions for named components of the TC21x/TC22x/TC23x:

- Functional units of the TC21x/TC22x/TC23x are given in plain UPPER CASE. For example: “The QSPI supports full-duplex and half-duplex synchronous communication”.
- Pins using negative logic are indicated by an overline. For example: “The external reset pin, $\overline{ESR0}$, has a dual function.”.
- Bit fields and bits in registers are in general referenced as “Module_Register name.Bit field” or “Module_Register name.Bit”. For example: “The Current CPU Priority Number bit field CPU_ICR.CCPN is cleared”. Most of the register names contain a module name prefix, separated by an underscore character “_” from the actual register name (for example, “QSPI0_GLOBALCON”, where “QSPI0” is the module name prefix, and “GLOBALCON” is the kernel register name). In chapters describing the kernels of the peripheral modules, the registers are mainly referenced with their kernel register names. The peripheral module implementation sections mainly refer to the actual register names with module prefixes.
- Variables used to describe sets of processing units or registers appear in mixed upper and lower cases. For example, register name “MOFCRn” refers to multiple “MOFCR” registers with variable n. The bounds of the variables are always given where the register expression is first used (for example, “n = 0-255”), and are repeated as needed in the rest of the text.
- The default radix is decimal. Hexadecimal constants are suffixed with a subscript letter “H”, as in 100_H. Binary constants are suffixed with a subscript letter “B”, as in: 111_B.
- When the extent of register fields, groups register bits, or groups of pins are collectively named in the body of the document, they are represented as “NAME[A:B]”, which defines a range for the named group from B to A. Individual bits, signals, or pins are given as “NAME[C]” where the range of the variable C is given in the text. For example: CFG[2:0] and SRPN[0].
- Units are abbreviated as follows:
  - **MHz** = Megahertz
  - **µs** = Microseconds
  - **kBaud, kbit** = 1000 characters/bits per second
  - **MBaud, Mbit** = 1000000 characters/bits per second
  - **Kbyte, KB** = 1024 bytes of memory
  - **Mbyte**, MB = 1048576 bytes of memory

    In general, the k prefix scales a unit by 1000 whereas the K prefix scales a unit by 1024. Hence, the Kbyte unit scales the expression preceding it by 1024. The kBaud unit scales the expression preceding it by 1000. The M prefix scales by 1,000,000 or 1048576, and µ scales by .000001. For example, 1 Kbyte is 1024 bytes, 1 Mbyte is 1024 × 1024 bytes, 1 kBaud/kbit are 1000 characters/bits

per second, 1 MBaud/Mbit are 1000000 characters/bits per second, and 1 MHz is 1000000 Hz.

- Data format quantities are defined as follows:
  - **Byte** = 8-bit quantity
  - **Half-word** = 16-bit quantity
  - **Word** = 32-bit quantity
  - **Double-word** = 64-bit quantity

Abbreviations and Acronyms

The following acronyms and terms are used in this document:

ADC	Analog-to-Digital Converter
ALU	Arithmetic and Logic Unit
ASCLIN	Asynchronous/Synchronous Serial Controller with LIN
BCU	Bus Control Unit
BROM	Boot ROM & Test ROM
CAN	Controller Area Network
CCU6	Capture Compare Unit 6
CCU	Clock Control Unit
CPS	CPU Slave Interface
CPU	Central Processing Unit
CRC	Cyclic Redundancy Code
CSA	Context Save Area
CSFR	Core Special Function Register
DAP	Device Access Port
DAS	Device Access Server
DCACHE	Data Cache
DFLASH	Data Flash Memory
DMA	Direct Memory Access
DMI	Data Memory Interface
DSPR	Data Scratch Pad RAM
ECC	Error Correction Code
EEC	Emulation Extension Chip
EMI	Electro-Magnetic Interference

E-Ray	Flexray Controller
EVR	Embedded Voltage Regulator
FCS	Flash Command State Machine
FM-PLL	PLL with Frequency Modulation support
FPI	Flexible Peripheral Interconnect (Bus protocol)
FPU	Floating Point Unit
GPIO	General Purpose Input/Output
GPR	General Purpose Register
GPT12	General Purpose Timer 12
GTM	Generic Timer Module
PCACHE	Program Cache
I2C	Inter-Integrated Circuit Controller
IFX	Infineon Technologies AG
I/O	Input / Output
IOM	I/O Monitor Unit
JTAG	Joint Test Action Group = IEEE1149.1
LIN	Local Interconnect Network
LMU	Local Bus Memory Unit
MBIST	Memory Build In Self Test
MCHK	Memory Checker module
MMU	Memory Management Unit
MSB	Most Significant Bit
MTU	Memory Test Unit
MultiCAN+	Enhanced Multiple CAN controller
NC	Not Connected
NMI	Non-Maskable Interrupt
OCDS	On-Chip Debug Support
OVRAM	Overlay Memory
PLL	Phase Locked Loop
PCACHE	Program Cache
PFLASH	Program Flash Memory
PMI	Program Memory Interface

PSPR	Program Scratch Pad RAM
QSPI	Queued SPI Controller
RAM	Random Access Memory
RISC	Reduced Instruction Set Computing
SBCU	System Peripheral Bus Control Unit
SCU	System Control Unit
SENT	Single Edge Nibble Transmission
SFI	Shared Resource Interconnect to FPI Bus Interface (SFI Bridge)
SFR	Special Function Register
SMU	Safety Management Unit
SPB	System Peripheral Bus (based on FPI protocol)
SPD	Single Pin DAP
SPI	Synchronous Serial Controller
SRAM	Static Data Memory
SRI	Shared Resource Interconnect
SRN	Service Request Node
STM	System Timer
SWD	Supply Watchdog
TC1.6E	TriCore CPU 1.6 (High Efficiency variant)
VADC	Versatile Analog-to-Digital Converter
WDT	Watchdog Timer

1 Introduction

This User's Manual describes the Infineon TC21x/TC22x/TC23x family, a family of 32-bit microcontroller DSPs based on the Infineon TriCore Architecture.

The term "TC21x/TC22x/TC23x" generally refers to the following devices:

- TC21x
- TC22x
- TC23x
- TC23x ADAS

1.1 System Architecture of the TC21x/TC22x/TC23x

The TC21x/TC22x/TC23x combines three powerful technologies within one silicon die, achieving new levels of power, speed, and economy for embedded applications:

- Reduced Instruction Set Computing (RISC) processor architecture
- Digital Signal Processing (DSP) operations and addressing modes
- On-chip memories and peripherals

DSP operations and addressing modes provide the computational power necessary to efficiently analyse complex real-world signals. The RISC load/store architecture provides high computational bandwidth with low system cost. On-chip memory and peripherals are designed to support even the most demanding high-bandwidth real-time embedded control-systems tasks.

Additional high-level features of the TC21x/TC22x/TC23x include:

- Efficient memory organization: instruction and data scratch memories, caches
- Serial communication interfaces – flexible synchronous and asynchronous modes
- DMA Controller – DMA operations and interrupt servicing
- Flexible interrupt system – configurable interrupt priorities and targets
- General-purpose timers
- High-performance on-chip buses
- On-chip debugging and emulation facilities
- Flexible interconnections to external components
- Flexible power-management

The TC21x/TC22x/TC23x is a high-performance microcontroller with one TriCore CPU, program and data memories, buses, bus arbitration, interrupt system, DMA controller and a powerful set of on-chip peripherals. The TC21x/TC22x/TC23x is designed to meet the needs of the most demanding embedded control systems applications where the competing issues of price/performance, real-time responsiveness, computational power, data bandwidth, and power consumption are key design elements.

The TC21x/TC22x/TC23x offers several versatile on-chip peripheral units such as serial controllers, timer units, and analog-to-digital converters. Within the TC21x/TC22x/TC23x, all these peripheral units are connected to the TriCore CPU /

system via the System Peripheral Bus (SPB) and the Shared Resource Interconnect (SRI). Several I/O lines on the TC21x/TC22x/TC23x ports are reserved for these peripheral units to communicate with the external world.

1.1.1 TC21x/TC22x/TC23x Block Diagram

Figure 1 shows the block diagram of the TC21x/TC22x/TC23x product device (PD) and the TC23x ADAS device. Please note that not all features that are shown in the block diagram are available in all TC21x/TC22x/TC23x variants.

Emulation devices (ED) contain additional components. A block diagram can be found in separate documentation.

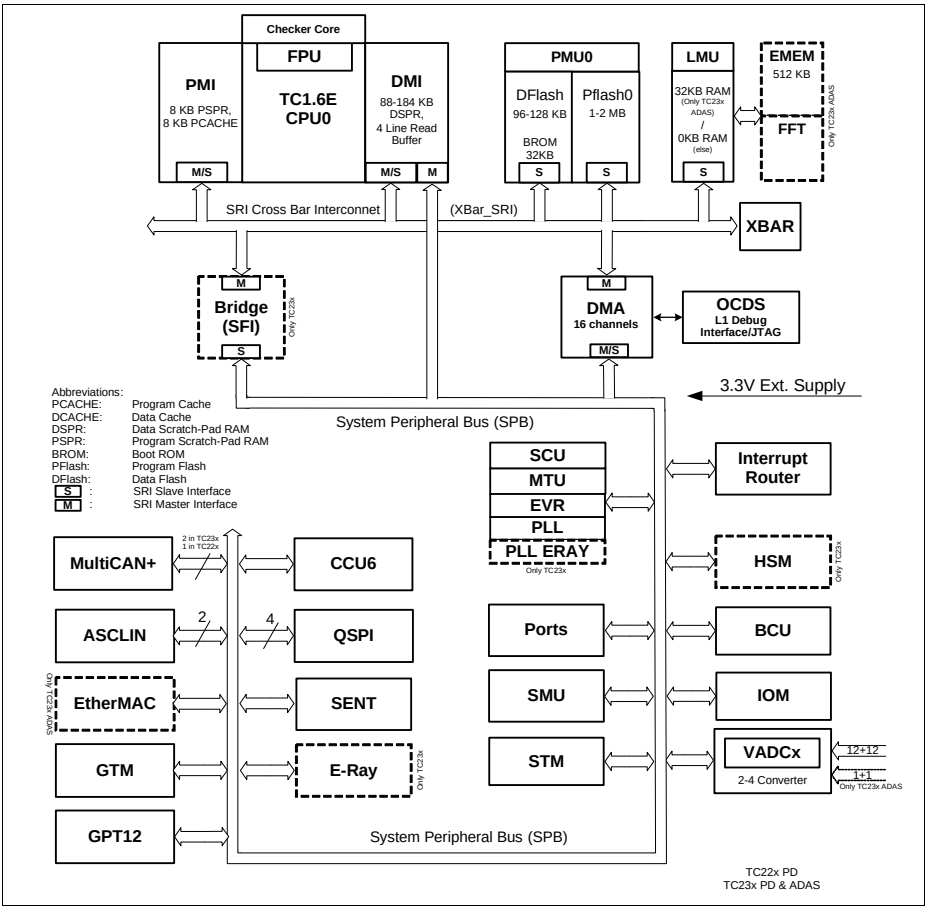

Figure 1 TC21x/TC22x/TC23x Block Diagram

1.1.2 Device Variants

Table 1 contains a comparative overview of the devices of the TC21x/TC22x/TC23x Family including TC21x as derivate of the TC22x. Additional derivates with different feature set might be specified. The feature set of a certain derivate is documented in its Data Sheet or Data Sheet Addendum.

Table 1 Overview of TC21x/TC22x/TC23x Family Devices

Feature		TC21x	TC22x	TC23x	TC23x ADAS
CPU Core	Type	TC1.6E			
	Cores / Checker Cores	1 / 1[1)]		1 / 1	
	Max. Freq.	133 MHz		200 MHz	
	FPU	yes			
	MPU	yes			
Program Flash	Size	512 Kbyte	1 Mbyte	2 Mbyte	
Data Flash	Size	64 Kbyte	96 Kbyte	128 Kbyte	
Cache	Instruction	8 Kbyte			
	Data	4 line read buffer			
SRAM	Size (DSPR/PSPR)	48 / 8 Kbyte	88 / 8 Kbyte	184 / 8 Kbyte	
	Size LMU	0 Kbyte			32 Kbyte
	Size EMEM	0 Kbyte			512 Kbyte
DMA	Channels	16			
ADC (SAR)	Voltage range	0 … 5.5 V (determined by ADC supply)			
	Inputs	24			
	Converters	2			4
	Resolution	12 Bits			
	Channels	12 + 12			12 + 12 + overlay 1 + 1

Table 1 Overview of TC21x/TC22x/TC23x Family Devices (cont'd)

Feature		TC21x	TC22x	TC23x	TC23x ADAS
GTM	TIM	1 (8 input channels)			
	TOM	2 (in sum up to 32 PWM channels)			
	ATOM / MCS	0 / 0			
	CMU / ICM	1 / 1			
	PSM	0			
	TBU	1			
	SPE	0			
	CMP / MON	0 / 0			
	BRC / DPLL	0 / 0			
	DTM	2			
Timer	GPT12	1			
	CCU6	1 module with 2 kernels			
STM	Modules	1			
FlexRay	Modules	–		1	
	Channels	–		2	
CAN	Modules	1		2	
	Nodes	3		3 per module	
	Message Objects	128		128 per module	
	CAN FD	yes		yes (in both modules)	
	Debug over CAN	yes		yes (only in CAN, not in CAN1 module)	
QSPI	Modules	4			
	Speed	up to 20 MBaud on dedicated pins (4 interfaces)			
ASCLIN	Interfaces	2			
SENT	Channels	4			
Ethernet	Channels	0			1
ASIL	Level	up to ASIL-D			
Safety support	SMU	1			
	IOM	1			

Table 1 Overview of TC21x/TC22x/TC23x Family Devices (cont'd)

Feature		TC21x	TC22x	TC23x	TC23x ADAS
FFT		0			1
HSIC (High Speed Input Capture)	Channels	2			
Security	HSM	0		1	
Embedded Voltage Regulator	Type	LDO from 3.3 V to 1.3 V		LDO and switched capacitor DCDC from 3.3 V to 1.3 V	
Low Power Feature	Standby RAM	DSPR			
	Wakeup Timer	yes			
Packages	Type (Pitch)	TQFP-80, TQFP-100, TQFP-144 (all 0.4mm)	TQFP-80, TQFP-100, TQFP-144 (all 0.4mm)	TQFP-100, TQFP-144 (all 0.4mm), LFBGA-292 (0.8mm)	TQFP-144 (0.4mm) LFBGA-292 (0.8mm)
I/O	Voltage	3.3V CMOS (5V input supported on ADC pins)			
$T_{ambient}$	Range (SAK)	−40 … +125°C			
	Range (SAL)	−40 … +150°C			
Clocking	System PLL with FM capability	yes			
	ERAY PLL	no		yes	
	Internal Load Caps C1/C2	None implemented.			

1) Some derivates without checker core.

2 Package Characteristics

This chapter gives a short overview about the package concepts and characteristics of the AURIX microcontroller family. Further package related parameters and characteristics may also be found in the corresponding sections of chapter “Electrical Specification” and/or in the Data Sheet.

The AURIX devices will be based on a family concept regarding compatible port mapping and compatible pinout / ballout between family devices in the same package. Both QFP packages (for devices with lower pin count) as well as BGA packages (for devices with higher pin count) and bare die variants will be offered according to customer requirements.

2.1 Feature List

- Lead free packages
- QFP and BGA package variants (BGA currently not planned for TC22x)
- Moisture Level 3 (JEDEC) or better
- Bare die versions (currently not planned for TC21x/TC22x/TC23x)
- EMC and ESD behavior according to automotive requirements

3 On-Chip System Buses and Bus Bridges

The TC21x/TC22x/TC23x has two independent on-chip buses:

- Shared Resource Interconnect (SRI)
- System Peripheral Bus (SPB)

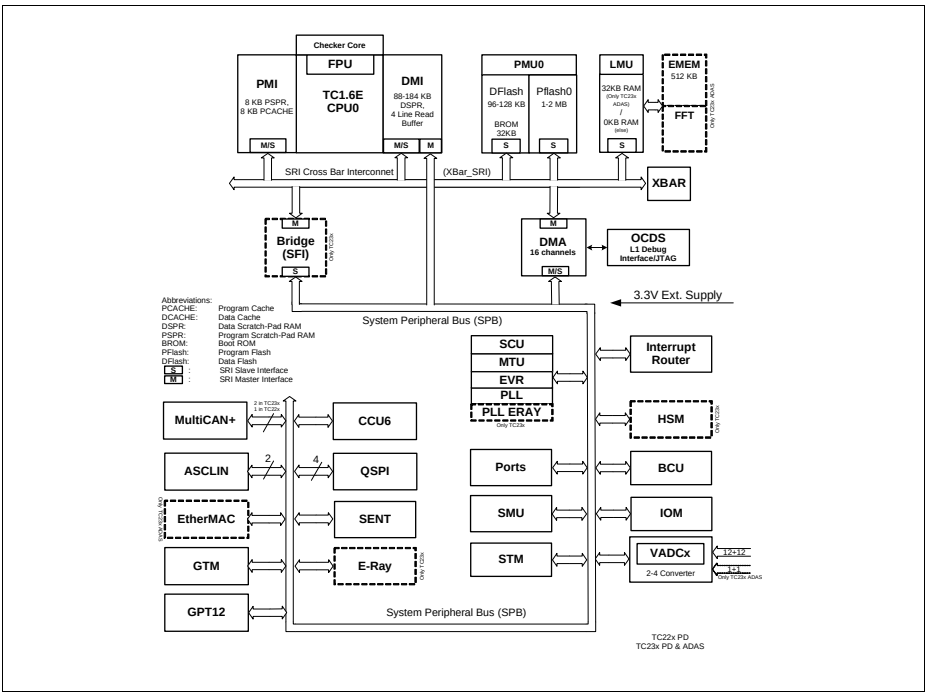

Figure 3-1 On Chip Buses in TC21x/TC22x/TC23x Processor Subsystem

The SRI connects the TC1.6 CPU , the main high bandwidth peripherals and the general purpose DMA module to its local resources for instruction fetches and data accesses.

The System Peripheral Bus connects the TC1.6 CPU and the general purpose DMA module to the medium and low bandwidth peripherals.

Note: The TC1.6 has one SRI slave interface that provides access to the TC1.6 SRAMs, SFRs and CSFRs.

3.1 What is new

Major differences of the TC21x/TC22x/TC23x XBar Bus System architecture compared to previous TC1.6 based products:

- Empty list (This is the initial version of AURIX Products)

3.2 SRI Crossbar (XBar_SRI)

3.2.1 Introduction

The Shared Resource Interconnection (SRI) is the high speed system bus for TriCore1.6.x CPU based devices. The central module of the interconnect is the XBar_SRI which connects all components in one SRI system. The XBar_SRI handles, arbitrates and forwards the communication between all connected SRI-Master and SRI-Slave peripherals.

The XBar_SRI supports parallel transaction between different SRI-Master and SRI-Slave peripherals. It supports also pipe lined requests from the SRI-Master interfaces and pipeline address phases to the connected SRI-Slave interfaces.

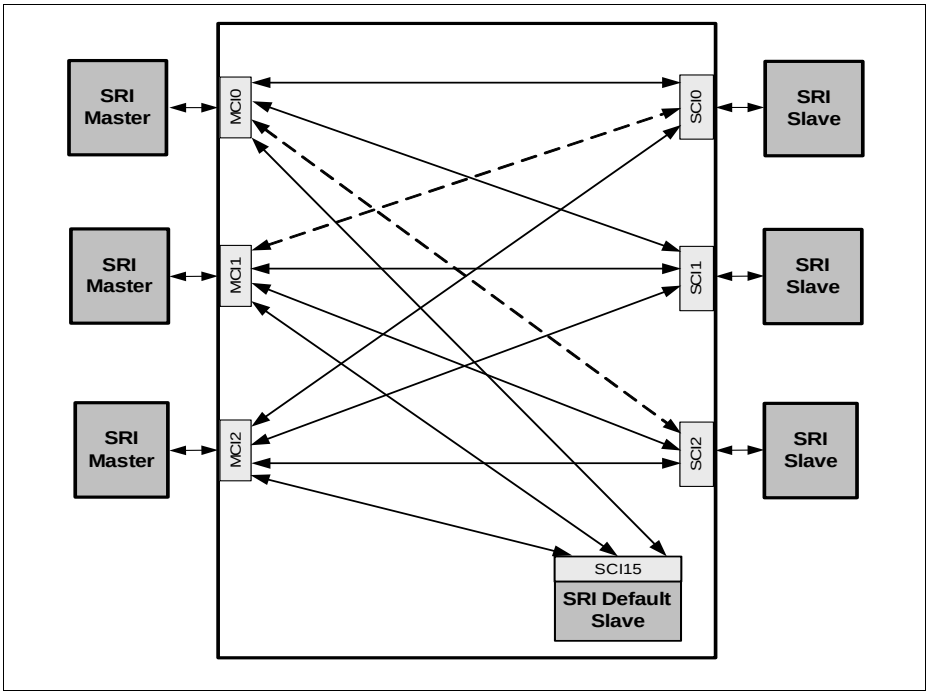

Figure 3-2 XBAR_SRI point to point connection scheme

The XBar_SRI provides SRI Slave Interfaces (SCIx) to connect SRI Slave modules and SRI Master Interfaces (MCIx) to connect SRI Master models to the XBar_SRI. The XBar_SRI includes an Default SRI Slave that provides access to the XBar_SRI control

registers and that takes over all SRI transactions to address outside the connected SRI Slave address ranges. The XBar_SRI includes also one Arbiter module per connected SRI slave module and the infrastructure for the enabled read/write data paths. Each connected SRI slave module as well as the default slave have an related arbiter module within the XBar_SRI.

Please note that only these SRI-Master <-> SRI-Slave connections are implemented that are required for the system functionality (example: connection between PMI Master and PMI Slave is not implemented, see also **Table 3-7**).

For performance optimization the XBar_SRI includes arbitration schemes that allows to configure SRI master priorities for each SRI slave individually (arbiter functionality). For debug support on system level the XBar_SRI includes debug support for SRI-Error and SRI-Transaction ID errors (local SRI slave module support in the related arbiter, global control in the Default Slave) .

Table 3-1 SRI Bus Terms

Term	Description
Agent	An SRI agent is any master or slave device which is connected to the SRI Bus.
Master	An SRI master device is an SRI agent which is able to initiate transactions on the SRI.
Slave	An SRI slave device is an SRI agent which is not able to initiate transactions on the SRI. It is only able to handle operations that are dedicated to it by SRI CrossBar (XBar_SRI).
XBar_SRI	The SRI CrossBar (XBar_SRI) provides the interconnects between connected Master and Slaves. The XBar_SRI includes arbitration mechanisms and debug capabilities. The XBar_SRI has 16 Master Connection Interfaces (MCI0 - MCI15) to connect SRI master devices to it and 15 Slave Connection Interfaces (SCI0 - SCI14) to connect SRI slave devices to it.
MCI	Each Master is connected via one Master Connection Interface (MCI x, x = 0 ...15). The XBar_SRI control registers include control and debug informations related to the Master Connection Interfaces MCI x (x = 0 ... 15).
SCI	Each Slave is connected via one Slave Connection Interface (SCI x, x = 0 ...14). The XBar_SRI control registers include control and debug informations related to the Slave Connection Interfaces SCI x (x = 0 ... 14). The XBar_SRI default slave is connected to SCI 15.

3.2.1.1 XBar_SRI Features

XBar_SRI feature overview:

- Single/Block Data Read Transaction Support (8/16/32/64 Bit)
- Single/Block Data Write Transactions Support (8/16/32/64 Bit)
- Read Modify Write Support
- Supports pipelined requests from SRI master peripherals
- Supports pipelined address phases to SRI slave peripherals
- Single arbiter module for each connected Slave device
- Arbitration priority scheme can be configured for each Slave device individually
- Flexible arbitration schemes (priority, two round robin groups, starvation prevention)
- Breakpoint signal generation based on SRI transactions (OCDS Level 1)
- Configurable MCDS trace interface
- Information integrity support covering SRI address phase signals and the transmitted read/write data
- SRI Address Phase includes Supervisor Mode information (covered by SRI information integrity support)

3.2.2 SRI Transactions

Each SRI transaction consists of:

- one request phase
- one or multiple data phases if not finished with error acknowledge

An SRI master that is requesting for access to an SRI slave is providing all necessary informations about the transaction in parallel with the request. This means that there are no separate on chip bus request and on chip bus address phases. An SRI request/address phase consists of:

- request signal
- lock signal (indicating a read modify write transaction)
- 32-bit address
- 4-bit SRI Op-Code (kind of single data or burst transaction)
- read/write signal (read, write or read modify transaction)
- supervisor mode signal
- Transaction ID (consists of a unique 6-bit Master TAG ID and a 2 bit running number increased for each new transaction of this master)
- 8-bit address phase ECC[1)] (Error Correction Code covering all address phase signals with the exception of request and grant)
- one or multiple data phases if not finished with error acknowledge

1) In the current implementation the Error Correction Code is only used for error detection. Detected errors are reported to the SMU but not corrected.

After the request for a slave access was granted by the related XBar_SRI arbiter module, the transaction can be either finished with error acknowledge or with the read/write data phases as defined during the request/address phase.

Each data phase ends with the transmission of data phase informations including:

- Read or Write Transaction ID (must be equal to the related Transaction ID otherwise the address phase is invalid)
- 8-bit read/write data ECC[1)] (Error Correction Code covering the 64-bit read/write data and the bits [23:3] of the related address.
- 64 bit read or write data. In case of an 8-bit, 16-bit or 32-bit read/write transaction the unused bits are filled with ´don't care´ data. The read/write data ECC[1)] covers the 64 data bits as transferred (including the possible don't care data).

3.2.3 SRI Op-Codes

The SRI Op-Code defines for a SRI transaction the number of data phases, the addressing mode in case of a multi beat transaction and valid bytes in case of a single data transaction.

Table 3-2 Operation Code Encoding

sri_opc[3:0]	Identifier	Description
0000	SDTB	Single Data Transfer Byte (8 bit)
0001	SDTH	Single Data Transfer Half-Word (16 bit)
0010	SDTW	Single Data Transfer Word (32 bit)
0011	SDTD	Single Data Transfer Double-Word (64 bit)
0100	-	Reserved
0101	-	Reserved
0110	-	Reserved
0111	-	Reserved
1000	BTR2	Block Transfer Request (2 transfers) Wrap Around Address Mode is used.
1001	BTR4	Block Transfer Request (4 transfers) Wrap Around Mode is used.
1010	BTRL2[1)]	Block Transfer Request (2 transfers) Linear Address Mode is used.
1011	BTRL4[1)]	Block Transfer Request (4 transfers) Linear Address Mode is used.
1100	-	Reserved

Table 3-2 Operation Code Encoding

sri_opc[3:0]	Identifier	Description
1101	-	Reserved
1110	-	Reserved
1111	-	Reserved

1) The SRI implementation in the TC21x/TC22x/TC23x does not support bursts with linear addressing modes.

3.2.4 SRI Error Conditions

The sri_err_n signal is used by the slave during a transaction to signal the corresponding master that an error has happened which results in an immediate termination of the current transaction. Errors during transaction are tracked by the XBar_SRI and are signalled to via an interrupt and directly to the SMU.

Only the following error conditions are supported and recognized by SRI slaves:

- access level is incorrect (user/supervisor)
- unmapped address access from an SRI master[1)]
- unsupported op-code
- reserved op-code

An SRI error can be generated by the application SW e.g. with an access to a reserved address (see chapter Memory Map):

3.2.5 SRI Transaction ID Error Conditions

Transaction ID is an identifier connected to all phases of a transaction in order to make the transaction unique in the SRI system during the transactions live time.

The transaction ID is used by SRI masters and slaves to identify problems in the SRI system that results in data packets received by a master or slave that do not match the corresponding arbitration/address phase. If the read/write transaction identifier doesn't match with the previous send transaction identifier in the address phase, this is identified as a transaction ID error and tracked by the XBar_SRI.

In situations where at the data source side (master for write transactions, slave for read transactions) a data phase has to be invalidated (e.g. detection of an not correctable SRAM ECC error) and invalid transaction ID is send in order to invalidate the data phase.

An SRI Transaction ID error condition can be generated by injecting an non correctable error into one of the SRAMs (e.g. CPU Instruction Scratch Pad SRAM) and than reading the corrupted data by a CPU.

1) The accesses to unmapped slaves is checked by a default slave.

3.2.6 Operational Overview

This chapter describes the functionality of the XBar_SRI module in order to enable the user to configure the XBar_SRI control registers and to use the XBar_SRI debug resources.

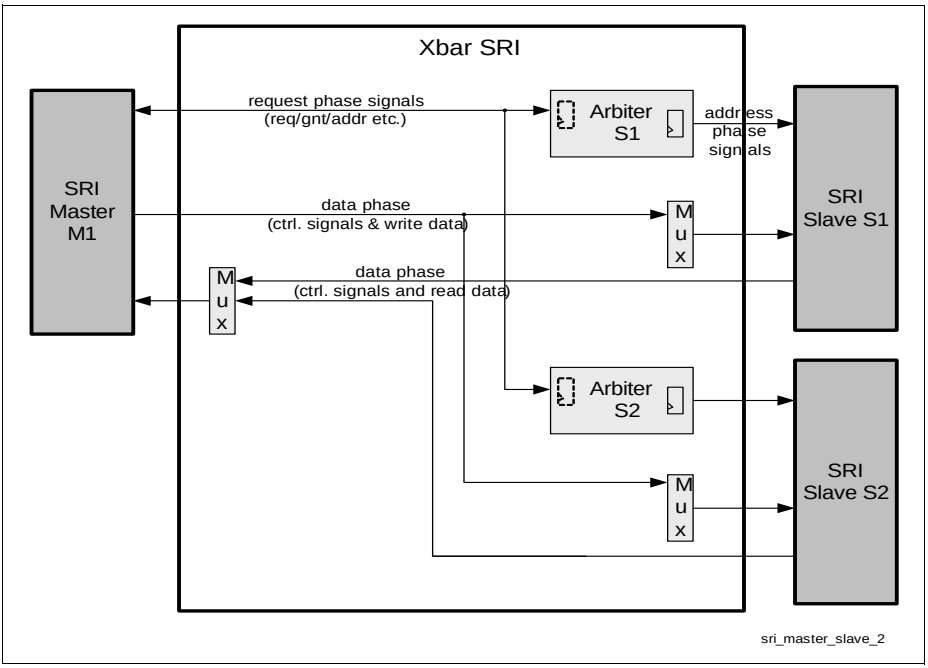

Figure 3-3 XBAR_SRI connections between SRI Master and SRI Slaves

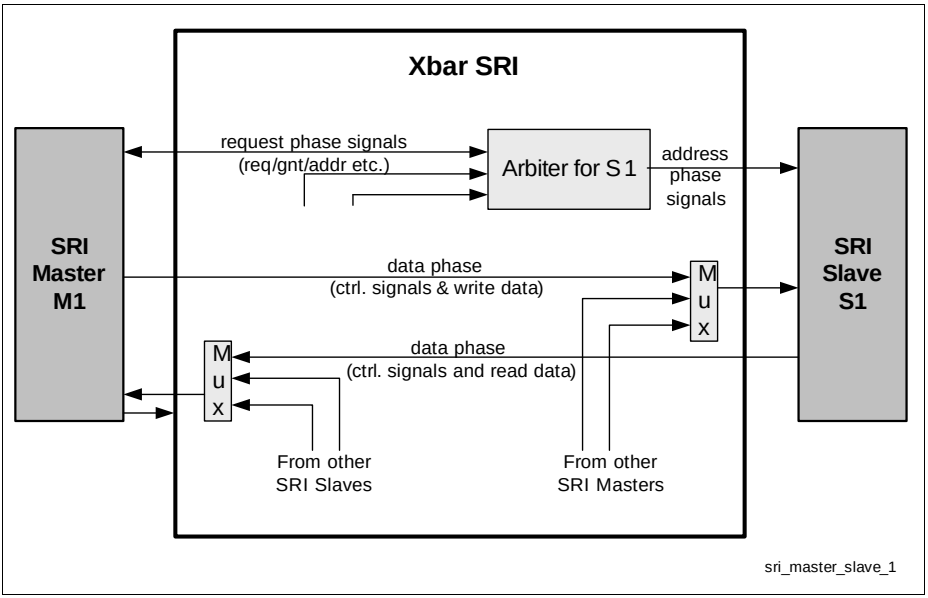

Figure 3-4 XBAR_SRI connections between SRI Slave and SRI Master modules

3.2.6.1 Functional Blocks

The XBar_SRI represents the highest level of the hierarchical SRI-Bus system. Since, it is closest to the TC1.6 core, peripherals critical to CPU performance can be attached to it.

The XBar_SRI module is partitioned into blocks for arbitration and data path control which are necessary for each XBar_SRI master- or slave interface and one block that covers the default slave - and debug functionality.

The XBar_SRI module can handle and process several transaction of different master in parallel if the masters requests different slaves.

XBar_SRI Master Connection Interface (MCI)

Each SRI master module in the system is mapped to one or more XBar_SRI Master Connection Interfaces (MCI). Each MCI is related within the XBAR_SRI module to a default arbitration priority and to register control bits and register control bit fields. So each SRI master in the system is mapped to an XBar_SRI internal default arbitration priority and to master related control register bits and bit fields via its MCI number (see also see also **Table 3-4** and **Table 3-6**).

XBar_SRI Slave Connection Interface (SCI)

Each SRI slave module in the system is mapped to one XBar_SRI Slave Connection Interfaces (SCIx). Each SCI is related within the XBAR_SRI module to one arbiter module with its arbiter module control register and to register control bits and register control bit fields related to this SCIx. So each SRI slave module in the system is mapped to an XBar_SRI internal arbiter module and to slave related control register bits and bit fields via its SCI number (see also see also **Table 3-7**).

XBar_SRI Arbiter

Each XBar_SRI slave connection interface is mapped to exactly one dedicated instantiation of the slave arbiter module in the XBar_SRI. This module includes all required functionality for the following tasks:

- Arbitration: the module includes all required functionality for the arbitration. This includes SRI address decoding, SRI request arbitration, SRI request starvation algorithm, SRI address phase generation and control registers for the priority of the connected master connection interfaces and an FSM to detect the end of the current SRI transaction.
- Debugging: the module tracks the SRI transactions to the dedicated slave connection interface for SRI errors. The transaction information of the first transaction where the SRI protocol error is captured in arbiter internal control registers.
  The module tracks the requests from all masters to detect starvation of masters in the arbitration rounds.
- Error signalling: The first SRI error or starvation error is signalled to the default slave module via two sideband signals.
- XBar_SRI control bus interface: the module has a slave interface to the XBar_SRI control bus. The slave arbiter decodes the address of each new control bus transaction and, if addressed, processes the read/write transaction to the module internal control registers.

Default Slave

The XBar_SRI default slave module is a XBar_SRI internal SRI slave module with its own, dedicated arbiter module inside the XBar_SRI. For accesses to the XBar_SRI control registers only SRI single data transactions of word size are supported. Other SIR op-codes are not supported by the default slave module and acknowledged with an error. The default slave module includes all required functionality for the following tasks:

- As a SRI default slave, it deals with all transactions that are directed to a nonexisting slave in the SRI system as it is described in the SRI protocol. The purpose of the SRI default slave in that situation is to guarantee a defined behavior by terminating these SRI transactions with an error.
- The XBar_SRI default slave module is the SRI interface to all XBar_SRI internal diagnostic- and control registers.

- The XBar_SRI default slave module samples the mci_id_err_n and sci_id_err_n signals from all XBar_SRI master and slave connection interface modules. If the default slave module detects mci_id_err_n and sci_id_err_n pulses it generates an interrupt to the system. The sampling of each mci_id_err_n and sci_id_err_n signal from an arbiter can be disabled via the default slave interrupt control register IDINTEN.
- The XBar_SRI default slave module includes the interrupt node control structure and the corresponding control register.

3.2.7 Functional Overview

3.2.7.1 Arbitration Block

The arbiter has access to all arbitration-/address phase signals from the master connector interfaces he is enabled for, therefore he sees requests from all master connector interfaces in parallel.

In order to check if a master request is addressed to 'its' slave connector interface for the next transaction the arbiter checks if the address transmitted together with the request from the master matches with the allocated address area of this slave via address decoding. Due to the fact that a master can access any slave for a transaction all arbiters of the XBar_SRI are checking the requested address from a requesting master in parallel.

Due to the fact that multiple masters can request for one slave in parallel, each slave has to decode the addresses from all the master connector interfaces it is enabled for in parallel.

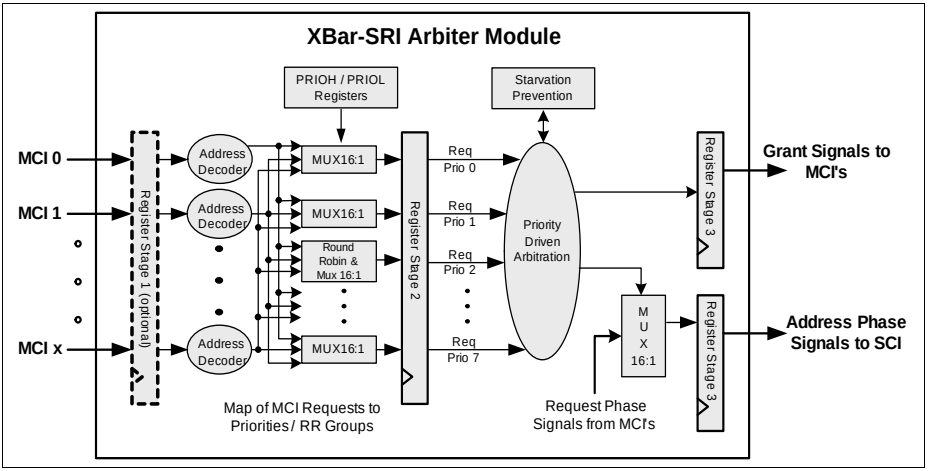

Figure 3-5 XBAR_SRI arbiter scheme

Address Map Checking

The arbiter performs the address comparison for all pending requests from the connected SRI master modules to its slave module in parallel.

Arbitration

A transaction request from a master that matches the address area of a slave connection interface takes part in the next arbitration cycle.

The arbitration is divided into two levels:

- priority driven arbitration
- arbitration within round robing groups (priority 2 and 5)

After reset all enabled master connector interface are mapped to the priorities 2 or 5 (also see also **Table 3-4**). The priorities and the priority algorithm of the master connection interfaces can be programmed for each arbiter individually. The programming of the master priorities can be done by SRI read/write transaction via the default slave module.

The highest priority for an arbiter is 0 and the lowest is 7.

According to the transaction rules described in the SRI protocol specification the arbiter asserts the sri_gnt_x signal to grant the slave to this winning master.

In parallel - or after granting the master, the arbiter sends the address phase for the next transaction to the slave by propagating all necessary informations via the slave connection interface to the slave. The arbiter sends the address phase in parallel with the grant or delayed depending on the address phase pipeline status of the corresponding SRI slave.

For debug purposes, the arbiter samples all necessary transaction informations and provides them to the XBar_SRI default slave module if an SRI error happened and the protocol error feature was enabled.

Arbitration Algorithms

The arbiter related to a slave connection interface (SCI) can be connected to all master connection interfaces (MCI), see also **Chapter 3.2.8.3**. The priority of each MCI can be controlled via the arbiter priority registers (PRIOx). The priority of a master is defined by 3 bit field in the PRIOL / PRIOH register that is related to this master / its MCI number. This can be configured individually for each arbiter so the same master can be handled with different priorities for accesses to different slaves. After reset all enabled MCI are configured with the priority 2 or 5 (Round Robin group).

Please Note:

It must be ensured that two enabled masters don’t have the same priority, with the exception of priority 2 and priority 5 (round robin group priorities).

For changing the priorities during runtime (switching the priorities), all master connection interfaces that should be remapped have to be mapped to the round robin group priorities (2 / 5) before mapping them to their new priorities can be done. This will prevent situations where two masters have the same priority but not a round robin one.

Priority Driven Arbitration

The general arbitration algorithm is priority driven where priority 0 is the highest priority and 7 the lowest one. If multiple masters are requesting for one slave, the master with the highest priority will win the next arbitration round (see also 'starvation prevention').

Round Robin Groups

The arbiter arbitrates in general priority driven, where Priority 2 and priority 5 contain a second 'arbitration' layer. Both priorities can be used as round robin priorities for a group of max. 8 MCI's each. If only one master is mapped to a round robin group priority, the master's request will be treated as normal master request with the priority of the round robin group. If more than one master is mapped to the priority of a round robin group, the requests of the mapped masters will be handled by the round robin algorithm, the winning request of the round robin group arbitration has the priority of the round robin group within the priority driven arbitration.

After the winner of a round robin group is granted, the round robin group starts with a new arbitration round which means the requesting MCI's of the round robin group with the next highest MCI ID number will win the next round robin arbitration round. If there is no requesting MCI with a higher ID number in the round robin group, the algorithm will start with the MCI with the lowest MCI ID number that is mapped to the group, going to the next higher MCI ID number and so on.

Request Latency

If no other request is pending, a request from an MCI has a latency of 1 clock cycle, starting with the detection of the SRI master request on the bus, ending with the SRI grant to the requesting MCI and the SRI address phase to the addressed SCI.

Table 3-3 XBar_SRI Request Latency

Clock Cycle Nr.:	Task(s)
0 (Default Slave)	sri_req_n is sampled at XBar_SRI MCI (Only valid for access to the XBar_SRI control registers)
1	address decoding, mapping of MCI's to priorities / round robin groups and starvation prevention. Round robin arbitrations, priority driven arbitration, mux request phase signals to the address phase registers masking sri_req_n from MCIx after granting the MCIx
2	sri_gnt_n to the requesting MCI, SRI address phase to SCI.

Grant -> New Request Latency (Request Dead Time)

After an MCI was granted, it takes 2 clock cycles before a new request from the same MCI will participate in a new arbitration round even when the SRI master has requested

permanently. This request dead time is a result of the synchronous sri_req_n de-assertion and the XBar_SRI request latency.

Default MCI x Priorities after Reset

After Reset all Master Connection interfaces are mapped to the round robin groups (priority 2 and 5, lower number means higher priority). **Table 3-4** shows the default priority of the MCI with the related coding in the XBAR_PRIOH and XBAR_PRIOL registers. After reset, the priority scheme of the MCIs can be re-configured via the XBAR_PRIOH and XBAR_PRIOL registers, for each SCI (accesses to the Slave connected to an SCI) individually. See also **Chapter 3.2.8.1**,

Note: If multiple CPUs are connected to the Aurix_Bus it is proposed to give the CPU master interfaces (DMI and PMI) the same round robin priority, e.g. 5. This ensures a fair arbitration between CPU access conflicts to the same on chip resource, e.g. Flash.

Table 3-4 Default MCI Priority in the XBar_SRI Arbiters

Priority	Coding	Round Robin Group	Default Mapping:	Comments
0	000	-	-	
1	001	-	-	
2	010	Yes, max 8 master	MCI 0-7	Maximal 8 MCI can be mapped to the priority 2 e.g. can have the priority ’010’.
3	011	-	-	
4	100	-	-	
5	101	Yes, max. 8 master	MCI 8-15	Maximal 8 MCI can be mapped to the priority 8 e.g. can have the priority ’101’.
6	110	-	-	
7	111	-	-	

Starvation Prevention

Starvation can occur when masters with high priority continuously request a dedicated slave, preventing other masters with lower priority from getting access to this slave. To prevent such a situation, a starvation counter has been implemented in each arbiter. This mechanism allows the promotion of weak masters.

Each time the starvation counter in a slave module has and underflow, all pending requests to this arbiter will be entered in the arbiters request list. This even applies to all masters mapped to a round robin group.

Next time when the starvation counter has an underflow, the masters of this request list will be entered in the arbiters request promotion list if:

- The request was not granted during the last starvation period

The masters in that request promotion list will be the next to be granted independent of their priorities. The masters in the request promotion list will be granted one after the other, starting with the master which has the lowest MCI number in this list if there are more than one. The master promotion list has the highest priority within the arbiters main arbitration algorithm, therefore all masters in the promotion list will be granted before the arbiter switches back to its 'normal' arbitration. A master is removed from both lists when it is granted.

If several masters are mapped to a round robin priority, all masters of that round robin arbitration round will be entered in the request list/request promotion list when not granted.

The value controlling the counter period is programmable. After reset the starvation counter has a value of zero. On a starvation counter underflow it is reloaded with the content of the arbiter control register ARBCON.SPC. An underflow occurs in the clock cycle when the counter tries to count down from zero.

The number of arbitration cycles a master must wait for the slave varies. But it's guaranteed to be no more than 2 x ARBCON.SPC until the master is promoted to the request promotion list.

Each time there is an underflow it is checked if there are any masters in the request promotion list that were not granted since the last underflow. This can happen if there are to many/to long transactions to be promoted compared to ARBCON.SPC value. In this case an error is generated via the xcb_sc_err_n signal to the default slave if the feature was enabled (bit ARBCONx.SCERREN set).

If currently a RMW transaction is processed the starvation counter is stopped before the next overflow. The starvation counter is released again after the address phase of the write part is generated or an error for the RMW transaction was received.

If currently a Read-Modify-Write (RMW) transaction is processed by the slave the starvation protection counter is stopped until this RMW is finished.

3.2.7.2 Default Slave

The default slave serves three features in the XBar_SRI implementation:

Control and Configuration Registers Interface

The XBar_SRI default slave module handles all read and write transactions to the debug- and control registers of the XBar_SRI. For this purpose, the default slave module has its own address space which must be mapped into the system address space by an address decoder, provided by the customer.

For a detailed description of the registers see **Chapter 3.2.9**.

Non Existing Addresses

The XBar_SRI internal default slave module has its own arbiter module.

If an SRI master sends a request with a non existing address[1)] to the XBar_SRI, the transaction will be directed to the default slave. The default slave finishes the transaction with error following the SRI protocol rules, which activates the error tracking mechanism of the arbiter. As a result of the error, the default slave module signals this incorrect behavior to the system by generating an interrupt.

A write from an SRI master to a non existing address on the System Peripheral Bus (SPB) will be handled by the Bus Control Unit on the SPB only. A read from an SRI master to a non existing address on the SPB will be handled by the by the Bus Control Unit on the SPB and also captured by the XBar_SRI arbiter as it will see the transaction as read transaction finished with Error Acknowledge.

Error Handling

If an arbiter detects an SRI protocol error during a transaction with a corresponding slave the involved arbiter samples all relevant information of the transaction in the arbiter internal diagnostic registers (ERRADDRx and ERRx) and signals this event via xcb_sri_err_n or xcb_sri_err_d_n sideband signal to the default slave module.

Note: The two error registers ERRx and ERRADDRx in each arbiter are updated with the content of the currently processed transaction in the data phase. The registers are only updated if they are not locked due to a pending protocol error and sri_ready_n was asserted in parallel with sri_err_n deasserted.

The error capture registers in the arbiter can't be changed until the interrupt was acknowledged to the slave arbiter module (set the ARBCON.INTACK) via the default slave.

The stored informations can be read from the default slave module with SRI single data read transactions, the acknowledge can be sent to the default slave via a write to a specific address.

1) non existing address = all Reserved address ranges described in the Memory Map chapter

This can result in a loss of interrupt data information of the same source beyond the first until the write was processed but as all SRI errors must be analyzed and fixed before the product will work, these kind of errors can be analyzed one after the other.

In case that a master or a slave signals an ID error to the XBar_SRI the default slave marks the source of the ID error by setting the according bit in register IDINTSAT if this feature was enabled for that specific master and/or slave interface.

As a result, the default slave generates an interrupt to the system.

Note: While a status bit for a error source is set in either the INTSAT or IDINTSAT register a new error from this particular source doesn't generate a new interrupt.

1. *Each participant in the SRI-Bus system has three interrupt sources; protocol errors, ID errors and time-out due to starvation. All error from the SRI-Bus components are combined in the single SRN of the XBar_SRI.*

Each arbiter has two 32 bit registers containing the error information. This registers are accessed as all other registers, via the default slave module.

The default slave module has one service request node (SRN) to start interrupts for detected SRI errors. Protocol errors, starvation errors as well as ID errors are handled together by this node.

3.2.7.3 Register Access Protection

The XBar_SRI registers are protected by a master TAG ID based access protection mechanism. Each on chip resource with direct or indirect bus master capability has a unique master TAG ID that can be use to identify the master of an on chip bus transaction.

Access Enable:

TAG ID based protection means that on chip bus write access to the XBar_SRI control registers can be disabled for each master TAG ID individually (with the exception of the Access Enable registers itself, which is Safety Endinit protected). For a disabled master TAG ID, write access will be disconnected with error acknowledge, read access will be processed.

Access Enable Registers (XBAR_ACCEN1/0):

-> defines which master TAG ID is allowed to write to XBar_SRI control registers

-> are Safe Endinit write protected

The Access Enable registers (XBAR_ACCEN1/0) are Safe Endinit protected. The Safe Endinit system status is defined by a Watchdog Unit in the System Control Unit (SCU)

After reset, all XBAR_ACCEN1/0 access enable bits and access control bits are enabled, access protection mechanism has to be configured and checked to bring the system in a safe state.

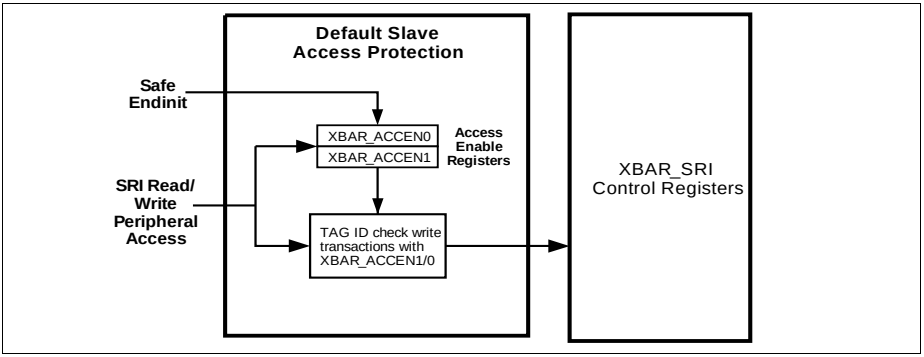

Figure 3-6 XBar_SRI: Control Register Access Protection scheme

3.2.7.4 SRI ECC Error Handling

The SRI protocol provides information integrity support covering:

- The address phase of an SRI transaction
- The transmitted read and write data

The integrity support mechanism is using Error Correction Code (ECC).

Note: In the current implementation the Error Correction Code (ECC) is only used for error detection. Detected errors are reported to the SMU but not corrected.

Detected SRI address phase ECC errors:

- If an SRI slave detects an SRI address phase ECC error it finishes the transaction with SRI error acknowledge and does not further process it (see also **Chapter 3.2.7.5**). Error is signalled to the SMU.

Detected SRI read data ECC errors:

- PMI and DMI: a bus error trap will be generated but only if and when a received 64 bit read data is really used by the CPU. This as PMI / DMI can read complete cache lines (4x64 bit) where the critical 64 bit is used, the other 3 x 64 bit are speculative reads and might not be used by the CPU later.
- DMA: the DMA ignores read data ECC errors but signals the error to the SMU.
- SFI: the SFI SRI master ignores read data ECC errors but signals the error to the SMU

Detected SRI write data ECC errors:

- An detected write data ECC error is signalled to the SMU

- SRI write data ECC errors to SRAMs will not be executed by the related slave modules.

It can happen that a data during a transaction shows an ECC error inside the data source peripheral (master during write, slave during read). Example: A burst read transaction from a memory slave peripheral where the second, third or forth data taken from the SRAM shows inside the slave/master an ECC error. In this situation a slave can finish a read transaction with error acknowledge (if the error is detected before the first data phase) or a slave / master can invalidate the related data phase with an invalid read / write transaction ID error (see also **Chapter 3.2.7.5**).

ECC Code

The ECC codes used for the IR Error Detection mechanism is a Hsiao 22_5 code with DED (double error detection) capability:

- SRI Address Phase informations are protected by the 64_8 code
- SRI Read / Write data are protected by the 96_8 code

```

3.2.7.5 Error Tracking Capability

The XBar_SRI tracks all SRI transactions for SRI protocol errors. Additionally it tracks informations about starvation errors and SRI transaction ID errors. This is done by all arbiters and the default slave in parallel as the XBar_SRI supports the processing of multiple transactions from master and slaves in parallel which can result in parallel events at different slave connector interfaces.

For this purpose, each arbiter has two error/debug registers where it samples the transaction informations of the transaction where the first protocol error happened.

Note: Protocol errors and debug trigger events can lock the error/debug registers. Only the first event of both sources can lock the registers. All other events are not captured with this two error/debug registers unless the lock was released in the meantime.

Further protocol errors will be ignored by an arbiter that has detected an protocol error until the tracking mechanism is re-activated via the arbiter internal control register. A detected protocol error or starvation error is signalled by the arbiter to the default slave module via two separate sideband signals for SRI- and starvation error. The default slave samples the sideband signals pulses in an error status register INTSAT. As each slave has its own sideband signals, the default slave has the information which arbiter has detected an SRI protocol or starvation error. Each error signal can be masked individually by control registers in the arbiter modules. All debug registers are accessible via the SRI-Bus interface of the default slave.

For transaction ID errors of write transactions the SCI propagates the sci_id_err_n signal via the sri_wr_tr_id_err signal from the slave to the default slave module. The default slave sets the assigned bit in register IDINTSAT.

For transaction ID error of read transactions the MCIs propagate the sri_id_err_n signal via the sri_rd_tr_id_err signal from the master to the default slave module. The default slave sets the assigned bit in register IDINTSAT.

Once an error was signalled from an arbiter or an MCI/SCI to the default slave, the default slave module sends an interrupt request to the system. The system can read out

the error status registers in the default slave module to find out which arbiter(s) or master/slave have detected an error, then the system can start with more detailed diagnostics by reading out the error/debug registers in the arbiter for a protocol error. The error informations captured for an SRI protocol error allows the identification of the master via the sampled master tag ID and the final destination via the sampled target address. Additionally the arbiter samples the op-code and the sri_rd_n, sri_wr_n and sri_svm control signals of the transaction.

In addition to the SRI transaction information, the XBar_SRI captures sideband signal informations (**XBAR_ERR0**.MCI_SBS and **XBAR_ERRD**.MCI_SBS). In the TC21x/TC22x/TC23x these sideband signals are used by the DMA SRI master interface to provide informations about the requestor of a transaction, in parallel to the SRI request phase. **Table 3-5** shows the encoding of the MCI_SBS bit field for the encoding of the TC21x/TC22x/TC23x.

Table 3-5 Encoding of ERRx.MCI_SBS in the TC21x/TC22x/TC23x

MCI_SBS[7:0]	Bit field encoding
MCI_SBS[7:0]	This bit field is only valid if the master TAG ID of the address phases is related to one of the DMA hardware resource groups. MCI_SBS[7:0] is showing the number of the DMA channel that initiated the transaction.

After reading all relevant error informations, the error/debug tracking mechanism can be reactivated.

3.2.7.6 Debug Trigger Event Generation (OCDS Level 1)

This functionality can be used to generate breakpoints on selectable and configurable events in the SRI-Bus traffic.

The debug trigger event generation is controlled via the three debug registers DBCON, DBADD and DBMADD and the three status registers DBSAT, ERR and ERRADDR.

All DBXXX registers reset only with the debug reset (Class 1 reset).

The register DBSAT collects all debug trigger events from all arbiters in the XBar_SRI module. When an arbiter generates a debug trigger event the according bit in register DBSAT is set.

The DBCON register defines the debug trigger event conditions for each arbiter individually. Several individual break conditions can be combined by enabling them in parallel. Possible break conditions are:

- Write transactions
  - If bit DBCON.WREN is set only transactions with an asserted sri_wr_n signal can generate a debug event.

Note: Only if DBCON.WREN and DBCON.RDEN are set together a RMW transaction generate a debug trigger event.

- Read transactions
  – If bit DBCON.RDEN is set only transactions with an asserted sri_rd_n signal can generate a debug event.

Note: Only if DBCON.WREN and DBCON.RDEN are set together a RMW transaction generate a debug trigger event.

- Supervisor mode transactions
  – If bit DBCON.SVMEN is set only transactions with an asserted sri_svm signal can generate a debug event.
- Transactions from a dedicated master
  – If bit DBCON.MASEN is set only transactions initiated by master DBCON.MASTER can generate a debug event.
- Transactions accessing a defined address area
  – If bit DBCON.ADDEN is set only transactions accessing an address in the selected address area can generate a debug event. The selected address area is defined by the registers DBADD and DBMADD. Register DBADD defines one global 32-bit address that is compared with sri_addr[31:0] for all bits where DBMADDR is set to ’1’.

All enabled debug trigger conditions are combined by a logical AND.

Example: If DBCON.WREN and DBCON.SVMEN are set and all other enables are cleared a debug trigger event is only generated for a write transaction operating in the supervisor mode.

Additionally a debug trigger event is generated if DBCON.ERREN is set and an error occurs. Please note that an error occurs only when the generation for this source is enabled in the linked registers ARBCON or IDINTEN.

The result of the logical AND of the first five debug trigger event options is combined with the result of the error debug trigger event by a logical OR.

A debug event is signaled to the default slave. The default slave combines all XBar_SRI arbiter debug event signals with its own and generates the debug event signal that is sent to the OTGM module.

The debug event signal to the OTGM will be asserted for as long at least one condition inside an XBar module or the XBar default slave module is met.

Debug Trigger events inside the XBar_SRI are sampled in the register DBSAT. Additionally an interrupt can be generated for debug trigger events by the XBar_SRI.

When debug condition is reached in one of the XBar_SRI arbiter modules, informations of the transaction that matched to the debug condition is captured in the two error/debug capture registers ERRx and ERRADDRx. If the two registers are already locked due to an earlier action the capturing is not performed.

Writing to DBCON.REARM will rearm the feature, this also sets DBCON.ARM.

3.2.7.7 Interrupt and Debug Events of the XBar_SRI Module

There are some interactions between interrupt them self and debug events. In general due to the nature of the crossbar concept several interrupts from the same or a different source (arbiter, MCI or SCI) can occur. One interrupt could occur several times before a service request routine is initiate. Additionally can all interrupts occur in parallel to one or more debug trigger events.

All following examples assume a time interval without any acknowledge either from a service routine or a debug routine and all consecutive interrupts/events come from the same source.

Two Consecutive Protocol Errors

The first protocol error is captured as normal together with a generation of an interrupt to the system. The second protocol error is not captured as the two registers ERR and ERRADD are already locked and no interrupt is generated.

Two Consecutive Starvation Errors

The first starvation error generate an interrupt to the system. The second starvation error will not generate an interrupt to the system.

Two Consecutive Transaction ID Errors

The first transaction ID error generate an interrupt to the system. The second transaction ID error will not generate an interrupt to the system.

Two Consecutive Debug Trigger Events

The first debug trigger event is captured as normal together with a generation of debug trigger event signal to the system. The second debug trigger event is not captured as the two registers ERR and ERRADD are already locked and a debug trigger event signal is generated.

Protocol Error followed by a Debug Trigger Event

The first protocol error is captured as normal together with a generation of an interrupt to the system. The later debug trigger event is not captured as the two registers ERR and ERRADD are already locked and a debug trigger event signal is generated to the system.

Debug Trigger Event followed by a Protocol Error

The first debug trigger event is captured as normal together with a generation of debug trigger event signal to the system. The later protocol error is not captured as the two registers ERR and ERRADD are already locked and no interrupt is generated.

Starvation/Transaction ID Error followed by a Debug Trigger Event

The first starvation/transaction ID error generate an interrupt to the system. The later debug trigger event is captured to the two registers ERR and ERRADD and a debug trigger event signal is generated to the system.

Debug Trigger Event followed by a Starvation/Transaction ID Error

The first debug trigger event is captured as normal together with a generation of debug trigger event signal to the system. The later starvation/transaction ID error generates an interrupt to the system.

Releasing the Lock from registers ERR and ERRADD

If the ERR and ERRADD registers are locked only from one even only (protocol error or debug trigger event) the lock can be releasing by:

- Writing a one to ARBCONx.INTACK when the registers are locked by a protocol error
- Writing a one to DBCONx.REARM when the registers are locked by a debug trigger event

If both, a protocol error and a debug trigger event occurred since the lock was released the last time both locks have to be released

- Writing a one to DBCONx.REARM AND Writing and to ARBCONx.INTACK when the registers are locked by a debug trigger event AND a protocol error

3.2.8 Implementation of the Cross Bar (XBar_SRI) in the TC21x/TC22x/TC23x

This chapter describes the SRI Interconnect implementation in the TC21x/TC22x/TC23x. The knowledge of the specific implementation (e.g. the connection of the SRI master / slave devices to the Interconnect) is necessary in order to:

- map error informations to the connected slave devices
- define the arbitration scheme for accesses to the connected slave devices
- map XBar_SRI (arbiter) control registers to connected slave devices

This chapter includes three tables that are describing: the relationship (mapping) of

- the relationship (mapping) of TC21x/TC22x/TC23x SRI master devices to the XBar_SRI Master Connection Interfaces MCI 0 - MCI 15 (**Table 3-6**)
- the relationship (mapping) of TC21x/TC22x/TC23x SRI slave devices to the XBar_SRI Slave Connection Interfaces SCI 0 - SCI 15 (**Table 3-7**)

- the point to point connections between TC21x/TC22x/TC23x SRI master and slave devices (**Table 3-7**)

3.2.8.1 Mapping of SRI Master Modules to XBar_SRI Master Interfaces

Table 3-6 shows the mapping of master devices to the XBar_SRI Master Interfaces (MCI 0 - MCI 15). Most of the XBar_SRI control registers are related to the XBar_SRI Slave Interfaces (SCI 0 - SCI 15) or the XBar_SRI Master Interfaces. Therefore it is important to know which TC21x/TC22x/TC23x SRI master device relates to which XBar_SRI Slave Interface.

Example 1:

The XBar_SRI includes error registers where each MCI is represented with 1 bit, showing if during the transfers requested by the master devices connected to the MCI´s an error situation occurred (e.g. **XBAR_IDINTSAT**).

Example 2:

The XBar_SRI includes one arbiter module per connected SRI slave device. Each arbiter module includes a four bit field where the priority requests from connected MCI can be defined. If the access priority of the DMI SRI master to one SRI slave device has to be changed, this can be done via the bit field related to MCI 4 in the arbiter control register related to this SRI slave (control registers: XBAR_PRIOHx, XBAR_PRIOLx, XBAR_PRIODx).

Table 3-6 Mapping of TC21x/TC22x/TC23x SRI master devices to MCI

XBar_SRI Master Connection Interface	MCI Number	Priority after Reset	Connected SRI master device
MCI 0	0	2	DMA
MCI 1	1	-	-
MCI 2	2	-	-
MCI 3	3	-	-
MCI 4	4	-	-
MCI 5	5	TC23x:2 TC22x: -	TC23x: SFI (HSM access to SRI) TC22x: -
MCI 6- MCI11	6-11	-	-
MCI 12	12	5	CPU0.DMI
MCI 13	13	5	CPU0.PMI
MCI 14- MCI 15	14-15	-	-

Note: If multiple CPUs are connected to the Aurix_Bus it is proposed to give the CPU master interfaces (DMI and PMI) the same round robin priority, e.g. 5. This ensures a fair arbitration between CPU access conflicts to the same on chip resource, e.g. Flash.

3.2.8.2 Mapping of SRI Slave modules to XBar_SRI Slave Interfaces

Table 3-7 shows the mapping of slave modules to the XBar_SRI Slave Interfaces (SCI 0 - SCI 15). Most of the XBar_SRI control registers are related to the XBar_SRI Slave Interfaces (SCI 0 - SCI 15) or the XBar_SRI Master Interfaces. Therefore it is important to know which TC21x/TC22x/TC23x SRI slave device relates to which XBar_SRI Slave Interface or arbiter module.

Example 1:

The XBar_SRI includes error registers where each SCI is represented with 1 bit, showing if during the transfers requested by the master devices connected to the MCI´s an error situation occurred (e.g. **XBAR_DBSAT**, **XBAR_IDINTSAT**, **XBAR_IDINTEN**).

Example 2:

The XBar_SRI includes one arbiter module per connected SRI slave device. Each arbiter module includes error capturing resources and breakpoint capabilities. These can be used e.g. to analyze accesses to the connected slave device that where answered with error acknowledge by the slave device (e.g. **XBAR_ERR0**, **XBAR_ERRADDRD**).

Table 3-7 Mapping of TC21x/TC22x/TC23x SRI slave devices to SCI

XBar_SRI Slave Connection Interface (SCI)	Connected SRI master device
SCI 0	CPU0 (PSPR, DSPR, SFR, CSFR, PCache RAM, PTAG)
SCI 1-2	-
SCI 3	-
SCI 4	LMU (EMEM)
SCI 5	-
SCI 6	PMU0: DFlash, BootROM, CTRL Reg
SCI 7	PMU0: PFlash0
SCI 8- SCI 14	-
SCI 15	XBar_SRI Default Slave

3.2.8.3 TC21x/TC22x/TC23x SRI Master / Slave Interconnection Matrix

Table 3-7 shows the SRI master to SRI Slave interconnects that are implemented in the TC21x/TC22x/TC23x (´ ´ in a table cell means connection implemented. ´x´ in a table cell means connection not implemented)

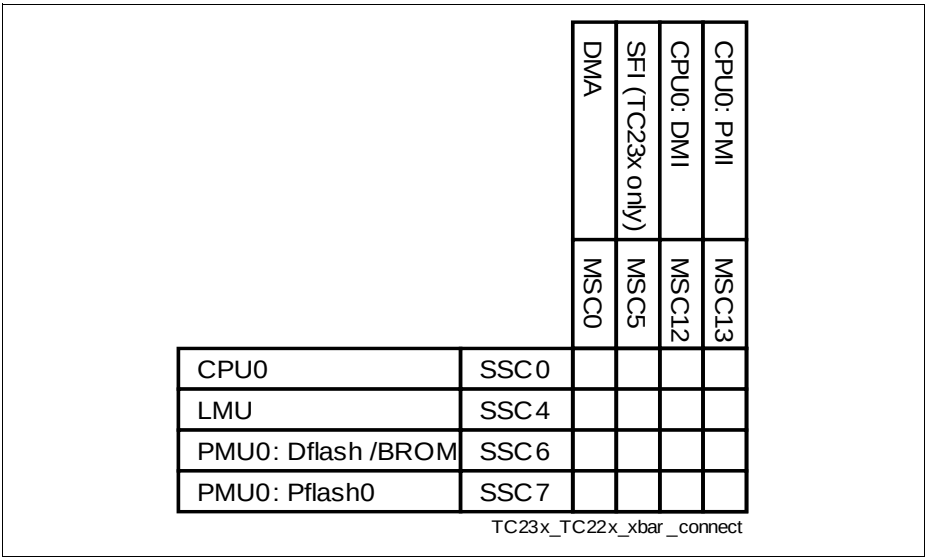

Figure 3-7 TC21x/TC22x/TC23x: SRI Master / Slave Interconnection Matrix

3.2.8.4 Connection Master-Slave in XBar_SRI

As the SRI-Bus protocol is a point to point based bus implementation multiplexer inside the data paths in front of the MCIs and arbiter/SCIs are required (see **Figure 3-3** and **Figure 3-4**).

The write data path multiplexer in front of the SCIs are controlled by the related arbiter modules. The read data path multiplexers in front of the MCIs are controlled by all arbiters.

Master - and Slave side MUX

During an SRI transaction, the corresponding arbiter has to establish the data path connection from his slave connection interface to the corresponding master connection interface in order to enable the master to receive the SCI control signals , if it is a read transaction the read data, send by the slave.

3.2.9 SRI Crossbar Registers

Figure 3-8 and **Table 3-8** are showing the address maps with all registers of the SRI Crossbar (XBar_SRI) module.

XBar_SRI Unit Register Overview

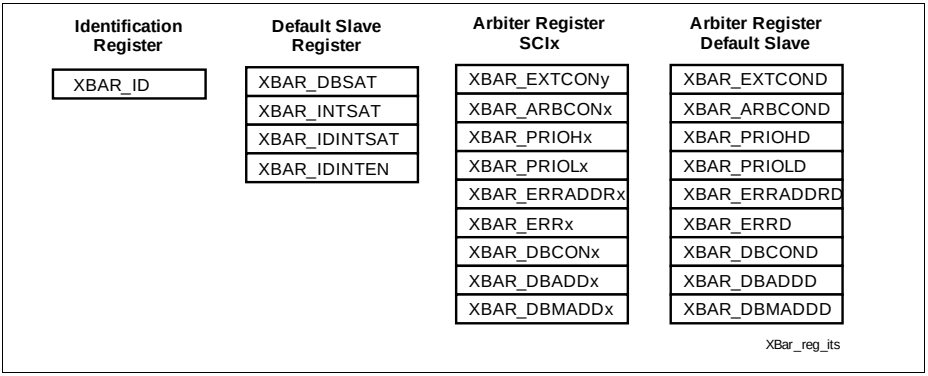

Figure 3-8 TC21x/TC22x/TC23x Control Registers

List of used Reset Class abbreviations:

- Reset Class 1 -> Debug Reset (see description in the chapter SCU / Reset Types)
- Reset Class 3 -> Power On Reset, Application Reset, System Reset (see description in the chapter SCU / Reset Types)

*Note: Addresses listed in column "Offset Address" of **Table 3-8** are word (32-bit) addresses.*

Note: XBar_SRI registers can be accessed only with SDTW (32 bit) transactions. 8, 16 bit and RMW transactions are not supported.

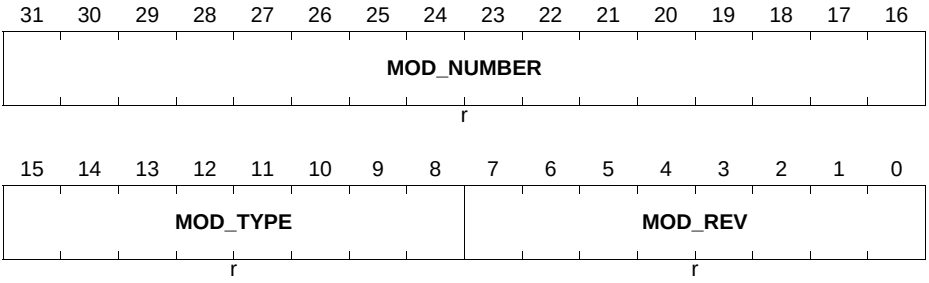
1) The absolute register address is calculated as follows:
Module Base Address (**Table 3-9**) + Offset Address (shown in this column)

2) This register is located inside the default slave

3.2.9.1 TC21x/TC22x/TC23x Control Registers

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the LBCU module.

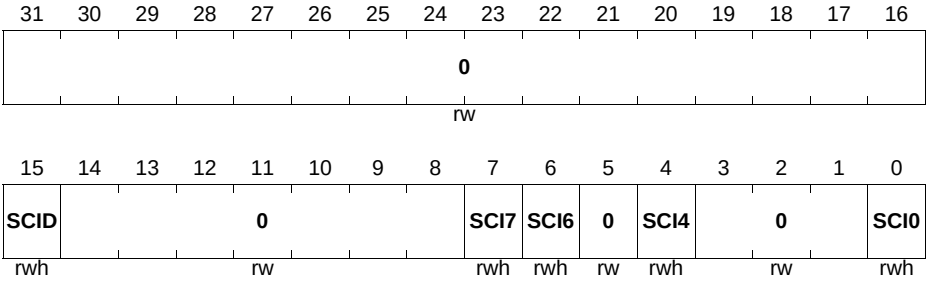
XBAR_ID
Module Identification Register (408$_H$) Reset Value: 0004 D0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to C0$_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the LBCU module is 000F$_H$.

XBAR_DBSAT

Debug Trigger Event Status Register ($40C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SCI0	0	rwh	**SCI Debug Trigger Event Status** 0_B No Debug Trigger Event was detected for SCI0 by its arbiter. 1_B A Debug Trigger Event was detected for SCI0 by its arbiter. Writing a '1' to this bit clears the bit.
SCI4	4	rwh	**SCI Debug Trigger Event Status** 0_B No Debug Trigger Event was detected for SCI4 by its arbiter. 1_B A Debug Trigger Event was detected for SCI4 by its arbiter. Writing a '1' to this bit clears the bit.
SCIn (n = 6-7)	n	rwh	**SCI Debug Trigger Event Status** 0_B No Debug Trigger Event was detected for SCIn by its arbiter. 1_B A Debug Trigger Event was detected for SCIn by its arbiter. Writing a '1' to this bit clears the bit.
SCID	15	rwh	**Default Slave Debug Trigger Event Status** 0_B No Debug Trigger Event was detected for the default slave by its arbiter. 1_B A Debug Trigger Event was detected for the default slave by its arbiter. Writing a '1' to this bit clears the bit.

Field	Bits	Type	Description
0	[31:16], [14:8], 5, [3:1]	rw	**Reserved** Read as 0; must be written with 0.

Note: This register is not reset with the normal system reset as all other registers in the XBar_SRI. This register is only reset with the special debug reset.

XBAR_INTSAT

Arbiter Interrupt Status Register (410$_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note: Only the bits assigned to configured SCIs are implemented. Not implemented bits treated as reserved bits, read as ´0´, should be written with ´0´.

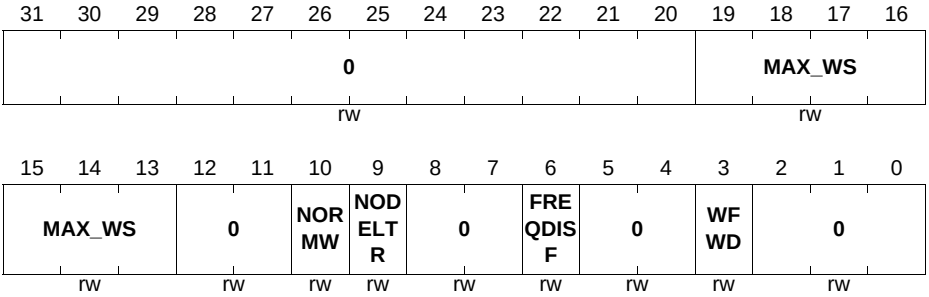
Note: Reset values for bits/bit fields coupled to masters or slaves that are not configured or enabled are zero.

XBAR_EXTCOND

External Control Register D **(000_H)** **Reset Value: 0000 0200$_H$**



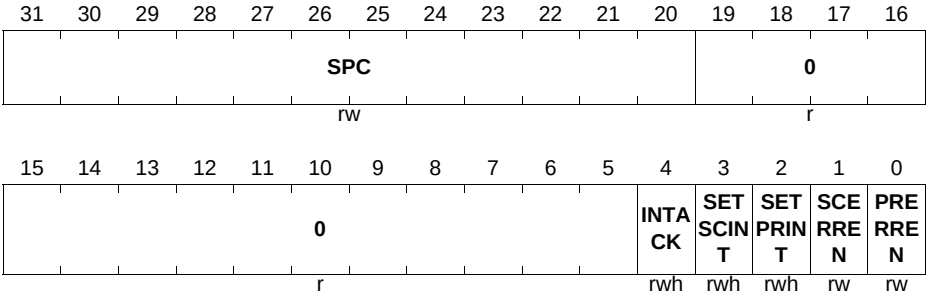
Field	Bits	Type	Description
WFWD	3	rw	**Wait for FPI Write Data** For FPI-Bus block write transfers the transaction request can be delayed until all write data arrived from the FPI-Bus in the SFI. As on thew FPI-Bus side very slow masters can resident SRI-Bus slaves can blocked for many SRI-Bus cycles if the write transaction is started with the first write data 0_B Write transactions on the SRI-Bus are requested with the first received write data from the FPI-Bus (default) 1_B Write transactions on the SRI-Bus are requested with the last received write data from the FPI-Bus
FREQDISF	6	rw	**Disable Fast Request Feature for FPI to SRI Transactions** 0_B Fast request feature is enabled (default) 1_B Fast request feature is disabled
NODELTR	9	rw	**Control Signal for deferred transactions** 0_B Deferred Transactions are generated 1_B Deferred Transactions are not generated (default)

Field	Bits	Type	Description
NORMW	10	rw	**Control Signal for deferred transactions** 0_B Deferred Transactions are generated for RMW (default) 1_B Deferred Transactions are not generated for RMW
MAX_WS	[19:13]	rw	**FPI-Bus Wait State Retry Ratio** SFI slave interface retries a read transaction to the FPI bus after the programmed value of wait states to change the read transaction in a delayed read transaction.
0	[31:20], [12:11], [8:7], [5:4], [2:0]	rw	**Reserved** Read as 0; shall be written with 0.

Note: Only the bits assigned to configured SCIs are implemented. Not implemented bits treated as reserved bits, read as ´0´, should be written with ´0´.

Note: Reset values for bits/bit fields coupled to masters or slaves that are not configured or enabled are zero.

XBAR_ARBCON0
Arbiter Control Register 0 **(044_H)** **Reset Value: FFF0 0003_H**
XBAR_ARBCON4
Arbiter Control Register 4 **(144_H)** **Reset Value: FFF0 0003_H**
XBAR_ARBCONx (x = 6-7)
Arbiter Control Register x **(044_H+x*40_H)** **Reset Value: FFF0 0003_H**
XBAR_ARBCOND
Arbiter Control Register D **(004_H)** **Reset Value: FFF0 0003_H**



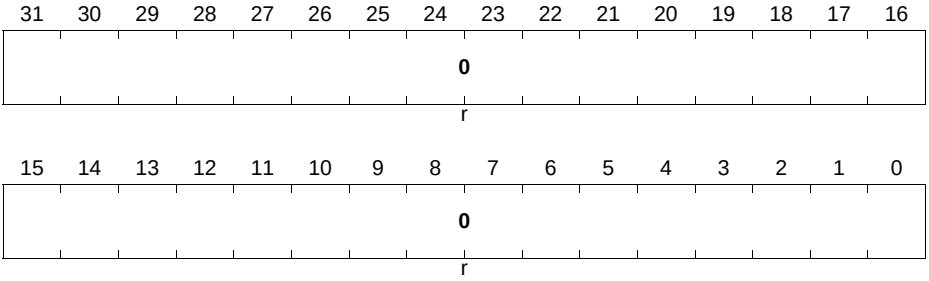
Field	Bits	Type	Description
PRERREN	0	rw	**SRI Protocol Error Enable** 0_B Protocol errors are not recognized and no information is captured. 1_B Protocol errors are recognized and information is captured.
SCERREN	1	rw	**SRI Starvation Error Enable** 0_B Starvation based errors are not recognized and no information is captured. 1_B Starvation based errors are recognized and information is captured.
SETPRINT	2	rwh	**Set SRI Protocol Interrupt** 0_B No protocol interrupt is generated 1_B A protocol interrupt is generated After the interrupt is generated by set the bit it's automatically cleared by the hardware

Field	Bits	Type	Description
SETSCINT	3	rwh	**Set SRI Starvation Interrupt** 0_B No starvation interrupt is generated 1_B A starvation interrupt is generated After the interrupt is generated by set the bit it's automatically cleared by the hardware
INTACK	4	rwh	**Interrupt Acknowledge** 0_B Default value 1_B An Error for this arbiter is pending. The ERRADDR and ERR registers are not updated for new errors. Writing a one to this bit field while it's set have the following results: The error lock of registers ERRADDR and ERR are released and the register could be updated with the next interrupt request detected (see **Chapter 3.2.7.5**). In the cycle after the write action the hardware automatically clears the bit.
SPC	[31:20]	rw	**Starvation Protection Counter Reload Value** The reload value defines the period for the starvation protection.
0	[19:5]	r	**Reserved** Read as 0; should be written with 0.

Note: Only the bits assigned to configured SCIs are implemented. Bits for non configured SCIs are treated as reserved bits.

Note: The ´D´ at ARBCOND stands for Default Slave.

XBAR_PRIOH0
Arbiter Priority Register 0 **(048_H)** **Reset Value: 0000 0000$_H$**
XBAR_PRIOH4
Arbiter Priority Register 4 **(148_H)** **Reset Value: 0055 5555$_H$**
XBAR_PRIOHx (x = 6-7)
Arbiter Priority Register x **(048_H+x*40_H)** **Reset Value: 0000 0000$_H$**
XBAR_PRIOHD
Arbiter Priority Register D **(008_H)** **Reset Value: 0000 0000$_H$**



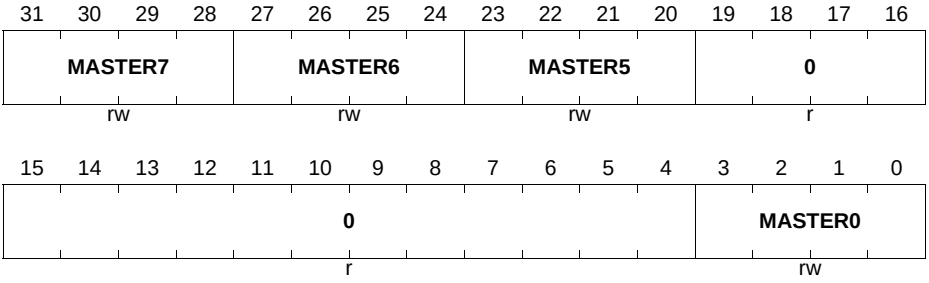
Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Note: Only the bits assigned to configured MCIs are implemented. Bits for non configured SCIs are treated as reserved bits.

Note: The ´D´ at XBAR_PRIOLD stands for Default Slave.

Note: Reset values for bits/bit fields coupled to masters or slaves that are not configured or enabled are zero.

XBAR_PRIOLD
Arbiter Priority Register D **($00C_H$)** **Reset Value: $7654\ 0000_H$**
XBAR_PRIOL0
Arbiter Priority Register 0 **($04C_H$)** **Reset Value: $7654\ 0000_H$**
XBAR_PRIOL4
Arbiter Priority Register 4 **($14C_H$)** **Reset Value: $7654\ 0000_H$**
XBAR_PRIOLx (x = 6-7)
Arbiter Priority Register x **($04C_H$+x*40_H)** **Reset Value: $7654\ 0000_H$**



Field	Bits	Type	Description
MASTER0	[3:0]	rw	**Master 0 Priority** (Priority of DMA access) This bit field contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER5	[23:20]	rw	**Master 5 Priority** (Priority of SFI access) This bit field contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.

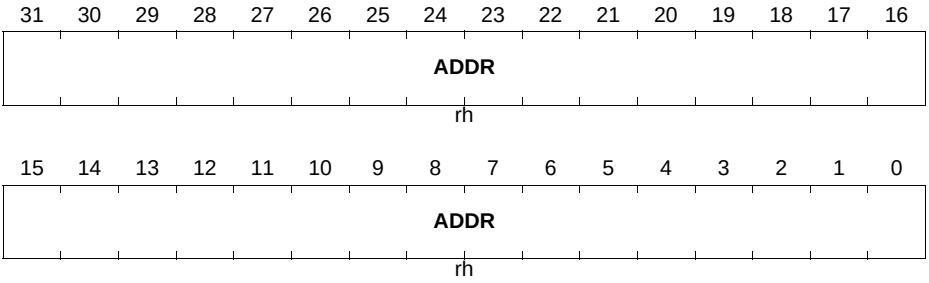
Field	Bits	Type	Description
MASTER6	[27:24]	rw	**Master 6 Priority** (Priority of CPU0.DMI access) This bit field contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER7	[31:28]	rw	**Master 7 Priority** (Priority of CPU0.PMI access) This bit field contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
0	[19:4]	r	**Reserved** Read as 0; should be written with 0.

Note: Only the bits assigned to configured MCIs are implemented. Bits for non configured SCIs are treated as reserved bits.

Note: The ´D´ at XBAR_PRIOLD stands for Default Slave.

Note: Reset values for bits/bit fields coupled to masters or slaves that are not configured or enabled are zero.

XBAR_ERRADDRD
Error/Debug Address Capture Register D(010_H) **Reset Value: $7000\ 0000_H$**
XBAR_ERRADDR0
Error/Debug Address Capture Register 0(050_H) **Reset Value: $6000\ 0000_H$**
XBAR_ERRADDR4
Error/Debug Address Capture Register 4(150_H) **Reset Value: $8000\ 0000_H$**
XBAR_ERRADDR6
Error/Debug Address Capture Register 6($1D0_H$) **Reset Value: $8800\ 0000_H$**
XBAR_ERRADDR7
Error/Debug Address Capture Register 7(210_H) **Reset Value: $8020\ 0000_H$**

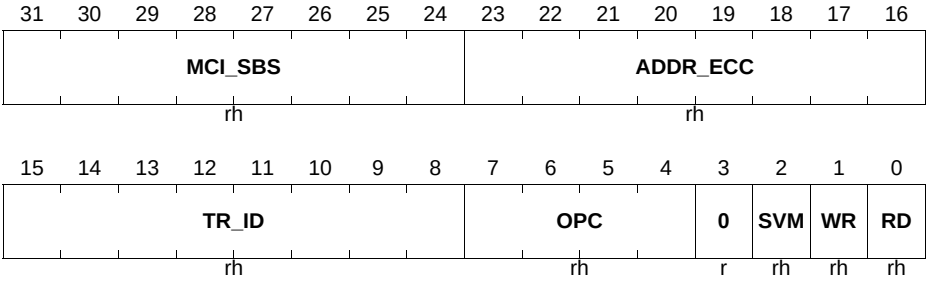


Field	Bits	Type	Description
ADDR	[31:0]	rh	**Transaction Address** This biffield contains the address of the erroneous transaction from the address phase

Note: The default value can differ from the one shown here because a constant can be used to reduce the number of compared bits in the arbitration if a slave occupies only a limited address area. For more details see the design specification of the XBar_SRI.

Note: The ´D´ at XBAR_ERRADDRD stands for Default Slave.

XBAR_ERR0
Error/Debug Capture Register 0 (054_H) Reset Value: 0000 0000$_H$
XBAR_ERR4
Error/Debug Capture Register 4 (154_H) Reset Value: 0000 0000$_H$
XBAR_ERRx (x = 6-7)
Error/Debug Capture Register x (054_H+x*40_H) Reset Value: 0000 0000$_H$
XBAR_ERRD
Error/Debug Capture Register D (014_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RD	0	rh	**Read Indication Status** 0_B The read indication SRI-Bus signal line was asserted (read or start of RMW transaction) 1_B The read indication SRI-Bus signal line was deasserted (no read transaction)
WR	1	rh	**Write Indication Status** 0_B The write indication SRI-Bus signal line was asserted (write or start of RMW transaction) 1_B The write indication SRI-Bus signal line was deasserted (no write transaction)
SVM	2	rh	**Supervisor Mode Indication Status** 0_B The supervisor mode indication SRI-Bus signal line was deasserted 1_B The supervisor mode indication SRI-Bus signal line was asserted
OPC	[7:4]	rh	**Operation Code** This bit field contains the op-code of the erroneous transaction.

Field	Bits	Type	Description
TR_ID	[15:8]	rh	**Transaction ID** This bit field contains the transaction ID of the erroneous transaction from the address phase. The Transaction ID is build out of an 6 bit unique TAG ID TR_ID[5:0] and a 2 bit running number TR_ID[7:6] (see also **Chapter 3.6**).
ADDR_ECC	[23:16]	rh	**SRI Address Phase ECC** This bit field contains the Address Phase ECC of the erroneous transaction *Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*
MCI_SBS	[31:24]	rh	**MCI Sideband Signals [7:0]** This bit field contains the MCI Sideband Signals [7:0] that are related to the address phase informations captured by the ERRD/ERRADDR registers. In the TC21x/TC22x/TC23x Family the sideband signals are used by the DMA SRI master interface to provide information about the DMA requestor of a DMA transaction (for the encoding see **Table 3-5**).
0	3	r	**Reserved** Read as 0; should be written with 0

Note: The ´D´ at XBAR_ERRD stands for Default Slave.

XBAR_DBCON0
Debug Control Register 0 **(058_H)** **Reset Value: 0000 0000$_H$**
XBAR_DBCON4
Debug Control Register 4 **(158_H)** **Reset Value: 0000 0000$_H$**
XBAR_DBCONx (x = 6-7)
Debug Control Register x **(058_H+x*40_H)** **Reset Value: 0000 0000$_H$**
XBAR_DBCOND
Debug Control Register D **(018_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												SETDBEVT	REARM	DBSAT	DBEN
r												w	w	rh	r

Field	Bits	Type	Description
DBEN	0	r	**Status of OCDS Enable Signal** Displays the value of the OCDS enable signal from Cerberus.
DBSAT	1	rh	**Debug (OCDS) Trigger Status** 0_B The debug (OCDS) trigger was used and has to be rearmed 1_B The debug (OCDS) trigger is armed

Field	Bits	Type	Description
REARM	2	w	**Rearm Debug (OCDS) Trigger** 0_B Read back value 1_B Writing a one to this bit arms sets bit DBCON.DBSAT. Writing a one to this bit field while it's set have the following results: The debug lock of registers ERRADDR and ERR are released and the register could be updated with the next debug event request detected (see **Chapter 3.2.7.5**). In the cycle after the write action the hardware automatically clears the bit. *Note: This bit is automatically reset by the hardware after DBCON.DBSAT was set.*
SETDBEVT	3	w	**Set Debug Event** 0_B Default value 1_B A debug trigger event will be generated by this arbiter if the debug feature is enabled (DBCON.ENST is set). The registers ERR and ERRADD capture the status if not locked already. *Note: This bit is automatically reset by the hardware.*
RDEN	16	rw	**Read Trigger Enable** 0_B Read Transaction are not used to trigger the debug trigger event (OCDS) 1_B Read Transaction are used to trigger the debug trigger event (OCDS)
WREN	17	rw	**Write Trigger Enable** 0_B Write Transaction are not used to trigger the debug trigger event (OCDS) 1_B Write Transaction are used to trigger the debug trigger event (OCDS)
SVMEN	18	rw	**SVM Trigger Enable** 0_B SVM Transaction are not used to trigger the debug trigger event (OCDS) 1_B SVM Transaction are used to trigger the debug trigger event (OCDS)

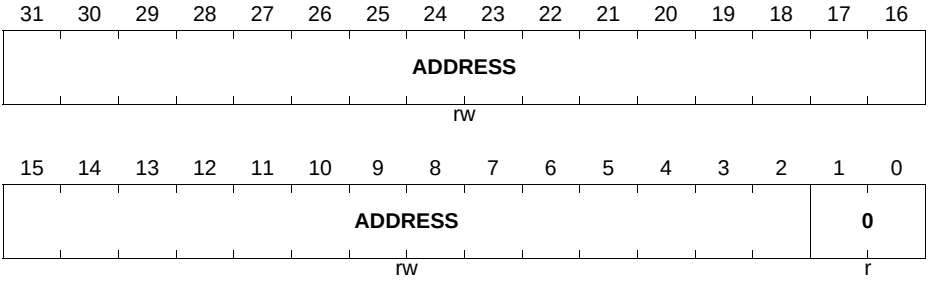
Field	Bits	Type	Description
ADDEN	19	rw	**Address Trigger Enable** 0_B Transaction addresses are not used to trigger the debug trigger event (OCDS) 1_B Transaction address defined by the registers DBADD and DBMADD are used to trigger the debug trigger event (OCDS)
ERREN	20	rw	**Error Trigger Enable** 0_B Errored Transactions are not used to trigger the debug trigger event (OCDS) 1_B Errored Transactions are used to trigger the debug trigger event (OCDS) Reading this bit return always zero. *Note: Protocol errors, starvation errors and transaction ID errors can be used where, but have to enabled before as usual in registers ARBCON or IDINTEN depending on the error type.*
MASEN	23	rw	**Master Trigger Enable** 0_B The Master TAG ID as defined in the bit field MASTER is not used to trigger the debug trigger event (OCDS) 1_B The Master TAG ID as defined in the bit field MASTER is used to trigger the debug trigger event (OCDS)
MASTER	[29:24]	rw	**Master TAG ID Trigger Selector** The value of this bit field define the Master TAG ID within the address phase of an SRI transaction to the related SRI slave module that triggers the debug trigger event (OCDS). The Master TAG IDs are defined here: **Table 3-15**.
0	[31:30], [22:21], [15:4]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is not reset with the normal system reset as all other registers in the XBar_SRI. This register is only reset with the special debug reset.

Note: The ´D´ at XBAR_DBCOND stands for Default Slave.

XBAR_DBADDD

Debug Address Register D **($01C_H$)** **Reset Value: 0000 0000_H**



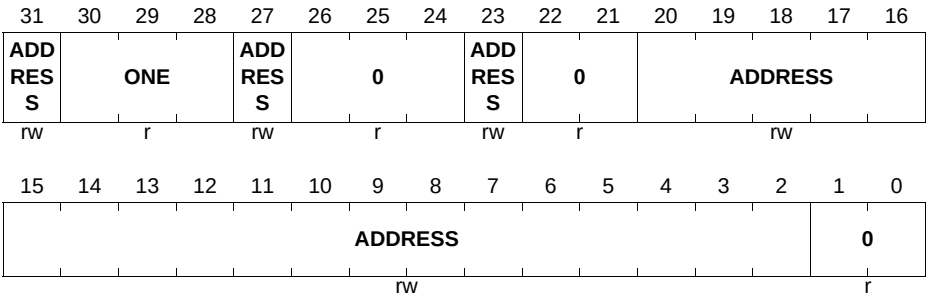
Field	Bits	Type	Description
ADDRESS	[31:2]	rw	**Debug Address Boundary**
0	[1:0]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is reset with the debug reset (Class 1 reset).

Note: The last ´D´ at XBAR_DBADDD stands for Default Slave.

XBAR_DBADD0

Debug Address Register 0 **($05C_H$)** **Reset Value: 7000 0000_H**



Field	Bits	Type	Description

ONE	31	r	**Reserved** Read as 1; should be written with 0.
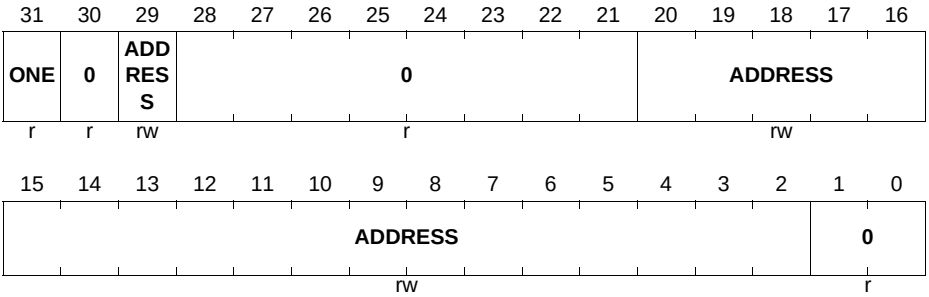
0	27, [1:0]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is reset with the debug reset (Class 1 reset).

XBAR_DBADD7
Debug Address Register 7 ($21C_H$) Reset Value: $8800\ 0000_H$



Field	Bits	Type	Description
ADDRESS, ADDRESS	29, [20:2]	rw	**Debug Address Boundary**
ONE	31	r	**Reserved** Read as 1; should be written with 0.
0	30, [28:21], [1:0]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is reset with the debug reset (Class 1 reset).

XBAR_DBMADDD
Debug Mask Address Register D (020_H) Reset Value: $0000\ 0000_H$

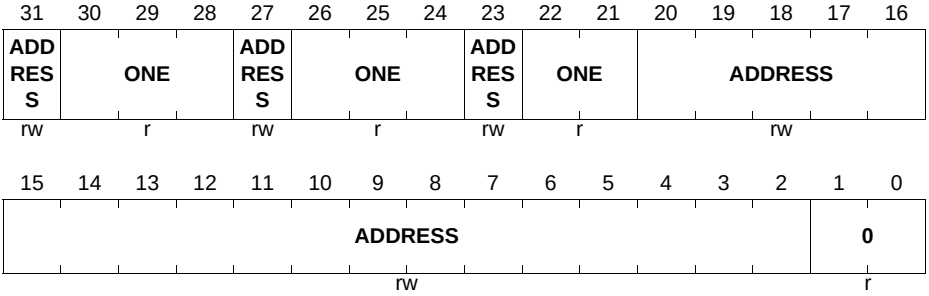
Field	Bits	Type	Description
ADDRESS	[31:0]	rw	**Debug Address Boundary**

Note: This register is reset with the debug reset (Class 1 reset).

Note: The last ´D´ at XBAR_DBMADDD stands for Default Slave.

XBAR_DBMADD0

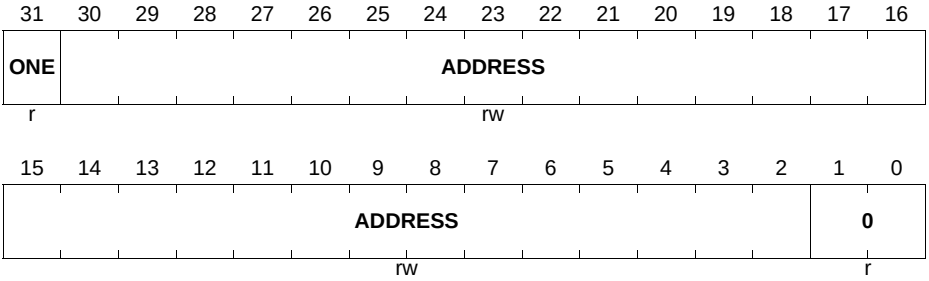
Debug Mask Address Register 0 (060_H) Reset Value: 7760 0000$_H$



Field	Bits	Type	Description
ADDRESS, ADDRESS, ADDRESS, ADDRESS	[20:2], 27, 23, 31	rw	**Debug Address Boundary**
ONE, ONE, ONE	[30:28], [26:24], [22:21]	r	**Reserved** Read as 1; should be written with 0.
0	[1:0]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is reset with the debug reset (Class 1 reset).

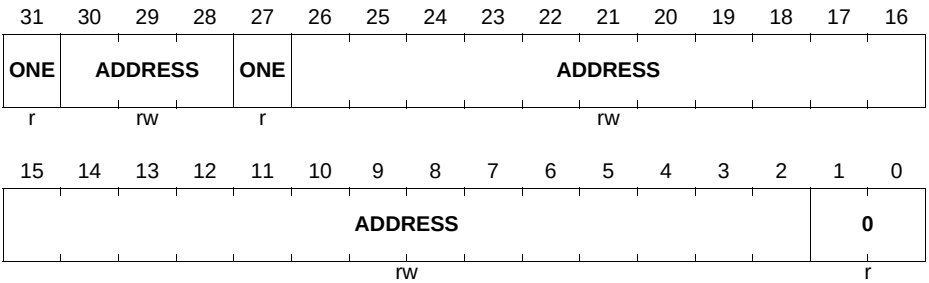
XBAR_DBMADD4
Debug Mask Address Register 4 (160_H) Reset Value: $8000\ 0000_H$



Field	Bits	Type	Description
ADDRESS	[30:2]	rw	**Debug Address Boundary**
ONE	31	r	**Reserved** Read as 1; should be written with 0.
0	[1:0]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is reset with the debug reset (Class 1 reset).

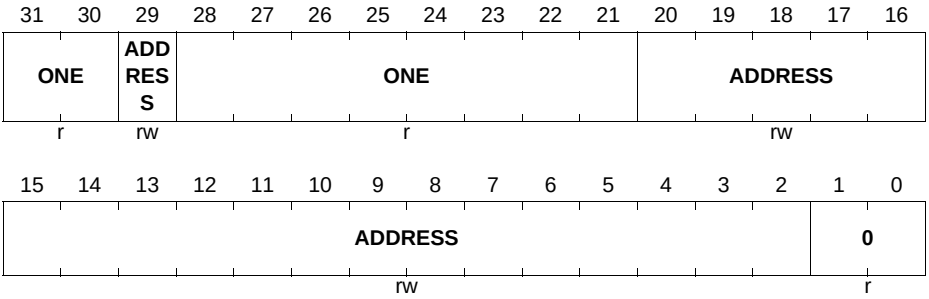
XBAR_DBMADD6
Debug Mask Address Register 6 ($1E0_H$) Reset Value: $8800\ 0000_H$



Field	Bits	Type	Description
ADDRESS, ADDRESS	[30:28], [26:2]	rw	**Debug Address Boundary**
ONE, ONE	31, 27	r	**Reserved** Read as 1; should be written with 0.
0	[1:0]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is reset with the debug reset (Class 1 reset).

XBAR_DBMADD7
Debug Mask Address Register 7 (220_H) Reset Value: DFE0 0000_H



Field	Bits	Type	Description
ADDRESS, ADDRESS	29, [20:2]	rw	**Debug Address Boundary**
ONE, ONE	[31:30], [28:21]	r	**Reserved** Read as 1; should be written with 0.
0	[1:0]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is reset with the debug reset (Class 1 reset).

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B , ... ,EN31 -> TAG ID 011111_B.

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... ,EN31 -> TAG ID 111111B.

3.3 Shared Resource Interconnect to FPI Bus Interface (SFI Bridge)

This section describes the basic functionality of the SFI Bridge.

3.3.1 Functional Overview

The SFI Bridge is implemented as an uni-directional bus bridge that forwards transactions from the System Peripheral Bus (SPB) to the SRI Interconnect. The bridge supports all transactions types of both the SRI Bus and FPI Bus.

The bridge is transparent, this means that the address of a transaction and the master TAG of a bus master is forwarded to the other side of the bridge. Addresses are only changed by the bridge where it is required by the transaction conversion from the 64 bit SRI Interconnect to the 32 bit SPB.

Bus Errors at Writes via the SFI Bridge

Write transactions are handled as posted writes. The SFI is able to buffer multiple posted writes. This means that a write operation from the SPB through the SFI Bridge to the SRI Interconnect can be finished on SPB and than generated on the SRI autonomously by the SFI. If this write operation results in a bus error on the SRI the Error information is not passed back to the SPB bus. This is also valid for transactions from SRI to SPB via SFI bridge. The bus error is detected by the on chip bus control logic of the target on chip bus system (BCU_FPI on the SPB, XBar_SRI on the SRI) which can generate an interrupt.

Note that this behavior occurs only at write operations via the SFI Bridge. It can also be triggered by an erroneous write cycle of a read-modify-write bus transaction.

3.4 System Peripheral Bus

The TC21x/TC22x/TC23x has one on-chip FPI Bus:

- System Peripheral Bus (SPB)
  - System bus for on-chip peripherals

This section gives an overview of the on-chip FPI Bus. It describes its bus control units, the bus characteristics, bus arbitration, scheduling, prioritizing, error conditions, and debugging support.

3.4.1 Overview

The FPI Bus interconnects the on-chip peripheral functional units with the TC21x/TC22x/TC23x processor subsystem.

The FPI Bus is designed to be quick to be acquired by on-chip functional units, and quick to transfer data. The low setup overhead of the FPI Bus access protocol guarantees fast FPI Bus acquisition, which is required for time-critical applications.

The FPI Bus is designed to sustain high transfer rates. For example, a peak transfer rate of up to 320 Mbyte/s can be achieved with the 32-bit data bus at 80 MHz bus clock. Multiple data transfers per bus arbitration cycle allow the FPI Bus to operate close to its peak bandwidth.

Additional features of the FPI Bus include:

- Optimized for high speed and high performance
- Support of multiple bus masters and pipelined transactions
- 32-bit wide address and data buses
- 8-, 16-, and 32-bit data transfers
- 64-, 128-, and 256-bit block transfers
- Central simple per-cycle arbitration
- Slave-controlled wait state insertion
- Support of atomic operations LDMST, ST.T and SWAP.W
- Starvation prevention mechanism that can take care that even low priority requests will be granted after a configurable number of arbitration cycles, permanently enabled
- Default slave that takes over transactions no other slave responds
- Timout detection and handling
- Capturing of transaction information in case of a bus error that cn be released by again by SW incl. transaction address, control incl. op-code, data
- Address Phase includes Supervisor Mode information
- All SPB (FPI) slave modules implemented with a TAG ID based access protection that provides a generic write protection for the control registers

The functional units of the TC21x/TC22x/TC23x are connected to the FPI Bus via FPI Bus interfaces. An FPI Bus interfaces acts as bus agents, requesting bus transactions on behalf of their functional unit, or responding to bus transaction requests.

There are two types of bus agents:

- FPI Bus master agents can initiate FPI Bus transactions and can also act as slaves.
- Slave agents can only react and respond to FPI Bus transaction requests in order to read or write internal registers of slave modules as for example memories.

When an FPI Bus master attempts to initiate a transfer on the FPI Bus, it first signals a request for bus ownership to the bus control unit (SBCU). When bus ownership is granted by the SBCU, an FPI Bus read or write transaction is initiated. The unit targeted by the transaction becomes the FPI Bus slave, and responds with the requested action.

Some functional units operate only as slaves, while others can operate as either masters or slaves on the FPI Bus.

FPI Bus arbitration is performed by the Bus Control Unit (SBCU) of the FPI Bus. In case of bus errors, the SBCU generates an interrupt request to the CPU and provides debugging information about the actual bus error to the CPU.

3.4.2 Bus Transaction Types

This section describes the SPB transaction types.

Single Transfers

Single transfers are byte, half-word, and word transactions that target any slave connected to SPB. Note that the SFI Bridge operates as an SPB master.

Block Transfers

Block transfers operate in principle in the same way as single transfers do, but one address phase is followed by multiple data phases. Block transfers can be composed of 2 word, 4 word, or 8 word transfers.

Note: In general, block transfers (2 word, 4 word, or 8 word) cannot be executed in the TC21x/TC22x/TC23x with peripheral units that operate as FPI Bus slaves during an FPI Bus transaction.

Block transfers are initiated by the following CPU instructions: LD.D, LD.DA, MOV.D, ST.D and ST.DA. Additionally there are communication peripherals that are able to generate block transfers (e.g. Ethernet).

Atomic Transfers

Atomic transfers are generated by LDMST, ST.T and SWAP.W instructions that require two single transfers. The read and write transfer of an atomic transfer are always locked and cannot be interrupted by another bus masters. Atomic transfers are also referenced as read-modify-write transfers.

*Note: See also **Table 3-11** for available FPI Bus transfer types.*

3.4.3 Reaction of a Busy Slave

If an FPI Bus slave is busy at an incoming FPI Bus transaction request, it can delay the execution of the FPI Bus transaction. The requesting FPI Bus master releases the FPI Bus for one cycle after the FPI Bus transaction request, in order to allow the FPI Bus slave to indicate if it is ready to handle the requested FPI Bus transaction. This sequence is repeated as long as the slave indicates that it is busy.

Note: For the FPI Bus default master, the one cycle gap does not result in a performance loss because it is granted the FPI Bus in this cycle as default master if no other master requests the FPI Bus for some other reasons.

3.4.4 Address Alignment Rules

FPI Bus address generation is compliant with the following rules:

- Half-word transactions must have a half-word aligned address (A0 = 0). Half-word accesses on byte lanes 1 and 2 addresses are illegal.
- Word transactions must always have word-aligned addresses (A[1:0] = 00_B).
- Block transactions must always have block-type aligned addresses.

3.4.5 FPI Bus Basic Operations

This section describes some basic transactions on the FPI Bus.

The example in **Figure 3-9** shows the three cycles of an FPI Bus operation:

1. **Request/Grant Cycle:** The FPI Bus master attempts to perform a read or write transfer and requests for the FPI Bus. If the FPI Bus is available, it is granted in the same cycle by the FPI Bus controller.
2. **Address Cycle:** After the request/grant cycle, the master puts the address on the FPI Bus, and all FPI Bus slave devices check whether they are addressed for the following data cycle.
3. **Data Cycle:** In the data cycle, either the master puts write data on the FPI Bus which is read by the FPI Bus slave (write cycle) or vice versa (read cycle).

Transfers 2 and 3 show the conflict when two master try to use the FPI Bus and how the conflict is resolved. In the example, the FPI Bus master of transfer 2 has a higher priority than the FPI Bus master of transfer 3.

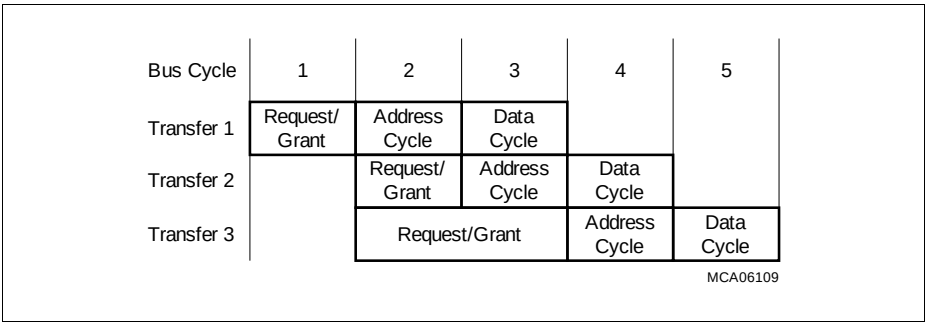

Figure 3-9 Basic FPI Bus Transactions

At a block transfer, the address cycle of a second transfer is extended until the data cycles of the block transfer are finished. In the example of **Figure 3-10**, transfer 1 is a block transfer, while transfer 2 is a single transfer.

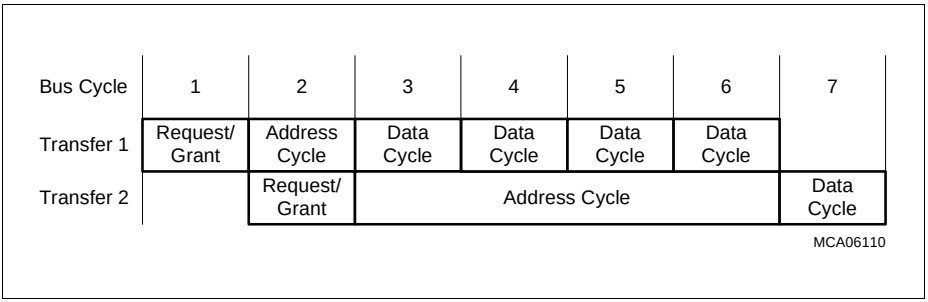

Figure 3-10 FPI Bus Block Transactions

3.5 FPI Bus Control Unit (SBCU)

The TC21x/TC22x/TC23x incorporates one FPI Bus control Unit (BCU) for the FPI based System Peripheral Bus (SPB), called System Bus Control Unit (SBCU).

3.5.1 FPI Bus Arbitration

The arbitration unit of the BCU determines whether it is necessary to arbitrate for FPI Bus ownership, and, if so, which available bus requestor gets the FPI Bus for the next data transfer. During arbitration, the bus is granted to the requesting agent with the highest priority. If no request is pending, the bus is granted to a default master. If no bus master takes the bus, the BCU itself will set the FPI Bus into an idle state.

3.5.1.1 Arbitration on the System Peripheral Bus

The TC21x/TC22x/TC23x SPB has multiple bus agents that can become SPB master:

- Each agent is assigned to 4-bit priority bit field in the PRIOH or in the PRIOL register
- The value in a priority bit field defines the related SPB master agent priority
- A lower priority number has a higher priority, ’0’ is the highest priority
- Each priority bit field in the PRIOH and PRIOL has a unique default value that can be changed during ramp up

Note: The DMA controller as an bus agent supports three priorities as this module covers two DMA Move Engines but also the Cerberus (JTAG/L1 Debug Interface) which might be used with the highest or lowest priority. Additionally the DMA Move Engine channels can be assigned to one of the three priorities.

3.5.1.2 Default Master

If no request is active, the FPI-Bus will be granted to a Default Master. The FPI master that was most recently granted will be granted to the Default Master. After reset, the master with the priority 0 will be the Default Master.

3.5.1.3 Arbitration Algorithms

The arbitration algorithm implemented in the BCU is based on:

- Priority driven arbitration of master agents with a pending request
- Starvation Prevention mechanism can increase master agent priorities during Starvation Prevention process

The default priority of each connected FPI master agent can be changed during runtime via the arbiter priority registers (PRIOH, PRIOL, see ´Changing Master Priorities´). There is a 4-bit priority bit field for each master agent in the PRIOH/PRIOL registers that defines the priority of this for this arbiter. After reset, each priority register has a default value, which means that each FPI master has unique default priority.

The default priority settings should be optimal for most applications. Where required, the arbitration setting can be adapted to the specific application needs (see ´Changing Master Priorities).

It must be ensured that two FPI master agents don’t have the same priority.

Priority Driven Arbitration

The general arbitration algorithm is priority driven where priority 0 is the highest priority and 15 the lowest one. If multiple masters are requesting for one slave, the master with the highest priority will win the next arbitration round (see also ’starvation prevention’).

Changing Master Priorities

Master priorities must be configured during ramp up as long only one FPI master agent is active (CPU0). Master priorities must not be changed while multiple FPI master agents are active / enabled.

3.5.1.4 Starvation Prevention

Starvation prevention is a feature of the SBCU that can take care that even requesting low priority master agents will be granted after a period, where the period length can be controlled by SBCU control registers. Because the priority assignment of the SPB agents is fixed, it is possible that a lower-priority bus requestor may never be granted the bus if a higher-priority bus requestor continuously asks for, and receives, bus ownership. To protect against bus starvation of lower-priority masters, the starvation prevention mechanism of the SBCU will detect such cases and momentarily raise the priority of the lower-priority requestor to the highest priority (above all other priorities), thereby guaranteeing it access.

Starvation protection employs a counter that is decremented each time an arbitration is performed on the connected FPI bus. The counter is re-loaded with the starvation period value in the SBCU_CON.SPC bit field as long it is enabled SBCU_CON.SPE. When this counter is counted down to zero, for each active bus request a request flag is stored in the BCU. This flag is cleared automatically when a master is granted the bus.

When the next period is finished, an active request of a master from which the request flag was set, a starvation event happened. This master will now be set to the highest priority and will be granted service. If there are several masters to which this starvation condition applies, they are served in the order of their configured priority ranking.

If a master that is processing its transaction under starvation condition is retried, its corresponding request flag is automatically again.

Starvation protection is permanently enabled. The sample period of the counter is programmed through bit field SBCU_CON.SPC. SPC should be set to a value at least greater than or equal to the number of masters. Its reset value is FF_H.

3.5.2 FPI Bus Error Handling

When an error occurs on an FPI Bus, its BCU captures and stores data about the erroneous condition and generates a service request if enabled to do so. The error conditions that force an error-capture are:

- Error Acknowledge: An FPI Bus slave responds with an error to a transaction.
- Un-implemented Address: No FPI Bus slave responds to a transaction request.
- Time-out: A slave does not respond to a transaction request within a certain time window. The number of bus clock cycles that can elapse until a bus time-out is generated is defined by bit field SBCU_CON.TOUT.

When a transaction causes an error, the address and data phase signals of the transaction causing the error are captured and stored in registers.

- The Error Address Capture Register (SBCU_EADD) stores the 32-bit FPI Bus address that has been captured during the erroneous FPI Bus transaction.
- The Error Data Capture Registers (SBCU_EDAT) stores the 32-bit FPI Bus data bus information that has been captured during the erroneous FPI Bus transaction.

- The Error Control Capture Register (SBCU_ECON) stores status information of the bus error event.

If more than one FPI Bus transaction generates a bus error, only the first bus error is captured. After a bus error has been captured, the capture mechanism must be released again by software. The lock is removed by reading the register SBCU_ECON which clears the SBCU_ECON.ERRCNT bit field.

Note: It is recommended to read in a debug season register ECON last as this removes the lock and a new error can already modify the content of the other two registers EDAT and EADD.

If a write transaction from TriCore causes an error on the SPB, the originating master is not informed about this error as it is not an SPB master agent. With each bus error-capture event, a service request is generated, and an interrupt can be generated if enabled and configured in the corresponding service request register.

Interpreting the BCU Control Register Error Information

Although the address and data values captured in registers SBCU_EADD and SBCU_EDAT, respectively, are self-explanatory, the captured FPI Bus control information needs some more explanation.

Register SBCU_ECON captures the state of the read (RDN), write (WRN), Supervisor Mode (SVM), acknowledge (ACK), ready (RDY), abort (ABT), time-out (TOUT), bus master identification lines (TAG) and transaction operation code (OPC) lines of the FPI Bus.

The SVM signal is set to 1 for an access in Supervisor Mode and set to 0 for an access in User Mode. The time-out signal indicates if there was no response on the bus to an access, and the programmed time (via SBCU_TOUT) has elapsed. TOUT is set to 1 in this case. An acknowledge code has to be driven by the selected slave during each data cycle of an access. These codes are listed in **Table 3-10**.

Table 3-10 FPI Bus Acknowledge Codes

Code (ACK)	Description
00_B	NSC: No Special Condition.
01_B	SPT: Split Transaction (not used in the TC21x/TC22x/TC23x).
10_B	RTY: Retry. Slave can currently not respond to the access. Master needs to repeat the access later.
11_B	ERR: Bus Error, last data cycle is aborted.

Transactions on the FPI Bus are classified via a 4-bit operation code (see **Table 3-11**). Note that split transactions (OPC = 1000_B to 1110_B) are not used in the TC21x/TC22x/TC23x.

Table 3-11 FPI Bus Operation Codes (OPC)

OPC	Description
0000_B	Single Byte Transfer (8-bit)
0001_B	Single Half-Word Transfer (16-bit)
0010_B	Single Word Transfer (32-bit)
0100_B	2-Word Block Transfer
0101_B	4-Word Block Transfer
0110_B	8-Word Block Transfer
1111	No operation
0011_B, 0111_B, 1000_B - 1110_B	Reserved

3.5.3 System Registers

Figure 3-11 shows these system registers which include registers for:

The SBCU module includes the following TC21x/TC22x/TC23x standard system registers

- Register access protection

The following TC21x/TC22x/TC23x standard system registers are not included:

- Module Clock Control
- Module Kernel Reset
- OCDS Control and Status Register

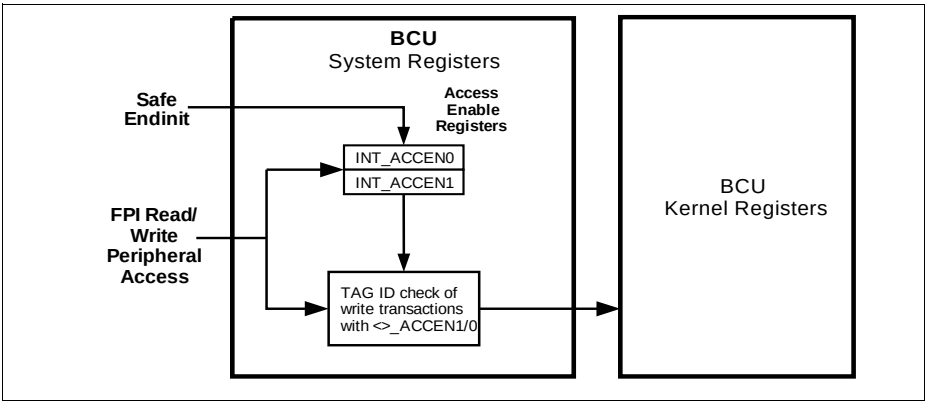

Figure 3-11 TC23 / TC22x OCB System System Registers

3.5.3.1 Register Access Protection (ACCEN1/0)

The TC23 / TC22x OCB System module provides a master TAG ID based write access protection as part of the AURIX safety concept. Each on chip resource with direct or indirect bus master capability has a unique master TAG ID that can be use to identify the master of an on chip bus transaction (see also chapter On Chip Bus Systems).

The SRC register is write protected via an On Chip Bus Master TAG-ID protection (see **Chapter 3.5.3.1**). This protection is controlled via the Interrupt Router control registers ACCEN10 and ACCEN00.

TAG ID based protection means that the support of write transactions to the TC23 / TC22x OCB System control registers can be enabled / disabled for each master TAG ID individually. For a disabled master TAG ID, write access will be disconnected with error acknowledge, read access will be processed (see also **Figure 3-11**).

The register access protection is controlled via the registers INT_ACCEN1 and INT_ACCEN0 where each bit is related to one encoding of the 6 bit On Chip Master TAG ID.

The INT_ACCEN1/0 registers are controlling the write access to all TC23 / TC22x OCB System control and system registers with the exception of the INT_ACCEN1/0 registers them self. INT_ACCEN1/0 are Safety Endinit protected.

After reset, all access enable bits and access control bits are enabled, access protection mechanism has to be configured and checked to bring the system in a safe state.

3.5.3.2 Kernel Reset Registers (KRST1/0, KRSTCLR)

The TC23 / TC22x OCB System module does not include the kernel reset registers (KRST1, KRST0, KRSTCLR).

Note: The TC23 / TC22x OCB System module does not support a module kernel reset.

3.5.3.3 Clock Control Register (CLC)

The TC23 / TC22x OCB System module does not include the module clock control (CLC).

Note: The TC23 / TC22x OCB System module does not support the Clock Control register functionality which means that the TC23 / TC22x OCB System module clock can not be disabled by the CLC register.

3.5.3.4 OCDS Control and Status Register (OCS)

The TC23 / TC22x OCB System module does not include OCDS Control and Status (OCS) register.

Note: The TC23 / TC22x OCB System module does not support the OCS register functionality.

3.5.4 BCU Debug Support

For debugging purposes, the BCU has the capability for breakpoint generation support. This OCDS debug capability is controlled by the Cerberus module and must be enabled by it (indicated by bit SBCU_DBCNTL.EO).

When BCU debug support has been enabled (EO = 1), any breakpoint request generated by the BCU to the Cerberus disarms the BCU breakpoint logic for further breakpoint requests. In order to rearm the BCU breakpoint logic again for the next breakpoint request generation, bit SBCU_DBCNTL.RA must be set. The status of the BCU breakpoint logic (armed or disarmed) is indicated by bit SBCU_DBCNTL.OA.

There are three types of trigger events:

- Address triggers
- Signal triggers
- Grant triggers

3.5.4.1 Address Triggers

The address debug trigger event conditions are defined by the contents of the SBCU_DBADR1, SBCU_DBADR2, and SBCU_DBCNTL registers. A wide range of possibilities arise for the creation of debug trigger events based on addresses. The following debug trigger events can be selected:

- Match on one signal address
- Match on one of two signal addresses
- Match on one address area
- Mismatch on one address area

Each pair of DBADRx registers and DBCNTL.ONAx bits determine one possible debug trigger event. The combination of these two possible debug trigger events defined by DBCNTL.CONCOM1 determine the address debug trigger event condition.

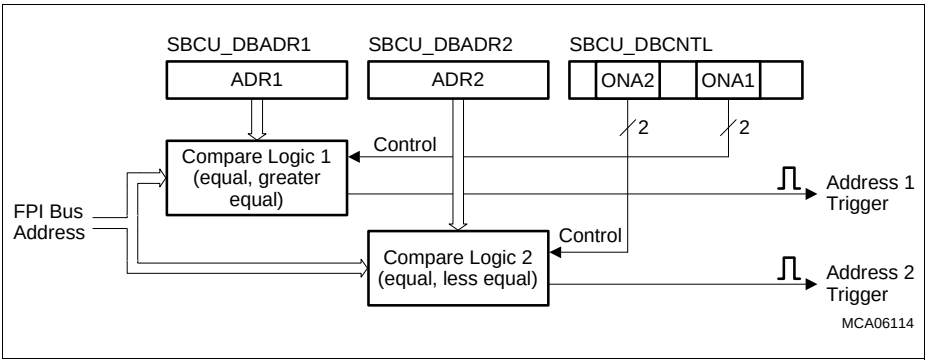

Figure 3-12 Address Trigger Generation

3.5.4.2 Signal Status Triggers

The signal status debug trigger event conditions are defined by the contents of the SBCU_DBBOS and SBCU_DBCNTL registers. Depending on the selected configuration a wide range of possibilities arise for the creation of a debug trigger event based on FPI Bus status signals. Possible combinations are:

- Match on a single signal status
- Match on a multiple signal status

With the multiple signal match conditions, all single signal match conditions are combined with a logical **AND** to the signal status debug trigger event signal. The selection whether or not a single match condition is selected can be enabled/disabled selectively for each condition via the SBCU_DBCNTL.ONBOSx bits.

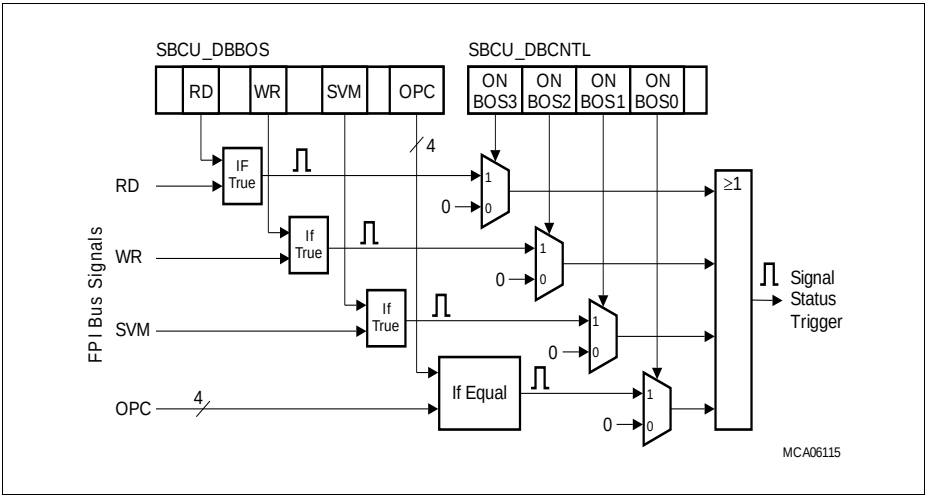

Figure 3-13 Signal Status Trigger Generation

3.5.4.3 Grant Triggers

The signal status debug trigger event conditions are defined via the registers SBCU_DBGRNT and SBCU_DBCNTL. Depending on the configuration of these registers, any combination of FPI Bus master trigger events can be configured. Only the enabled masters in the SBCU_DBGRNT register are of interest for the grant debug trigger event condition. The grant debug trigger event condition can be enabled/disabled via bit SBCU_DBCNTL.ONG (see **Figure 3-14**).

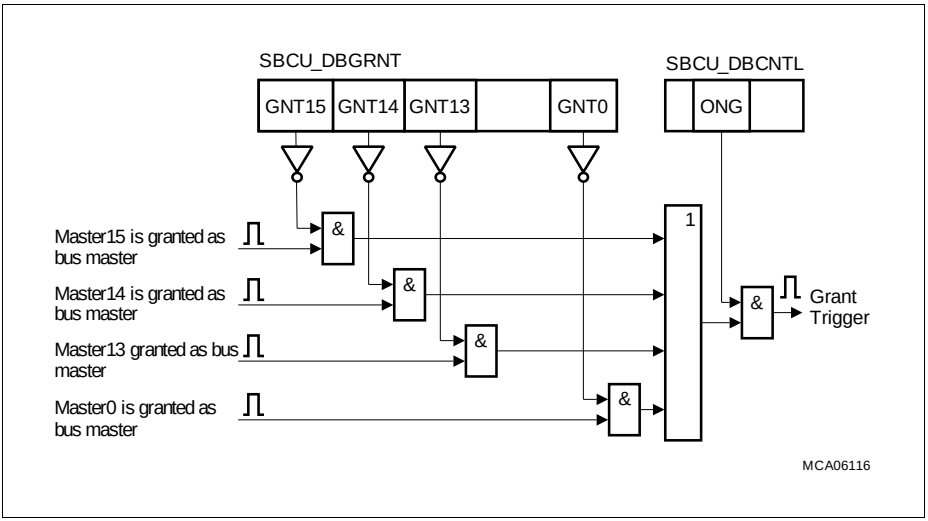

Figure 3-14 Grant Trigger Generation

3.5.4.4 Combination of Triggers

The combination of the four debug trigger signals to the single BCU breakpoint trigger event is defined via the bits CONCOM[2:0] of register SBCU_DBCNTL (see **Figure 3-15**). The two address triggers are combined to one address trigger that is further combined with signal status and grant trigger signals. A logical AND or OR combination can be selected for the BCU breakpoint trigger generation.

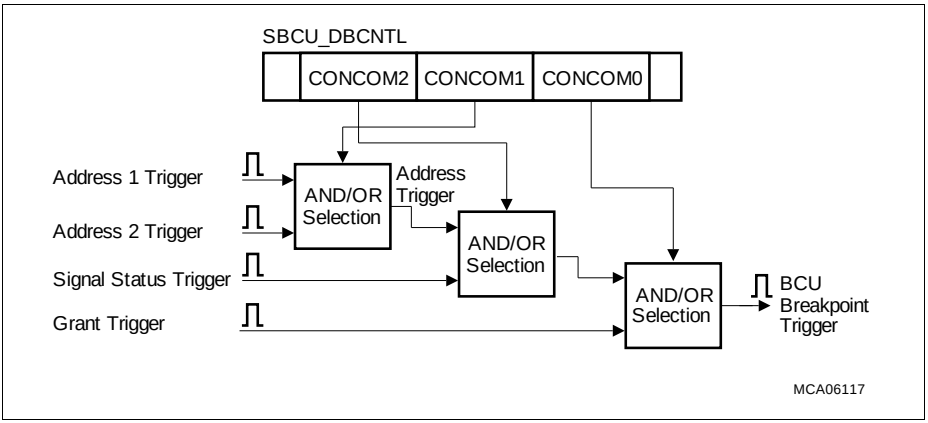

Figure 3-15 BCU Breakpoint Trigger Combination Logic

3.5.4.5 BCU Breakpoint Generation Examples

This section gives three examples of how BCU debug trigger events are programmed.

OCDS Debug Example 1

- Task: Generation of a BCU debug trigger event on any SPB write access to address 00002004_H or $000020A0_H$ by an SPB master.

For this task, the following programming settings for the BCU breakpoint logic must be executed:

1. Writing SBCU_DBADR1 = 0000 2004_H
2. Writing SBCU_DBADR2 = 0000 $20A0_H$
3. Writing SBCU_DBCNTL = $C1115010_H$:
   a) ONBOS[3:0] = 1100_B means that no signal status trigger is generated (disabled) for a read signal match AND write signal match condition according to the settings of bits RD and WR in register SBCU_DBBOS. Debug trigger event generation for Supervisor Mode signal match and op-code signal match condition is disabled.
   b) ONA2 = 01_B means that the equal match condition for debug address 2 register is selected.

c) ONA1 = 01_B means that the equal match condition for debug address 1 register is selected.
d) ONG = 1 means that the grant debug trigger is enabled.
e) CONCOM[2:0] = 101_B means that the address trigger is created by address trigger 1 OR address trigger 2 (CONCOM1 = 0), and that the grant trigger is ANDed with the address trigger (CONCOM0 = 1), and that the signal status trigger is ANDed with the address trigger (CONCOM2 = 1).
f) RA = 1 means that the BCU breakpoint logic is rearmed.

4. Writing SBCU_DBGRNT = $FFFFFFD7_H$:
means that the grant trigger for the SPB master is enabled.
5. Writing SBCU_DBBOS = 00001000_H:
means that the signal status trigger is generated on a write transfer and not on a read transfer.

OCDS Debug Example 2

- Task: generation of a BCU debug trigger event on any half-word access in User Mode to address area $01FFFFFF_H$ to $02FFFFFF_H$ by any master.

For this task, the following programming settings for the BCU breakpoint logic must be executed:

1. Writing SBCU_DBADR1 = $01FFFFFF_H$
2. Writing SBCU_DBADR2 = $02FFFFFF_H$
3. Writing SBCU_DBCNTL = 32206010_H:
a) ONBOS[3:0] = 0011_B means that the signal status trigger is disabled for a read or for write signal status match but enabled for Supervisor Mode match AND op-code match conditions according to the settings of bit SVM and bit field OPC in register SBCU_DBBOS.
b) ONA2 = 10_B means that the address 2 trigger is generated if the FPI Bus address is less or equal to SBCU_DBADR2.
c) ONA1 = 10_B means that the address 1 trigger is generated if the FPI Bus address is greater or equal to SBCU_DBADR1.
d) ONG = 0 means that the grant debug trigger is disabled.
e) CONCOM[2:0] = 110_B means that the address trigger is created by address trigger 1 AND address trigger 2 (CONCOM1 = 1), and that the grant trigger is OR-ed with the address trigger (CONCOM0 = 0), and that the signal status trigger is AND-ed with the address trigger (CONCOM2 = 1).
f) RA = 1 means that the BCU breakpoint logic is rearmed.
4. Writing SBCU_DBGRNT = $FFFFFFFF_H$:
means that no grant trigger for SPB masters is selected (“don’t care” because also disabled by ONG = 0).
5. Writing SBCU_DBBOS = 00000001_H:
means that the signal status trigger is generated for read (RD = 0) and write (WR = 0) half-word transfers (OPC = 0001_B) in User Mode (SVM = 0).

3.5.5 System Bus Control Unit Registers

Figure 3-16 and **Table 3-13** are showing the address maps with all registers of the System Bus Control Unit (SBCU) module.

List of used Reset Class abbreviations:

- Reset Class 1 -> Debug Reset (see description in the chapter SCU / Reset Types)
- Reset Class 3 -> Power On Reset, Application Reset, System Reset (see description in the chapter SCU / Reset Types)

SBCU Control Registers Overview

Table 3-13 Registers Overview - SBCU Control Registers

Short Name	Description	Offset Addr.[1]	Access Mode		Reset Class	Description See
			Read	Write		
SBCU_ DBADRT	SBCU Debug Trapped Address Register	048_H	U, SV	BE	1	Page 3-105
SBCU_ DBBOST	SBCU Debug Trapped Bus Operation Signals Register	$04C_H$	U, SV	BE	1	Page 3-106
SBCU_ DBDAT	SBCU Debug Data Status Register	050_H	U, SV	BE	1	Page 3-109
–	Reserved	054_H - $0F4_H$	BE	BE	-	-
SBCU_ ACCEN1	Access Enable Register 1 (Access Mode, Write: P1)	$0F8_H$	U, SV	SV, SE	3	Page 3-86
SBCU_ ACCEN0	Access Enable Register 0 (Access Mode, Write: P1)	$0FC_H$	U, SV	SV, SE	3	Page 3-87

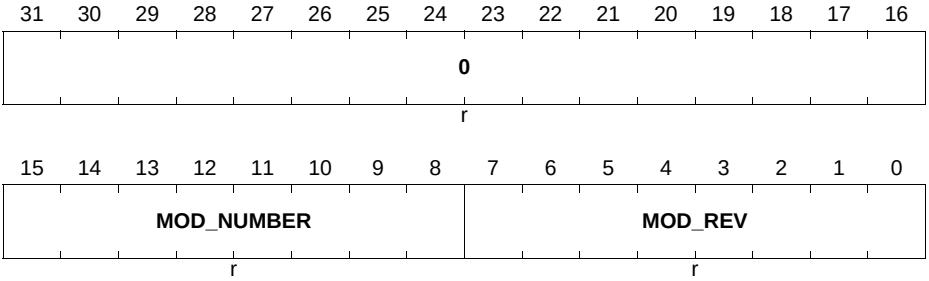
1) The absolute register address is calculated as follows:
Module Base Address (Table 3-12) + Offset Address (shown in this column)

3.5.5.1 SBCU System Registers

Module Identification Register (ID)

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the SBCU module.

SBCU_ID
Module Identification Register **(008_H)** **Reset Value: 0000 6AXX$_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_NUMBER	[15:8]	r	**Module Number Value** This bit field defines a module identification number. The value for the LBCU module is 006AH.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The registers ACCEN00 / ACCEN01 are providing one enable bit for each 6-bit On Chip Bus Master TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B , ... ,EN31 -> TAG ID 011111_B.

SBCU_ACCEN0
Access Enable Register 0 ($0FC_H$) Reset Value: $FFFF\ FFFF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN31	EN30	EN29	EN28	EN27	EN26	EN25	EN24	EN23	EN22	EN21	EN20	EN19	EN18	EN17	EN16
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN15	EN14	EN13	EN12	EN11	EN10	EN9	EN8	EN7	EN6	EN5	EN4	EN3	EN2	EN1	EN0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

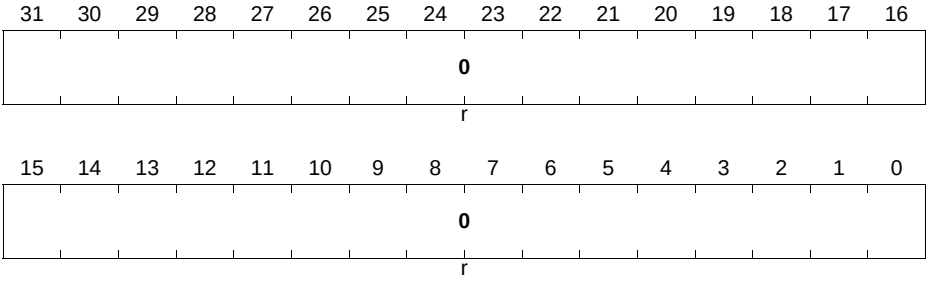
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). ACCEN11/01 are not implemented with register bits as the related On Chip Bus Master TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... ,EN31 -> TAG ID 111111B.

SBCU_ACCEN1
Access Enable Register 1 **($0F8_H$)** **Reset Value: $0000\ 0000_H$**

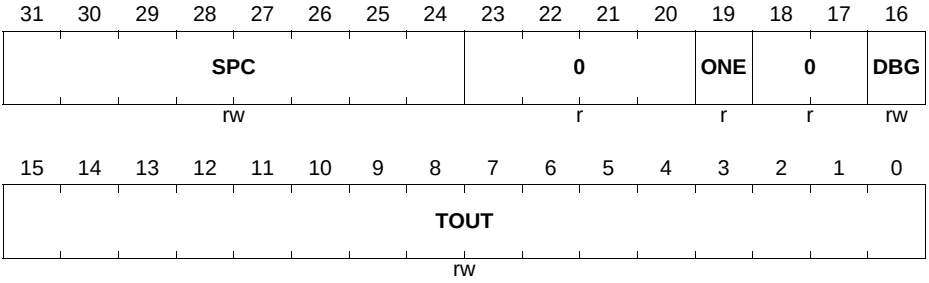


Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

3.5.5.2 SBCU Control Registers Descriptions

The SBCU Control Register controls the overall operation of the SBCU, including setting the starvation sample period, the bus time-out period, enabling starvation-protection mode, and error handling.

SBCU_CON
SBCU Control Register **(010_H)** **Reset Value: FF09 FFFF$_H$**

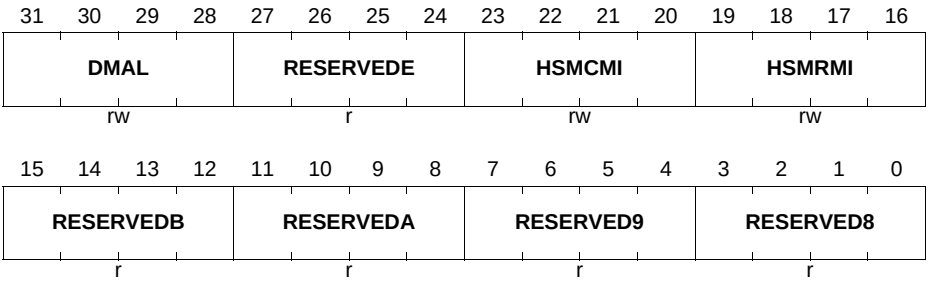


Field	Bits	Type	Description
TOUT	[15:0]	rw	**SBCU Bus Time-Out Value** The bit field determines the number of System Peripheral Bus time-out cycles. Default after reset is FFFF$_H$ (= 65536 bus cycles). Please Note: TOUT value must be >= 5.
DBG	16	rw	**SBCU Debug Trace Enable** The bit enables/disables the error capture mechanism for the registers BCU_ECON, BCU_EADD, BCU_EDAT 0_B SBCU debug trace disabled 1_B SBCU debug trace enabled (default after reset) *Note: The bit does not affect the SMU alarm or the BCU interrupt that are send in case of an error condition.*
SPC	[31:24]	rw	**Starvation Period Control** Determines the sample period for the starvation counter. Must be larger than the number of masters. The reset value is FF$_H$.
ONE	19	r	**Reserved** Read as 1; should be written with 0.

Field	Bits	Type	Description
0	[23:20], [18:17]	r	**Reserved** Read as 0; should be written with 0.

SBCU_PRIOH

Arbiter Priority Register High **(014_H)** **Reset Value: FEDC BA98$_H$**



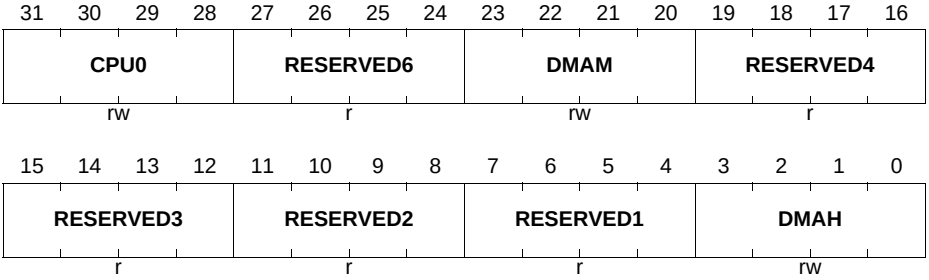
Field	Bits	Type	Description
DMAL	[31:28]	rw	**Master 15 Priority**[1)] This bit field contains the master priority for master connected to BCU request input 15 A lower number has a higher priority in the arbitration round than a higher one.
HSMRMI	[19:16]	rw	**Master 12 Priority** This bit field contains the master priority for master connected to BCU request input 12 A lower number has a higher priority in the arbitration round than a higher one.
HSMCMI	[23:20]	rw	**Master 13 Priority** This bit field contains the master priority for master connected to BCU request input 13 A lower number has a higher priority in the arbitration round than a higher one.

Field	Bits	Type	Description
RESERVEDE, **RESERVEDB,** **RESERVEDA,** **RESERVED9,** **RESERVED8**	[27:24], [15:12], [11:8], [7:4], [3:0]	r	**Reserved** Read as 1; should be written with 0.

1) Including DMA transactions from DMA channels with low priority, MLI and from Cerberus with low priority.

SBCU_PRIOL

Arbiter Priority Register Low **(018_H)** **Reset Value: 7654 3210$_H$**



Field	Bits	Type	Description
DMAH	[3:0]	rw	**Master 0 Priority**[1)] This bit field contains the master priority for master connected to BCU request input 0 A lower number has a higher priority in the arbitration round than a higher one.
DMAM	[23:20]	rw	**Master 5 Priority**[2)] This bit field contains the master priority for master connected to BCU request input 5 A lower number has a higher priority in the arbitration round than a higher one.
CPU0	[31:28]	rw	**Master 7 Priority** This bit field contains the master priority for master connected to BCU request input 8 A lower number has a higher priority in the arbitration round than a higher one.

Field	Bits	Type	Description
RESERVED6, RESERVED4, RESERVED3, RESERVED2, RESERVED1	[27:24], [19:16], [15:12], [11:8], [7:4]	r	**Reserved** Read as 1; should be written with 0.

1) Including DMA transactions from DMA channels with high priority and from Cerberus with high priority.

2) Including DMA transactions from DMA channels with medium priority.

Note: Reset values for bits/bit fields coupled to masters or slaves that are not configured or enabled are zero

3.5.5.3 SBCU Error Registers Descriptions

The capture of bus error conditions is enabled by setting SBCU_CON.DBG to 1. In case of a bus error, information about the condition will then be stored in the SBCU error capture registers. The SBCU error capture registers can then be examined by software to determine the cause of the FPI Bus error.

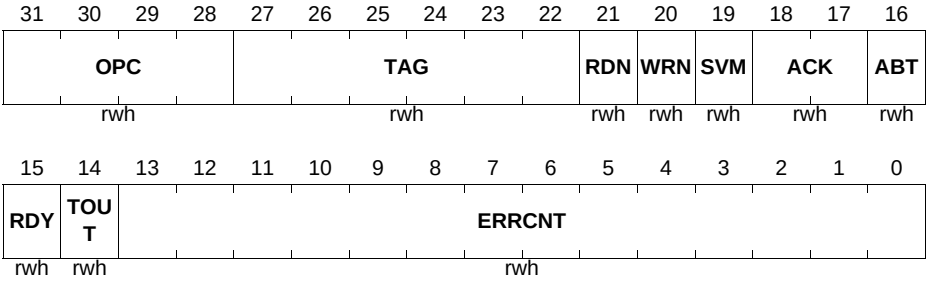
If enabled and an FPI Bus error occurs, the SBCU_ECON register holds the captured FPI Bus control information and an error count of the number of bus errors. The SBCU_EADD register stores the captured FPI Bus address. The SBCU_EDAT register stores the captured FPI Bus data.

If the capture of FPI Bus error conditions is disabled (SBCU_CON.DBG = 0), the SBCU error capture registers remain untouched.

Note: The SBCU error capture registers store only the parameters of the first error. In case of multiple bus errors, an error counter SBCU_ECON.ERRCNT shows the number of bus errors since the first error occurred. An application reset clears this bit field to zero, but the counter can be set to any value through software. This counter is prevented from overflowing, so a value of 2^{16} - 1 indicates that at least this many errors have occurred, but there may have been more. After SBCU_ECON has been read, the SBCU_ECON, SBCU_EADD and SBCU_EDAT registers are re-enabled to trace FPI Bus error conditions.

SBCU_ECON

SBCU Error Control Capture Register (020_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
ERRCNT	[13:0]	rwh	**FPI Bus Error Counter** ERRCNT is incremented on every occurrence of an FPI Bus error. ERRCNT is reset to 0 after the SBCU_ECON register is read.[1)]
TOUT	14	rwh	**State of FPI Bus Time-Out Signal** This bit indicates the state of the time-out signal at an FBI Bus error. 0_B No time-out occurred 1_B Time-out has occurred
RDY	15	rwh	**State of FPI Bus Ready Signal** This bit indicates the state of the ready signal at an FBI Bus error. 0_B Wait state(s) have been inserted. Ready signal was active 1_B Ready signal was inactive
ABT	16	rwh	**State of FPI Bus Abort Signal** This bit indicates the state of the abort signal at an FBI Bus error. 0_B Master has aborted an FPI Bus transfer. Abort signal was active 1_B Abort signal was inactive
ACK	[18:17]	rwh	**State of FPI Bus Acknowledge Signals** This bit field indicates the acknowledge code that has been output by the selected slave at an FPI Bus error. Coding see **Table 3-10**.

Field	Bits	Type	Description
SVM	19	rwh	**State of FPI Bus Supervisor Mode Signal** This bit indicates whether the FPI Bus error occurred in Supervisor Mode or in User Mode. 0_B Transfer was initiated in User Mode 1_B Transfer was initiated in Supervisor Mode
WRN	20	rwh	**State of FPI Bus Write Signal** This bit indicates whether the FPI Bus error occurred at a write cycle (see**Table 3-14**).
RDN	21	rwh	**State of FPI Bus Read Signal** This bit indicates whether the FPI Bus error occurred at a read cycle (see**Table 3-14**).
TAG	[27:22]	rwh	**FPI Bus Master Tag Number Signals** This bit field indicates the FPI Bus master TAG number (definitions see **Table 3-15**).
OPC	[31:28]	rwh	**FPI Bus Operation Code Signals** The FPI Bus operation codes are defined in **Table 3-11**.

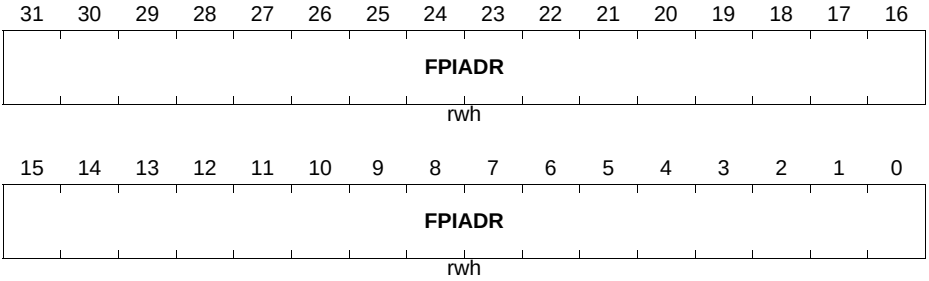
1) In the TC21x/TC22x/TC23x, aborted accesses to a 0 wait state SPB slave may also increment ERRCNT when the slave generates an error acknowledge.

Table 3-14 FPI Bus Read/Write Error Indication

$\overline{RD}$	$\overline{WR}$	FPI Bus Cycle
0	0	FPI Bus error occurred at the read transfer of a read-modify-write transfer.
0	1	FPI Bus error occurred at a read cycle of a single transfer.
1	0	FPI Bus error occurred at a write cycle of a single transfer or at the write cycle of a read-modify-write transfer.
1	1	Does not occur.

SBCU_EADD

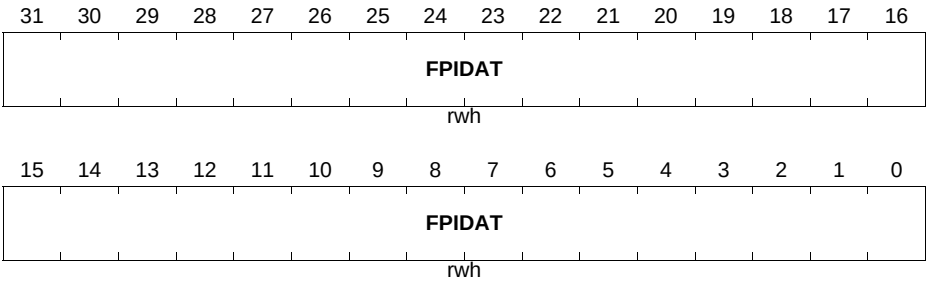
SBCU Error Address Capture Register (024_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FPIADR	[31:0]	rwh	**Captured FPI Bus Address** This bit field holds the 32-bit FPI Bus address that has been captured at an FPI Bus error. Note that if multiple bus errors occurred, only the address of the first bus error is captured.

SBCU_EDAT

SBCU Error Data Capture Register (028_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FPIDAT	[31:0]	rwh	**Captured FPI Bus Data** This bit field holds the 32-bit FPI Bus data that has been captured at an FPI Bus error. Note that if multiple bus errors occurred, only the data of the first bus error is captured.

3.5.5.4 SBCU OCDS Registers Descriptions

SBCU_DBCNTL
SBCU Debug Control Register **(030_H)** **Reset Value: 0000 7003$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ONBOS3	ONBOS2	ONBOS1	ONBOS0	0		ONA2		0		ONA1		0			ONG
rw	rw	rw	rw	r		rw		r		rw		r			rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CONCOM2	CONCOM1	CONCOM0	0							RA	0		OA	EO
r	rw	rw	rw	r							w	r		r	r

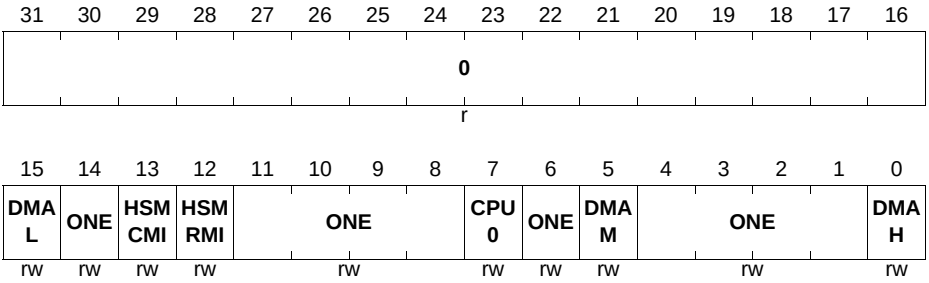
Field	Bits	Type	Description
EO	0	r	**Status of SBCU Debug Support Enable** This bit is controlled by the Cerberus and enables the SBCU debug support. 0_B SBCU debug support is disabled 1_B SBCU debug support is enabled (default after reset)
OA	1	r	**Status of SBCU Breakpoint Logic** 0_B The SBCU breakpoint logic is disarmed. Any further breakpoint activation is discarded 1_B The SBCU breakpoint logic is armed The OA bit is set by writing a 1 to bit RA. When OA is set, registers SBCU_DBGNTT, SBCU_DBADRT, and SBCU_DBDAT are reset. Also SBCU_DBBOST is reset with the exception of the bit field FPIRST.
RA	4	w	**Rearm SBCU Breakpoint Logic** Writing a 1 to this bit rearms SBCU breakpoint logic and sets bit OA = 1. RA is always reads as 0.

Field	Bits	Type	Description
CONCOM0	12	rw	**Grant and Address Trigger Relation** 0_B The grant phase trigger condition and the address trigger condition (see CONCOM1) are combined with a logical OR for further control 1_B The grant phase trigger condition and the address trigger condition (see CONCOM1) are combined with a logical AND for further control (see **Figure 3-15**)
CONCOM1	13	rw	**Address 1 and Address 2 Trigger Relation** 0_B Address 1 trigger condition and address 2 trigger condition are combined with a logical OR to the address trigger condition for further control 1_B Address 1 trigger condition and address 2 trigger condition are combined with a logical AND to the address trigger condition for further control (see **Figure 3-15**)
CONCOM2	14	rw	**Address and Signal Trigger Relation** 0_B Address trigger condition (see CONCOM1) and signal status trigger conditions are combined with a logical OR for further control 1_B Address phase trigger condition (see CONCOM1) and the signal status trigger conditions are combined with a logical AND for further control (see **Figure 3-15**)
ONG	16	rw	**Grant Trigger Enable** 0_B No grant debug event trigger is generated 1_B The grant debug event trigger is enabled and generated according the settings of register SBCU_DBGRNT (see **Figure 3-15**)
ONA1	[21:20]	rw	**Address 1 Trigger Control** 00_B No address 1 trigger is generated 01_B An address 1 trigger event is generated if the FPI Bus address is equal to SBCU_DBADR1 10_B An address 1 trigger event is generated if FPI Bus address is greater or equal to SBCU_DBADR1 11_B same as 00_B (See also **Figure 3-12**).

Field	Bits	Type	Description
ONA2	[25:24]	rw	**Address 2 Trigger Control** 00_B No address 2 trigger is generated 01_B An address 2 trigger event is generated if the FPI Bus address is equal to SBCU_DBADR2 10_B An address 2 trigger event is generated if FPI Bus address is less or equal to SBCU_DBADR2 11_B same as 00_B See also **Figure 3-12**.
ONBOS0	28	rw	**Opcode Signal Status Trigger Condition** 0_B A signal status trigger is generated for all FPI Bus op-codes except a “no operation” op-code 1_B A signal status trigger is generated if the FPI Bus op-code matches the op-code as defined in DBBOS.OPC (see **Figure 3-13**)
ONBOS1	29	rw	**Supervisor Mode Signal Trigger Condition** 0_B The signal status trigger generation for the FPI Bus Supervisor Mode signal is disabled 1_B A signal status trigger is generated if the FPI Bus Supervisor Mode signal state is equal to the value of DBBOS.SVM (see **Figure 3-13**)
ONBOS2	30	rw	**Write Signal Trigger Condition** 0_B The signal status trigger generation for the FPI Bus write signal is disabled 1_B A signal status trigger is generated if the FPI Bus write signal state is equal to the value of DBBOS.WR (see **Figure 3-13**)
ONBOS3	31	rw	**Read Signal Trigger Condition** 0_B The signal status trigger generation for the FPI Bus read signal is disabled 1_B A signal status trigger is generated if the FPI Bus read signal state is equal to the value of DBBOS.RD (see **Figure 3-13**)

Field	Bits	Type	Description
0	[3:2], [11:5], 15, [19:17], [23:22], [27:26]	r	**Reserved** Read as 0; should be written with 0.

SBCU_DBGRNT
SBCU Debug Grant Mask Register (034_H) Reset Value: $0000\ FFFF_H$



Field	Bits	Type	Description
DMAH	0	rw	**Cerberus Grant Trigger Enable, High Priority[1)]** 0_B FPI Bus transactions with high-priority DMA as bus master are enabled for grant trigger event generation 1_B FPI Bus transactions with high-priority DMA as bus master are disabled for grant trigger event generation
DMAM	5	rw	**DMA Grant Trigger Enable, Medium Priority[2)]** 0_B FPI Bus transactions with medium-priority DMA channels as bus master are enabled for grant trigger event generation 1_B FPI Bus transactions with medium-priority DMA channels as bus master are disabled for grant trigger event generation

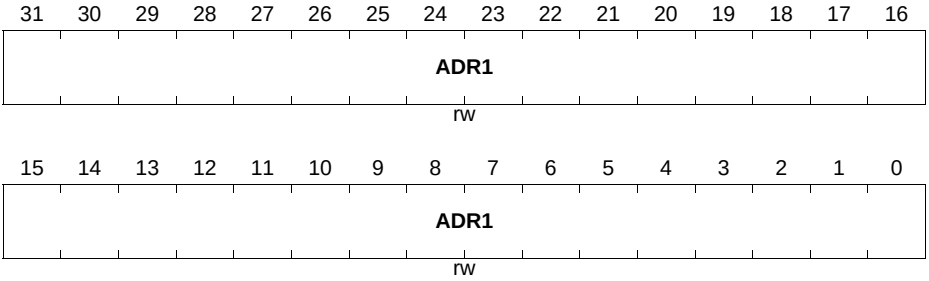
Field	Bits	Type	Description
CPU0	7	rw	**CPU0 Grant Trigger Enable** 0_B FPI Bus transactions with CPU0 as bus master are enabled for grant trigger event generation 1_B FPI Bus transactions with CPU as bus master are disabled for grant trigger event generation
HSMRMI	12	rw	**HSM Register Master Interface Grant Trigger Enable** 0_B FPI Bus transactions requested by the HSM bus master are enabled for grant trigger event generation 1_B FPI Bus transactions requested by the HSM bus master are disabled for grant trigger event generation
HSMCMI	13	rw	**HSM Cache Master Interface Grant Trigger Enable** 0_B FPI Bus transactions requested by the HSM bus master are enabled for grant trigger event generation 1_B FPI Bus transactions requested by the HSM bus master are disabled for grant trigger event generation
DMAL	15	rw	**DMA Grant Trigger Enable, Low Priority[3)]** 0_B FPI Bus transactions with low-priority DMA channels as bus master are enabled for grant trigger event generation 1_B FPI Bus transactions with low-priority DMA channels as bus master are disabled for grant trigger event generation
ONE, ONE, ONE, ONE	14, [11:8], 6, [4:1]	rw	**Reserved** Read as 1 after reset; reading these bits will return the value last written.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

1) Including DMA transactions from DMA channels with high priority and from Cerberus with high priority.

2) Including DMA transactions from DMA channels with medium priority.

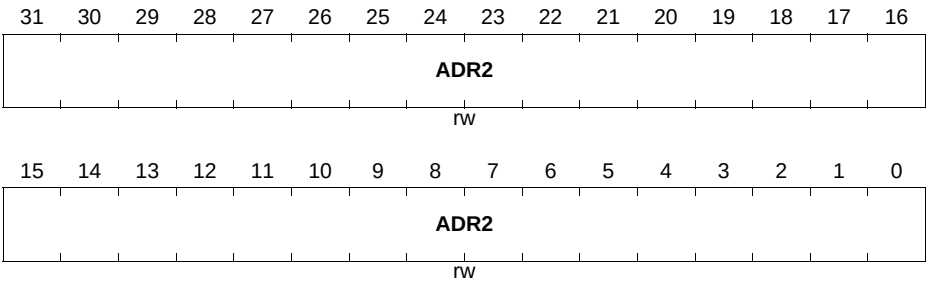
3) Including DMA transactions from DMA channels with low priority and from Cerberus with low priority.

SBCU_DBADR1
SBCU Debug Address 1 Register (038_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
ADR1	[31:0]	rw	**Debug Trigger Address 1** This register contains the address for the address 1 trigger event generation.

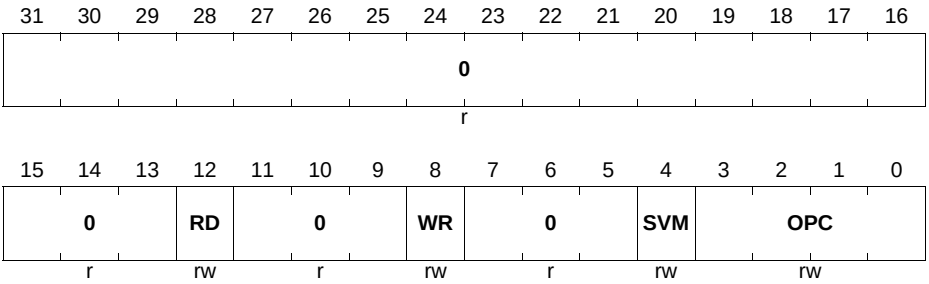
SBCU_DBADR2
SBCU Debug Address 2 Register ($03C_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
ADR2	[31:0]	rw	**Debug Trigger Address 2** This register contains the address for the address 2 trigger event generation.

SBCU_DBBOS
SBCU Debug Bus Operation Signals Register

(040_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
OPC	[3:0]	rw	**Opcode for Signal Status Debug Trigger** This bit field determines the type (opcode) of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS0 = 1). 0000_B Trigger on single byte transfer selected 0001_B Trigger on single half-word transfer selected 0010_B Trigger on single word transfer selected 0100_B Trigger on 2-word block transfer selected 0101_B Trigger on 4-word block transfer selected 0110_B Trigger on 8-word block transfer selected 1111_B Trigger on no operation selected Other bit combinations are reserved.
SVM	4	rw	**SVM Signal for Status Debug Trigger** This bit determines the mode of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS1 = 1). 0_B Trigger on User Mode selected 1_B Trigger on Supervisor Mode selected

Field	Bits	Type	Description
WR	8	rw	**Write Signal for Status Debug Trigger** This bit determines the state of the $\overline{WR}$ signal of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS2 = 1). 0_B Trigger on a single write transfer or write cycle of an atomic transfer selected 1_B No operation or read transaction selected
RD	12	rw	**Write Signal for Status Debug Trigger** This bit determines the state of the $\overline{RD}$ signal of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS3 = 1). 0_B Trigger on a single read transfer or read cycle of an atomic transfer selected 1_B No operation or write transfer selected
0	[7:5], [11:9], [31:13]	r	**Reserved** Read as 0; should be written with 0.

SBCU_DBGNTT

SBCU Debug Trapped Master Register

(044_H) **Reset Value: 0000 FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ONE								DMACHNR							
rw								rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMAL	ONE	HSMCMI	HSMRMI	ONE				CPU0	ONE	DMAM	ONE				DMAH
rw	rw	rw	rw	rw				rw	rw	rw	rw				rw

Field	Bits	Type	Description
DMAH	0	rw	**High-Priority DMA FPI Bus Master Status[1)]** This bit indicates whether the DMA with a medium priority request was FPI Bus master when the break trigger event occurred. 0_B The medium-priority DMA was the FPI bus master. 1_B The medium-priority DMA was not the FPI Bus master.
DMAM	5	rw	**Medium-Priority DMA FPI Bus Master Status[2)]** This bit indicates whether the DMA with a medium priority request was FPI Bus master when the break trigger event occurred. 0_B The medium-priority DMA was the FPI bus master. 1_B The medium-priority DMA was not the FPI Bus master.
CPU0	7	rw	**CPU0 FPI Bus Master Status** This bit indicates whether the CPU0 was FPI Bus master when the break trigger event occurred. 0_B The CPU0 was the FPI Bus master. 1_B The CPU0 was not the FPI Bus master.
HSMRMI	12	rw	**HSM Register FPI Bus Master Interface Status** This bit indicates whether the HSM was FPI Bus master when the break trigger event occurred. 0_B HSMRMI was the FPI bus master. 1_B HSMRMI was not the FPI Bus master.
HSMCMI	13	rw	**HSM Cache FPI Bus Master Interface Status** This bit indicates whether the HSM was FPI Bus master when the break trigger event occurred. 0_B HSMCMI was the FPI bus master. 1_B HSMCMI was not the FPI Bus master.

Field	Bits	Type	Description
DMAL	15	rw	**Low-Priority DMA FPI Bus Master Status**[3)] This bit indicates whether the DMA with a low-priority request was the FPI Bus master when the break trigger event occurred. 0_B The low-priority DMA was the FPI Bus master. 1_B The low-priority DMA was not the FPI Bus master.
DMACHNR	[23:16]	rw	**DMA-FPI Channel Grant Status** The encoding is directly dedicated to the dma channel number
ONE, **ONE,** **ONE,** **ONE,** **ONE**	[31:24], 14, [11:8], 6, [4:1]	rw	**Reserved** Read as 1; shall be written with 0.

1) Including DMA transactions from DMA channels with high priority and from Cerberus with high priority.

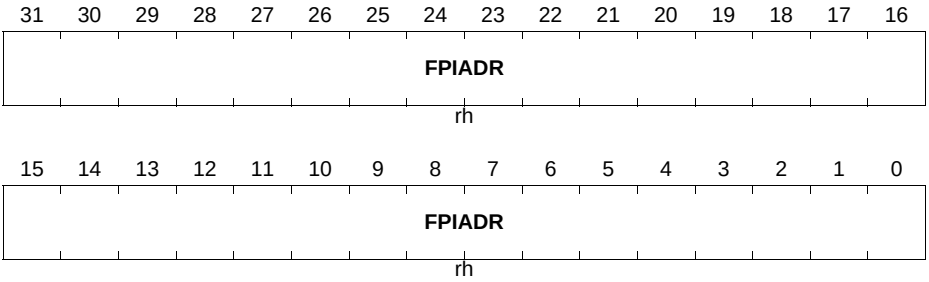
2) Including DMA transactions from DMA channels with medium priority.

3) Including DMA transactions from DMA channels with low priority, MLI and from Cerberus with low priority.

SBCU_DBADRT

SBCU Debug Trapped Address Register

(048_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FPIADR	[31:0]	rh	**FPI Bus Address Status** This register contains the FPI Bus address that was captured when the OCDS break trigger event occurred.

SBCU_DBBOST
SBCU Debug Trapped Bus Operation Signals Register
(04C$_H$) **Reset Value: 0000 3180$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh		rh	rh	rh		rh	rh			

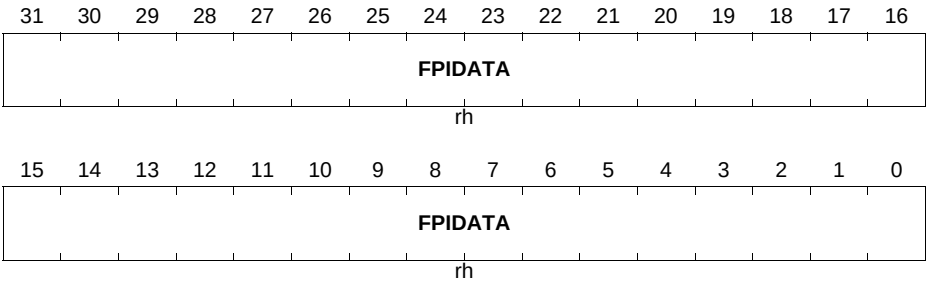
Field	Bits	Type	Description
FPIOPC	[3:0]	rh	**FPI Bus Opcode Status** This bit field indicates the type (opcode) of the FPI Bus transaction captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0000_B Single byte transfer 0001_B Single half-word transfer 0010_B Single word transfer 0100_B 2-word block transfer 0101_B 4-word block transfer 0110_B 8-word block transfer 1111_B No operation Other bit combinations are reserved.

Field	Bits	Type	Description
FPISVM	4	rh	**FPI Bus Supervisor Mode Status** This bit indicates the state of the Supervisor Mode signal captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B User mode 1_B Supervisor mode
FPIACK	[6:5]	rh	**FPI Bus Acknowledge Status** This bit field indicates the acknowledge signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 00_B No special case 01_B Error 10_B Reserved 11_B Retry, slave did not respond
FPIRDY	7	rh	**FPI Bus Ready Status** This bit indicates the ready signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B Last cycle of transfer 1_B Not last cycle of transfer
FPIWR	8	rh	**FPI Bus Write Indication Status** This bit indicates the write signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B Single write transfer or write cycle of an atomic transfer 1_B No operation or read transfer
FPIRST	[10:9]	rh	**FPI Bus Reset Status** This bit field indicates the reset signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 00_B Reset of all FPI Bus components 11_B No reset Others Reserved

Field	Bits	Type	Description
FPIOPS	11	rh	**FPI Bus OCDS Suspend Status** This bit indicates the OCDS suspend signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B No OCDS suspend request is pending 1_B An OCDS suspend request is pending
FPIRD	12	rh	**FPI Bus Read Indication Status** This bit indicates the read signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B Single read transfer or read cycle of an atomic transfer 1_B No operation or write transfer
FPIABORT	13	rh	**FPI Bus Abort Status** This bit indicates the abort signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B A transfer that has already started was aborted 1_B Normal operation
FPITOUT	14	rh	**FPI Bus Time-out Status** This bit indicates the time-out signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B Normal operation 1_B A time-out event was generated
ENDINIT	15	rh	**FPI Bus Endinit Status** This bit indicates the ENDINIT signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B Normal operation 1_B System was in ENDINIT state
FPITAG	[21:16]	rh	**FPI Bus Master TAG Status** This bit field indicates the master TAG captured from the FPI Bus signal lines when the BCU break trigger event occurred (see **Table 3-15**). The master TAG identifies the master of the transfer which generated BCU break trigger event.
0	[31:22]	rh	**Reserved** Read as 0; should be written with 0.

SBCU_DBDAT
SBCU Debug Data Status Register

(050_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FPIDATA	[31:0]	rh	**FPI Bus Data Status** This register contains the FPI Bus data that was captured when the OCDS break trigger event occurred.

3.6 On Chip Bus Master TAG Assignments

Each master interface on the System Peripheral Bus and on the SRI Bus is assigned to a 6-bit identification number, the master TAG number (see **Table 3-15**). This makes it possible for software debug and MCDS purposes to distinguish which master has performed the current transaction (see **"XBAR_ERR0" on Page 3-51**[1)] and **"SBCU_DBADRT" on Page 3-105**).

Table 3-15 On Chip Bus Master TAG Assignments

TAG-Number	Module	Location	Description
000000_B	CPU0	SRI/SPB	DMI.NonSafe TAG ID
000001_B	CPU0	SRI/SPB	DMI.Safe TAG ID
000010_B	-	-	Reserved
000011_B	-	-	Reserved
000100_B	-	-	Reserved

1) Pls. note that the Transaction ID bit field in the register **"XBAR_ERR0" on Page 3-51** includes the TAG ID on the 6 MSB (TRID[5:0]).

Table 3-15 On Chip Bus Master TAG Assignments

TAG-Number	Module	Location	Description
000101_B	-	-	Reserved
000110_B	DMA	SRI/SPB	DMA Resource Partition 0
000111_B	DMA	SRI/SPB	DMA Resource Partition 1
001000_B	DMA	SRI/SPB	DMA Resource Partition 2
001001_B	DMA	SRI/SPB	DMA Resource Partition 3
001010_B	DMA	SRI/SPB	Cerberus
001011_B	-	-	Reserved
001100_B	Ethernet	SPB	TC23x ED: Ethernet TC23x: Reserved TC22x: Reserved
001101_B	HSM	SPB	TC23x: HSMCMI, HSMRMI[1)] TC22x: Reserved
001110_B	-	-	Reserved
001111_B	-	-	Reserved
010000_B	CPU0	SRI	PMI
010001_B	-	-	Reserved
011100_B	IOC32	BBB	Cerberus on Back Bone Bus (ED)
011101_B	EMEM	BBB	EMEM Master on Back Bone Bus (ED)
Others	-	-	Reserved

1) Both HSM FPI Master Interfaces (HSMCMI, HSMRMI) are using the sam TAG ID

3.7 On Chip Bus Access Times

The table describes the CPU access times in CPU clock cycles for the TC21x/TC22x/TC23x. The access times are described as maximum CPU stall cycles where e.g. an data access to the local DSPR results in zero stall cycles. Pls. note that the CPU does not always immediately stall after the start of a data read from another SPR due to instruction pipelining effects. This means that the average number will be below the here shown numbers[RF00105].

Note: All values are preliminary

Table 3-16 CPU access latency in CPU clock cycles for TC21x/TC22x/TC23x

CPU Access Mode	CPU clock cycles
Data read access to own DSPR	0
Data write access to own DSPR	0
Data read access to own or other PSPR	5
Data write access to own or other PSPR	0
Data read access to own or other DSPR	5
Data write access to own or other DSPR	0
Instruction fetch from own PSPR	0
Instruction fetch from other PSPR (critical word)	5
Instruction fetch from other PSPR (any remaining words)	0
Instruction fetch from other DSPR (critical word)	5
Instruction fetch from other DSPR (any remaining words)	0
Initial Pflash Access (critical word)	5 + configured PFlash Wait States[1)]
Initial Pflash Access (remaining words)	0
PMU PFlash Buffer Hit (critical word)	4
PMU PFlash Buffer Hit (remaining words)	0
Initial Dflash Access	5 + configured DFlash Wait States[2)]
TC1.6E/P Data read from System Peripheral Bus (SPB)	4 ($f_{CPU}=f_{SPB}$) 7 ($f_{CPU}=2*f_{SPB}$)
TC1.6E/P Data write to System Peripheral Bus (SPB)	0

1) FCON.WSPFLASH + FCON.WSECPF (see PMU chapter for the detailed description of these parameters).

2) FCON.WSDFLASH + FCON.WSECDF (see PMU chapter for the detailed description of these parameters).

4 Memory Maps

This chapter gives an overview of the TC23x and TC22x memory maps, and describes the address locations and access possibilities for the units, memories, and reserved areas as “seen” from the two different on-chip buses’ point of view.

The TC23x has the following CPU related memories:

- Program Memory Unit (PMU0) with
  - 2 Mbyte of Program Flash Memory (PFLASH)
  - Data Flash Memory (DF_EEPROM)
  - User Configuration Blocks (DF_UCB)
  - 32 Kbyte of Boot ROM (BROM)
- CPU0:
  - 8 Kbyte of Program Scratch-Pad SRAM (PSPR)[1)]
  - 184 Kbyte of Data Scratch-Pad SRAM (DSPR)[1)]
  - 8 Kbyte of Program Cache (PCache)
- LMU:
  - 0 Kbyte SRAM (LMURAM)[1)]

The TC22x has the following CPU related memories:

- Program Memory Unit (PMU0) with
  - 1 Mbyte of Program Flash Memory (PFLASH)
  - Data Flash Memory (DF_EEPROM)
  - User Configuration Blocks (DF_UCB)
  - 32 Kbyte of Boot ROM (BROM)
- CPU0:
  - 8 Kbyte of Program Scratch-Pad SRAM (PSPR)[1)]
  - 88 Kbyte of Data Scratch-Pad SRAM (DSPR)[1)]
  - 8 Kbyte of Program Cache (PCache)
- LMU:
  - 0 Kbyte SRAM (LMURAM)[1)]

Furthermore, the each device has two on-chip buses:

- System Peripheral Bus (SPB)
- Shared Resource Interconnect (SRI)

1) Before used by the application, the memory has to be initialized (see chapter ´Memory Test Unit´, MTU)

4.1 How to Read the Address Maps

The bus-specific address maps describe how the different bus master devices react on accesses to on-chip memories and modules, and which address ranges are valid or invalid for the corresponding buses.

The detailed address mapping of e.g. control registers, sram blocks or flash banks/sectors within a module is described in the related module chapter.

The SPB Bus address map shows the system addresses from the point of view of the SPB master agents[1)].

The SRI address map shows the system addresses from the point of view of the SRI master agents[1)].

The SFI is a bi-directional bridge between SRI and SPB and therefore not mentioned here as SRI or SPB master in the Address Map. The SFI is fully transparent and does not include an address translation mechanism.

Note: In addition to the here described system address map, each TriCore has a TriCore IP internal access to its PSPR via C000_0000 and an internal access to its DSPR via D000_0000. This additional/private view to the local scratch pad srams is described in the CPU chapter.

1) Available SRI / SPB master agents are described in the On Chip Bus System chapter

Table 4-1 defines the acronyms and other terms that are used in the address maps (Table 4-2 and Table 4-3).

Table 4-1 Definition of Acronyms and Terms

Term	Description
…BE	Means “Bus error” generation.
SPBBE	A bus access is terminated with a bus error on the SPB.
SRIBE	A bus access is terminated with a bus error on the SRI.
access	A bus access is allowed and is executed.

4.2 Contents of the Segments

This section summarizes the contents of the segments.

The CPU attributes (cached / non-cached) of these segments can be configured for each CPUs data and program side individually (see CPU chapter: Physical Memory Attribute Registers, PMAx).

Segments 0-6

These memory segments are reserved.

Segment 7

This memory segment allows access to the CPUs Program and Data Scratch Pad SRAM (PSPR, DSPR), Program Cache SRAM (PCache) and to the TAG SRAM related to the Program Cache (PTAG SRAM[1)]).

PCache and PTAG SRAMs[1)] can be only accessed if the related Program Cache is disabled[2)].

CPU default attribute for this segment: non-cached.

Segment 8

This memory segment allows access to PFlash and BROM.

The attribute of segments (cached / non-cached) can be configured for each CPUs data and program side individually (see CPU chapter: Physical Memory Attribute Registers, PMAx).

CPU default attributes for this segment: cached.

Segment 9

This memory segment allows access to LMU SRAM (if implemented) and to the EMEM (Emulation Device only).

CPU default attributes for this segment: cached.

Segment 10

This memory segment allows access to PFlash, DFlash and BROM.

CPU default attributes for this segment: non-cached.

1) TAG SRAMs are not meant to be used as general SRAMs and can be accessed only with single data access and only with 64 bit aligned address.

2) Mapping of Cache and TAG SRAMs is controlled via the MTU register MTU_MEMMAP.

Segment 11

This memory segment allows access to LMU SRAM (if implemented) and to the EMEM (Emulation Device only).

CPU default attributes for this segment: non-cached.

Segment 12

This memory segment is reserved.

Segment 13

This memory segment is reserved.

Segment 14

This memory segment is reserved.

Segment 15

This memory segment allows accesses to all SFRs, CSFRs.

Access from DMA Move Engine, Cerberus to the lower 128 MB of this segment are processed by the DMA FPI master interface on the SPB Bus, to the upper 128 MB of this segment by the DMA SRI master interface on the SRI Bus.

Data access from TC1.6 CPUs to the lower 128 MB of this segment are processed by the CPU.DMI FPI master interface on the SPB Bus, to the upper 128 MB of this segment by the CPU.DMI SRI master interface on the SRI Bus.

CPUx attributes for this segment: non-cached.

4.3 Address Map of the On Chip Bus System

This chapter describes the system address map as it is seen from the SRI and SPB bus masters (bus master agents are described in the chapter On Chip Bus System).

All bus master agents can address identical peripherals and memories at identical address. The system address map is visible and valid for all CPUs which means that all peripherals and resources are accessible from all TriCore CPUs and other on chip bus master agents.

Parallel access by more than one bus master agents to one slave agent are executed sequentially. Additionally the SRI and SPB bus do support atomic Read Modify Write sequences from the CPUs. Hardware semaphores for temporary exclusive bus access from one master to a slave are not implemented

4.3.1 Segments 0 to 14

Table 4-2 shows the address map of segments 0 to 14.

Table 4-2 On Chip Bus Address Map of Segment 0 to 14

Segment	Address Range	Size	Description	Access Type	
				Read[1)]	Write[2)]
0-6	$0000\ 0000_H$ - $0000\ 0007_H$	8 byte	Reserved (virtual address space)	SRIBE	SRIBE

1) A read transaction through the SRI to FPI bridge that is terminated with Bus Error will result in Bus Errors on SRI and FPI (valid for transactions from FPI to SRI and SRI to FPI).

2) Write access to Flash resources are handled by the PMU module (Flash command sequence, see PMU chapter for details).
3) PCache SRAMs and the corresponding TAG SRAM can be only accessed when mapped into the address space (PCache / DCache disabled. See TAG chapter, register MTU_MEMMAP for details).
4) TAG SRAMs are not meant to be used as general SRAMS and can be accessed only with single data access and only with 64 bit aligned address. Mapping of TAG SRAMs in the address map can be used as additional option for memory testing.
5) Online Data Acquisition address space can be disabled/enabled via LMU control register bit LMU_MEMCON.OLDAEN.
6) DF0 is the address where all Data Flash blocks are mapped to. The details about the Data Flash block sizes, segmentation and exact mapping are described in the chapter PMU.
7) See also chapter ´CPU, ´Local and Global Adressing´ for CPU local views to segment ´C´ and segment ´D´.

4.3.2 Segment 15

Table 4-3 shows the address map of segment ´F´ as seen from the SRI and SPB bus masters (bus master agents are described in the chapter On Chip Bus System).

Table 4-1 gives an overview about the address mapping of the module address ranges:

- which modules are mapped into the first 16 KB of segment ´F´ and can be accessed by the TC1.6E/P with absolute addressing modes (left side)
- examples of covering modules with relative addressing mode (base address +- 32 KB, in the middle)

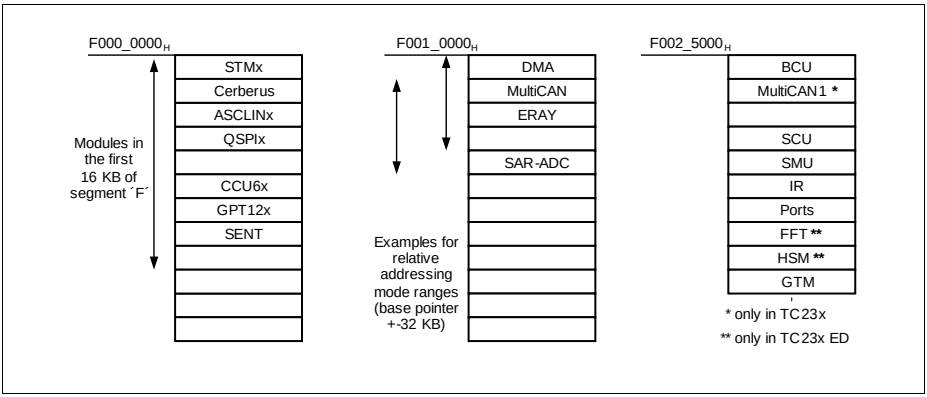

Figure 4-1 Segment F Structure

Please note that **Table 4-3** describes the mapping of modules to segment F. The details of the module address ranges can be found in the module chapters register overview.

Table 4-3 On Chip Bus Address Map of Segment 15

Unit	Address Range	Size	Access Type

4.4 Memory Module Access Restrictions

Table 4-4 describes which type of accesses are possible to the different memories in the TC21x/TC22x/TC23x.

Table 4-4 Possible Memory Accesses[1)]

Memory		Bit	Byte		Half-word		Word		Double-word	
		rmw	r	w	r	w	r	w	r	w
PMI[2)]	PSPR	y	y	y	y	y	y	y	y	y
	PTAG[3)]	-	-	-	-	-	y	y	-	-
	PCACHE	y	y	y	y	y	y	y	y	y
DMI[2)]	DSPR	y	y	y	y	y	y	y	y	y
LMU[2)]	LMURAM	y	y	y	y	y	y	y	y	y
PMU	BROM	-	y	-	y	-	y	-	y	-
	PFLASH	-	y	-	y	-	y	y	y	y
	DFLASH	-	y	-	y	-	y	y	y	y

1) ´y´ means: supported. ´-´ means: not supported

2) The module also supports SRI 2-Word and 4-Word Block read and write accesses.

3) TAG SRAMs are not meant to be used as general SRAMS and can be accessed only with 32-bit data access and only with 64 bit aligned address. Mapping of TAG SRAMs in the address map can be used as additional option for memory testing. The TAG SRAM size is below 24 bit, so the 8 MSB of a 32 bit write or read are dont care.

4.5 Side Effects from Modules to CPU0 Data Scratch Pad SRAM (DSPR0)

Pls. note that a part of the CPU0 DSPR will be overwritten by the start-up (BootROM) procedure after cold power-on as well as the information in this area should be used and in case modified by the (user) SW procedure when preparing the device to enter Stand-By mode. The details are described in the Firmware chapter, sub-chapter ´RAMs Handling´.

5 TC21x/TC22x/TC23x BootROM Content

The TC21x/TC22x/TC23x BootROM consists basically of three parts:

- Startup Software (short name SSW);
- Software modules implementing additional functions (Bootstrap Loaders);
- Test Firmware.

5.1 Startup Software

The Startup Software is the first software executed after a chip reset.

SSW is executed on CPU0 - all other CPUs are kept in Halt-state during boot, to be started by user software whereas:

- SSW start address in BootROM is the reset value in Program Counter register of the CPU0. From this location an instruction is fetched and this is the first instruction executed after any device start-up.
  - immediately after this entry point the firmware checks for testmode, and in case testmode is selected - jump to test firmware is executed
- the last SSW instruction performs a jump to the first user code instruction. This first user instruction can be fetched from different locations depending on the start-up configuration as selected by the user.

The Startup Software contains procedures to initialize the device depending on one or more from the following:

- information previously stored into dedicated Flash locations
- the current state of special bits/fields in dedicated register/memory locations
- the type of event which has triggered the SSW-execution (the last reset event)
- values applied to external (configuration-) pins (optional)

The SSW also calls - in case - other firmware modules.

5.1.1 Events triggering SSW execution

SSW execution can be triggered by different events. SSW recognizes the triggering (reset) event and takes (partially) different execution flows.

5.1.1.1 Power-on

This is the initial powering-up of the device after the supply has been switched off, or in other words - the only way to generate this reset event is by applying power to a previously un-powered device.

The conditions at which the SSW execution starts upon this event include:

- all the registers are in their initial (reset) state
- Flash is under reset - meaning not active, and not ready to perform any (read/erase/program) operation

- RAMs' content is undefined
- clock system is in its initial state

Due to the overall "fully initial" state of the device upon power-on, the SSW flow is respectively longer in this case and covers the biggest amount of activities compared to other reset events.

5.1.1.2 System reset

Attention: From SSW point of view, the handling of system reset is generally the same as of "warm power-on".
Therefore further in this Chapter when system reset is referred - the same SSW handling applies upon warm power-on, exceptions will be in case specially notified.

This reset event can be requested by different sources:

- device internal hardware - from modules like watchdog timer and security/memory control logic
- external hardware - when active signal is applied to defined device pin(s)
- software - when defined control bit(s) are respectively installed during user code execution

For most of the sources, generating system reset is a feature configurable by software.

The exception is PORST pin, applying active low level to which generates system reset only if the supply voltage is above defined level permanently in the surrounding time window - e.g. the device is continuously powered before and during system reset activation. Otherwise - upon a supply drop below some level - power-on is immediately triggered. All this functionality is supported by the EVR module.

The conditions at which SSW execution starts upon system reset include:

- all the registers are in their initial (reset) state
- Flash is under reset - meaning not active, and not ready to perform any (read/erase/program) operation
- RAMs' content is the same as just before the system reset has been triggered
- clock system is in its initial state

As seen from the above list, the only difference in the initial system status after power-on and system reset is in that the content of RAMs is not changed by the reset event.

5.1.1.3 Application reset

Similarly to system reset, an application reset can be requested by different sources: internal/external hardware as well as software. For all the sources, generating system reset is a feature configurable by software.

The conditions at which SSW execution starts upon application reset include:

- registers connected to this reset type are in their initial (reset) state

- Flash is in read mode
- all the rest - RAMs and surround logic, clock system, registers under system reset - is not affected by this event.

Following the limited changes within the device status upon application reset, the SSW flow is shortest in this case.

5.1.2 Clock system during start-up

The state of clock system during device start-up depends on the reset event type:

- upon power-on and system reset - clock system is in its initial state, namely:
  - f_{SRI}= f_{CPU0} = f_{FSI}=f_{BACK}=100MHz nominal
  - f_{SPB}=f_{STM}=f_{BACK}/2=50MHz nominal
  - in Emulation Device (ED) f_{BBB}=f_{BACK}/2=50MHz nominal
  - PLL and VCO are in power-down mode
- upon application reset - clock system does not change its state, therefore the device runs at same frequency and clock source as before the reset event

With the same clock system state the first user code is started, with exception of the Bootstrap Loader mode upon power-on - refer to **Chapter 5.2**.

5.1.3 RAM overwrite during start-up

Start-up procedure can overwrite up to 8kByte at the beginning of CPU0 DSPR. Therefore this area should not be used by application software to save data, which must be preserved through device resets.

Additionally, SSW performs a special handling of CPU0 DSPR upon exit from stand-by mode if this RAM has been kept supplied during stand-by. To assure this handling will be correct:

- upon cold power-on reset, SSW stores 16 Words (total of 64 Bytes) information into so-called “reserved area” in CPU0_DSPR starting at address $D000'2000_H$
- if the application wants to keep CPU0 DSPR supplied during stand-by mode and to save information there:
  - before going into stand-by mode, the user code must execute CPU0 DSPR preparation as described in **Chapter 5.4**
  - the user code must not touch the data within reserved area (see above) at $D000'2000_H$...$D000'203F_H$ except when executing **Preparation before to enter Stand-by mode**

5.1.4 Boot Options Summary

This chapter summarizes the TC23x startup configurations in user mode.

Internal Start

In this basic startup mode, the first user instruction is fetched from address A000 0020_H in Internal Program Flash of the device.

Bootloader Modes

Different Bootstrap Loader routines are used in these modes to download code/data into the Instruction Scratchpad Memory SPRAM (PSPR), as follows:

- ASC bootloader
- CAN bootloader
- Generic bootloader mode - the bootloading procedure itself here is in fact one of the two above possibilities - ASC/CAN. The selection either to use ASC- or CAN-communication protocol is done by the SSW upon the first byte received at the couple of pins, which are then respectively configured to ASC or to MultiCAN module.

Alternate Boot Modes

In these modes, program code is started from user-defined address but only if all defined check-conditions are satisfied. Otherwise Generic Bootstrap Loader mode can be entered to download the code into device, this code is afterwards started by the SSW.

All the information needed for the SSW to handle ABM startup mode is collected into the so-called Headers. The checks are performed according to **Start-up mode selection** flow as defined in **Chapter 5.1.5**.

5.1.5 Start-up mode selection

TC21x/TC22x/TC23x start-up flow in regard to mode selection is shown at **Figure 5-1**.

There is one way only to select start-up configuration in TC21x/TC22x/TC23x:

- **Configuration by Boot Mode Index (BMI)** - according to values taken from dedicated locations in Flash (new feature for AURIX products)

Additionally, as an option of the BMI-configuration flow the well known proceeding from previous devices is supported:

- **Hardware configuration** - according to the values at configuration pins

The flow to evaluate start-up configuration in TC21x/TC22x/TC23x is as follows:

1. if error happens during Flash ramp-up or Flash Config sector is corrupted (unrecoverable data error) - SSW terminates immediately
2. SSW evaluates sequentially up to four Boot Mode Headers BMHD0...BMHD3 - for header locations refer to **Table 5-2**, evaluation procedure - see below and **Figure 5-2**
   a) if evaluation procedure is exited with OK - valid BMI and (in case) code found, start-up mode is taken accordingly
   b) if evaluation procedure is exited with FAIL - continue with step 3.
3. check the firmware internal flag CFGPIN:

a) if set - meaning valid BMI enabling pin-configuration was found, ABM was selected from pins but code check failed (refer to **Figure 5-2**): re-install STSTAT.HWCFG from ABM to BSL (Generic/ASC) accordingly and take the respective start-up mode
b) if not set - no valid BMI and code are found, continue with step 4.

4. check if the condition (HSM boot disabled) AND (OTP protected mode disabled) is true:
   a) if yes - initialize security relevant RAMs, then check either debugger is connected and halt-after-reset is requested (OSTATE.HARR=1)
      - if yes - execute Internal start mode - CPU0 will be halted before the first user instruction
      - if not - execute Generic Bootstrap Loader mode - default mode if no valid BMI
   b) if not - check and in case enable debug access using the general evaluation sequence, then enter endless loop - HSM or an external debugger (if access granted) are able to handle further the device start-up

Note: The initialization of security relevant RAMs here is to prevent using BSL mode as back door for reading out user information previously stored into some RAM(s).

Table 5-1 Boot Mode Header (BMHD) structure

Offset Addr.	Size Byte	Field Name	Description
00_H	4	STADABM	User Code Start Address
04_H	2	BMI [1]	Boot Mode Index (BMI)
06_H	2	BMHDID [1]	Boot Mode Header ID (Confirmation code) = $B359_H$
08_H	4	ChkStart	Memory Range to be checked - Start Address
$0C_H$	4	ChkEnd	Memory Range to be checked - End Address
10_H	4	CRCrange	Check Result [2] for the Memory Range
14_H	4	$\overline{\text{CRCrange}}$	Inverted Check Result for the Memory Range
18_H	4	CRChead	Check Result [2] for the ABM Header (offset 00_H..17_H)
$1C_H$	4	$\overline{\text{CRChead}}$	Inverted Check Result for the ABM Header

1) These fields are different from the ABM Headers in previous devices.

2) CRC calculation is based on IEEE 802.3, the CRC32 ethernet polynomial used is $04C11DB71_H$

Table 5-2 Boot Mode Headers locations

Header	Start address	End address
BMHD0	$A000\ 0000_H$	$A000\ 001F_H$
BMHD1	$A002\ 0000_H$	$A002\ 001F_H$

Table 5-2 Boot Mode Headers locations

Header	Start address	End address
BMHD2	A000 FFE0$_H$	A000 FFFF$_H$
BMHD3	A001 FFE0$_H$	A001 FFFF$_H$

Table 5-1 shows the Boot Mode Header (BMHD) structure, the procedure to evaluate one BMHD includes following steps (refer to **Figure 5-2**):

1. check either Boot Mode Header ID is correct
   a) if BMHDID = B359$_H$ - continue with 2.
   b) if not - continue with 8.
2. calculate the CRC of the first 24 Bytes from the ABM Header (refer to **Table 5-1**) - process the fields STADABM...CRCRange at offsets 00$_H$...17$_H$
   a) compare the result with the CRChead value (offset 18$_H$)
      - if OK - continue with 2.b)
      - if not - continue with 8.
   b) inverse the result value and compare with $\overline{\text{CRChead}}$ (offset 1C$_H$)
      - if OK - continue with 3.
      - if not - continue with 8.
3. check either BMI[15:10, 7:0] value is valid - refer to **Chapter 5.1.5.2**
   a) if yes - continue with 4.
   b) if not - continue with 8.

Note: Bits BMI[9:8] are excluded from this check because they control Lockstep Logic and can have arbitrary values.

4. check the conditions BMI[3]=0 (pin-configuration enabled) AND HWCFG[3] pin value=0 (pin-configuration selected) AND PROCONOTP[30:29]=00$_B$ (OTP protected mode not enabled):
   a) if all the conditions are true - **Hardware configuration** is taken (refer to **Chapter 5.1.5.1** and respective value installed in STSTAT.HWCFG, then continue with 5.
   b) if not - **Configuration by Boot Mode Index (BMI)** is taken (refer to **Chapter 5.1.5.2**) and respective value installed in STSTAT.HWCFG, then continue with 5.
5. check either STSTAT.HWCFG value selects Alternate Boot Mode (ABM)
   a) if yes - continue with 6.
   b) if not - exit this procedure, BMI is OK, mode is selected in STSTAT.HWCFG
6. calculate the CRC over the memory address range ChkStart...ChkEnd (start- and end- addresses taken from offsets 08$_H$ and 0C$_H$ respectively)
   a) compare the result with the CRCrange value (offset 10$_H$)
      - if OK - continue with 6.b)
      - if not - continue with 7.

b) inverse the result value and compare with $\overline{\text{CRCrange}}$ (offset 14_H)
- if OK - exit this procedure, BMI and code are OK, ABM is selected in STSTAT.HWCFG
- if not - continue with 7.

7. check how is ABM selected
   a) from BMI value - continue with 8.
   b) from HWCFG pins - install Generic Bootstrap Loader ABM in STSTAT.HWCFG, exit this procedure with OK
8. check again so called Magic number in Flash Config sector
   a) if OK - exit this procedure, header and BMI check failed
   b) if wrong - terminate SSW immediately on error

Note: The last step above is to reduce the probability that a hacker attack disturbs BMI/ABM checks targeting to cause unintentional (from the original user code) entry into Bootstrap Loader mode.

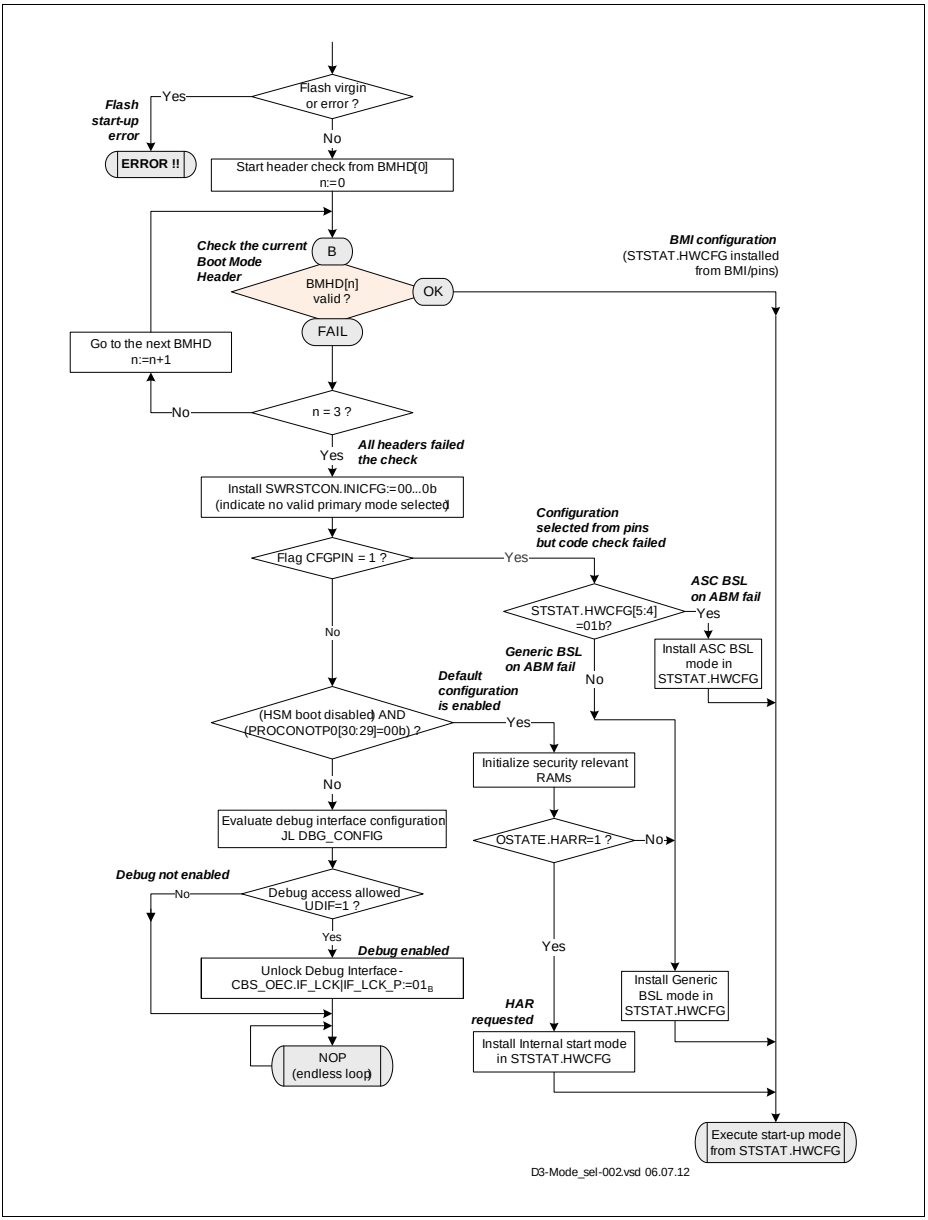

Figure 5-1 Start-up mode selection flow in TC21x/TC22x/TC23x

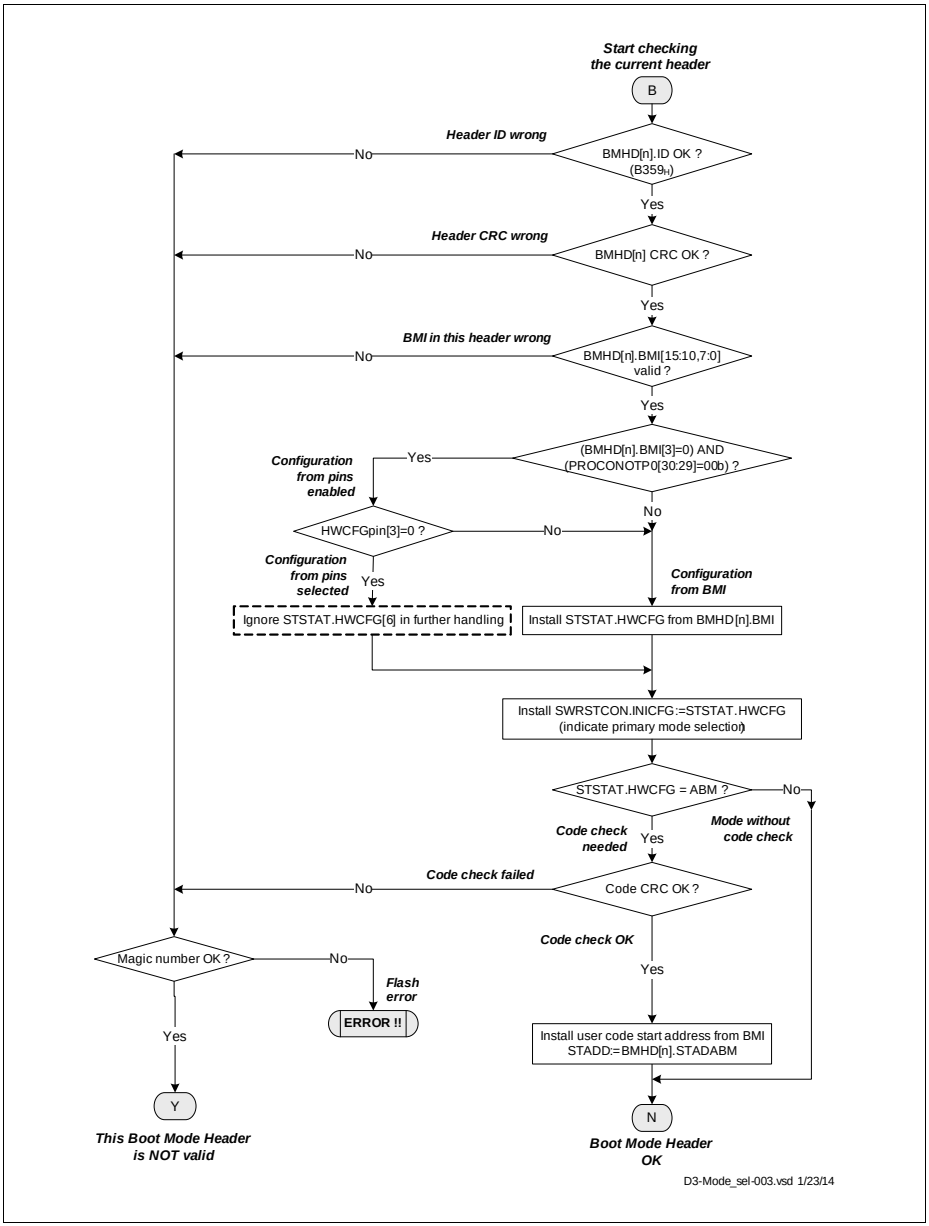

Figure 5-2 Mode selection in TC21x/TC22x/TC23x: check of one Boot Mode

Header

5.1.5.1 Hardware configuration

The start-up mode selection by configuration pins HWCFG[5:4] in TC21x/TC22x/TC23x is shown in **Table 5-3**. The values at these pins are latched by hardware upon any reset (deactivation - rising edge) into register which is read and evaluated by SSW during start-up processing.

Note: HWCFG[2:0] pins are used for EVR control, HWCFG[6] - for pull-up/tristate pin configuration,HWCFG[7] is not available for TC21x/TC22x/TC23x.

Table 5-3 Start-up mode selection by pins in TC21x/TC22x/TC23x

HWCFG pins		Start-up Mode
[5]	[4]	
1	1	Internal start from Flash
1	0	ABM, Generic Bootstrap Loader on fail
0	1	ABM, ASC Bootstrap Loader on fail
0	0	Generic Bootstrap Loader

5.1.5.2 Configuration by Boot Mode Index (BMI)

The Boot Mode Index (BMI) is 2 Byte value holding information about start-up mode of the device and Lockstep mode enable/disable.
The data structure of BMI is described below, followed by the definition of FLASH0_PROCOND bits which control RAM initialization, oscillator circuit (OSC) configuration and ESR0 pin handling by SSW.
***NOTE**: The start-up mode selections defined as "Reserved" in BMI.HWCFG are treated as invalid by SSW*

5.1.6 Startup Software Main Flow

Below the SSW functionality is outlined during different execution-steps (refer to **Figure 5-3**) and upon various configuration settings.

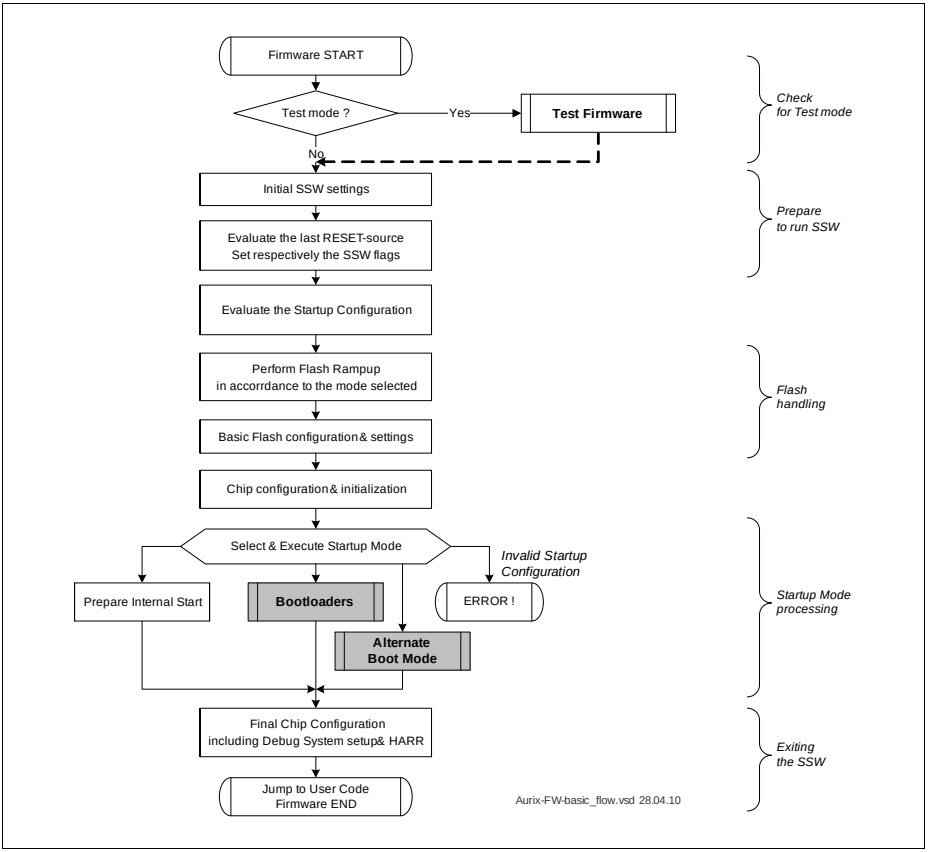

Figure 5-3 TC23x Firmware: Firmware main flow

5.1.6.1 Basic Device Settings

The target of this functional module is to initialize several TC23x-registers with the values, which will be first seen by the user - or generally available - after exiting the SSW.

5.1.6.2 RAMs Handling

Only HSM RAM is initialized after any power-on by Startup Software in TC23x.

For other RAMs initialization upon cold and/or warm power-on can be requested by **FLASH0_PROCOND** (refer to **Chapter 5.1.5.2**).

5.1.6.3 Select and Prepare Startup Modes

TC21x/TC22x/TC23x User Startup Configurations and modes are summarized below.

Internal Start

This is the basic TC23x type of operation in which the user code is started out of the Internal Flash Memory.

The User Start Address is set to A000'0020$_H$.

Bootstrap Loader Modes

The selected Bootstrap Loader (these routines are described in **Chapter 10.2**) is executed only if the SSW-flag “Reset Configuration Updated” is set. This is to avoid multiple executions of the Bootstrap Loader and to start directly the code already downloaded after some - intended to be “application only” - reset events, for example after a Watchdog Timer reset which has been configured to trigger application reset.

The supported Bootloader selections are:

- ASC Bootloader - ASC communication protocol via ASC pins
- Generic Bootloader via CAN pins - the communication protocol is automatically selected by the SSW between ASC and CAN

After downloading (in case) the code, the User Start Address STADD is set to the beginning of Program Scratchpad RAM PSPR at C000 0000$_H$.

Alternate Boot Mode

The handling of this (ABM) start-up mode is according to the flow at **Figure 5-1** and **Figure 5-2**.

If this mode is selected by a valid BMI Header (or by pins if pin configuration is enabled in a valid Header) and the code check pass - the User Start Address STADD is set to the respective value from the header (STADABMx).

If the code check fails, the handling depends how ABM was selected:

- if selected by BMI - this BMI is considered then as not valid and not used for configuration, the next header (of any) is taken for evaluation
- if selected by pins and no more Headers are available - Generic or ASC Bootloader mode is taken in accordance to the pin-selection (refer to **Chapter 5.1.5.1**)

Secure Boot option handling

If HSM module is available for the user (according to device configuration) - Secure Booting is supported in which the user code is processed by HSM.

SSW supplies information about the current device mode, reset type, the primary selected and the effectively taken start-up mode, which information is available for HSM module to perform accordingly boot and user code processing.

5.1.6.4 Final Chip Settings

The last device configuration steps performed by the SSW include:

Flash access handling

SSW flow here includes:

- fetches (code/data, from Program/Data/HSM Flash) control
  - if user code will be started from internal flash - all fetches are enabled
  - otherwise - according to the protection (active/not) state
- Program and Erase operations are enabled

No handling of Unique Chip ID and Calibration data

This information (Unique Chip ID and Calibration data) is now stored in User Configuration Block which is readable for the user. As consequence it is no more installed into DSPR but can be read directly by the application software.

Debug System handling

As first point of this processing, the SSW internal flag Unlock Debug Interface is set if debug access to device will be enabled according to the following evaluation sequence:

1. SSW checks either an external tool has requested debug access by writing a defined content (32-bit value CMD_KEY_EXCHANGE=$76D6E24A_H$ for TC21x/TC22x/TC23x) into COMDATA register
   a) if yes - continue with the next step
   b) if not - go to step 4.
2. still in Cerberus Communication mode, SSW confirms request reception and receives 8 further words through COMDATA register
3. the data received (256 bits) is sent by SSW to PMU to be checked as debug interface password and the result is evaluated by SSW:
   a) if OK - debug password is correct, go to step 6.
   b) if fail - continue with the next step
4. install into COMDATA 32-bit value serving for an external tool to identify the device connected - UNIQUE_CHIP_ID_32BIT
5. check if Flash protection is activated:

a) if yes - debug interface will be left locked, no debug access to device, exit the sequence
b) if not - set SSW internal flag, debug interface will be unlocked, exit the sequence

The following steps are introduced to support so called “Debug Self-destructive Entry” feature. The target is, if this feature is activated and debugging is requested by correct debug password (see steps 1...3 above) - to destroy vital functions of the device (so that it is not usable in a real application anymore) before effectively granting debug access. The steps performed are:

6. check either “Debug Self-destructive Entry” feature is activated for the device (PROCONHSMOTP.DESTDBG=11_B):
   a) if yes - continue with the next step
   b) if no - debug access granted, go to step 5.b)
7. using PMU command sequences, erase and re-program UCB_DBG with the previous password but setting “Entered Debug Mode” marker (EDM=11_B) in PROCONDBG; then go to step 5.b) - debug access granted

Next, Halt after Reset is prepared if requested. The SSW processing here is as follows:

- check either external (debug) access to the device will be generally granted
  – if Not -> exit this procedure
- check either Halt After Reset is requested
  – if Not -> exit this procedure
- configure a Break After Make breakpoint at the last SSW instruction
- enable On-Chip Debug Support system.

Note: The final debug-related operation - unlocking (in case) the debug interface - is performed later.

ESR0 pin handling

If both the conditions

- ESR0CNT<>FFF_H in **FLASH0_PROCOND** (refer to register description in **Chapter 5.1.5.2**) AND
- ESR0-pin configuration upon SSW entry is open-drain reset output (SCU_IOCR.PC0 in [1110_B, 1010_B])

are satisfied, SSW will:

- release ESR0 pin - by installing SCU_ESROCFG.ARC:=1 which clears Application Reset Indicator in SCU_ESROCFG.ARI - with some delay after device internal reset is released (i.e. CPU0 started), the delay is defined as follows
  – if **FLASH0_PROCOND**.ESR0CNT=000_H - about 500µsec upon cold power-on, not longer than 20µsec otherwise
  – if **FLASH0_PROCOND**.ESR0CNT=001_H...FFE_H - (ESR0CNT)*10µsec
- wait until ESR0 pin is effectively high - indicated by SCU_IN.P0=1 - at the very SSW end and before jumping to the first user instruction

To generate configurable ESR0 delay after device reset release, SSW uses System Timer 0 (STM0) and especially takes into account the following default settings after power-on/system reset:

- STM is reset and starts counting from zero
- STM is clocked with 50MHz i.e. $f_{STM}=F_{BACK}/2$

Attention: Both the above conditions could not be true after application reset, if default settings are changed by user code executed after power-on/system reset. In such a case, ESR0 handling by SSW will not work correctly, meaning the real prolongation will not correspond to ESR0CNT value configured.

Lockstep configuration

Upon cold power-on only SSW performs Lockstep configuration as follows:

- if valid BMI has been found during start-up mode evaluation:
  - Lockstep control for CPU0 is installed in LCLCON0.LSEN from BMI[8]
- if no valid BMI has been found during start-up mode evaluation:
  - Lockstep control for CPU0 is disabled by installing LCLCON0.LSEN=0

5.1.6.5 Ending the SSW and Starting the User Code

The last steps executed by the SSW are:

- activate the Startup Protection
- unlock (in case) Debug Interface
- jump to the first User Instruction at address STADD.

Additionally, if all the following conditions are satisfied:

- the device is an ED
- debug access to device is allowed
- halt after reset is not requested
- the last reset has been a power-on (cold or warm)

SSW performs at its very end additional checks and in case all these succeed - the last SSW instruction jumps not to the “standard” STADD but to an address inside EMEM (Emulation Memory). This SSW part implements the sequence defined in TC21x/TC22x/TC23x ED Target Specification, Chapter “Startup with prolog code in EMEM”.

5.2 Bootstrap Loaders

These routines provide mechanisms to load an user program via selected interface by moving code into PMI Scratchpad RAM (an Internal Program memory). The loaded code is started after exiting the BootROM.

5.2.1 ASC Bootstrap loader

The ASC Bootloading routine implements the following steps:

- RxD/TxD pins configuration is done in accordance to the TC23x definitions, as well as depending either the routine is invoked upon “ASC Bootloader”-startup mode (ASC-only pins are used) or following an ASC-protocol detection upon “Generic Bootloader”-mode (CAN/ASC-shared pins are used but configured to ASC module)
- baudrate calculation is done based on the zero Byte sent by the host
- ASCLIN channel n (refer to **Table 5-4**) is initialized (without enabling the receiver) to the baudrate as determined, 8 data and 1 stop bit
- acknowledge byte $D5_H$ is sent to the host indicating the device is ready to accept a data transfer
- after the acknowledge byte is transmitted, the receiver is enabled
- the bootloader enters a loop waiting to receive exactly 128 bytes which are stored as 32 words in CPU0 Program Scratchpad RAM starting from address C000 0000_H

Once 128 bytes are received, the SSW continues further - refer to **Figure 5-3**. After exiting the SSW, user code will be started from address C000 0000_H (CPU0_PSPR).

5.2.2 CAN Bootstrap Loader

The CAN bootstrap loader transfers program code/data via node 1 of the MultiCAN module into CPU0 Program Scratchpad RAM.

The CAN Bootstrap Loader transfers data from an external host to the TC21x/TC22x/TC23x using eight-byte data frames. The number of data frames to be received is programmable and determined by the 16-bit data message count value DMSGC.

Attention: When selected upon power-on or system reset, CAN Bootstrap Loader requires that an external clock source/oscillator is connected to XTAL pins of the device.

The communication between TC21x/TC22x/TC23x and external host is based on the following three CAN standard frames:

- Initialization frame - sent by the external host to the TC21x/TC22x/TC23x
- Acknowledge frame - sent by the TC21x/TC22x/TC23x to the external host
- Data frame(s) - sent by the external host to the TC21x/TC22x/TC23x

The initialization frame is used in the TC21x/TC22x/TC23x for baud rate detection. After a successful baud rate detection is reported to the external host by sending the acknowledge frame, data is transmitted using data frames.

Initialization Phase

The first task is to determine the CAN baud rate at which the external host is communicating. This task requires the external host to send initialization frames continuously to the TC21x/TC22x/TC23x. The first two data bytes of the initialization frame include a 2-byte baud rate detection pattern (5555_H), an 11-bit (2-byte) identifier ACKID for the acknowledge frame, a 16-bit data message count value DMSGC, and an 11-bit (2-byte) identifier DMSGID to be used by the data frame(s).

The CAN baud rate is determined by analyzing the received baud rate detection pattern (5555_H) and the baud rate registers of the MultiCAN module are set accordingly. The TC21x/TC22x/TC23x is now ready to receive CAN frames with the baud rate of the external host.

Acknowledge Phase

In the acknowledge phase, the bootstrap loader waits until it receives the next correctly recognized initialization frame from the external host, and acknowledges this frame by generating a dominant bit in its ACK slot. Afterwards, the bootstrap loader transmits an acknowledge frame back to the external host, indicating that it is now ready to receive data frames. The acknowledge frame uses the message identifier ACKID that has been received with the initialization frame.

Data Transmission Phase

In the data transmission phase, data frames are sent by the external host and received by the TC21x/TC22x/TC23x. The data frames use the 11-bit data message identifier DMSGID that has been sent with the initialization frame. Eight data bytes are transmitted with each data frame. The first data byte is stored in Program Scratchpad RAM starting from address $C000\ 0000_H$. Consecutive data bytes are stored at incrementing addresses.

Both communication partners evaluate the data message count DMSGC until the requested number of CAN data frames has been transmitted.

After the reception of the last CAN data frame, the SSW continues further - refer to **Figure 5-1**. After exiting the SSW, user code will be started from address $C000\ 0000_H$ (CPU0_PSPR).

5.2.3 Summary of Bootstrap Loader Modes

This table summarizes the external hardware provisions for bootstrap loader modes in TC21x/TC22x/TC23x.

Table 5-4 Configuration Data for Bootstrap Loader Modes

Bootstrap Loader Mode	Channel/ node	RxD Line	TxD Line	Transferred Data	Supported baudrates
ASC Bootstrap Loader mode	ASCLIN0	P15.3	P15.2	128 Bytes	28k...2500k
Generic Bootstrap Loader mode - ASC protocol	ASCLIN0	P14.1	P14.0	128 Bytes	28k...2500k
Generic Bootstrap Loader mode - CAN protocol	CAN1	P14.1	P14.0	8×n Bytes 1)	up to 1000k 2)

1) n = DMSGC, Data Message Count sent by the host with Initialization frame.

2) with 20MHz XTAL clock source

5.3 Shutdown request handler

All the active CPUs in TC21x/TC22x/TC23x jump unconditionally to the entry point of this handler upon any warm reset request - refer to Reset Control Unit Section in SCU ITS.

It is guaranteed by hardware, this handler can not be interrupted by any other (interrupt/trap) request, and upon its end all the CPUs are in stable passive state reached by a controlled ramp-down sequence, preventing big current jumps.

At its entry point - common for all the CPUs - the firmware causes any running CPU to jump further to its own handler. For this purpose CORE_ID register is read and because this register value is individual for any CPU - upon CORE_ID=0, 1 or 2 the firmware jumps to the routine for respective CPU.

The functionality of all handlers is similar, namely:

- prepare work data for execution of average-power loop
- execute average-power loop until SCU_RSTCON2.TOUTyy=1
- execute WAIT instruction

Upon completion of the above sequence, CPUx has reached passive state yy microseconds after shutdown request activation, whereas:

- yy=60 for CPU0

5.4 Preparation before to enter Stand-by mode

During stand-by mode preparation, the user software must do the following:

- read sequentially 16 words from the “reserved area” in CPU0_DSPR starting at address $D000'2000_H$

- for any word check either it equals FFFF FFFF$_H$ or zero
  – if yes - skip it and go to the next reserved location
  – if no
    - use this word as 32-bit address, read the data from that address and store this data back into the same reserved location
    - go to the next reserved location

6 CPU Subsystem

This chapter describes the implementation-specific options of the TriCore CPUs found in the AURIX series of devices. Details of both TriCore1.6P (TC1.6P) and TriCore1.6E (TC1.6E) CPUs are included. The CPU and local memory configurations of the various members of the AURIX family are detailed in the following table.

This chapter should be read in conjunction with the TriCore Architecture Manual. Topics covered by the architecture manual include:-

- Architectural Overview
- Programing Model
- CPU Registers
- Tasks and Functions
- Interrupt Handling
- Traps
- Memory Protection System
- Temporal Protection System
- Floating Point Operations
- Debug
- Instruction Set

6.1 AURIX Family CPU configurations

The different CPU and local memory configurations for the AURIX family of devices are detail in the following tables:-

Table 6-1 Processor and local memory configuration of the TC29x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6P	2	32 KB	32 KB	8 KB	240 KB	No	No
TC1.6P	1	32 KB	32 KB	8 KB	240 KB	No	Yes
TC1.6P	0	16 KB	32 KB	8 KB	120 KB	Yes	No

Table 6-2 Processor and local memory configuration of the TC27x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6P	2	16 KB	32 KB	8 KB	120 KB	No	No
TC1.6P	1	16 KB	32 KB	8 KB	120 KB	No	Yes
TC1.6E	0	8 KB	24 KB	0[1)]	112 KB	Yes	Yes

1) TC1.6E has a 128Byte read buffer in place of a data cache

Table 6-3 Processor and local memory configuration of the TC26x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6P	1	16 KB	32 KB	8 KB	120 KB	No	Yes
TC1.6E	0	8 KB	16 KB	0[1)]	72 KB	Yes	No

Table 6-4 Processor and local memory configuration of the TC24x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6E	0	8 KB	16 KB	0[1)]	80 KB	Yes	No

Table 6-5 Processor and local memory configuration of the TC23x

Processor	Core-ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6E	0	8 KB	8 KB	0[1)]	184 KB	Yes	Yes

Table 6-6 Processor and local memory configuration of the TC22x

Processor	Core-ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6E	0	8 KB	8 KB	0[1)]	88 KB	Yes	Yes

1) TC1.6E has a 128Byte read buffer in place of a data cache

6.2 Central Processing Unit Features

Key CPU Features include:-

Architecture

- 32-bit load store architecture
- 4 Gbyte address range (2^{32})
- 16-bit and 32-bit instructions for reduced code size
- Data types:
  - Boolean, integer with saturation, bit array, signed fraction, character, double-word integers, signed integer, unsigned integer, IEEE-754 single-precision floating point
- Data formats:
  - Bit, byte (8-bits), half-word (16-bits), word (32-bits), double-word (64-bits)
- Byte and bit addressing
- Little-endian byte ordering for data, memory and CPU registers
- Multiply and Accumulate (MAC) instructions: Dual 16 × 16, 16 × 32, 32 × 32
- Saturation integer arithmetic
- Packed data
- Addressing modes:
  - Absolute, circular, bit reverse, long + short, base + offset with pre- and post-update
- Instruction types:
  - Arithmetic, address arithmetic, comparison, address comparison, logical, MAC, shift, coprocessor, bit logical, branch, bit field, load/store, packed data, system
- General Purpose Register Set (GPRS):
  - Sixteen 32-bit data registers
  - Sixteen 32-bit address registers
  - Three 32-bit status and program counter registers (PSW, PC, PCXI)
- Debug support (OCDS):
  - Level 1, supported in conjunction with the CPS block
  - Level 3, supported in conjunction with the MCDS block (Emulation Device only).
- Flexible memory protection system providing multiple protection sets with multiple protection ranges per set.
- Temporal protection system allowing time bounded real time operation.

TC1.6P Implementation

- Most instructions executed in 1 cycle
- Branch instructions in 1, 2 or 3 cycles (using dynamic branch prediction)
- Wide memory interface for fast context switch
- Automatic context save-on-entry and restore-on-exit for: subroutine, interrupt, trap
- Four memory protection register sets
- Dual instruction issuing (in parallel into Integer Pipeline and Load/Store Pipeline)
- Third pipeline for loop instruction only (zero overhead loop)

- Single precision Floating Point Unit (IEEE-754 Compatible)
- Dedicated Integer divide unit
- Implementation optimised for performance.
- 16 data protection ranges, 8 code protection ranges

TC1.6E Implementation

- Most instructions executed in 1 cycle
- Branch instructions in 1 or 2 cycles (using static branch prediction)
- Wide memory interface for fast context switch
- Automatic context save-on-entry and restore-on-exit for: subroutine, interrupt, trap
- Four memory protection register sets
- Single instruction issue per cycle
- Single precision Floating Point Unit (IEEE-754 Compatible)
- Dedicated Integer divide unit
- Implementation optimised for power
- 16 data protection ranges, 8 code protection ranges

6.3 TC1.6P Implementation Overview

The following sections give an overview of the TC1.6P Implementation

6.3.1 CPU Diagram

The Central Processing Unit (CPU) comprises of an Instruction Fetch Unit, an Execution Unit, a General Purpose Register File (GPR), a CPU Slave interface (CPS), and Floating Point Unit (FPU).

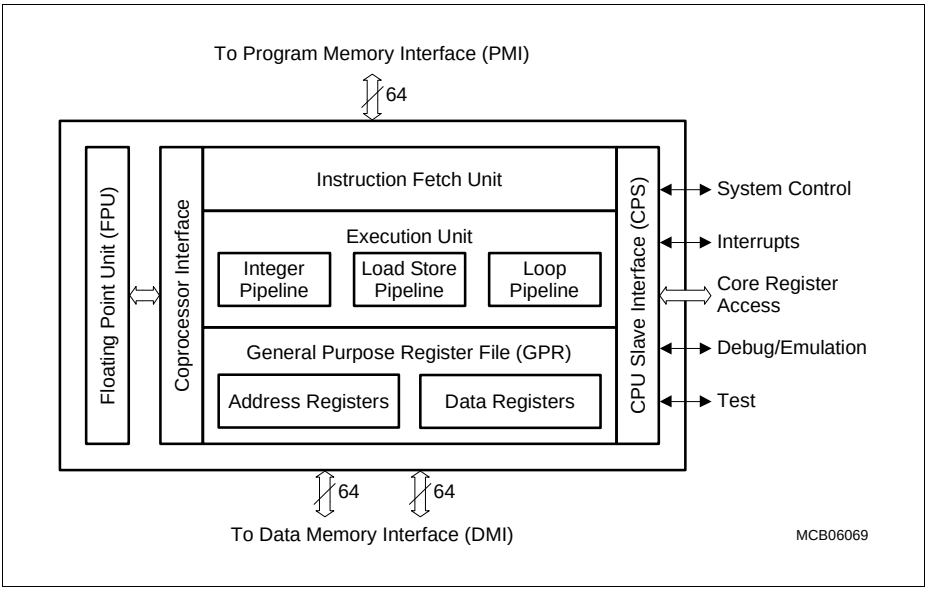

Figure 6-1 CPU Block Diagram

6.3.2 Instruction Fetch Unit

The Instruction Fetch Unit pre-fetches and aligns incoming instructions from the 64-bit wide Program Memory Interface (PMI). Instructions are placed in predicted program order in the Issue fifo. The Issue fifo buffers up to six instructions and directs the instruction to the appropriate execution pipeline.

The Instruction Protection Unit checks the validity of accesses to the PMI and the integrity of incoming instructions fetched from the PMI.

The branch unit examines the fetched instructions for branch conditions and predicts the most likely execution path based on previous branch behavior. The Program Counter Unit (PC) is responsible for updating the program counters.

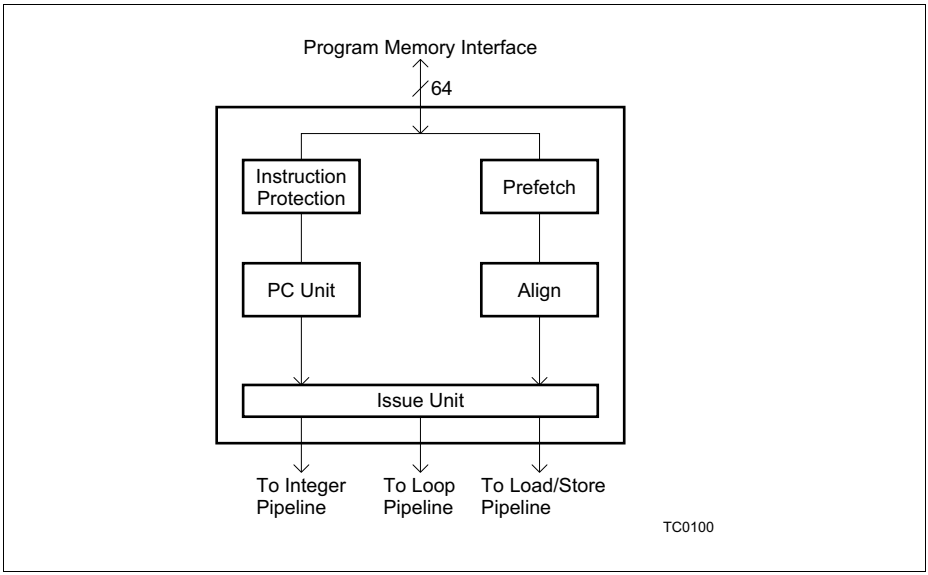

Figure 6-2 Instruction Fetch Unit

6.3.3 Execution Unit

The Execution Unit contains the Integer Pipeline, the Load/Store Pipeline and the Loop Pipeline. All three pipelines operate in parallel, permitting up to three instructions to be executed in one clock cycle. In the execution unit all instructions pass through a decode stage followed by two execute stages. Pipeline hazards (stalls) are minimised by the use of forwarding paths between pipeline stages allowing the results of one instruction to be used by a following instruction as soon as the result becomes available.

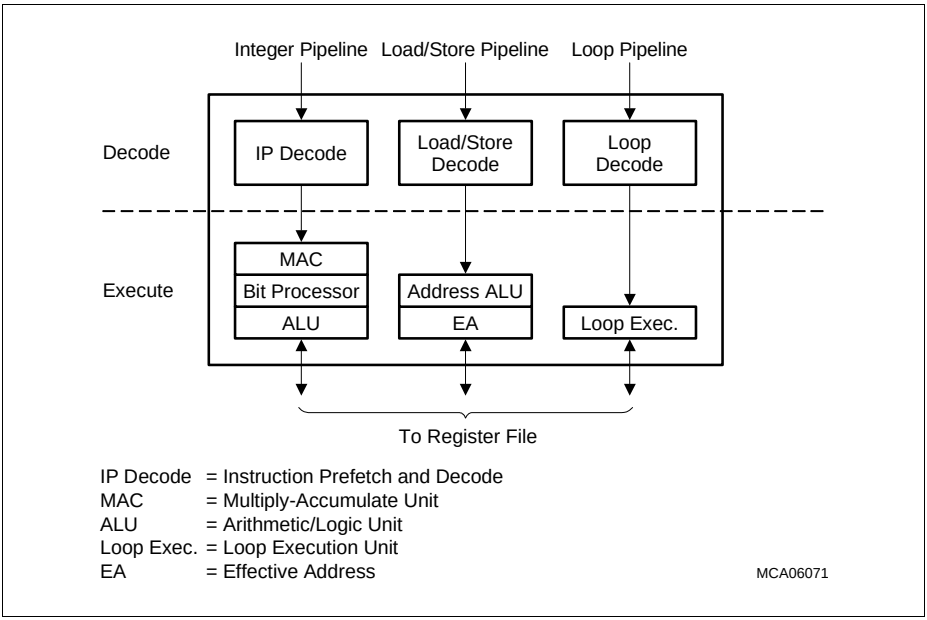

Figure 6-3 Execution Unit

6.3.4 General Purpose Register File

The CPU has a General Purpose Register (GPR) file, divided into an Address Register File (registers A0 through A15) and a Data Register File (registers D0 through D15).

The data flow for instructions issued to the Load/Store Pipeline is steered through the Address Register File.

The data flow for instructions issued to/from the Integer Pipeline and for data load/store instructions issued to the Load/Store Pipeline is steered through the Data Register File.

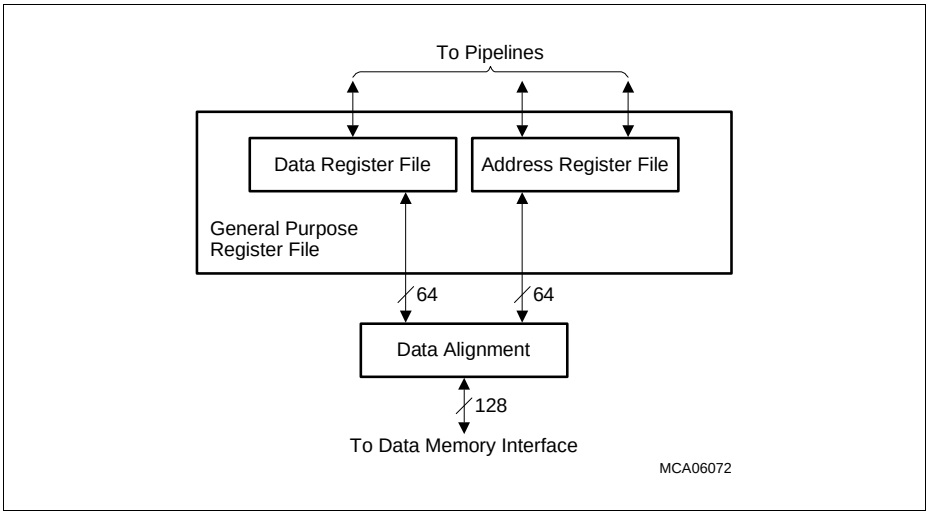

Figure 6-4 General Purpose Register File

6.4 TC1.6E Implementation Overview

The following sections give an overview of the TC1.6E Implementation

6.4.1 CPU Diagram

The Central Processing Unit (CPU) comprises of an Instruction Fetch Unit, an Execution Unit, a General Purpose Register File (GPR), a CPU Slave interface (CPS), and Floating Point Unit (FPU).

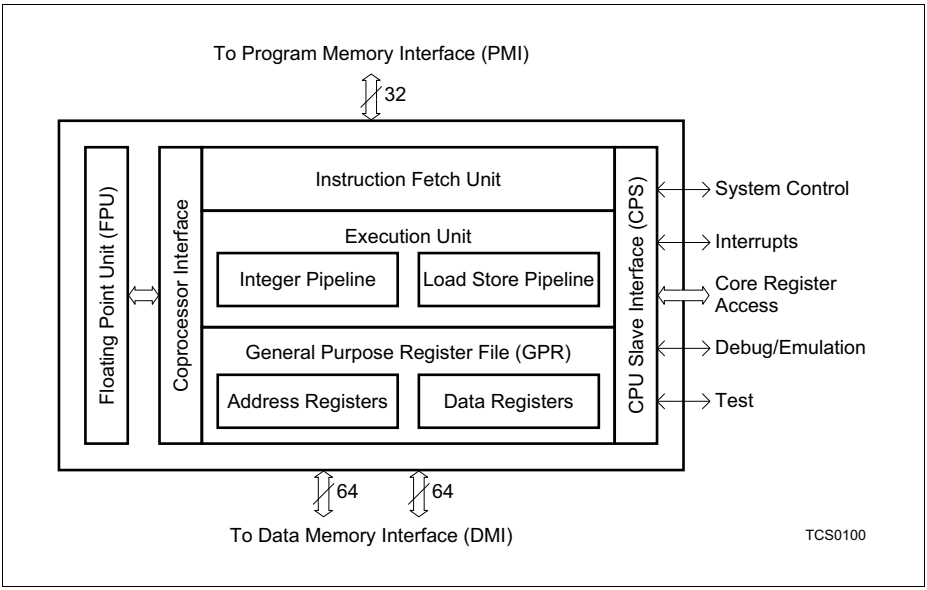

Figure 6-5 CPU Block Diagram

6.4.2 Instruction Fetch Unit

The Instruction Fetch Unit pre-fetches and aligns incoming instruction half-words from the 32-bit wide Program Memory Interface (PMI). The Issue Unit directs a single aligned instruction to the appropriate execution pipeline.

The Instruction Protection Unit checks the validity of accesses to the PMI and the integrity of incoming instructions fetched from the PMI.

The Program Counter Unit (PC) is responsible for updating the program counters.

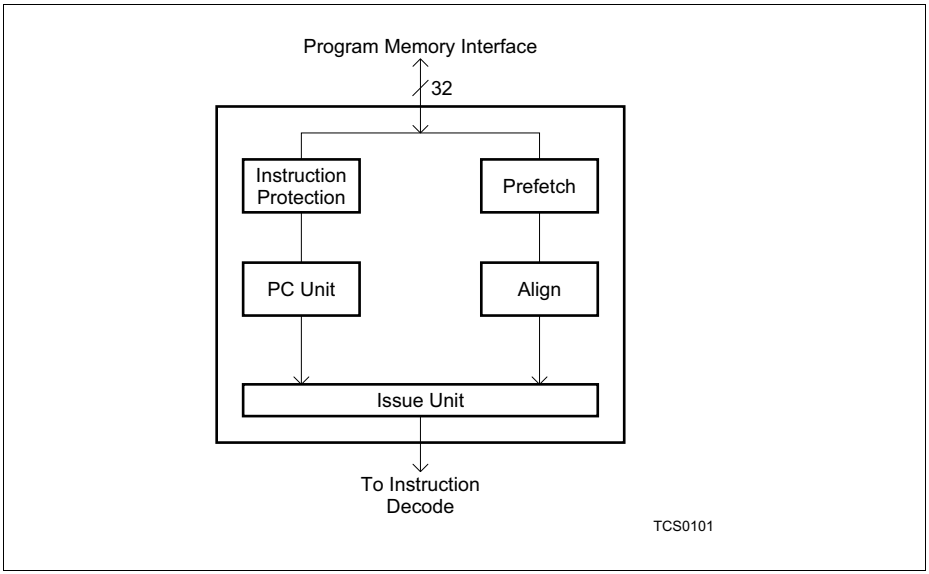

Figure 6-6 Instruction Fetch Unit

6.4.3 Execution Unit

The Execution Unit contains the Integer Pipeline and the Load/Store Pipeline. In TC1.6E, loop instructions are always executed by the Load/Store pipeline.

The TC1.6E issues a single instruction per clock cycle, and as such no more than one instruction will be executed in one clock cycle.

In the execution unit all instructions pass through a decode stage followed by two execute stages. Pipeline hazards (stalls) are minimised by the use of forwarding paths between pipeline stages allowing the results of one instruction to be used by a following instruction as soon as the result becomes available.

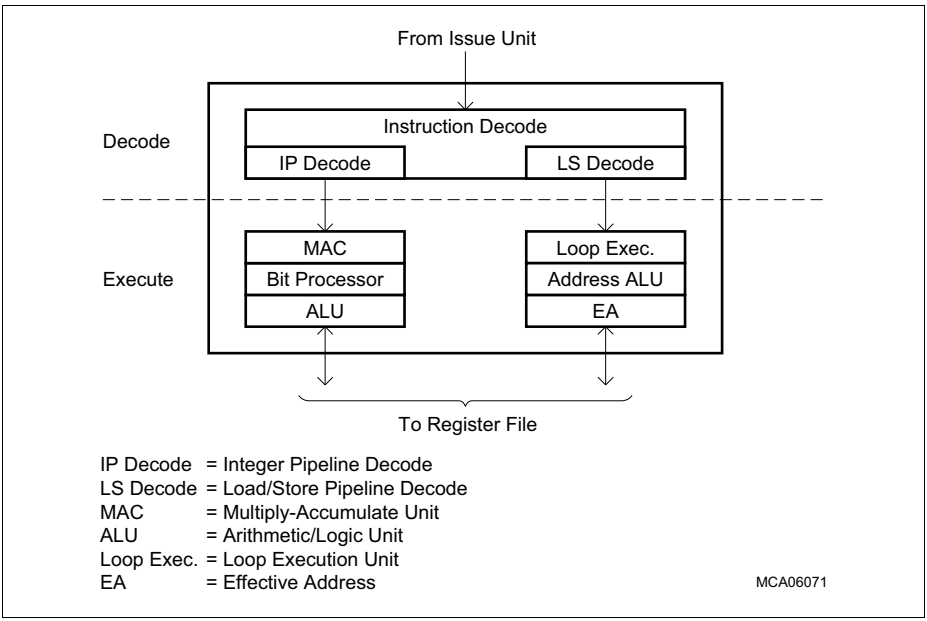

Figure 6-7 Execution Unit

6.4.4 General Purpose Register File

The CPU has a General Purpose Register (GPR) file, divided into an Address Register File (registers A0 through A15) and a Data Register File (registers D0 through D15).

The data flow for instructions issued to the Load/Store Pipeline is steered through the Address Register File.

The data flow for instructions issued to/from the Integer Pipeline and for data load/store instructions issued to the Load/Store Pipeline is steered through the Data Register File.

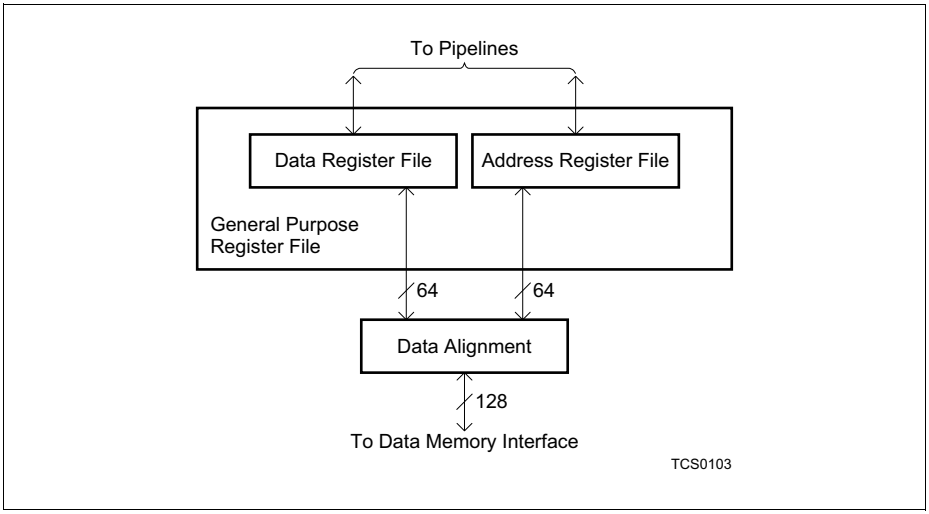

Figure 6-8 General Purpose Register File

6.5 Summary of functional changes from TC1.3.1

The TC1.6P and TC1.6E CPUs utilise different pipeline organisations than that used in the TC1.3. One effect of the new pipeline organisation is to increase the load-use penalty to 1 from 0. This necessitates re-scheduling of code to achieve optimum performance.

Other significant adaptations to the existing TC1.3.1 CPU are as follows:

- Fully Pipelined Floating Point Unit (FPU)
  - Most floating point instructions now have a repeat rate of 1
- Improved debug system - now decoupled from protection system.
  - 8 comparators proving up to 4 ranges, selectable for PC or load-store address
- Expanded and enhanced memory protection unit (MPU)
  - 16 data ranges and 8 code ranges.
- New Temporal protection system.
  - Guards against task runtime overrun.
- New Safety protection system. Tasks identified as safe by new PSW bit (PSW.S)
- New instructions for improved Interrupt and Data Cache manipulation support.
  - DISABLE, RESTORE, CACHEI.I
- New instructions for Fast Integer Divide
  - DIV, DIV.U
- New Instructions for fast call and return with minimal saving of state.
  - FCALL,FCALLA,FCALLI, FRET
- Long offset addressing mode introduced for byte, half word and address accesses.
  - LD.BU, LD.B, LD.HU, LD.H, ST.B, ST.H, ST.A
- Extended range of 16 bit jumps
  - JEQ, JNE
- New Synchronisation Instructions
  - CMPSWAP.W, SWAPMSK.W
- New CRC instruction
  - CRC32
- New wait for interrupt instruction
  - WAIT
- Increased flexibility in the system address map.
- Full SECDED ECC protection for all scratch, cache and tag memory structures.
- Cache and Scratchpad memory systems now entirely separated.
  - Cache memories may be mapped as additional scratchpad.
- Selectable interrupt vector table size (32bytes/entry, 8bytes/entry).

6.6 CPU Implementation-Specific Features

This section describes the implementation-specific features of the TC1.6P and TC1.6E CPUs. For a complete description of all registers, refer to the TriCore Architecture Manual.

6.6.1 Context Save Areas / Context Operations

The CPU uses a uniform context-switching method for function calls, interrupts and traps. In all cases the Upper Context of the task is automatically saved and restored by hardware. Saving and restoring of the Lower Context may be optionally performed by software.

In TC1.6P, Context Save Areas (CSA) and addresses targeted by explicit context load/store instructions (e.g. LDLCX) may be placed in DSPR or external memory (cached or uncached).

In TC1.6E, Context Save Areas (CSA) and addresses targeted by explicit context load/store instructions may be placed in DSPR only.

CSA Placement in DSPR

The actual timing of context operations is dependent upon the placement of the Context Save Areas. Maximum performance is achieved when the Context Save Area is placed in DSPR. In this case all context save and restores operations take four cycles.

CSA Placement in Cached External Memory (TC1.6P Only)

In this case, the timing is also dependent on the state of the Data Cache. The best case Data Cache operation occurs when context saves do not incur a cache line writeback, and context restores hit in the data cache. In this case all context saves and restores take eight cycles.

6.6.2 Program Counter (PC) Register

The Program Counter (PC) holds the address of the instruction that is currently fetched and forwarded to the CPU pipelines. The CPU handles updates of the PC automatically.

Software can use the current value of the PC for various tasks, such as performing code address calculations. Reading the PC through software executed by the CPU must only be done with an MFCR instruction. Such a read will return the PC of the MFCR instruction itself. Explicit writes to the PC through an MTCR instruction must not be done due to possible unexpected behavior of the CPU. The PC may be written only when the CPU is halted.

The CPU must not perform Load/Store instructions to the mapped address of the PC in Segment 15. A MEM trap will be generated in such a case. Bit 0 of the PC register is read-only and hard-wired to 0.

6.6.3 Store Buffers

To increase performance the TC1.6P/E CPUs implements store buffering to decouple memory write operations from CPU instruction execution. All stores from the CPU are placed in the store buffer prior to being written to local memory or transferred via the bus system. Write data is taken from the store buffers and written to memory when the target memory or bus interface becomes available. In normal operation the CPU will prioritise memory load operations over store operations in order to improve performance unless:-

- The store buffer is full.
- The load is to peripheral space and a store to peripheral space exists in the store buffer. (In order peripheral space access).
- The load or store is part of an atomic operation.

Typically the operation of the store buffer is invisible to the end user. If there is a requirement that data is written to memory prior to execution of a subsequent instruction then a DSYNC instruction may be used to flush the store buffers.

To further improve performance consecutive byte writes to the same half word location are merged in the store buffer.

The TC1.6P CPU store buffer can hold the data for up to 6 stores. The TC1.6E CPU store buffer can hold the data for up to 2 stores.

Store buffer operation may be disabled be setting the SMACON.IODT bit. This should not be done in normal execution as it will severely limit performance.

6.6.4 Interrupt System

An interrupt request can be generated by the on-chip peripheral units, or it can be generated by external events. Requests can be targeted to any CPU.

The interrupt system evaluates service requests for priority and to identify whether the CPU should receive the request. The highest-priority service request is then presented to the CPU by way of an interrupt.

On taking an interrupt the CPU will vector to a unique PC generated from the interrupt priority number and the Base Interrupt Vector (BIV). The spacing between the vector PCs in the interrupt vector table may be selected to be either 32 Bytes or 8 Bytes using BIV[0].

Both the TC1.6P and TC1.6E implement a fast interrupt system. This system avoids unnecessary context save and restore operations and hence speeds up interrupt routine entry. A fast interrupt is triggered when:-

- An Interrupt is pending
- A Return From Interrupt instruction is being executed (RFE)
- The priority of the pending interrupt is greater than the priority level that would be returned to should the RFE be executed (ICR.PIPN > PCXI.PCPN).
- Interrupts will be enabled should the RFE be executed. (PCXI.PIE == 1)
- Fast Interrupts are not otherwise disabled due to the presence of MTCR instructions or context operations in the pipeline.

Without the fast interrupt operation the RFE would cause a restore of the upper context immediately followed by a save of the same upper context back to exactly the same memory location (Minimum 8 cycles). The fast interrupt system replaces this redundant restore/save sequence with a load of PCXI/PSW/A10/A11 (Minimum 1 Cycle) from the saved context. System state at the end of the fast interrupt is the same as if the standard RFE/Interrupt sequence had been performed.

6.6.5 Trap System

The following traps have implementation-specific properties.

UOPC - Unimplemented Opcode (TIN 2)

The UOPC trap is raised on optional MMU instructions, coprocessor two and coprocessor three instructions.

OPD - Invalid Operand (TIN 3)

The CPU raised OPD traps for instructions that take even-odd register pairs as an operand where if the operand specifier is odd.

DSE - Data Access Synchronous Error (TIN 2)

The Data Access Synchronous Bus Error (DSE) trap is generated by the DMI module when a load access from the CPU encounters certain error conditions, such as a Bus error, or an out-of-range access to DSPR. When a DSE trap is generated, the exact cause of the error can be determined by reading the Data Synchronous Trap Register, DSTR. For details of possible error conditions and the corresponding flag bits in DSTR, see **“DMI Trap Generation” on Page 6-103**.

DAE - Data Access Asynchronous Error (TIN 3)

The Data Access Asynchronous Error Trap (DAE) is generated by the DMI module when a store or cache management access from the CPU encounters certain error conditions, such as an Bus error. When a DAE trap is generated, the exact cause of the error can be determined by reading the Data Asynchronous Trap Register, DATR. For details of possible error conditions and the corresponding flag bits in DATR, see **“DMI Trap Generation” on Page 6-103**.

PIE Program Memory Integrity Error (TIN 5)

The PIE trap is raised whenever an uncorrectable memory integrity error is detected in an instruction fetch from a local memory or the SRI bus. The trap is synchronous to the erroneous instruction. The trap is of Class-4 and has a TIN of 5.

Program memories are protected from memory integrity errors on a 64 bit basis (TC1.6P) or 32 bit basis (TC1.6E). A PIE trap is raised when an attempt is made to execute an instruction from any fetch group containing a memory integrity error.

The PIEAR and PIETR registers may be interrogated to determine the source of any error more precisely.

DIE Data Memory Integrity Error (TIN 6)

The DIE trap is raised whenever an uncorrectable memory integrity error is detected in a data access to a local memory or the SRI bus. The trap is of Class-4 and has a TIN of 6.

DIE traps are always asynchronous independent of the operation which encountered the error.

A DIE trap is raised if any memory half word (local memory) or double word (SRI bus) accessed by a load/store operation contains an uncorrectable error. The DIEAR and DIETR registers may be interrogated to determine the source of any error more precisely.

MPX Memory Protection Execute (TIN 4)

The MPX trap is raised whenever a program attempts to execute an instruction from a memory area for which it does not have execute permission and memory protection is enabled. The trap is of Class-1 and has a TIN of 4.

The TC1.6E compares the PC of the instruction with the range(s) defined by the memory protection system to determine whether or not execution is permitted.

The TC1.6P compares the 64bit aligned fetch group address with the range(s) defined by the memory protection system to determine whether or not execution is permitted.

6.6.6 Memory Integrity Error Handling

The TriCore CPUs contain integrated support for the detection and handling of memory integrity errors. The handling of memory integrity errors for the various memory types in the CPU is as follows:

6.6.6.1 Program Side Memories

The program side memories of the CPU consist of two independent memory structures:- The Program Scratchpad RAM (PSPR) and Program Cache (PCACHE). Both memory structures are ECC protected from memory integrity errors on a 64bit basis (TC1.6P) or on a 32 bit basis (TC1.6E). Any sub-width write access to the PSPR from the Bus interface is converted to a Read-Modify-Write sequence by the PMI module.

Program Scratchpad RAM (PSPR)

The Scratchpad RAM of the CPU is protected from memory integrity errors on a 64bit basis (TC1.6P) or 32 bit basis (TC1.6E). ECC protection of is enabled via the MBIST ECCS register.

For instruction fetch requests from the TriCore CPU to PSPR, the ECC bits are read along with the data bits and are passed to the CPU along with their corresponding instructions. Whenever an attempt is made to issue an instruction containing an uncorrectable memory integrity error a synchronous PIE trap is raised. The trap handler is then responsible for correcting the memory entry and re-starting program execution.

For PSPR read operations from the Bus interface, either from the DMI module or another Bus master agent, an access that results in the detection of an uncorrectable memory integrity error in the requested data causes a bus error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate error is also flagged to the SCU module to optionally generate an NMI trap back to the CPU.

Writes to program scratchpad memory are only ever performed from the bus interface. For write operations less than the protection width of the PSPR the memory transaction is transformed into a read-modify-write sequence inside the PMI module. Such a write

operation may result in the detection of an uncorrectable memory integrity errors during the read phase which are handled as standard read operations.

Program Cache (PCACHE)

The Scratchpad RAM of the CPU is protected from memory integrity errors on a 64bit basis (TC1.6P) or 32 bits (TC1.6E).ECC protection of is enabled via the MBIST ECCS register.

For instruction fetch requests from the TriCore CPU to PCACHE, the ECC bits are read along with the data bits of all cache ways, and an uncorrectable error signal generated for each cache way. In the case of a tag hit, the uncorrectable error signals for the corresponding cache way are passed to the CPU along with their corresponding instructions. Whenever an attempt is made to issue an instruction containing an uncorrectable error a synchronous PIE trap is raised. The trap handler is then responsible for checking the source of the memory integrity error.

Program Tag (PTag)

ECC protection of is enabled via the MBIST ECCS register.

For instruction fetch requests from the TriCore CPU to PCACHE, the program tag ECC bits are read along with the data bits and an error flag is computed. A way hit is triggered only if the tag address comparison succeeds, the valid bit is set and no ECC error in the associated tag way is detected, any other result is considered a miss. In the normal case where no error is detected in either cache way then the cache line is filled/refilled as normal. In the case where an error is detected the cache controller replacement algorithm forces the way indicating an error to be replaced. In the case where one cache way flags a cache hit, and another cache way detects an uncorrectable ECC error, the error condition is masked and has no effect on the memory integrity error handling mechanisms.

6.6.6.2 Data Side Memories

The TC1.6P CPU implements both data scratch and data cache memories. The TC1.6E implements a data scratch memory but replaces the data cache with a data read buffer (DRB). All data memory structures are ECC protected from memory integrity errors on a per-half word basis. Any byte write access to either DSPR or DCache (TC1.6P) is converted to a halfword Read-Modify-Write sequence. In normal operation isolated byte write transactions to the data memories result in no additional stall cycles.

Data Scratchpad Ram (DSPR)

The DSPR memory of both TC1.6P and TC1.6E are protected from memory integrity errors on a per-halfword basis. ECC protection of is enabled via the MBIST ECCS register.

For data load requests from the TriCore CPU to DSPR, the ECC bits are read along with the data bits and an uncorrectable error signal is generated for each half-word. If an error is detected associated with any of the data half-words passed to the CPU an error is flagged to the CPU. If such an error condition is detected an asynchronous DIE trap is raised. The trap handler is then responsible for correcting the memory entry, or for taking alternative action (such as system soft reset) if correction of the data is not possible.

For DSPR read operations from the Bus interface, either from the PMI module or another Bus master agent, an access that results in the detection of an uncorrectable error in the requested data half-words causes a bus error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate error is also flagged to the SCU module to optionally generate an NMI trap back to the CPU.

For write operations to DSPR of half-word size or greater, the ECC bits are pre-calculated and written to the memory in parallel with the data bits. For byte write operations the memory transaction is transformed into a half-word read-modify-write sequence inside the DMI module. As such, byte write operations may result in the detection of uncorrectable memory integrity errors, which are handled as per standard read operations.

Data Cache (DCache) - TC1.6P Only

ECC protection of is enabled via the MBIST ECCS register.

For data load requests from the TriCore CPU to DCache, the ECC bits are read along with the data bits of both cache ways, and an uncorrectable error flag computed for each half-word of each cache way. In the case where an error is detected with any of the requested data half-words in a cache way which has a corresponding tag hit, an error is flagged to the CPU. If such an error condition is detected an asynchronous DIE trap is raised. The trap handler is then responsible for correcting the memory entry, or for taking alternative action (such as system soft reset) if correction of the data is not possible.

For write operations of half-word size or greater, the check bits are pre-calculated and written to the memory in parallel with the data bits. For byte write operations the memory transaction is transformed into a half-word read-modify-write sequence inside the DMI module. As such, byte write operations may result in the detection of uncorrectable memory integrity errors as for read operations.

For cache line writeback, uncorrectable error detection is performed as dirty data is transferred to the store buffers. In all cases (normal cache line eviction, cachex.xx instruction) where an error condition is detected in a valid cache line a DIE trap is raised. The trap handler is then responsible for taking corrective action (such as system soft reset) since correction of the data is not possible.

Data Tag (DTag) - TC1.6P Only

ECC protection of is enabled via the MBIST ECCS register.

For data load or store requests from the TriCore CPU to DCache, the data tag ECC bits are read along with the data bits and an uncorrectable error flag is computed. A way hit is triggered only if the tag address comparison succeeds, the tag location is valid and no uncorrectable error in the associated tag way is detected, any other result is considered a miss. In the normal case where no error is detected in either tag way then the cache line is filled/refilled as normal. In the case of a cache miss where an error is detected in one of the tag ways and the cache line does not contain dirty data the cache controller replacement algorithm forces the way indicating an error to be replaced when the refill operation returns. In the case where one cache way flags a cache hit, and the another way detects an uncorrectable error, the error condition is masked and has no effect on the memory integrity error handling mechanisms. If a cache miss occurs, with an uncorrectable error detected on the associated data tag way and dirty data detected, then an asynchronous DIE trap is signalled to the CPU and any writeback / refill sequence aborted. The trap handler is responsible for invalidating the cache line and processing any associated dirty data if possible, or taking other corrective action. Similar action is taken for forced cache writeback using the cache manipulation instructions.

6.6.6.3 Memory Initialisation

To avoid the generation of spurious ECC errors the DSPR, PSPR must be fully initialised prior to use. This may be done either by software or by automatically by hardware (see the PMU.PROCOND register for details). The entire physical memory as detailed in **Chapter 6.1** must be initialised irrespective of any memory size variants produced for derivative products.

6.6.7 WAIT Instruction

The WAIT instruction will suspend execution until the occurrence of one of the following events.

- Enabled Interrupt
- Non-Maskable Interrupt
- Asynchronous Trap
- Idle Request
- Suspend Request
- Asynchronous Debug Halt or Trap Request

6.6.8 Instruction Memory Range Limitations

To ensure the processor cores are provided with a constant stream of instructions the Instruction Fetch Units will speculatively fetch instructions from up to 64 bytes ahead of the current PC.

If the current PC is within 64 bytes of the top of an instruction memory the Instruction Fetch Unit may attempt to speculatively fetch instruction from beyond the physical

memory range. This may then lead to error conditions and alarms being triggered by the bus and memory systems.

It is therefore recommended that the upper 64 bytes of any memory are not used for instruction storage.

6.6.9 Atomicity of Data Accesses

The data alignment rules along with the number of bus transactions for each access type are detailed in the following tables: -

Alignment Rules

Table 6-7 Alignment rules for non-peripheral space

Access type	Access size	Alignment of address in memory	Min/Max number of SRI bus transactions
Load, Store Data Register	Byte	Byte (1_H)	1/1
	Half-Word	2 bytes (2_H)	1/1
	Word	2 bytes (2_H)	1/2 *
	Double-Word	2 bytes (2_H)	1/2 *
Load, Store Address Register	Word	4 bytes (4_H)	1/1
	Double-Word	4 bytes (4_H)	1/2 *
SWAP.W, LDMST, CMPSWAP.W, SWAPMSK.W	Word	4 bytes (4_H)	1/1
ST.T	Byte	Byte (1_H)	1/1
Context Operations	16 x 32-bit registers	64 bytes (40_H)	2/2 *

Table 6-8 Alignment rules for peripheral space

Access type	Access size	Alignment of address in memory	Min/Max Number of SPB bus transactions	Min/Max Number of SRI bus transactions
Load, Store Data Register	Byte	Byte (1_H)	1/1	1/1
	Half-Word	2 bytes (2_H)	1/1	1/1
	Word	4 bytes (4_H)	1/1	1/1
	Double-Word	8 bytes (8_H)	1/1	1/1
Load, Store Address Register	Word	4 bytes (4_H)	1/1	1/1
	Double-Word	8 bytes (8_H)	1/1	1/1
SWAP.W, LDMST, CMPSWAP.W, SWAPMSK.W	Word	4 bytes (4_H)	1/1	1/1
ST.T	Byte	Bytes (1_H)	1/1	1/1
Context Operations	16 x 32-bit registers	Not Permitted	-	-

In the case where a single access results in a single bus transaction atomicity of the data is preserved when viewed from any bus master.

In the case where a single access leads to multiple bus transactions (marked as “*” in the above tables) then atomicity needs to be considered. In these accesses it is possible for another bus master to read or write the target memory location between the bus transactions required to complete the access.

In the case of word and double word access to the SRI bus the number of bus transactions will be 1 for naturally aligned data values and hence atomicity will be preserved.

6.6.10 A11 usage

In normal usage A11 will always contain the target of the next RET or RFE instruction. The processor uses this fact to speculatively load the return target ahead of the execution of the RET/RFE instruction. Code that modifies the A11 (e.g. test code) should be aware that any value stored in A11 may be used as the target of such speculation. If the value in A11 is not a valid address the speculation may lead to error conditions and alarms being triggered by the bus and memory systems.

It is therefore recommended that A11 should only ever contain a valid address value.

6.7 Memory Addressing

This chapter details the CPU specific addressing.

6.7.1 CSFR and SFR base Locations

Each CPU has a dedicated set of control and status registers accessed at the addresses detailed in the following table.These registers are divided into Special Function Registers (SFRs) and Core Special Function Registers (CSFRs).

A CPU must access its own CSFR registers using MTCR and MFCR instructions. CSFR registers of other CPUs may be accessed using load and store instructions via the XBAR_SRI.

SFR registers of any CPU may only be accessed using load and store instructions via XBAR_SRI. Currently the overlay control and the access protection registers of CPUx are mapped into CPUx SFR address range.

The base locations for the TC1.6P and TC1.6E SFR and CSFR registers are as follows:-

Table 6-9 CSFR and SFR Base Locations

Core-ID Value	CSFR Base Address	SFR Base Address
0	$F881\_0000_H$	$F880\_0000_H$
1	$F883\_0000_H$	$F882\_0000_H$
2	$F885\_0000_H$	$F884\_0000_H$

6.7.2 Local and Global Addressing

The TriCore architecture supports closely coupled program and data SRAM memories known as Program Scratch Pad RAM (PSPR) and Data Scratch Pad RAM (DSPR). The local PSPR memory is always located at $C0000000_H$. The local DSPR is always located at $D0000000_H$. In a multiprocessor system the local scratch pad memories appear in the global address map in the following locations:-

Table 6-10 Global Address Locations

Core-ID Value	PSPR_base	DSPR_base
0	70100000_H	70000000_H
1	60100000_H	60000000_H
2	50100000_H	50000000_H

The CPUs always use the global addresses for bus transactions. Thus a data load from $C0000000_H$ (a CPUs local PSPR) will result in a bus transaction with an address in the range 50100000_H - $701FFFFF_H$ dependent on the Core-ID value of the processor.

Similarly a code fetch form $D0000000_H$ (a CPUs local DSPR) will result in a bus transaction with an address in the range 50000000_H - $700FFFFF_H$ dependent on the Core-ID value of the processor.

6.7.3 Cache Memory Access

The cache and tag memories may be mapped into the CPUs address space. When mapped the cache memories are contiguous with the DSPR/PSPR memories as detailed in the following table.When mapped the cache memories behave identically to the PSPR/DSPR memories and may be used as standard memory.

The mapping of cache and tag memories to the TriCore address space is controlled by the MTU_MEMMAP register. See the MTU chapter for details.

Table 6-11 Cache Memory Locations when mapped

Memory	Local Address	Global Address
Program Cache	$C000\_0000_H$+ PSPR_Memory_Size	PSPR_Base + PSPR_Memory_Size
Data Cache (TC1.6P)	$D000\_0000_H$+ DSPR_Memory_Size	DSPR_Base + DSPR_Memory_Size

When mapped the tag memories are available at the locations detailed in the following table. The mapping of the Tag memories is provided test purposes only. They may not be used as standard memory.

Table 6-12 Tag Memory Locations when mapped

Memory	Local Address	Global Address
Program Tag	$C00C\_0000_H$	PSPR_Base + $0x000C\_0000_H$
Data Tag (TC1.6P)	$D00C\_0000_H$	DSPR_Base + $0x000C\_0000_H$

The CACHEI.* instructions require a way and index value to be supplied in a valid address. The location of these bits in the 32bit address is as follows.

Table 6-13 Way and Index Location

Function	Address Bits
Way	[0]
Index	[11:5]

6.8 CPU Subsystem Registers

This section describes the implementation-specific features of the CPU Subsystem registers listed in **Table 6-14**. For complete descriptions of all registers refer to the TriCore Architecture Manual.

Table 6-14 CPU Subsystem Registers

Registers	Purpose	Description
CPU Core Special Function Registers (CSFRs)	Program state information, context and stack management, interrupt and trap control, system control	see **Page 6-28**
CPU General Purpose Registers (GPRs)	General Purpose Address and Data Registers	see **Page 6-40**
CPU Memory Protection Registers (CSFRs)	Memory protection control and mode selection	see **Page 6-40**
FPU Registers (CSFRs)	Support for the standard floating point instructions.	see **Page 6-41**
Memory Integrity Registers (CSFRs)	Integrity and Protection Core Special Function Registers.	see **Page 6-42**
Core Debug Registers (CSFRs)	Debug control	see **Page 6-53**
Implementation Specific Reset Values	Reset values for CPU registers not defined in this chapter	see **Page 6-56**
Program Memory Interface Registers (PMI CSFRs)	PMI program cache control, status and trap information	see **Page 6-93**
Data Memory Interface Registers (DMI CSFRs)	DMI data cache control, status and trap information	see **Page 6-105**

Note: To increase performance all stores to CSFR or SFR register locations are posted writes and complete silently. Stores to non-existent CSFR or SFR locations are not errored.

6.8.1 CPU Core Special Function Registers (CSFR)

This section describes implementation specific features of the Core Special Function Registers.

6.8.1.1 Registers

The implementation-specific Program Status Word Register (PSW) is an extension of the PSW description in the TriCore Architecture Manual. The status flags used for FPU operations overlay the status flags used for Arithmetic Logic Unit (ALU) operations.

Program Status Word Register

Note: The non-shaded areas in the register description define the implementation-specific bits/bit fields. The shaded areas are defined in the TriCore Architecture Manual.

PSW

Program Status Word Register (CSFR_Base + FE04$_H$) Reset Value: 0000 0B80$_H$

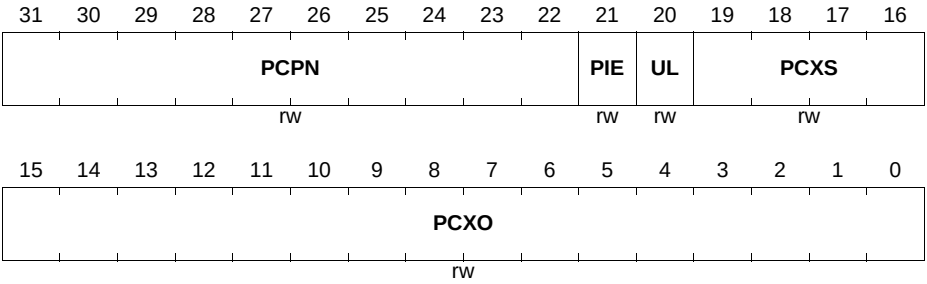
Previous Context Information Register

PCXI
Previous Context Information Register
(CSFR_Base + FE00$_H$) **Reset Value: 0000 0000$_H$**

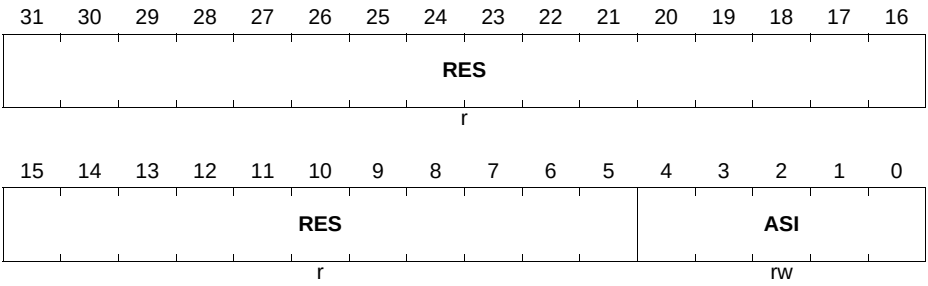


Field	Bits	Type	Description
PCXO	[15:0]	rw	**Previous Context Pointer Offset Field** The PCXO and PCXS fields form the pointer PCX, which points to the CSA of the previous context.
PCXS	[19:16]	rw	**Previous Context Pointer Segment Address** Contains the segment address portion of the PCX. This field is used in conjunction with the PCXO field.
UL	20	rw	**Upper or Lower Context Tag** Identifies the type of context saved. If the type does not match the type expected when a context restore operation is performed, a trap is generated. 0_B Lower Context 1_B Upper Context
PIE	21	rw	**Previous Interrupt Enable** Indicates the state of the interrupt enable bit (ICR.IE) for the interrupted task.
PCPN	[31:22]	rw	**Previous CPU Priority Number** Contains the priority level number of the interrupted task.

Address Space Identifier Register (TASK_ASI)

The Task Address Space Identifier (ASI) register description.

TASK_ASI
Task Address Space Identifier Register
(CSFR_Base + 8004_H) **Reset Value: $0000\ 001F_H$**

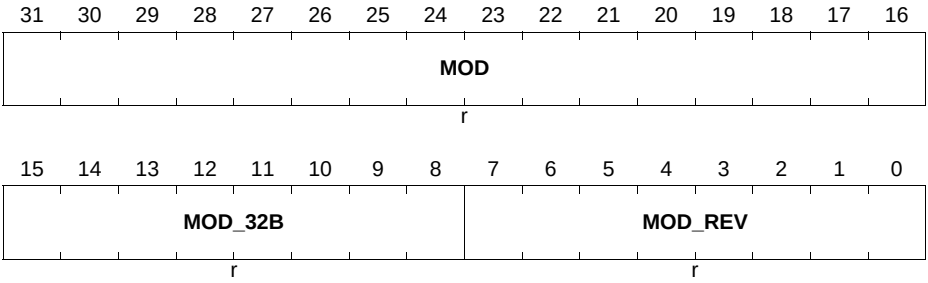


Field	Bits	Type	Description
RES	[31:5]	r	**Reserved**
ASI	[4:0]	rw	**Address Space Identifier** The ASI register contains the Address Space Identifier of the current process.

CPU Identification Register (TC1.6P)

CPU_ID
CPU Identification Register

(CSFR_Base + FE18$_H$) **Reset Value: 00C0 C012$_H$**

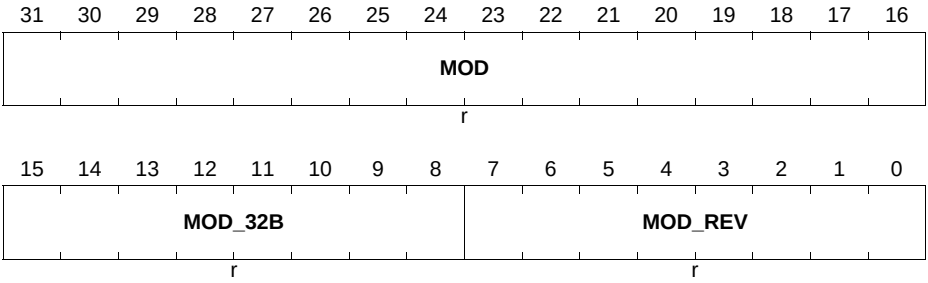


Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Revision Number** 12$_H$ Reset value
MOD_32B	[15:8]	r	**32-Bit Module Enable** C0$_H$ A value of C0$_H$ in this field indicates a 32-bit module with a 32-bit module ID register.
MOD	[31:16]	r	**Module Identification Number** 00C0$_H$ For module identification

CPU Identification Register (TC1.6E)

CPU_ID
CPU Identification Register

(CSFR_Base + FE18$_H$) **Reset Value: 00B7 C002$_H$**

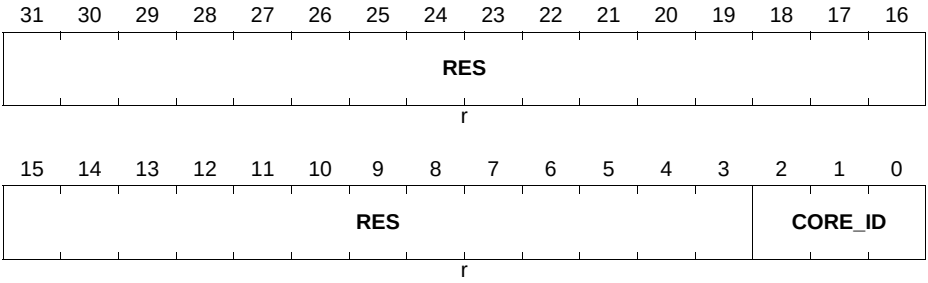


Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Revision Number** 02$_H$ Reset value
MOD_32B	[15:8]	r	**32-Bit Module Enable** C0$_H$ A value of C0$_H$ in this field indicates a 32-bit module with a 32-bit module ID register.
MOD	[31:16]	r	**Module Identification Number** 00B7$_H$ For module identification

Core Identification Register

CORE_ID
Core Identification Register

(CSFR_Base + FE1C$_H$) **Reset Value: 0000 000X$_H$**

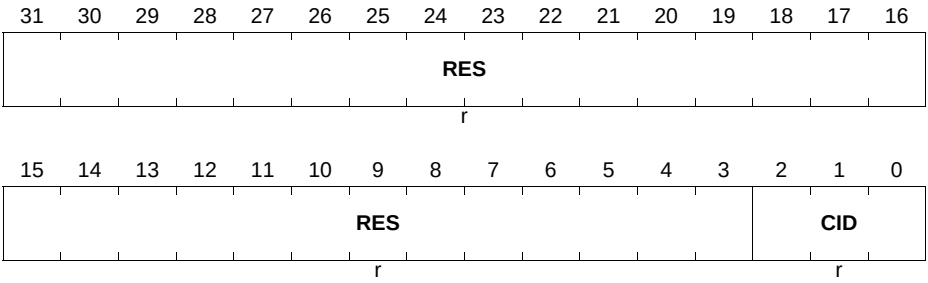


Field	Bits	Type	Description
RES	[31:3]	r	**Reserved**
CORE_ID	[2:0]	r	**Core Identification Number** The identification number of the core.

Customer ID Register

In circumstances where the Infineon defined Core identification numbering scheme is insufficient or incompatible with a customer numbering scheme a customer ID value may be supplied via the CUS_ID register.

CUS_ID
Customer ID register **(CSFR_Base + FE50$_H$)** **Reset Value: 0000 000X**



Field	Bits	Type	Description
RES	[31:3]	r	**Reserved**
CID	[2:0]	r	**Customer ID**

Physical Memory Attributes Registers

The Physical Memory Attributes registers (PMA0,PMA1,PMA2) define the physical memory attribute for each segment in the physical address space. The register is ENDINIT protected and can be read with the MFCR instruction and written by the MTCR instruction. Note that when changing the value of the registers both the instruction and data caches should be invalidated, a DSYNC instruction should be executed immediately prior to the MTCR with an ISYNC instruction executed immediately following. This is required to maintain coherency of the processors view of memory.

The register PMA0 defines the data access cacheability of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as cacheable for data accesses.

The register PMA1 defines the code access cacheability of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as cacheable for code accesses.

The register PMA2 defines the peripheral space identifier of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as a peripheral segment.PMA2 is a read-only register.

Registers PMA0 and PMA1 are freely programmable with the following restrictions:-

- In PMA0 Segment-C and Segment[7-CoreID] must have the same value.
- In PMA1 Segment-D and Segment[7-CoreID] must have the same value.

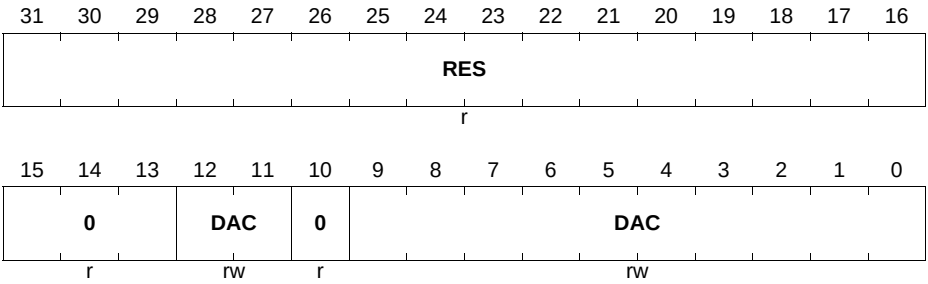
Irrespective of the setting of the PMA registers the following constraints are always enforced.

- Segments-F and segment-E are constrained to be Peripheral space and hence non-cacheable.
- Segment-A is constrained to be non-cacheable memory
- Segment-D and Segment[7-CoreID] are constrained to be non-cacheable for data accesses.
- Segment-C and Segment[7- CoreID] are constrained to be non-cacheable for code accesses.

Note: The PMA registers are ENDINIT protected.

PMA0
Data Access Cacheability Register

(CSFR_Base + 8100_H) **Reset Value: $0000\ 0300_H$**



Field	Bits	Type	Description
RES	[31:16]	r	**Reserved**
DAC	[15:13]	r	**Data Access Cacheability Segments F_H,E_H,D_H** (non-cacheable)

PSI	[15:0]	r	**Peripheral Attribute Segments F_H-0_H** = $C000_H$

Compatibility Control Register

The Compatibility Control Register (COMPAT) is an implementation-specific CSFR which allows certain elements of backwards compatibility with TriCore 1.3.x behavior to be forced. The reset value of the COMPAT register ensures that backwards compatibility with TriCore 1.3 is enabled by default. This register is safety_endinit protected.

COMPAT

6.8.2 CPU General Purpose Registers

There are no implementation specific features of the General Purpose Registers. They are described in detail in the TriCore Architecture Manual.

6.8.3 CPU Memory Protection Registers

There are four Memory Protection Register Sets per CPU. The sets specify memory protection ranges and permissions for code and data. The PSW.PRS bit field determines which of these sets is currently in use by the CPU. The CPUs each implement 16 data and 8 code range comparators. These may be flexibly shared amongst the of protection sets to provide a maximum of 16 data ranges and 8 code ranges per set.

The protection registers protect the whole address space (In previous TriCore implementations the memory protection system did not cover peripheral space.) The granularity of the protection ranges is 8 bytes.

Code protection ranges define which memory areas the CPU may fetch instructions from. Instruction fetches from an area outside a valid code protection range will lead to a trap condition.

Data protection ranges define which memory areas the CPU may access for read and/or write operations. Each range may be separately enabled for read and/or write access. Data read accesses from an area outside a valid data protection range with read permissions will lead to a trap condition. Data write accesses to an area outside a valid data protection range with write permissions will lead to a trap condition

There are no implementation specific features of the Memory Protection Registers. They are described in detail in the TriCore Architecture Manual.

6.8.4 Temporal Protection Registers

To Guard against task runtime overrun the CPU implements a temporal protection system. This system consists of three independent decrementing counters (TPS_TIMERn) arranged to generate a Temporal Asynchronous Error trap (TAE - Class-4, Tin-7) on decrement to zero. A control register (TPS_CON) contains status and control bits for temporal protection system. The temporal protection system is enabled by the SYSCON.TPROTEN register bit. The Temporal Protection Registers are Core Special Function Registers. They are described in detail in the TriCore Architecture Manual.

There are no implementation specific features of the Memory Protection Registers. They are described in detail in the TriCore Architecture Manual.

6.8.5 FPU Registers

There are no implementation specific features of the FPU Registers. They are described in detail in the TriCore Architecture Manual.

6.8.6 Memory Integrity Registers

To monitor and debug the integrity of the memory subsystems the following registers are provided.

Table 6-15 Memory Integrity Registers

Short Name	Description	Offset Address	Access Mode		Reset Type, Value
			Read	Write	
PIEAR	Program Integrity Error Address Register	9210_H	U, SV, 32	SV, 32,P	Application $0000\ 0000_H$
PIETR	Program Integrity Error Trap Register	9214_H	U, SV, 32	SV, 32,P	Application $0000\ 0000_H$
DIEAR	Data Integrity Error Address Register	9020_H	U, SV, 32	SV, 32,P	Application $0000\ 0000_H$
DIETR	Data Integrity Error Trap Register	9024_H	U, SV, 32	SV, 32,P	Application $0000\ 0000_H$
SMACON	SIST Mode Access Control Register	$900C_H$	U, SV, 32	SV, SE, 32,P	Application $0000\ 0000_H$

6.8.6.1 Register Descriptions

Program Integrity Error Information Registers

Two architecturally visible registers (PIETR, PIEAR) allow software to localise the source of the last detected program memory integrity error.

These registers are updated when a program integrity error condition is detected and the PIETR.IED bit is zero. On update the PIETR.IED bit is set to one and remains set until cleared by software. Whilst PIETR.IED is set further hardware updates of PIETR and PIEAR are inhibited. The various error scenarios are defined below.

Program Integrity errors during instruction fetch from program memory

When an error is detected during a program fetch from a program memory the IE_S, IE_C bits are updated to denote in which memory structure the error was detected. If the IE_C bit is set the E_INFO field will be updated with the cache way. The PIEAR register is updated with the address of the access. If the error detected is an uncorrectable bit error the IE_UNC bit is set. The IED bit is set and all other PIETR register bits are set to zero. Since instruction fetches are speculative, the PIETR and PIEAR registers may be updated without a corresponding PIE trap

Program Integrity errors during a memory read initiated by an external access

When an error is detected during an external bus read from program memory the IE_S, IE_C bits are updated to denote in which memory structure the error was detected. The IE_BS is set and E_INFO updated. The PIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other PIETR register bits are set to zero. Note that a memory read can be generated by a sub word write operation. The IE_C bit can only ever be set is the cache is mapped into memory in SIST mode. In this case the E_INFO field indicates the tag of the requesting master.

Program Integrity errors due to safety protection

When a safety protection violation is detected during a program memory access or during access to the CPU registers the IE_SP, IE_BS bits are set and the E_INFO field updated. The PIEAR register is updated with the address of the access. The IED bit is set and all other PIETR register bits are set to zero.

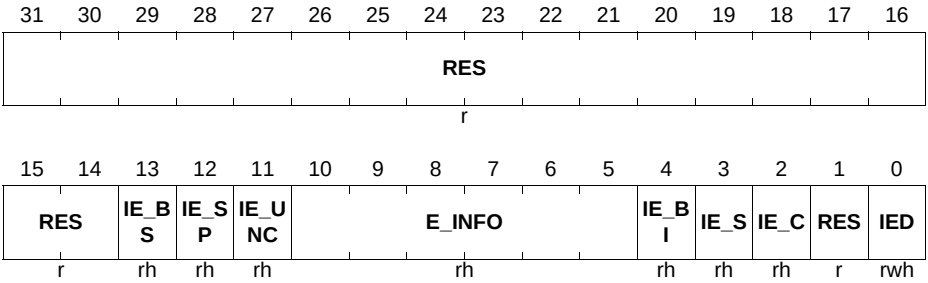
Program Integrity errors due ECC errors at the bus interface

When an ECC error is detected at the program bus interface (either master or slave) the IE_BI bit is set. If the error is during an external access the IE_BS bit is set and the E_INFO fields updated. The PIEAR register is updated with the address of the access.

If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other PIETR register bits are set to zero.

Program Integrity Error Trap Register (PIETR)

PIETR
Program Integrity Error Trap Register
(CSFR_Base + 9214_H) **Reset Value: $0000\ 0000_H$**

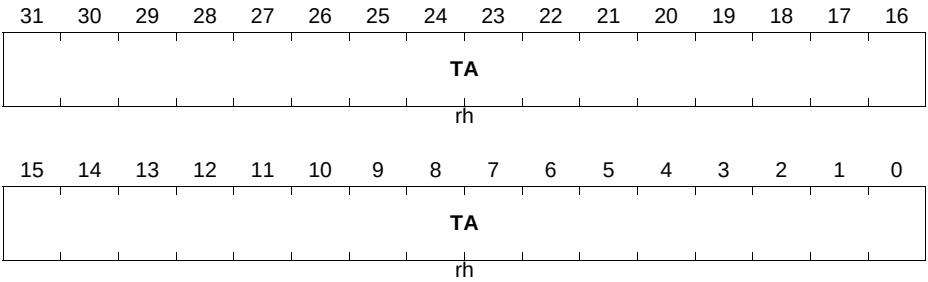


Field	Bits	Type	Description
IED	0	rwh	**Integrity Error Detected** Read Operation: 0_B No program integrity error condition occurred. 1_B Program integrity error condition detected. PIETR and PIEAR contents valid, further updates disabled. Write Operation: 0_B Clear IED bit, re-enable updates. 1_B No effect.
RES	1	r	**Reserved**
IE_C	2	rh	**Integrity Error - Cache Memory**
IE_S	3	rh	**Integrity Error - Scratchpad Memory**
IE_BI	4	rh	**Integrity Error - Bus Interface**
E_INFO	[10:5]	rh	**Error Information** If IE_BS= 1: Bus Master Tag ID of requesting master If IE_C = 1: Cache way.
IE_UNC	11	rh	**Integrity Error - Uncorrectable Error Detected**
IE_SP	12	rh	**Safety Protection Error Detected**
IE_BS	13	rh	**Bus Slave Access Indicator**
RES	[31:14]	r	**Reserved** Read as 0; should be written with 0.

Program Integrity Error Address Register

This register contains the physical address accessed by the operation that encountered a uncorrectable program memory integrity error. This register is only updated if PIETR.IED is zero.

PIEAR
Program Integrity Error Address Register
(CSFR_Base + 9210_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TA	[31:0]	rh	**Transaction Address** Physical address being accessed by operation that encountered program integrity error.

Data Integrity Error Information Registers

Two architecturally visible registers (DIETR, DIEAR) allow software to localise the source of the last detected uncorrectable data memory integrity error.

These registers are updated when an uncorrectable data integrity error condition is detected and the DIETR.IED bit is zero. On update the DIETR.IED bit is set to one and remains set until cleared by software. Whilst DIETR.IED is set further hardware updates of DIETR and DIEAR are inhibited. The various error scenarios are defined below.

Note that the TC1.6E has no data cache but will report Data Read Buffer errors as cache errors from way0.

Data Integrity errors during load from data memory

When an error is detected during a load from a data memory the IE_S, IE_C and IE_T bits are updated to denote in which memory structure the error was detected. If the IE_C bit is set the E_INFO field will be updated with the cache way. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero. Note that a memory read may also be generated by a sub word write operation or a cache line eviction.

Data Integrity errors during a memory read initiated by an external access

When an error is detected during an external bus read from data memory the IE_S, IE_C bits are updated to denote in which memory structure the error was detected. The IE_BS is set and E_INFO updated. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero. Note that a memory read may also be generated by a sub word write operation or a cache line eviction. The IE_C bit can only ever be set is the cache is mapped into memory in SIST mode. In this case the E_INFO field indicates the tag of the requesting master.

Data Integrity errors due to safety protection

When a safety protection violation is detected during a data memory access the IE_SP, IE_BS bits are set and the E_INFO field updated. The DIEAR register is updated with the address of the access. The IED bit is set and all other DIETR register bits are set to zero.

Data Integrity errors due ECC errors at the bus interface

When an ECC error is detected at the data bus interface (either master or slave) the IE_BI bit is set. If the error is during an external access the IE_BS bit is set and the E_INFO fields updated. The DIEAR register is updated with the address of the access.

If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero.

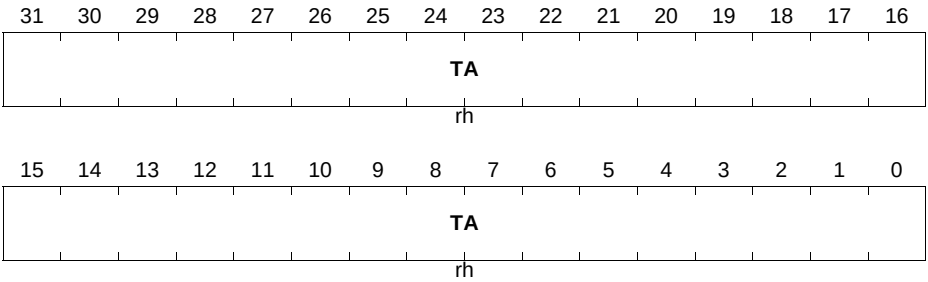
Data Integrity Error Address Register

This register contains the physical address accessed by the operation that encountered a uncorrectable data memory integrity error. This register is only updated if DIETR.IED is zero.

DIEAR
Data Integrity Error Address Register

(CSFR_Base + 9020_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TA	[31:0]	rh	**Transaction Address** Physical address being accessed by operation that encountered data integrity error.

SIST (Software In-System) Test Support

The CPU protects against memory integrity errors by ECC protection of the local CPU memories. This has the side-effect of requiring memory blocks wider than the normal data access path to the memory. The additional ECC storage bits are not easily accessible via the existing data paths, causing problems where software based testing of the memories is required. The CPU memories also include embedded memory arrays, such as the tag memories, which are not ordinarily accessible by the usual CPU datapaths. In order to address this problem, the CPUs include a modes allowing all local memory arrays to be accessed, both as a backup for MBIST based memory test and to allow the test and debug of the fault tolerant memory systems.

Each memory may be access either in normal operation, data array only or ECC check array only. This is controlled by the ECCS registers of the associated MBIST controller.

The IODT bit controls read/write operation ordering. In normal operation (IODT=0) non-dependent read operations may overtake write operations. When SMA.IODT is set all memory operations are performed in program order.

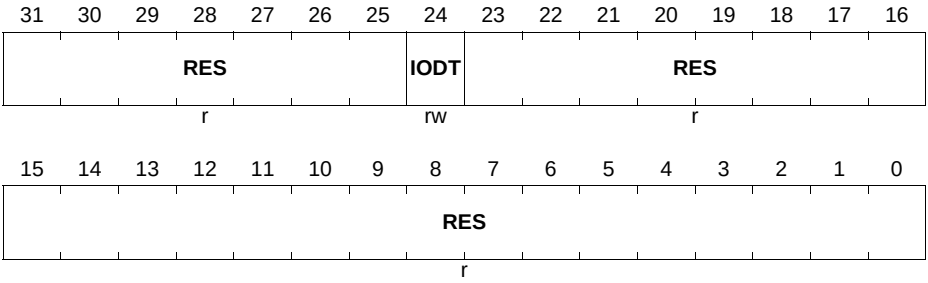
The SMACON register is protected by the safety_endinit signal.

The mapping of cache and tag memories to the TriCore address space is controlled by the MTU_MEMMAP register. See the MTU chapter for details.

SIST Mode Access Control Register

SMACON
SIST Mode Access Control Register

(CSFR_Base + 900C$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RES	[31:25]	r	**Reserved** Read as 0; should be written with 0.
IODT	24	rw	**In-Order Data Transactions** 0_B Normal operation, Non-dependent loads bypass stores. 1_B In-order operation, Loads always flush preceding stores, processor store buffer disabled.
RES	[23:0]	r	**Reserved** Read as 0; should be written with 0.

6.8.7 CPU Core Debug and Performance Counter Registers

The CPU Core Debug and performance counter registers are available for debug purposes. For a complete description of all registers, refer to the TriCore Architecture Manual.

6.8.7.1 Counter Source Details

Details of the Performance counter sources is given below.

IP_DISPATCH_STALL

The counter is incremented on every cycle in which the Integer dispatch unit is stalled for whatever reason.

LS_DISPATCH_STALL

The counter is incremented on every cycle in which the Load-Store dispatch unit is stalled for whatever reason.

LP_DISPATCH_STALL

The counter is incremented on every cycle in which the Loop dispatch unit is stalled for whatever reason.

PCACHE_HIT

The counter is incremented whenever the target of a cached fetch request from the fetch unit is found in the program cache.

PCACHE_MISS

The counter is incremented whenever the target of a cached fetch request from the fetch unit is not found in the program cache and hence a bus fetch is initiated.

MULTI_ISSUE

The counter is incremented in any cycle where more than one instruction is issued.

DCACHE_HIT

The counter is incremented whenever the target of a cached request from the Load-Store unit is found in the data cache.

DRB_HIT

The counter is incremented whenever the target of a cached request from the Load-Store unit is found in the data read buffer.

DCACHE_MISS_CLEAN

The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data cache and hence a bus fetch is initiated with no dirty cache line eviction.

DRB_MISS

The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data read buffer and hence a bus fetch is initiated.

DCACHE_MISS_DIRTY

The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data cache and hence a bus fetch is initiated with the writeback of a dirty cache line.

TOTAL_BRANCH

The counter is incremented in any cycle in which a branch instruction is in a branch resolution stage of the pipeline (IP_EX1, LS_DEC, LP_DEC).

PMEM_STALL

The counter is incremented whenever the fetch unit is requesting an instruction and the Instruction memory is stalled for whatever reason.

DMEM_STALL

The counter is incremented whenever the Load-Store unit is requesting a data operation and the data memory is stalled for whatever reason.

RGNACCENB7	Safety Protection Access Enable Register B Range 7	$E07C_H$	U, SV, 32	U,SV, 32,NC	Application $0000\ 0000_H$
ACCENA	Access Enable Register A	$E100_H$	U, SV, 32	U,SV, 32,SE	Application $0000\ 0000_H$
ACCENB	Access Enable Register B	$E104_H$	U, SV, 32	U,SV, 32,SE	Application $0000\ 0000_H$

Note: A disallowed access to any CPU register (e.g. attempted write to read only register, attempted user mode access to SV, attempted access to E without Endinit, etc.) will NOT result in a Bus Error.

6.9 CPU Instruction Timing

This section gives information on CPU instruction timing by execution unit. The Integer Pipeline and Load/Store Pipeline are always present, and the Floating Point Unit (FPU) is optional. The Load/Store unit implements the optional TLB instructions.

Definition of Terms:

- **Repeat Rate**

Assuming the same instruction is being issued sequentially, repeat is the minimum number of clock cycles between two consecutive issues. There may be additional delays described elsewhere due to internal pipeline effects when issuing a different subsequent instruction.

- **Result Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the result value is available to be used as an operand to a subsequent instruction or written into a GPR. Result latency is not meaningful for instructions that do not write a value into a GPR.

- **Address Latency**

The number of clocks cycles from the cycle when the instruction is issued to the cycle when the addressing mode updated value is available as an operand to a subsequent instruction or written into an Address Register.

- **Flow Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the next instruction (located at the target location or the next sequential instruction if the control change is conditional) is issued.

6.9.1 Integer-Pipeline Instructions

These are the Integer-Pipeline instruction timings for each instruction.

6.9.1.1 Simple Arithmetic Instruction Timings

Each instruction is single issued.

Table 6-28 Simple Arithmetic Instruction Timing

DVINIT.U	2	2	1	1	**DIV**	4-11	3-10	3-9	3-9
DVINIT.B	2	2	1	1	**DIV.U**	4-11	3-10	3-9	3-9
DVINIT.H	2	2	1	1					
DVINIT.BU	2	2	1	1					
DVINIT.HU	2	2	1	1					

The latency and repeat rate values listed for the DIV and DIV.U instructions are the minimum and maximum values.The algorithm used allows for early termination of the instruction once the full result is available.

6.9.1.2 Multiply Instruction Timings

Each instruction is single issued.

Table 6-29 Multiply Instruction Timing

Instruction	Result Latency TC16P-TC16E		Repeat Rate TC16P-TC16E		Instruction	Result Latency TC16P -TC16E		Repeat Rate TC16P-TC16E	
MUL	2	2	1	1	**MUL.Q**	3	2	1	1
MUL.U	2	2	1	1	**MULM.H**	3	2	1	1
MULS	3	2	1	1	**MULR.H**	3	2	1	1
MULS.U	3	2	1	1	**MULR.Q**	3	2	1	1
MUL.H	3	2	1	1					

6.9.1.3 Multiply Accumulate (MAC) Instruction Timing

Each instruction is single issued.

Table 6-30 Multiply Accumulate Instruction Timing

Instruction	Result Latency TC16P-TC16E		Repeat Rate TC16P-TC16E		Instruction	Result Latency TC16-TC16E		Repeat Rate TC16P-TC16E	
MADD	3	2	1	1	**MSUB**	3	2	1	1
MADD.U	3	2	1	1	**MSUB.U**	3	2	1	1
MADDS	3	2	1	1	**MSUBS**	3	2	1	1
MADDS.U	3	2	1	1	**MSUBS.U**	3	2	1	1
MADD.H	3	2	1	1	**MSUB.H**	3	2	1	1
MADD.Q	3	2	1	1	**MSUB.Q**	3	2	1	1
MADDM.H	3	2	1	1	**MSUBM.H**	3	2	1	1
MADDMS.H	3	2	1	1	**MSUBMS.H**	3	2	1	1
MADDR.H	3	2	1	1	**MSUBR.H**	3	2	1	1
MADDR.Q	3	2	1	1	**MSUBR.Q**	3	2	1	1
MADDRS.H	3	2	1	1	**MSUBRS.H**	3	2	1	1
MADDRS.Q	3	2	1	1	**MSUBRS.Q**	3	2	1	1
MADDS.H	3	2	1	1	**MSUBS.H**	3	2	1	1
MADDS.Q	3	2	1	1	**MSUBS.Q**	3	2	1	1
MADDSU.H	3	2	1	1	**MSUBAD.H**	3	2	1	1
MADDSUM.H	3	2	1	1	**MSUBADM.H**	3	2	1	1
MADDSUMS.H	3	2	1	1	**MSUBADMS.H**	3	2	1	1
MADDSUR.H	3	2	1	1	**MSUBADR.H**	3	2	1	1
MADDSURS.H	3	2	1	1	**MSUBADRS.H**	3	2	1	1
MADDSUS.H	3	2	1	1	**MSUBADS.H**	3	2	1	1

For All MADD, MSUB and MUL type instructions the result latency is reduced to 1 for accumulator forwarding between similar instructions.

For MADD.Q, MADDS.Q, MSUB.Q, MSUBS.Q Instructions:

MADD.Q, MADDS.Q, MSUB.Q, MSUBS.Q	Result Latency TC1.6P	Result Latency TC1.6E	Repeat Rate TC1.6P	Repeat Rate TC1.6E
16 × 16	3	2	1	1
16 × 32	3	2	1	1
32 × 32	3	2	1	1

6.9.1.4 Control Flow Instruction Timing TC1.6P

Control flow instruction timing for TC1.6P is complicated by the use of branch target buffers and fetch FIFOs.

- Incorrectly predicted LS instructions incur a three cycle branch recovery penalty.
- Incorrectly predicted IP instructions incur a four cycle branch recovery penalty.
- Correctly predicted not taken branches incur no penalty
- Correctly predicted taken branch incur a penalty of up to two cycles depending on the state of the fetch FIFOs and the branch target buffer.
- Loop instructions incur the same penalty as an LS conditional jump instruction.

Assumptions

- All target locations yield a full instruction in one access (i.e. not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle.
- Timing is best case; no cache misses for context operations, no pending stores.

Table 6-31 Control flow timing(TC1.6P)

Prediction-Result	Flow Latency (LS, LP)	Repeat rate (LS,LP)	Flow Latency (IP)	Repeat Rate (IP)
Correct Not-Taken	1	1	1	1
Correct Taken	1-2	1-2	1-2	1-2
Incorrect Not-Taken	3	4	3	4
Incorrect Taken	3	4	3	4

6.9.1.5 Control Flow Instruction Timing TC1.6E

The TC1.6E implements a simple static branch prediction scheme. 16 bit instruction format (either direction) and 32 bit format backwards conditional branches are predicted taken. 32 bit format forwards conditional branches are predicted not taken.

- Correctly predicted not taken branches incur no penalty.
- Correctly predicted taken branches incur a single cycle penalty.
- Incorrectly predicted branches incur a two cycle branch recovery penalty.
- Loop instructions incur the same penalty as LS conditional jump instructions.

Assumptions

- All target locations yield a full instruction in one access (i.e. not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle.
- Timing is best case; no cache misses for context operations, no pending stores.

Table 6-32 Control flow timing(TC1.6E)

Prediction-Result	Flow Latency	Repeat rate
Correctly predicted, not taken	1	1
Correctly predicted, taken	2	2
Incorrectly predicted	3	3

6.9.2 Load-Store Pipeline Instructions

This section summarizes the Load-Store Pipeline instructions.

6.9.2.1 Address Arithmetic Timing

Each instruction is single issued.

Table 6-33 Address Arithmetic Instruction Timing

Instruction	Result Latency TC16P- TC16E		Repeat Rate TC16P- TC16E		Instruction	Result Latency TC16P -TC16E		Repeat Rate TC16P-TC16E	
Load Store Arithmetic Instructions									
ADD.A	1	1	1	1	**GE.A**	1	1	1	1
ADDIH.A	1	1	1	1	**LT.A**	1	1	1	1
ADDSC.A	2	1	1	1	**NE.A**	1	1	1	1
ADDSC.AT	2	1	1	1	**NEZ.A**	1	1	1	1
EQ.A	1	1	1	1	**SUB.A**	1	1	1	1
EQZ.A	1	1	1	1	**NOP**	1	1	1	1
Trap and Interrupt Instructions									
DEBUG	–	–	1	1	**TRAPSV**[1)]	–	–	1	1
DISABLE	–	–	1	1	**TRAPV**[1)]	–	–	1	1
ENABLE	–	–	1	1	**RSTV**	–	–	1	1
RESTORE	–	–	1	1	**WAIT**[2)]	-	-	1	1
Move Instructions									
MFCR	2	2	1	1	**MOV.A**	1	1	1	1
MTCR	1	1	1	1	**MOV.AA**	1	1	1	1
MOVH.A	1	1	1	1	**MOV.D**	1	1	1	1
Sync Instructions									
DSYNC	–	–	1	1	**ISYNC**[3)]	–	–	1	1

1) Execution cycles when no TRAP is taken. The execution timing in the case of raising these TRAPs is the same as other TRAPs such as SYSCALL.

2) The latency of the WAIT instruction is hidden by the context save of the interrupt. Effective latency is zero.

3) Repeat rate assumes that code refetch takes a single cycle.

6.9.2.2 CSA Control Flow Instruction Timing

This section summarizes the timing of CSA Control Flow instructions.

- All targets yield a full instruction in one access (not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle. Timing is best case; no cache misses for context operations, no pending stores.

Table 6-34 CSA Control Flow Instruction Timing

Instruction	Result Latency TC16P-TC16E		Repeat Rate TC16P-TC16E		Instruction	Result Latency TC16P-TC16E		Repeat Rate TC16P-TC16E	
CALL	4-8	4	4-8	4	**SYSCALL**	4-8	4	4-8	4
CALLA	4-8	4	4-8	4	**SVLCX**	4-8	4	4-8	4
CALLI	4-8	4	4-8	4	**RSLCX**	4-8	4	4-8	4
RET	4-8	4	4-8	4	**RFE**	4-8	4	4-8	4
BISR	4-8	4	4-8	4	**RFM**	4-8	4	4-8	4
FCALL	1	1	1	1	**FCALLA**	1	1	1	1
FCALLI	1	1	1	1	**FRET**	1	1	1	1

Access to DSPR require 4 cycles, accesses to cached external memory require 8 cycles (TC1.6P only).

6.9.2.3 Load Instruction Timing

Load instructions can produce two results if they use the pre-increment, post-increment, circular or bit-reverse addressing modes. Hence, in those cases there are two latencies that must be specified, the result latency for the value loaded from memory and the address latency for using the updated address register result.

- Each instruction is single issued.
- The memory references is naturally aligned.
- The memory accessed takes a single cycle to return a data item.
- Timing is best case; no cache misses, no pending stores.

Table 6-35 Load Instruction Timing TC1.6P

Instruction	Address Latency	Result Latency	Repeat Rate	Instruction	Address Latency	Result Latency	Repeat Rate
Load Instructions							
LD.A	1	3	1	**LD.Q**	1	2	1
LD.B	1	2	1	**LD.W**	1	2	1

Table 6-35 Load Instruction Timing TC1.6P (cont'd)

Instruction	Address Latency	Result Latency	Repeat Rate	Instruction	Address Latency	Result Latency	Repeat Rate
LD.BU	1	2	1	**LDLCX**	5-9	5-9	5
LD.D	1	2	1	**LDUCX**	5-9	5-9	5
LD.DA	1	3	1	**SWAP.W**	2	3	2
LD.H	1	2	1	**LEA**[1)]	–	1	1
LD.HU	1	2	1	**CMPSWAP**	2	3	1
SWAPMSK	2	3	1				

1) The addressing mode returning an updated address is not relevant for this instruction.

Table 6-36 Load Instruction Timing TC1.6E

Instruction	Address Latency	Result Latency	Repeat Rate	Instruction	Address Latency	Result Latency	Repeat Rate
Load Instructions							
LD.A	1	3	1	**LD.Q**	1	2	1
LD.B	1	2	1	**LD.W**	1	2	1
LD.BU	1	2	1	**LDLCX**	5	5	5
LD.D	1	2	1	**LDUCX**	5	5	5
LD.DA	1	3	1	**SWAP.W**	2	3	2
LD.H	1	2	1	**LEA**[1)]	–	1	1
LD.HU	1	2	1	**CMPSWAP**	2	3	1
SWAPMSK	2	3	1				

1) The addressing mode returning an updated address is not relevant for this instruction.

6.9.2.4 Store Instruction Timing

Cache and Store instructions similar to Load instructions will have a result for the pre-increment, post-increment, circular or bit-reverse addressing modes, but do not produce a ‘memory’ result.

- Each instruction is single issued.
- The memory references is naturally aligned.
- The memory accessed takes a single cycle to accept a data item.
- Timing is best case; no cache misses, no pending stores.

Table 6-37 Cache and Store Instruction Timing

Instruction	Result Latency TC16P- TC16E		Repeat Rate TC16P- TC16E		Instruction	Result Latency TC16P -TC16E		Repeat Rate TC16P-TC16E	
Cache Instructions									
CACHEA.I	1	1	1	1	**CACHEA.WI**[1]	1	1	1	1
CACHEA.W[1]	1	1	1	1	**CACHEI.W**	1	1	1	1
CACHEI.WI	1	1	1	1	**CACHEI.I**	1	1	1	1
Store Instructions									
ST.A	1	1	1	1	**ST.T**	1	1	2	2
ST.B	1	1	1	1	**ST.W**	1	1	1	1
ST.D	1	1	1	1	**STLCX**	1	1	9	5
ST.DA	1	1	1	1	**STUCX**	1	1	9	5
ST.H	1	1	1	1	**LDMST**	1	1	2	2
ST.Q	1	1	1	1					

1) Repeat rate assumes that no memory writeback operation occurs. Otherwise the repeat rate will depend upon the time for the castout buffers to clear.

6.9.3 Floating Point Pipeline Timing

These instructions are only valid if the optional Floating Point Unit is implemented.

Each instruction is single issued.

Table 6-38 Floating Point Instruction Timing

FTOUZ	2	1	1	1	**UTOF**	2	1	1	1

6.10 Program Memory Interface (PMI)

The program Memory Interface (PMI) provides the instruction stream to the CPU.

6.10.1 TC1.6P PMI Description

Figure 6-9 shows the block diagram of the Program Memory Interface (PMI) of the TC1.6P.

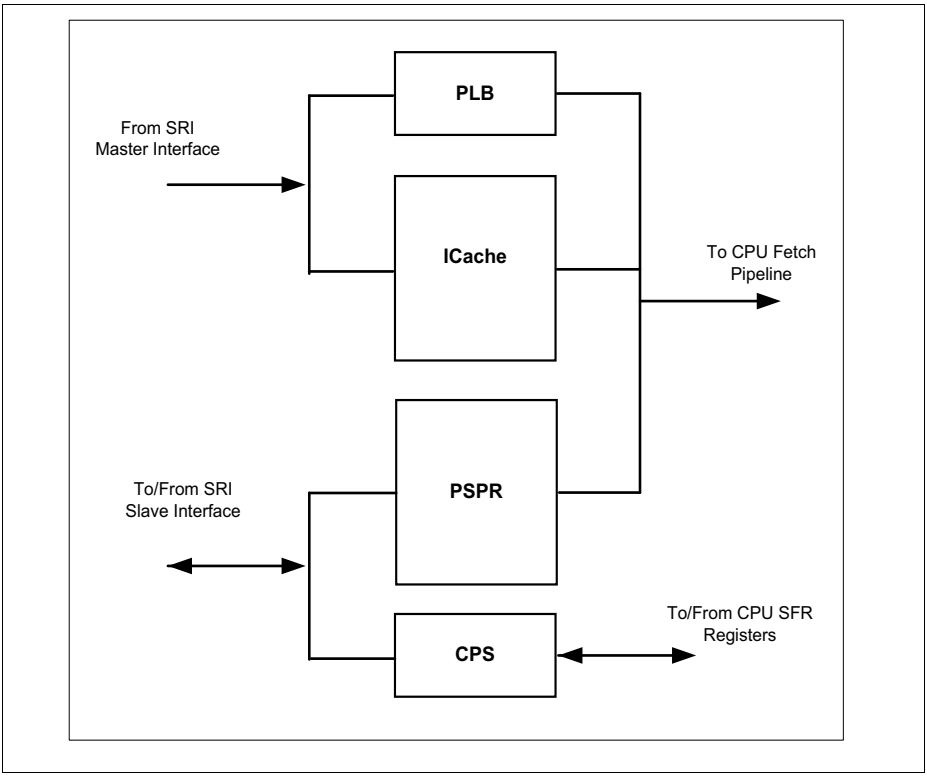

Figure 6-9 PMI Block Diagram

The Program Memory Interface (PMI) has the following features:

- Program Cache (PCACHE)
  - Two-way set associative cache
  - LRU (Least-Recently Used) replacement algorithm
  - Cache line size: 256 bits (4 double-words)
  - Validity granularity: One valid bit per cache line
  - Single cycle access for hit.

  - PCACHE can be globally invalidated to provide support for software cache coherency (to be handled by the programmer)
  - PCACHE can be bypassed to provide a direct fetch from the CPU to on-chip and off-chip resources
  - PCACHE refill mechanism:
    Critical word first, line wrap around, streaming to CPU
- Program Scratchpad memory (PSPR)
- CPU interface
  - Supporting 64bit aligned fetches. (TC1.6P)
- CPU Slave interface (CPS)
- Shared Resource Interconnect Bus (SRI) Master Interface
- Shared Resource Interconnect Bus (SRI) Slave Interface to scratchpad RAM and CPS.
- All PMI SRAMs (PSPR, PCACHE, and cache tag SRAM) are ECC protected
  - ECC is calculated on 64bit data for the PSPR and PCACHE

6.10.1.1 TC1.6P Scratchpad RAM

The TC1.6P of Program scratchpad RAM provides a fast, deterministic program fetch access from the CPU for use by performance critical code sequences.

- CPU program fetch accesses to scratchpad RAM are never cached in the program cache and are always directly targeted to the scratchpad RAM.

The TC1.6P CPU fetch interface will generate aligned accesses (64-bit), which will result in 64-bits of instruction being returned to the CPU.

Note that the CPU Fetch Unit can only read from the scratchpad RAM and can never write to it.

The scratchpad RAM may also be accessed from the SRI Slave interface by another bus master, such as the Data Memory Interface (DMI). The scratchpad RAM may be both read and written from the SRI. The SRI Slave interface supports all SRI transaction types.

The scratchpad RAM is ECC protected across 64bit data.

6.10.1.2 TC1.6P Program Cache

The program Cache is a two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each PCACHE line contains 256 bits of instruction and associated ECC bits.

CPU program fetch accesses which target a cacheable memory segment (and where the PCACHE is not bypassed) target the PCACHE. If the requested address and its associated instruction are found in the cache (Cache Hit), the instruction is passed to the CPU Fetch Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the PMI cache controller issues a cache refill sequence and wait states

are incurred whilst the cache line is refilled. The fetch request always returns an aligned packet to the CPU.

The program cache is ECC protected on 64bit data.

The program TAG Ram is ECC protected on 22bit data.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

Program Cache Refill Sequence

Program Cache refills are performed using a critical double-word first strategy with cache line wrapping such that the refill size is always 4 double-words. PCACHE refills are always performed in 64-bit quantities. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line.

PCACHE refills are therefore implemented using an SRI Burst Transfer 4 (BTR4) transfers. The program cache supports instruction streaming, meaning that it can deliver available instruction half-words to the CPU Fetch Unit whilst the refill operation is ongoing.

Program Cache Bypass

The Program Cache may be bypassed, under control of PCON0.PCBYP, to provide a direct instruction fetch path for the CPU Fetch Unit. The default value of PCON0.PCBYP is such that the PCACHE is bypassed after reset.

Whilst PCACHE bypass is enabled, a fetch request by the CPU to a cacheable address will result in a forced cache miss, such that the cache controller issues a standard refill sequence and supplies instruction half-words to the CPU using instruction streaming, without updating the cache contents. Any valid cache lines within the PCACHE will remain valid and unchanged whilst the PCACHE is bypassed. As such, instruction fetch requests to cacheable addresses with PCACHE bypass enabled behave identically to instruction fetch requests to non-cacheable addresses.

The PCON0 register is endinit protected.

Program Cache Invalidation

The PMI does not have automatic cache coherency support. Changes to the contents of memory areas external to the PMI that may have already been cached in the PCACHE are not detected. Software must provide the cache coherency in such a case. The PMI supports this via the cache invalidation function. The PCACHE contents may be globally invalidated by writing a ‘1’ to PCON1.PCINV. The PCACHE invalidation is performed over 64 cycles by a hardware state machine which cycles through the PCACHE entries marking each as invalid. During an invalidate sequence the CPU may continue to fetch instructions from non-cacheable memory. Any attempt to fetch instructions from a cacheable memory location during an invalidation sequence will result in the CPU

stalling until the sequence completes. The status of the PCACHE invalidation sequence may be determined by reading the PCON1.PCINV bit.

6.10.1.3 TC1.6P Program Line Buffer

The PMI module contains a 256-bit Program Line Buffer (PLB). Program fetch requests to non-cacheable addresses (or to cacheable addresses with the cache in bypass) utilize the PLB as a single line cache. A single valid bit is associated with the PLB, denoting that the PLB contents are valid. As such all fetch requests resulting in an update of the PLB, whether to a cacheable address or not, are implemented as SRI Burst Transfer 4 (BTR4) transactions, with the critical double-word of the PLB line being fetched first size. The PLB may be invalidated by writing PCON1.PBINV.

6.10.1.4 TC1.6P CPU Slave Interface (CPS)

The CPU Slave Interface provides access from the SRI bus to the CPU CSFR and SFR registers.

6.10.2 TC1.6E PMI Description

Figure 6-10 shows the block diagram of the Program Memory Interface (PMI) of the TC1.6E.

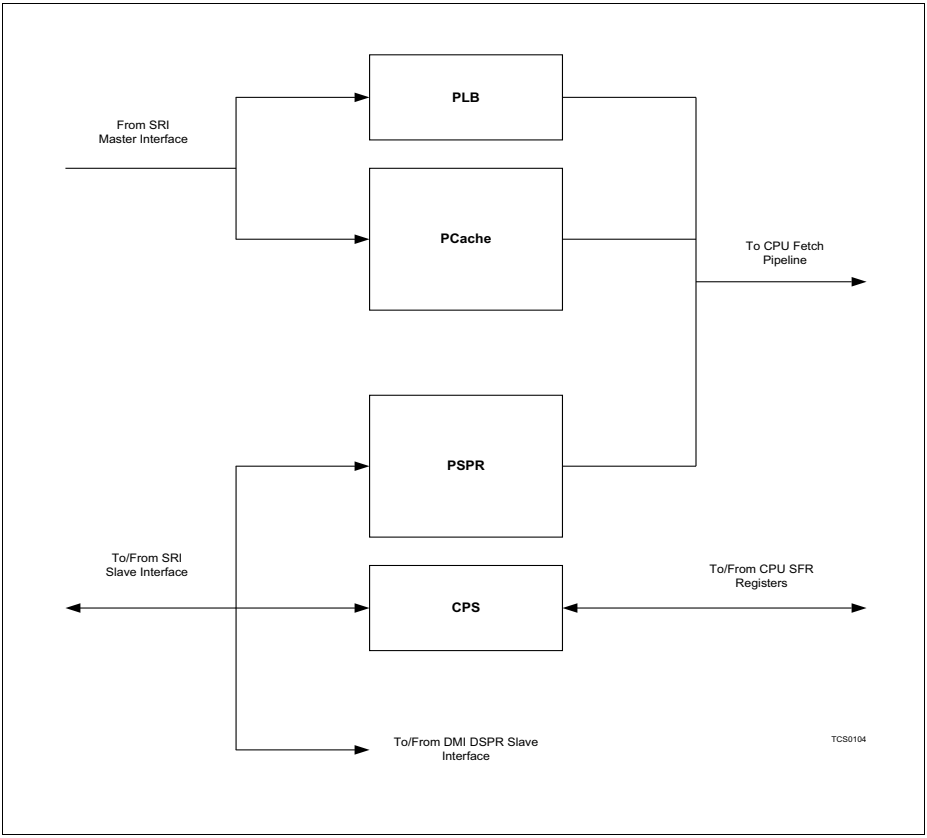

Figure 6-10 PMI Block Diagram

The Program Memory Interface (PMI) has the following features:

- Program Cache (PCACHE)
  - Two-way set associative cache
  - LRU (Least-Recently Used) replacement algorithm
  - Cache line size: 256 bits (4 double-words)
  - Validity granularity: One valid bit per cache line

  - PCACHE can be globally invalidated to provide support for software cache coherency (to be handled by the programmer)
  - PCACHE can be bypassed to provide a direct fetch from the CPU to on-chip and off-chip resources
  - PCACHE refill mechanism:
    Critical word first, line wrap around, streaming to CPU
- Program Scratchpad memory (PSPR)
- CPU interface
  - Supporting 32-bit aligned fetches. (TC1.6E)
- CPU Slave interface (CPS)
- Shared Resource Interconnect Bus (SRI) Master Interface
- Shared Resource Interconnect Bus (SRI) Slave Interface to Program Scratchpad RAM and CPU Slave interface.
  - SRI Slave Interface is shared with DMI for Data Scratchpad RAM access.
- All PMI SRAMs (PSPR, PCACHE, and cache tag SRAM) are ECC protected.
  - ECC is calculated on 32bit data for the PSPR and PCACHE

6.10.2.1 TC1.6E Program Scratchpad RAM

The Program Scratchpad RAM provides a fast, deterministic program fetch access from the CPU for use by performance critical code sequences.

- CPU program fetch accesses to scratchpad RAM are never cached in the program cache and are always directly targeted to the scratchpad RAM.

The TC1.6E CPU fetch interface will generate aligned accesses (32-bit), which will result in 32-bits of instruction being returned to the CPU.

Note that the CPU Fetch Unit can only read from the scratchpad RAM and can never write to it.

The scratchpad RAM may also be accessed from the SRI Slave interface by another bus master, such as the Data Memory Interface (DMI). The scratchpad RAM may be both read and written from the SRI. The SRI Slave interface supports all SRI transaction types.

The scratchpad RAM is ECC protected across 32bit data.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

6.10.2.2 TC1.6E Program Cache

The Program Cache is a two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each PCACHE line contains 256 bits of instruction along with associated ECC bits.

CPU program fetch accesses which target a cacheable memory segment (and where the PCACHE is not bypassed) target the PCACHE. If the requested address and its

associated instruction are found in the cache (Cache Hit), the instruction is passed to the CPU Fetch Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the PMI cache controller issues a cache refill sequence and wait states are incurred whilst the cache line is refilled. The fetch request always returns an aligned packet to the CPU.

The Program cache is ECC protected on 32bit data.

The Program TAG Ram is ECC protected on 22bit data.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

Program Cache Refill Sequence

Program Cache refills are performed using a critical double-word first strategy with cache line wrapping such that the refill size is always 4 double-words. PCACHE refills are always performed in 64-bit quantities. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line.

PCACHE refills are therefore implemented using an SRI Burst Transfer 4 (BTR4) transfers. The program cache supports instruction streaming, meaning that it can deliver available instruction half-words to the CPU Fetch Unit whilst the refill operation is ongoing.

Program Cache Bypass

The Program Cache may be bypassed, under control of PCON0.PCBYP, to provide a direct instruction fetch path for the CPU Fetch Unit. The default value of PCON0.PCBYP is such that the PCACHE is bypassed after reset.

Whilst PCACHE bypass is enabled, a fetch request by the CPU to a cacheable address will result in a forced cache miss, such that the cache controller issues a standard refill sequence and supplies instruction half-words to the CPU using instruction streaming, without updating the cache contents. Any valid cache lines within the PCACHE will remain valid and unchanged whilst the PCACHE is bypassed. As such, instruction fetch requests to cacheable addresses with PCACHE bypass enabled behave identically to instruction fetch requests to non-cacheable addresses.

The PCON0 register is endinit protected.

Program Cache Invalidation

The PMI does not have automatic cache coherency support. Changes to the contents of memory areas external to the PMI that may have already been cached in the PCACHE are not detected. Software must provide the cache coherency in such a case. The PMI supports this via the cache invalidation function. The PCACHE contents may be globally invalidated by writing a ‘1’ to PCON1.PCINV. The PCACHE invalidation is performed over 64 cycles by a hardware state machine which cycles through the PCACHE entries

marking each as invalid. During an invalidate sequence the CPU may continue to fetch instructions from non-cacheable memory. Any attempt to fetch instructions from a cacheable memory location during an invalidation sequence will result in the CPU stalling until the sequence completes. The status of the PCACHE invalidation sequence may be determined by reading the PCON1.PCINV bit.

6.10.2.3 TC1.6E Program Line Buffer

The PMI module contains a 256-bit Program Line Buffer (PLB). Program fetch requests to non-cacheable addresses (or to cacheable addresses with the cache in bypass) utilize the PLB as a single line cache. A single valid bit is associated with the PLB, denoting that the PLB contents are valid. As such all fetch requests resulting in an update of the PLB, whether to a cacheable address or not, are implemented as SRI Burst Transfer 4 (BTR4) transactions, with the critical double-word of the PLB line being fetched first size. The PLB may be invalidated by writing PCON1.PBINV.

6.10.2.4 TC1.6E CPU Slave Interface (CPS)

The CPU Slave Interface provides access from the SRI bus to the CPU CSFR and SFR registers.

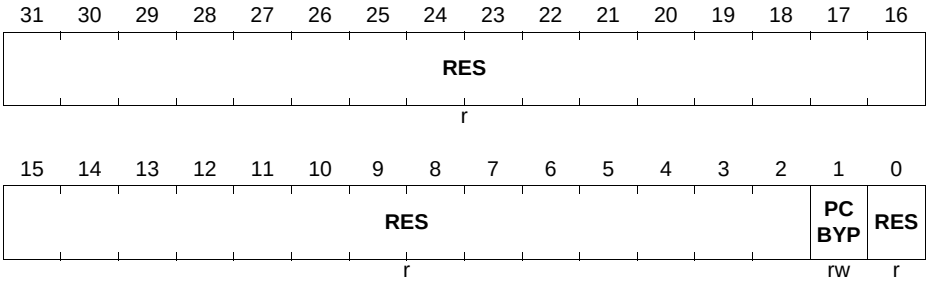
6.10.3 PMI Registers

Three control registers are control the operation of the Program Memory Interface. These registers and their bits are described in this section.

6.10.3.1 PMI Register Descriptions

PMI Control Register 0

PCON0
Program Memory Control Register 0
(CSFR_Base + 920C$_H$) **Reset Value: 0000 0002$_H$**



Field	Bits	Type	Description
RES	0	r	**Reserved** Read as 0; should be written with 0.
PCBYP	1	rw	**Program Cache Bypass** 0_B Cache enabled 1_B Cache bypassed (disabled)
RES	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is endinit protected.

PMI Control Register 1

PCON1
Program Memory Control Register 1

(CSFR_Base + 9204_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES															
r															

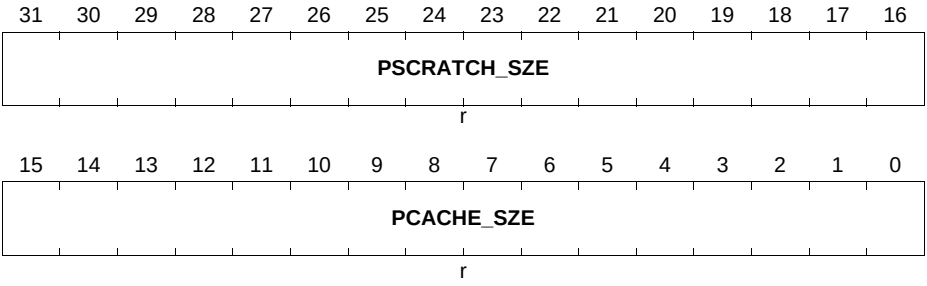
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES														PB INV	PC INV
r														rw	rwh

Field	Bits	Type	Description
PCINV	0	rwh	**Program Cache Invalidate** Write Operation: 0_B No effect. Normal program cache operation. 1_B Initiate invalidation of entire program cache. Read Operation: 0_B Normal operation. Program cache available. 1_B Program cache invalidation in progress. Program cache unavailable.
PBINV	1	rw	**Program Buffer Invalidate** Write Operation: 0_B No effect. Normal program line buffer operation. 1_B Invalidate the program line buffer. This field returns 0 when read.
RES	[31:2]	r	**Reserved** Read as 0; should be written with 0.

PMI Control Register 2

PCON2 contains size information for the Program memory system.

PCON2
Program Memory Control Register 2
(CSFR_Base + 9208_H) Reset Value: CPU Dependent



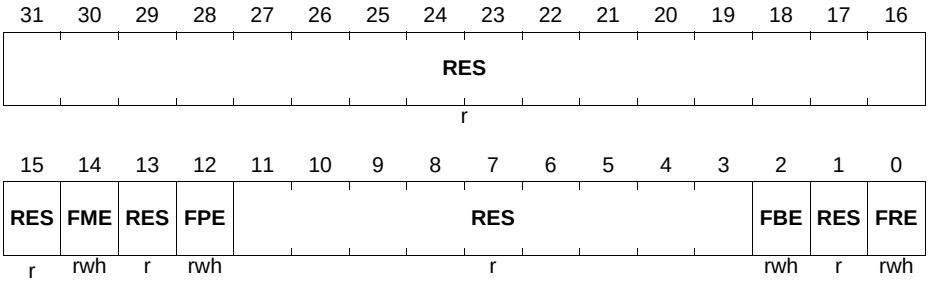
Field	Bits	Type	Description
PCACHE_SZE	[15:0]	r	**Program Cache (PCACHE) Size** In KBytes
PSCRATCH_SZE	[31:16]	r	**Program Scratch Size** In KBytes

Program Memory Interface Synchronous Trap Register (PSTR)

PSTR contains synchronous trap information for the program memory system. The register is updated with trap information for PSE traps to aid the localisation of faults.

The register is only set whenever a trap is detected and the register has no bits already set. It is cleared by a CSFR write (independent of data value).

PSTR
Program Synchronous Trap Register
(CSFR_Base + 9200_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FRE	0	rwh	**Fetch Range Error** Code fetch from local PSPR area outside of physically implemented memory
RES	1	r	**Reserved**
FBE	2	rwh	**Fetch Bus Error** Code fetch from bus address giving an error
RES	[11:3]	r	**Reserved**
FPE	12	rwh	**Fetch Peripheral Error** Code fetch from peripheral space
RES	13	r	**Reserved**
FME	14	rwh	**Fetch MSIST Error** Code fetch from memory mapped PTAG.
RES	[31:15]	r	**Reserved**

Fetch Range Error

A Fetch Range Error occurs whenever an access to the Program Scratch is outside the range of the SRAM.

Fetch Global Address Error

A Fetch Global Address Error occurs whenever an there is access to an address that cannot be translated to a valid global address.This will occur for accesses in the range D1000000 to D7FFFFFF

Fetch Bus Error

A Fetch bus error will be set whenever the SRI flags an error due a fetch from external memory. This will be set for both direct fetches from the bus and for cache refills.

Fetch Peripheral Error

A Fetch peripheral error will be flagged whenever a fetch is attempted to peripheral space.

Fetch MSIST Error

During SIST mode, a fetch from the PTAG will cause a PSE trap to occur.

6.11 Data Memory Interface (DMI)

The Data Memory Interface (DMI) provides data values to the CPU and stores data values supplied by the CPU.

6.11.1 TC1.6P DMI Description

This figure shows the block diagram of the Data Memory Interface (DMI) of the TC1.6P.

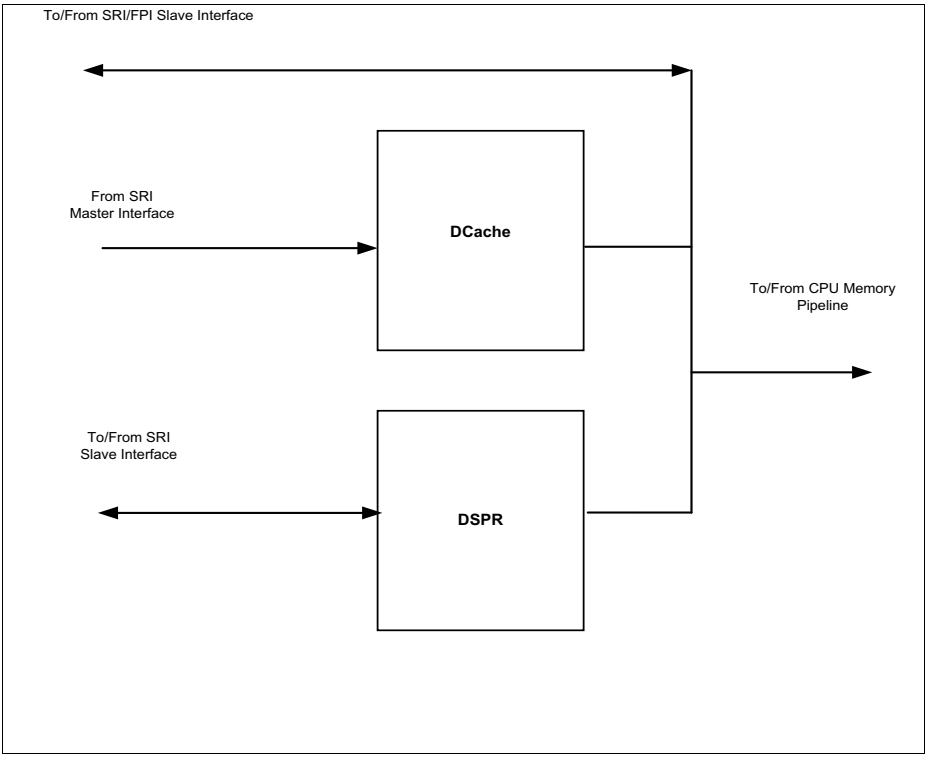


Figure 6-11 DMI Block Diagram

The Data Memory Interface (DMI) has the following features:

- Data Scratchpad Ram (DSPR)
  - Supporting unaligned access (16-bit aligned) with no penalty.
- Data Memory (DCACHE):
  - Two-way set associative cache, Least recently used (LRU) replacement algorithm
  - Cache line size: 256 bits
  - Validity granularity: One valid bit per cache line

  - Write-back Cache: Writeback granularity: 256 bits
  - Refill mechanism: full cache line refill
  - Single cycle access for hit.
- CPU interface
- Shared Resource Interconnect Bus (SRI) Master interface
- Shared Resource Interconnect (SRI) Slave interface to DSPR
- Flexible Peripheral Interconnect Bus (FPI) Master interface for fast access to peripherals
- All DMI SRAMs (DSPR, DCACHE, and cache tag SRAM) are ECC protected

6.11.1.1 TC1.6P Data Scratchpad RAM (DSPR)

The DSPR provides fast, deterministic data access to the CPU for use by performance critical code sequences.

The DSPR is organised as multiple memory “towers”. This organisation allow the CPU to access 64bits of data from any 16bit aligned address

The DSPR may also be accessed from the SRI Slave interface by another bus master, with both read and write transactions supported. The DSPR may be accessed by the SRI Slave interface using any SRI transaction type, including burst transfers. In accordance with the SRI protocol, accesses to the SRI Slave interface must be naturally aligned.

All TC1.6P Data scratchpad RAMs are ECC protected.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

6.11.1.2 TC1.6P Data Cache (DCACHE)

The DCache is a Two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each line contains 256 bits of data along with ECC bits. A single valid bit and a single dirty bit are associated with each line.

CPU data accesses to a cacheable memory segment target the DCache. If the requested address and its associated data are found in the cache (Cache Hit), the data is passed to/from the CPU Load-Store Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the DMI cache controller issues a cache refill sequence and wait states are incurred whilst the cache line is refilled. The CPU load-store interface will generate unaligned accesses (16-bit aligned), which will result in up to 64-bits of data being transferred to or from the CPU (for non-context operations). If the data access is made within a DCache line, no matter the alignment, and a cache hit is detected then the requested data is returned to the CPU in a single cycle. If the data access is made to the end of a DCache line, such that the requested data would span two DCache lines, a single wait cycle is incurred (if both cache lines are present in the cache, otherwise a refill sequence is required for the missing cache line(s)).

The TC1.6P data cache is of the writeback type. When the CPU writes to a cacheable location the data is merged with the corresponding cache line and not written to main memory immediately. Associated with each cache line is a single ‘dirty’ bit, to denote that the data in the cache line has been modified. Whenever a CPU load-store access results in a cache miss, and each of the potential cache ways that could hold the requested cache line are valid, one of the cache lines is chosen for eviction based upon the LRU replacement algorithm. The line selected for eviction is then checked to determine if it has been modified using its dirty bit. If the line has not been modified the line is discarded and the refill sequence started immediately. If the line has been modified then the dirty data is first written back to main memory before the refill is initiated. Due to the single dirty bit per cache line, 256 bits of data will always be written back, resulting in a SRI Burst-4 Transfer (BTR4) transactions.

Data Cache refills always result in the full cache line being refilled, with the critical double-word of the DCache line being fetched first. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line. Due to the uniform size of DCache refill sequences, such refills are always implemented using SRI Burst Transfer 4 (BTR4) transactions.

All TC1.6P Cache SRAMs are ECC protected.

All TC1.6P TAG SRAMs are ECC protected

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

Data Cache Bypass

The Data Cache may be bypassed, under control of DCON0.DCBYP, to provide a direct data access path to memory. The default value of DCON0.DCBYP is such that the data cache is bypassed after reset.

Whilst the data cache bypass is enabled, a data access request by the CPU to a cacheable address will result in a forced cache miss. Any valid cache lines within the data cache will remain valid and unchanged whilst the data cache is bypassed. As such data accesses to cacheable addresses with the data cache bypass enabled behave identically to data accesses to non-cacheable addresses.

The DCON0 register is endinit protected.

6.11.2 TC1.6E DMI Description

This figure shows the block diagram of the Data Memory Interface (DMI) of the TC1.6E.

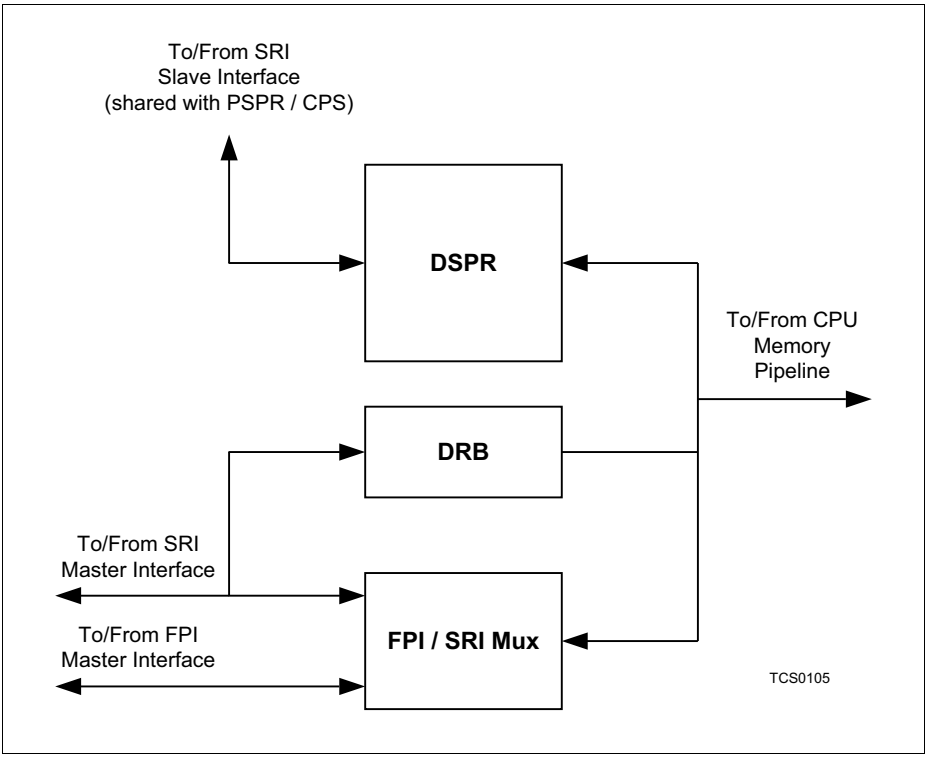

Figure 6-12 DMI Block Diagram

The Data Memory Interface (DMI) has the following features:

- Data Scratchpad Ram (DSPR)
  - Supporting unaligned access (16-bit aligned) with no penalty.
- Data Read Buffer (DRB)
  - Four-entry fully associative Data Read Buffer
  - Least recently used (LRU) replacement algorithm
  - Buffer line size: 256 bits
  - Validity granularity: One valid bit per buffer line
  - Refill mechanism: full buffer line refill, critical double-word first
- CPU interface
- Shared Resource Interconnect Bus (SRI) Master interface

- Flexible Peripheral Interconnect Bus (FPI) Master interface for fast access to peripherals
  - CPU accesses to lower half of segment F_H are directed to FPI master interface, other accesses directed to SRI master interface
- Shared Resource Interconnect (SRI) Slave interface to DSPR
  - SRI slave interface shared with PMI for access to PSPR / CPS
- All TC1.6E DMI SRAM (DSPR) ECC protected

6.11.2.1 TC1.6E Data Scratchpad RAM (DSPR)

The DSPR provides fast, deterministic data access to the CPU for use by performance critical code sequences.

The DSPR is organised as multiple memory “towers”. This organisation allow the CPU to access 64bits of data from any 16bit aligned address

The DSPR may also be accessed from the SRI Slave interface by another bus master, with both read and write transactions supported. The DSPR may be accessed by the SRI Slave interface using any SRI transaction type, including burst transfers. In accordance with the SRI protocol, accesses to the SRI Slave interface must be naturally aligned.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

6.11.2.2 TC1.6E Data Read Buffer (DRB)

The TC1.6E implements a 128-byte Data Read Buffer (DRB). The DRB contains four fully associative buffer lines, with a Least-Recently-Used (LRU) replacement algorithm. Each buffer line contains 256-bits of data. A single valid bit is associated with each buffer line. The DRB will buffer CPU read data from cacheable memory segments.

CPU load data accesses, where the addressed memory segment is defined as cacheable, target the DRB. If the requested address and its associated data are found in the DRB (Buffer Hit), the data is passed to/from the CPU Load-Store Unit without incurring any wait states. If the address is not found in the DRB (Buffer Miss), the DMI controller issues a buffer refill sequence and wait states are incurred whilst the buffer line is refilled. The CPU load-store interface will generate unaligned accesses (16-bit aligned), which will result in up to 64-bits of data being transferred to or from the CPU (for non-context operations). If the data access is made within a DRB buffer line, no matter the alignment, and a buffer hit is detected then the requested data is returned to the CPU in a single cycle. If the data access is made to the end of a DRB line, such that the requested data would span two DRB lines, a single wait cycle is incurred (if both buffer lines are present in the DRB, otherwise a refill sequence is required for the missing buffer line(s)).

DRB refills always result in the full buffer line being refilled, with the critical double-word of the DRB line being fetched first. A refill sequence will always affect only one buffer

line. There is no prefetching of the next buffer line. Due to the uniform size of DRB refill sequences, such refills are always implemented using SRI Burst Transfer 4 (BTR4) transactions.

The TC1.6E DRB will buffer read data only. Any CPU store access which results in a hit in a DRB line will invalidate that DRB line and the store will continue as normal, bypassing the DRB. In addition, the execution of any CACHEA.xx or CACHEI.xx instruction by a TC1.6E CPU will invalidate all its DRB lines.

DRB Bypass

The DRB may be bypassed, under control of DCON0.DCBYP, to provide a direct data access path to memory. The default value of DCON0.DCBYP is such that the DRB is bypassed after reset.

Whilst the DRB bypass is enabled, a data read request by the CPU to a cacheable address will result in a forced buffer miss. Any valid lines within the DRB will remain valid and unchanged whilst the DRB is bypassed. As such data reads to cacheable addresses with the DRB bypass enabled behave identically to data accesses to non-cacheable addresses.

The DCON0 register is endinit protected.

6.11.3 DMI Trap Generation

CPU data accesses to the DMI may encounter one of a number of potential error conditions, which result in one of the following trap conditions being reported by the DMI.

ALN Trap

An ALN trap is raised for the following conditions:

- An access whose effective address does not conform to the alignment rules
- An access where the length, size or index of a circular buffer is incorrect

Whenever an ALN trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

MEM Trap

A MEM trap is raised for the following conditions:

- An access whose effective address has a different segment to that of the base address (Segment Difference Error)
- An access whose effective address causes the data to span two segments (Segment Crossing Error)
- A memory address is used to access a CSFR area (CSFR Access Error)
- A context load or store instruction is executed where the effective address is not within the local DSPR range (Context Location Error)(TC1.6E only)

Whenever a MEM trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

DSE Trap

A DSE trap is raised for the following conditions:

- An access outside the range of the DSPR (Scratch Range Error)
- An access to the lower half of segment C which cannot be translated into a global address, i.e. from C1000000 to C7FFFFFF (Global Address Error)
- An error on the bus for an external accesses due to a load (Load Bus Error)
- An error from the bus during a cache refill (Cache Refill Error)
- An error during a load whilst in SIST mode (Load MSIST Error)
- An error generated by the overlay system during a load.

Whenever a DSE trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

DAE Trap

A DAE trap is raised for the following conditions:

- An error on the bus for an external accesses due to a store (Store Bus Error)
- An error on the bus due to a cache writeback (Cache writeback Error)(TC1.6P only)
- An error from the bus due to a cache flush (Cache Flush Error)(TC1.6P only)
- An error due to a store whilst in SIST mode (Store MSIST Error)
- An error generated by the overlay system during a store.

Whenever a non-inhibited DAE trap occurs, the DATR (Data Asynchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated. DAE traps are inhibited if the DATR register is non-zero.

Data Memory Protection Traps

Data memory protection traps (MPW, MPR, MPP, MPN) are raised by the memory protection system when a protection violation occurs. Whenever a data memory protection trap occurs the DSTR (Data synchronous trap register) and the DEADD (Data Error Address Register) are updated.

6.11.4 DMI Registers

Two control registers and three trap flag registers control the operation of the DMI. These registers and their bits are described in this section.

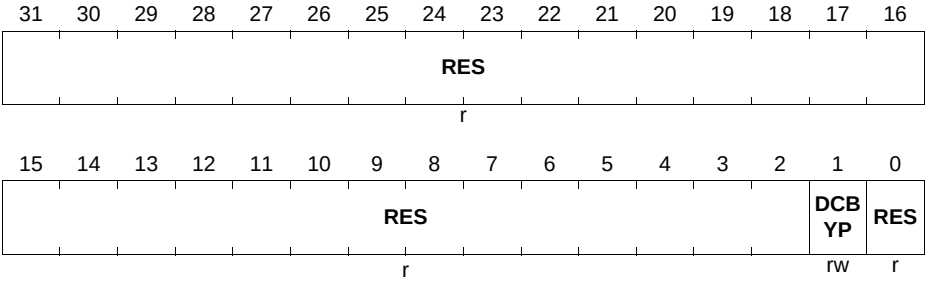
6.11.4.1 DMI Register Descriptions

Note: There is no DCON1 register in this implementation.

Data Memory Control Register 0 (DCON0)

The DCON0 register allows the Data cache to be bypassed.

DCON0
Data Memory Control Register
(CSFR_Base + 9040_H) **Reset Value: $0000\ 0002_H$**



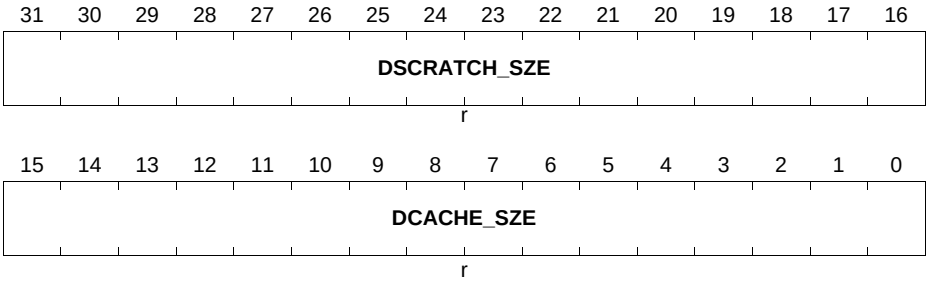
Field	Bits	Type	Description
RES	0	-	**Reserved**
DCBYP	1	rw	**Data Cache/Data Read Buffer Bypass** 0_B DCache / DRB enabled 1_B DCache / DRB Bypassed (disabled)
RES	[31:2]	-	**Reserved**

Note: This register is endinit protected

Data Control Register 2 (DCON2)

DCON2 contains size information for the Data memory system.

DCON2
Data Control Register 2 (CSFR_Base + 9000_H) Reset Value: CPU Dependent



Field	Bits	Type	Description
DCACHE_SZE	[15:0]	r	**Data Cache Size** In KBytes
DSCRATCH_SZE	[31:16]	r	**Data Scratch Size** In KBytes

DMI Synchronous Trap Flag Register

The DSTR contains synchronous trap information for the data memory system. The register is updated with trap source information to aid the localisation of faults.

The register is updated whenever a valid trap is detected and the register has no bits already set. It is cleared by a write (independent of data value).

DSTR
Data Synchronous Trap Register

(CSFR_Base + 9010_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
SDE	16	rwh	**Segment Difference Error** Load or store access where base address is in different segment to access address
SCE	17	rwh	**Segment Crossing Error** Load or store access across segment boundary
CAC	18	rwh	**CSFR Access Error** Load or store to local CSFR space
MPE	19	rwh	**Memory Protection Error** Data access violating memory protection.
CLE	20	rwh	**Context Location Error** Context operation to invalid location
RES	[23:21]	r	**Reserved**
ALN	24	rwh	**Alignment Error** Data access causing alignment error
RES	[31:25]	r	**Reserved**

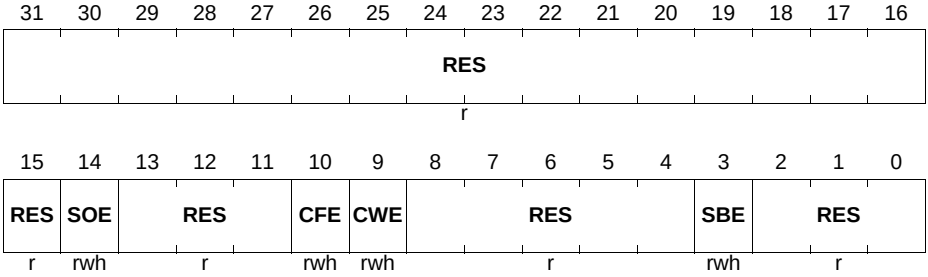
DMI Asynchronous Trap Flag Register

The DATR contains asynchronous trap information for the data memory system. The register is updated with trap information for DAE traps to aid the localisation of faults.

The register is updated whenever a valid trap is detected and the register has no bits already set. It is cleared by a write (independent of data value).

DAE traps are inhibited if the DATR register is non-zero.

DATR
Data Asynchronous Trap Register
(CSFR_Base + 9018_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RES	[2:0]	r	**Reserved**

RES	[13:11]	r	**Reserved**
SOE	14	rwh	**Store Overlay Error** Store to invalid overlay address
RES	[31:15]	r	**Reserved**

Data Error Address Register

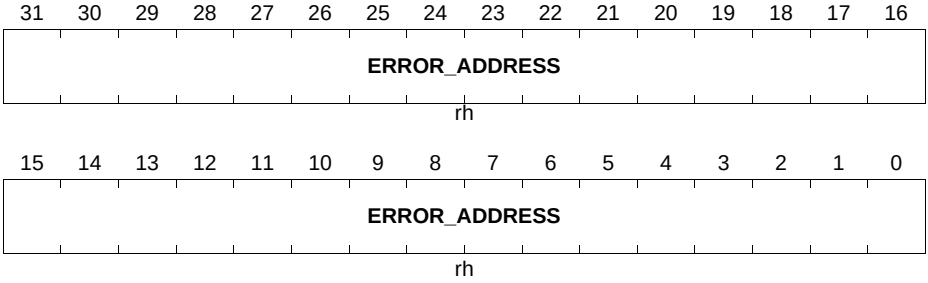
DEADD contains trap address information for the Data memory system. The register is updated with trap information for MEM, ALN, DSE or DAE traps to aid the localisation of faults.

The register is only set whenever a trap is detected and either the DATR or DSTR registers have no bits already set.

The register contents are only valid when either the DATR or DSTR register is non-zero and hence should be read prior to clearing these registers.

DEADD

Data Error Address Register (CSFR_Base + 901C$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
ERROR_ADDRESS	[31:0]	rh	**Error Address**

6.12 Safety Features

The CPUs implements a number of safety concepts These are detailed in the following sections.

6.12.1 SRI Data Master Address Phase Error Injection

To allow the SRI address phase error detection system to be tested it is necessary to inject errors during the address phase of an SRI transaction. This is done by the TC1.6P or TC1.6E data master. The data master selectively inverts individual bits of the address phase of an SRI read or write phase ECC packet and is controlled using the SEGEN register. The SEGEN register contains three fields:- an enable (AE), an error descriptor (ADTYPE) and a bit flip (ADFLIP) field. When enabled for an address phase error the address ECC bits indicated by the flip field are inverted for the next SRI data read or write bus transaction performed by the DMI. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI address ECC to be corrupted for a single transaction. The SEGEN register is ENDINIT protected.

6.12.2 SRI Data Master Write Phase Error Injection

To allow the SRI data phase error detection system to be tested it is necessary to inject errors during the data phase of an SRI write transaction. This is done by the TC1.6P or TC1.6E data master. The data master selectively inverting individual bits of the SRI write phase ECC packet and is controlled using the SEGEN register. The SEGEN register contains three fields:- an enable (AE), an error descriptor (ADTYPE) and a bit flip (ADFLIP) field. When enabled for a data phase error the data phase ECC bits indicated by the flip field are inverted for the next SRI write bus transaction performed by the DMI. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI data ECC to be corrupted for a single transaction. The SEGEN register is ENDINIT protected.

6.12.3 SRI Data Slave Read Phase Error Injection

To allow the SRI data phase error detection system to be tested it is necessary to inject errors during the data phase of an SRI read transaction. This is done by the TC1.6P or TC1.6E slave. The data slave selectively inverts individual bits of the SRI read phase ECC packet and is controlled using the SEGEN register. The SEGEN register contains three fields:- an enable (AE), an error descriptor (ADTYPE) and a bit flip (ADFLIP) field. When enabled for a data phase error the data phase ECC bits indicated by the flip field are inverted for the next SRI read bus transaction performed by the DMI. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI data ECC to be corrupted for a single transaction. The SEGEN register is ENDINIT protected.

6.12.4 SRI Error Capture

The SRI master and slave interfaces of the CPU implement the standard SRI ECC system. Error information detected during SRI transactions at the SRI master and slave interfaces is captured in the PIETR and PIEAR, or DIETR and DIEAR registers. On detection of an error the error information is captured and the relevant IED bit is set. No further error information is captured until this bit is cleared by software.

Error conditions at the SRI program interfaces are notified to the Safety Monitor Module via the pbus_err_o output from the CPU.

Error conditions at the SRI data interfaces are notified to the Safety Monitor Module via the dbus_err_o output from the CPU.

If an error is detected at an SRI slave interface during a write operation then the erroneous data will not be written.

6.12.5 SRI Safe Data Master tag

In order to differentiate between data accesses from safe and regular tasks a new safe task identification bit is introduced into the PSW register (PSW.S).

An SRI data access performed by a task when the PSW.S bit is set uses the safe data master tag. When this bit is not set the regular data master tag is used for the access. There is only one program master tag. This is used for SRI program fetches by both safe and regular tasks.

The initial value of the PSW.S bit for interrupt handlers is defined by the SYSCON.IS bit. The initial value of the PSW.S bit for trap handlers is defined by the SYSCON.IT bit.

On a trap the save of the current context is performed using the data master tag defined by SYSCON.TS

On an interrupt the save of the current context is performed using the data master tag defined by SYSCON.IS

6.12.6 Safety Memory Protection

The CPUs each allow for the definition of eight, protected regions of local SRAM memory.

The protection applies only to write or read-modify-write accesses to local SRAM included in the DMI or PMI from the bus.

Read accesses are not protected.

The protection scheme is based on the use of SRI tags to identify the master attempting the access and allows for a six bit tag individually identifying up to 64 masters. 32 masters are supported in the current implementation.

Each region is defined using the registers, SPROT_RGNLAx (x=0-7) to define the lower address of the region, SPROT_RGNUAx (x=0-7) to define the upper address of the

region and SPROT_RGNACCENx (x=0-7) to individually select the master tags permitted write access to the defined address range.

A write or read-modify-writes access is seen as valid if the master tag of the access is enabled in the SPROT_RGNACCENx register and the address of the access satisfies the following relationship:-

SPROT_RGNLAx <= address < SPROT_RGNUAx

The SPROT_RGNLAx, SPROT_RGNUAx, SPROT_RGNACCENx registers are protected by the safety_endinit signal.

After reset, the region address registers will be set to include the whole of the CPUs SRAM address space and write access by all masters will be enabled.

When altering protection settings, it should be noted that, due to access pipelining and resynchronization delays in the register block, a write to a memory address affected by the protection change occurring immediately after the register write initiating the change may, or may not, be affected by the changed settings.

Whenever a Safety Memory Protection violation occurs the event is notified to the Safety Management Unit via the tc16_safe_prot_err_o output signal from the CPU. The PIETR/DIETR and PIEAR/DIEAR registers are updated to aid localisation of the error

6.12.7 Safety Register Protection

The CPUs implement the standard memory protection scheme for peripheral registers using the SPROT_ACCEN register. This allows all CPU CSFR and SFR registers to be protected from corruption by untrusted masters. The SPROT_ACCEN register defines which masters may modify the SFR and CSFR registers via bus access through the SRI slave interface.

The SPROT_ACCEN register is protected by the safety_endinit signal.

In all cases the master is identified using the SRI tag of the access. See On Chip Bus chapter for the product's TAG ID to master peripheral mapping.

Whenever a Safety Register Protection violation occurs the event is notified to the Safety Management Unit via the safe_prot_err_o output signal from the CPU. The PIETR and PIEAR registers are updated to aid localisation of the error.

6.12.8 Lock Step Implementation

The TC1.6E and TC1.6P CPUs may be implemented as standard CPU (as described in the chapter) or as a checker CPU for use in lockstep comparison system. The checker CPU implementation has the following features.

- No Memories

- All signals that would normally be fed to the memories become additional outputs from the checker CPU.
- All signals that would normally be fed from the memories become additional inputs to the checker CPU.
- All outputs from the checker CPU are inverted.

The lockstep system compares the following CPU interfaces.

- Interface to the interrupt router.
- Interface to the SCU.
- Interface to the DMI Data Scratch pad memory.
- Interface to the PMI Program Scratch memory.
- Interface to the PMI Program Cache memory.
- Interface to the PMI Program Tag memory.
- Master interface to the Peripheral bus.
- Master interface to the SRI bus for PMI accesses.
- Master interface to the SRI bus for DMI accesses.
- Slave accesses from the SRI bus for PMI and DMI accesses.
- The CPUs run in lockstep mode at the full specified frequency. Enabling lockstep does not require operational frequency to be reduced.
- The Checker CPU is implemented using inverse state storage “AntiCore”.

6.12.9 MBIST usage recommendations

The following usage of the CPU SRAM MBIST system is recommended.

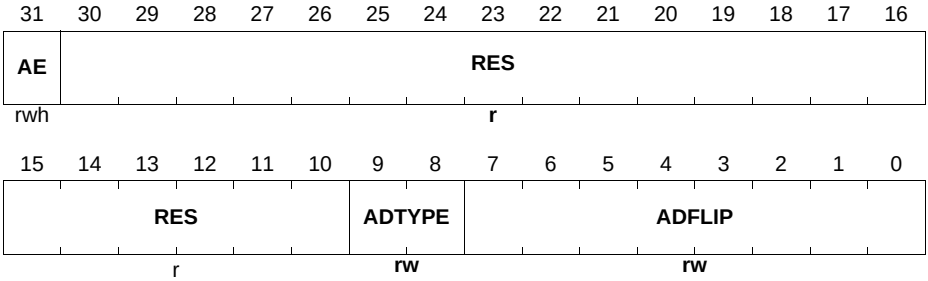
- When any one of the CPU local data memories (DSPR/DCACHE or DTAG) is in MBIST test mode (MEMTEST enabled), then other CPU local data memories will be not be accessible. It is therefore recommended to enable DSPR/DCACHE MBIST mode and DTAG memory MBIST mode together.
- When any one of the CPU local program memories (PSPR/PCACHE or PTAG) is in MBIST test mode (MEMTEST enabled), then other CPU local program memories will be not be accessible. It is therefore recommended to enable PSPR/PCACHE MBIST mode and PTAG memory MBIST mode together.
- For configurations that use dual MBIST controllers for a single logical memory (e.g TC29x DSPR/DCACHE for CPU1,2), MBIST tests run on one CPU will report errors to both controllers. It is therefore recommended to enable MBIST mode on both controllers together and that the error notification bits of both controllers are cleared at the end of testing.

6.12.10 Registers Implementing Safety Features

SRI Error Generation Register

The SEGEN register controls the injection of SRI address phase errors from the DMI. This register is ENDINIT protected.

SEGEN
SRI Error Generation Register (CSFR_Base + 1030_H) **Reset Value: $0000\ 0000_H$**

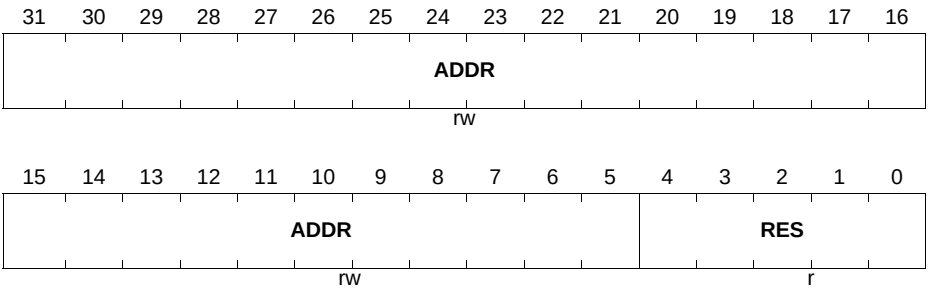


Field	Bits	Type	Description
ADFLIP	[7:0]	rw	**Address ECC Bit Flip** SRI address ECC Bits to be flipped on the next read or write transaction from the DMI when enabled by AE. 0_B No Flip 1_B Flip
ADTYPE	[9:8]	rw	**Type of Error** 00_B Data Master Address Phase 01_B Data Master Write Data 10_B Data Slave Read Data 11_B Reserved
RES	[30:10]	r	**Reserved**
AE	31	rwh	**Activate Error Enable** Enabled the selective inverting of SRI ECC packet bits defined by ADFLIP. This bit will be cleared by hardware after the next SRI read or write transaction from the DMI. 0_B Not Enabled 1_B Enabled

Safety Protection Region Lower Address Register

In conjunction with the associated SPROT_RGNUAx and SPROT_RGNACCENx registers, the SPROT_RGNLA register provides control of a memory protection region. SPROT_RGNLAx defines the lower address of a region of memory, SPROT_RGNUAx defines the upper address and the SPROT_RGNACCENx registers define the SRI tags allowed write access to the region. Address ranges can bet set to be larger than the SRAM address space but only accesses to the SRAM are affected by these registers. The minimum resolution of the comparison logic is 32_D bytes so address bits 4_D down to 0_D are not used

SPROT_RGNLAx (x=0-7)
Safety Protection Region Lower Address Register
(SFR_Base + $E000_H$+x*10_H) Reset Value: 0000 0000_H

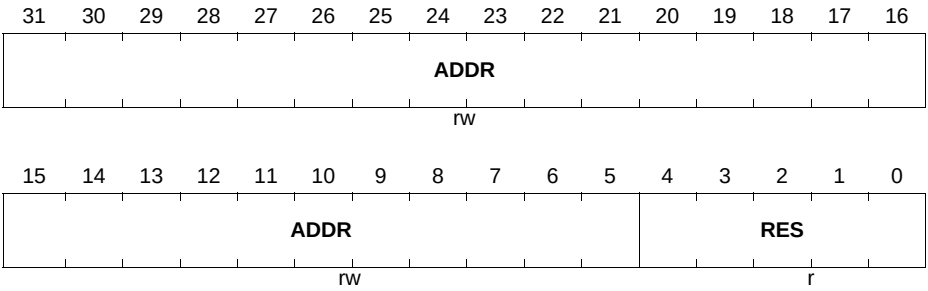


Field	Bits	Type	Description
RES	[4:0]	r	**Reserved**
ADDR	[31:5]	rw	**Region Lower Address** Bits 32 to 5 of the address which is the lower bound of the defined memory region

Safety protection Region Upper Address Register

In conjunction with the associated SPROT_RGNLAx and SPROT_RGNACCENx registers, the SPROT_RGNUAx register provides control of a memory protection region. SPROT_RGNUA defines the upper address of the memory region

SPROT_RGNUAx (x=0-7)
Safety protection Region Upper Address Register
(SFR_Base + $E004_H$+x*10_H) Reset Value: FFFF $FFE0_H$



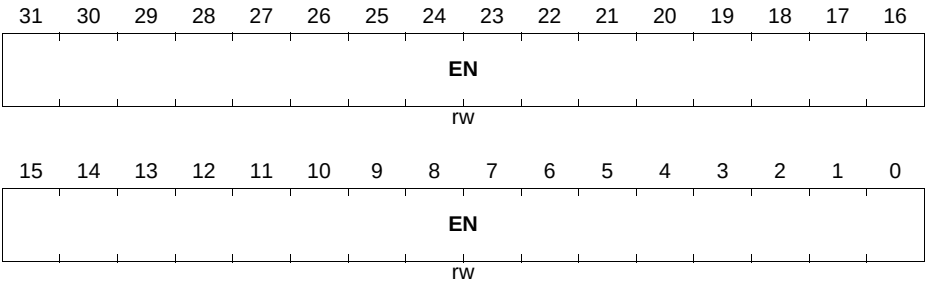
Field	Bits	Type	Description
RES	4:0	r	**Reserved** Unused bits will always read as 0_B. Written value will be ignored
ADDR	31:5	rw	**Region Upper Address** Bits 31 to 5 of the address which is the upper bound of the defined memory region

Safety Region Access Enable Register A

The Access Enable Register A controls write access for transactions to the protected memory region with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The Safety protection is prepared for an 6 bit TAG ID. The registers SPROT_RACCEN0 / SPROT_RACCEN1 are provide one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... ,EN31 -> TAG ID 011111_B.

SPROT_RGNACCENAx (x=0-7)
Safety Protection Region Access Enable Register A
(SFR_Base+ $E008_H$+x*10_H) Reset Value: FFFF $FFFF_H$



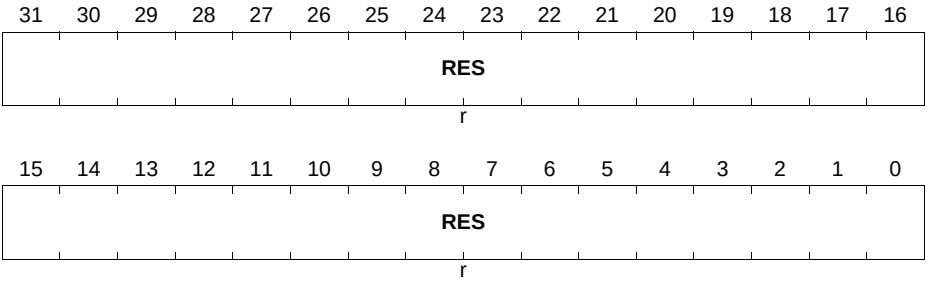
Field	Bits	Type	Description
EN	[31:0]	rw	**Access Enable for Master TAG ID n (n=0-31)** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Safety Protection Region Access Enable Register B

The Access Enable Register B controls write access for transactions to the protected memory region with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The CPU is prepared for an 6 bit TAG ID. The registers SPROT_RACCEN0 / SPROT_RACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to SPROT_ACCENB.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... ,EN31 -> TAG ID 111111_B.

SPROT_RGNACCENBx (x=0-7)
Safety Protection Region Access Enable Register B (SFR_Base + $E00C_H$+x*10_H)
Reset Value: 0000 0000_H



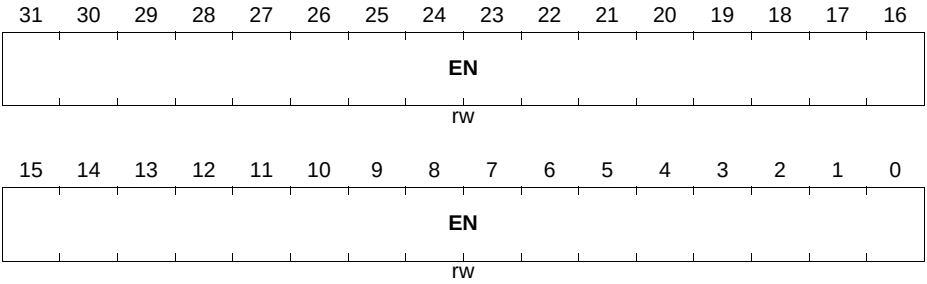
Field	Bits	Type	Description
RES	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Safety Register Access Enable Register A

The Access Enable Register A controls write access for transactions to CSFR/SFR registers with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The Safety protection is prepared for an 6 bit TAG ID. The registers SPROT_RACCEN0 / SPROT_RACCEN1 are provide one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... ,EN31 -> TAG ID 011111_B.

SPROT_ACCENA
Safety Protection Register Access Enable Register A
(SFR_Base + $E100_H$) **Reset Value: FFFF FFFF$_H$**



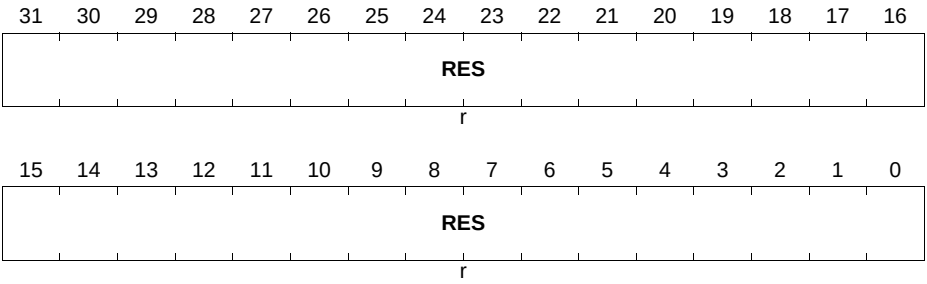
Field	Bits	Type	Description
EN	[31:0]	rw	**Access Enable for Master TAG ID n (n= 0-31)** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Safety Protection Register Access Enable Register B

The Access Enable Register B controls write access for transactions to CSFR/SFR registers with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The CPU is prepared for an 6 bit TAG ID. The registers SPROT_RACCEN0 / SPROT_RACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to SPROT_ACCENB.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... ,EN31 -> TAG ID 111111_B.

SPROT_ACCENB
Safety Protection Region Access Enable Register B
(SFR_Base + E104$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RES	[31:0]	r	**Reserved** Read as 0; should be written with 0.

7 Lockstep Comparator Logic (LCL)

The Lockstep Comparator Logic module provides access to the control and self test functions of the processor lockstep comparators.

7.1 Feature List

An overview of the features implemented in the LCL follows:

- Monitoring the core comparators for the lockstep core and its shadow and flagging any detected differences
- Running background, continuous self test on the lockstep comparators to validate the correct operation of the logic.

7.2 Lockstep Control

The lockstep control function is enabled by the LSEN bitfield in a control register in the SCU. Each core capable of lockstep has its own instance of the control register. In this product, the CPU0 instance of the Tricore can be lockstepped so there is one register, LCLCON0 for CPU0.

These registers are only initialised by a cold power-on reset. In this initialisation state, all lockstepped processors in the system will have lockstep enabled. The lockstep function can only be disabled by the system initialisation software writing a 0_B to the LSEN bitfield. Application software cannot enable or disable the lockstep function.

The current mode of the lockstep logic can be monitored by reading the lockstep status bit, LS, in the associated LCLCON register.

Writes to the control registers will be subject to the protection mechanisms of the SCU.

7.3 Lockstep Monitoring

The lockstep monitoring function will compare the outputs from the master and checker cores and report that a failure has occurred to the Safety Management Unit (SMU) for appropriate action.

The monitoring function temporally separates the cores by inserting synchronisation delays to re-align the signals being compared. To achieve this, the checker core inputs and the master core outputs fed to the comparators are delayed by two clock cycles.

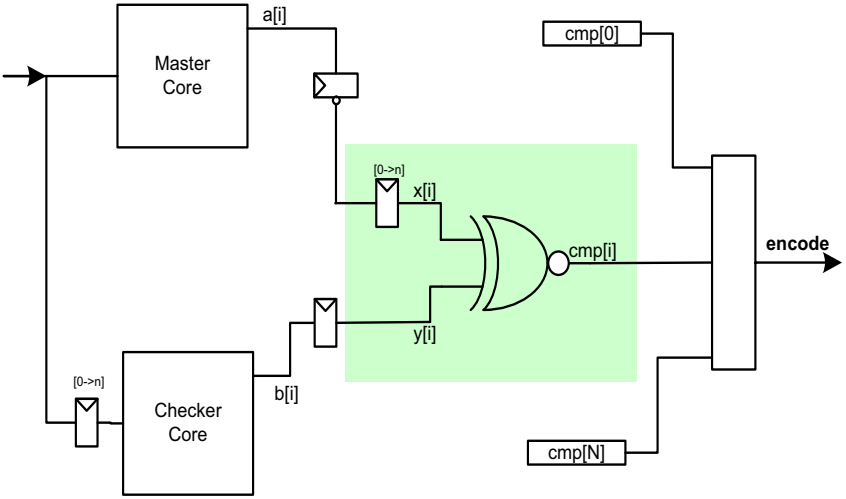


Figure 7-1 Node Comparator

Figure 7-1 above shows the equivalent circuit of an arbitrary node comparator, i, of 0 to N comparators. The comparator monitors two signals, **a** and **b**, which are connected to the same node in the master and checker cores. The signals can be synchronised in the relevant core using the core clock to minimise impact on the core timing.

After the optional synchronisation, the master core monitor point is inverted to reduce the risk of a common mode failure in the two monitored signals. Therefore, **x** is equivalent to **a** delayed by a n clock cycles, where n=2 in this implementation, to allow for the temporal shift between the master and checker cores and **y** is equivalent to **b**. If the nodes differ (i.e. **x** and **y** are the same), the CMP signal is set to 1_B. This will cause the **encode** signal to flag the failing node and the failure will be detected. In the event that multiple nodes fail, the encode output will be the minimum and maximum values of all the indices, **i**, of the failing nodes. This has no impact on normal functioning but allows the self test logic to detect a real failure occurring in the same clock cycle that a fault is injected for test purposes.

7.4 Lockstep Self Test

Each core capable of lockstep also has a continuously running background self test of the lockstep comparator.

The self test function will inject faults into both inputs of each of the monitored nodes and verify that the fault is correctly detected by the monitoring logic.

In the event of a self test failure being detected, the failure will be reported to the Safety Management Unit for an appropriate response.

An equivalent circuit of a node comparator showing the fault injection logic is shown in **Figure 7-2**

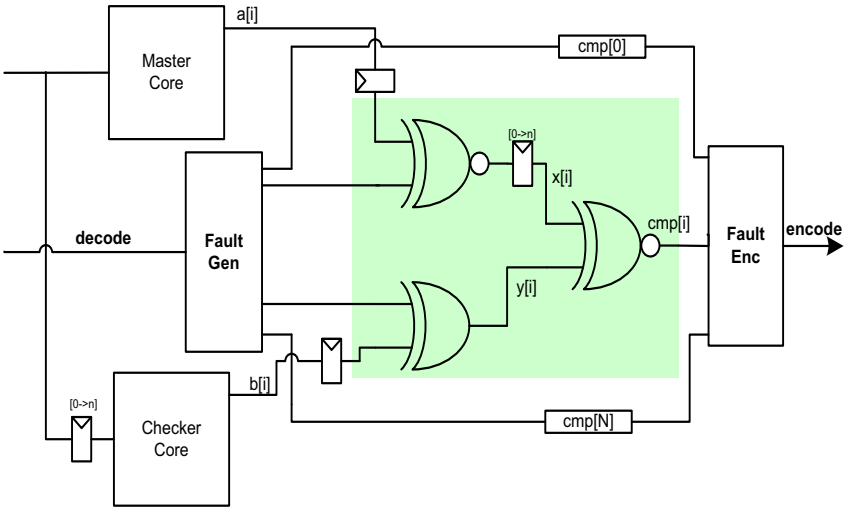

Figure 7-2 Node Comparator with Fault Injection

Faults are injected using the **Fault Gen** block. This will use a binary number, **decode**, to calculate which node is to be tested. **decode** will be generated from a free running, binary counter using gray code number representation (the **input counter**). The Self test circuit will test every node once every 8192 clock cycles. Alternate test cycles will inject faults into either the **a** or **b** side of the comparator node. The complete self test cycle will therefore repeat every 16384 clock cycles.

Injecting a fault into either side of the comparator node will cause that node to fail unless a real fault occurs in the same clock cycle in which case the two faults will cancel out.

The node failing is processed by the **Fault Enc** block to generate a binary representation of the failing node, **encode**. This contains two numbers, the node index of the first node found to be failing counting up from the lowest minimum node index and the node index of the first node found to be failing counting down from the maximum node index.

If the lockstep block is functioning correctly, both values in **encode**, will either be 0 if no failures have been detected or the number of the node which has had a fault induced by the self test logic.

The values in **encode** are checked against a second, independent binary counter (the **monitor counter**). The **monitor counter** is also compared against the value of the **input counter**. In the event that either of the values in **encode** or the **input counter** fails to match the value of the monitor counter, a failure condition will be flagged to the SMU.

With this implementation, any of the following conditions will cause a self test fail:

- an actual fault occurring on any of the **a** or **b** nodes
- a stuck at 0_B fault occurring on any of the **cmp** nodes
- a stuck at 1_B fault occurring on any of the **cmp** nodes
- a failure in the **Fault Gen** block causing an incorrect or no fault to be injected
- a failure in the **Fault Enc** block causing an incorrect detection or no fault to be detected
- a stuck at fault on **x** (assuming that an injected fault does not always coincide with a masking pulse on **b**)
- a stuck at fault on **y** (assuming that an injected does not always coincide with a masking pulse on **a**)
- an actual fault on any of the **a** or **b** nodes coinciding with an injected fault
- a soft error occurring on either the **input counter** or **monitor counter**.

7.5 Lockstep Failure Signalling Test

The lockstep comparator allows a failure to be injected into one of the comparator nodes to allow the signalling of failures to be verified. A failure can be injected by writing 1_B to the LCLT0 bitfield of the LCLTEST register. The failure will be injected for a single cycle of the SPB clock. It is not necessary to write a 0_B to clear the test.

7.6 Functional Redundancy

All registers in the lockstep block which are not capable of being directly monitored for correct operation by the self test function will be duplicated. In the event of the duplicated registers not storing the same state, an error will be flagged to the SMU.

7.7 Revision History

Deltas from Lockstep version 1.1 to version 1.2

- Bitfield names updated for LCLCON register. See **sections “Lockstep Monitoring” and “Lockstep Self Test”.**
- Multiple failure detecton algorithm updates. See Lockstep Self Test section.

Deltas from Lockstep version 1.2 to 1.3

- Revision History Added

Deltas from Lockstep version 1.3 to 1.4

- Description of self test updated

Deltas from Lockstep version 1.4 to 1.5

- Control bits for self test and delay removed. Both functions will now be permanently enabled.
- Lockstep will now be on after reset and cannot be enabled once switched off

Deltas from Lockstep version 1.5 to 1.6

- Additional control bit added to allow injection of fault condition under software control.

Deltas from Lockstep version 1.6 to 1.7

- Specifying cold power-on reset / typo’s.

Deltas from Lockstep version 1.7 to 1.8

- No functional change, updates to Requirements tags only.

Deltas from Lockstep version 1.8 to 1.9

- No functional change, correction of typos and support for TC23x configuration.

8 System Control Units

The System Control Cluster comprises various modules which each handle system control functions.

The System Control Cluster includes the following functional modules:

- Clock Control Unit (CCU)
- Reset Control Unit (RCU)
- Power Management Controller (PMC)
- System Control Unit (SCU), including ERU,LCL, WDT, EMS, NMI and OVC registers

8.1 Clocking and Clock Control Unit (CCU)

This section describes the TC21x/TC22x/TC23x clock system, its configuration and the principles upon which it is based.

The clock system itself is build up as chain composing out of different building blocks which allow different certain function parts for this complete chain.

Building blocks are:

- Basic clock generation (Clock Source)
- Clock speed upscaling
- Clock distribution
- Individual clock configuration

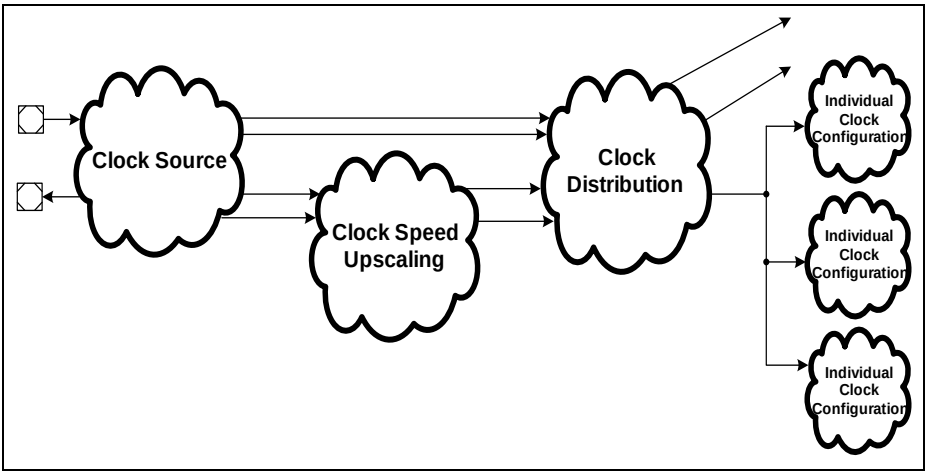

Figure 8-1 Clock Tree

Aside from the pure clock generation options there are several support functions which have been integrated in order to support easy and convenient controls.

In the following subsections the clock tree is explained from left to the right. Using this flow for the initial configuration is also recommended. Expert users can of course execute the configuration in a individual order.

Note: If a running system needs to be reconfigured not all parts of the clock tree need to be configured, only these parts that are required can be updated.

8.1.1 Clock Sources

There are several clock sources available which either source the complete device, a major or minor part, or only dedicated modules. This depends on the sources and the configuration.

Please note that several clock sources can be used in parallel inside the system but the main function of each peripheral is only related to one source at any time.

8.1.1.1 Oscillator Circuit (OSC)

The oscillator circuit, a Pierce oscillator, is designed to work with both an external crystal / ceramic resonator or an external stable clock source, consists of an inverting amplifier with XTAL1 as input, and XTAL2 as output with an integrated feedback resistor.

External Input Clock Mode

When using an external clock signal it must be connected to XTAL1. XTAL2 is left open (unconnected).

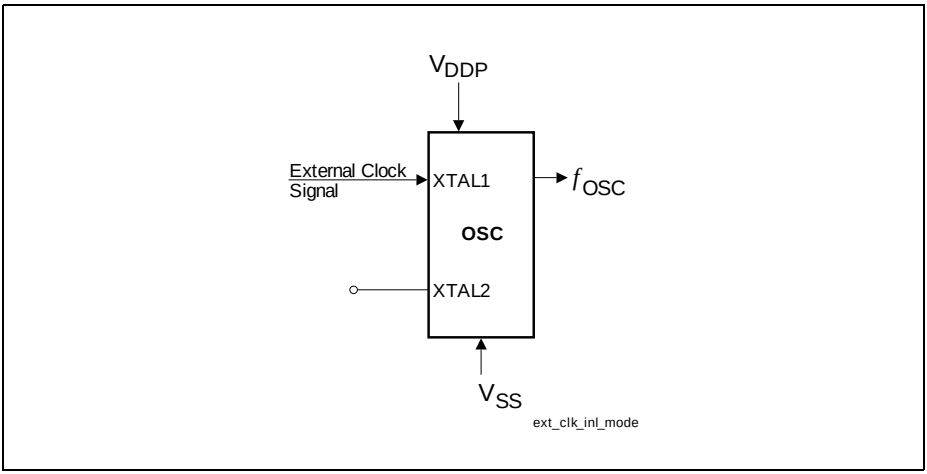

Figure 8-2 TC21x/TC22x/TC23x Direct Clock Input

When supplying the clock signal directly, not using an external crystal / ceramic resonator and bypassing the oscillator, the input frequency needs to be equal or greater than PLL VCO input frequency (the value is listed in the Data Sheet) if used in normal Mode.

External Crystal / Ceramic Resonator Mode

Figure 8-3 shows the recommended external circuitries for both operating modes, External Crystal / Ceramic Resonator Mode with and without external components.

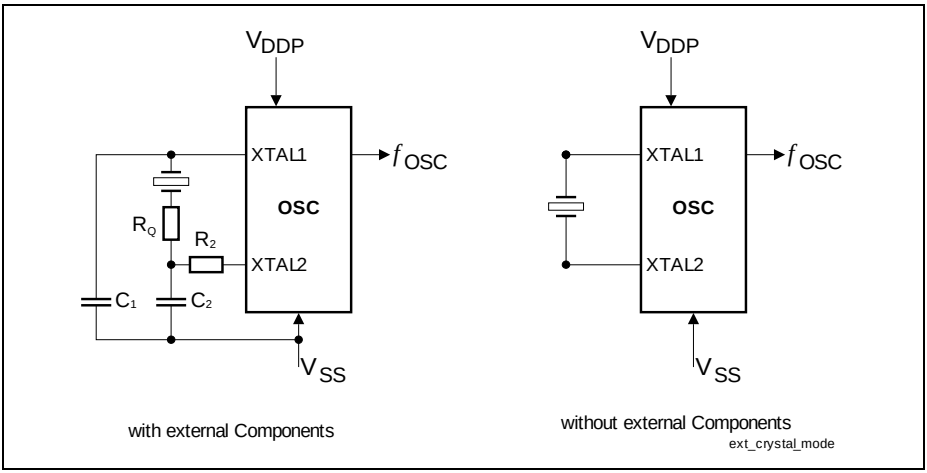

Figure 8-3 External Circuitry for Crystal / Ceramic Resonator operation

When using an external crystal / ceramic resonator, its frequency can be within the allowed range (the values are listed in the Data Sheet). An external oscillator load circuitry can be used, connected to both pins, XTAL1 and XTAL2. Additionally are necessary, two load capacitances C_1 and C_2 (see **Figure 8-3**), and depending on the crystal / ceramic resonator type, a series resistor R_2 to limit the current. A test resistor R_Q may be temporarily inserted to measure the oscillation allowance (negative resistance) of the oscillator circuitry. R_Q values are typically specified by the crystal / ceramic resonator vendor. The C_1 and C_2 values shown in the Data Sheet can be used as starting points for the negative resistance evaluation and for non-productive systems. The exact values and related operating range are dependent on the crystal / ceramic resonator frequency and have to be determined and optimized together with the crystal / ceramic resonator vendor using the negative resistance method. Oscillation measurement with the final target system is strongly recommended to verify the input amplitude at XTAL1 and to determine the actual oscillation allowance (margin negative resistance) for the oscillator-crystal / ceramic resonator system.

The oscillator can also be used in combination with a ceramic resonator. The final circuitry must be also verified by the resonator vendor.

Oscillator Circuit Control Register

OSCCON
OSC Control Register **(010_H)** **Reset Value: 0000 0X1X$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0				X1D EN	X1D	0	PLL HV	SH BY	MODE		GAINSEL		OSC RES	PLL LV	0
r				rw	rh	r	rh	rw	rw		rw		w	rh	

Field	Bits	Type	Description
PLLLV	1	rh	**Oscillator for PLL Valid Low Status Bit** This bit indicates if the frequency output of OSC is usable for the VCO part of the PLL. This is checked by the Oscillator Watchdog of the PLL. 0_B The OSC frequency is not usable. Frequency f_{REF} is too low. 1_B The OSC frequency is usable *Note: The default value depends on the status of the clock received from pin XTAL1.*
OSCRES	2	w	**Oscillator Watchdog Reset** 0_B The Oscillator Watchdog of the PLL is not cleared and remains active 1_B The Oscillator Watchdog of the PLL is cleared and restarted *Note: Always read as zero.*

Field	Bits	Type	Description
GAINSEL	[4:3]	rw	**Oscillator Gain Selection** In Normal Mode this value should not be changed from the reset value 11_B. 00_B The gain control is configured for frequencies from 4 MHz to 8 MHz 01_B The gain control is configured for frequencies from 4 MHz to 16 MHz 10_B The gain control is configured for frequencies from 4 MHz to 20 MHz 11_B The gain control is configured for frequencies from 4 MHz to 25 MHz External Crystal / 40 MHz Ceramic Resonator *Note: Default value after reset is 11_B.*
MODE	[6:5]	rw	**Oscillator Mode** This bit field defines which mode can be used and if the oscillator entered the Power-Saving Mode or not. 00_B External Crystal / Ceramic Resonator Mode and External Input Clock Mode. The oscillator Power-Saving Mode is not entered. 01_B OSC is disabled. The oscillator Power-Saving Mode is not entered. 10_B External Input Clock Mode and the oscillator Power-Saving Mode is entered 11_B OSC is disabled. The oscillator Power-Saving Mode is entered. *Note: Default value after reset is 00_B.*
SHBY	7	rw	**Shaper Bypass** 0_B The shaper is not bypassed 1_B The shaper is bypassed *Note: Default value after reset is 0_B.*

Field	Bits	Type	Description
PLLHV	8	rh	**Oscillator for PLL Valid High Status Bit** This bit indicates if the frequency output of OSC is usable for the VCO part of the PLL. This is checked by the Oscillator Watchdog of the PLL. 0_B The OSC frequency is not usable. Frequency f_{OSC} is too high. 1_B The OSC frequency is usable *Note: The default value depends on the status of the clock received from pin XTAL1.*
X1D	10	rh	**XTAL1 Data Value** This bit monitors the value (level) of pin XTAL1. If XTAL1 is not used as clock input it can be used as GPI pin. This bit is only updated if X1DEN is set. *Note: The default value depends on the status of the clock received from pin XTAL1.*
X1DEN	11	rw	**XTAL1 Data Enable** 0_B Bit X1D is not updated 1_B Bit X1D can be updated *Note: Default value after reset is 0_B.*
OSCVAL	[20:16]	rw	**OSC Frequency Value** This bit field defines the divider value that generates the reference clock that is supervised by the oscillator watchdog. f_{OSC} is divided by OSCVAL + 1 in order to generate f_{OSCREF}.
APREN	23	rw	**Amplitude Regulation Enable** 0_B Amplitude Regulation is disabled 1_B Amplitude Regulation is enabled
0	[27:24]	rw	**Reserved** Should be written with 0.
0	0, 9, [15:12], [22:21], [31:28]	r	**Reserved** Read as 0; should be written with 0.

Configuration of the Oscillator

A configuration of the oscillator is always required before an external crystal / ceramic resonator could be used as clock source. For this start-up configuration two options are supported:

- Configuration via the SSW
- Configuration after the execution of the SSW

Configuration via SSW

This option is enabled when bit FLASH0_PROCOND.OSCCFG is set. In this mode the control information for the register OSCCON is loaded from FLASH0_PROCOND by the SSW. Therefore the required information needs to be stored with the UCB_DFlash at offset 00_H.

In this mode OSCCON.MODE and OSCCON.CAPxEN together with bit OSCCON.APREN are controllable.

Note: A control for OSCCON.GAINSEL is not required as it is recommended always to keep the default configuration of 11_B.

If the oscillator was disabled it must be enabled by setting bit field OSCCON.MODE = 00_B.

If the integrated capacitors should be used this can be enabled via the bits OSCCON.CAPxEN. If OSCCON[27:24] ≠ 0000_B then bit OSCCON.APREN need to be set too. Please note that the Amplitude Regulation needs to be enabled always when integrated caps are used. Enabling the Amplitude Regulation does not require a change for OSCCON.GAINSEL, which should be left at 11_B.

Configuration after SSW

After the optional configuration in the SSW there is always an option to configure the oscillator in the application software.

This is done via register OSCCON. The register itself is Safety ENDINIT protected.

In general the same rules apply for configuration as described in the section before.

Miscellaneous Oscillator Features

Support for two additional features which are related to the oscillator are also located in the OSCCON register.

XTAL1 as General Purpose Input Pin

For the rare case that XTAL1 / 2 are not used for clocking purpose XTAL1 could be used as an input pad instead. Setting bit OSCCON.X1DEN enables this function and the input value can be read thereafter via bit OSCCON.XD1.

Please note that this defines only a basic input function and supports no output features for XTAL1 or XTAL2.

Note: For XTAL2 no input function is supported.

Note: If XTAL1 is used for clock functions bit OSCCON.X1DEN should be cleared, as otherwise bit OSCCON.X1D would toggle with the input clock frequency.

Oscillator Watchdog

In combination with the PLL, a monitoring function is implemented. This feature is defined to detect severe malfunctions of an external crystal / ceramic resonator. Detectable errors are loss of clock input or a much too high input frequency.

The oscillator watchdog monitors the incoming clock frequency f_{OSC} from OSC. A stable and defined input frequency is a mandatory requirement for operation in both Prescaler Mode and Normal Mode of the PLLs. For operation in Freerunning Mode no f_{OSC} input frequency is required. Therefore this mode is selected automatically after each System Reset. In addition for the Normal Mode it is required that the input frequency f_{OSC} is in a certain frequency range to obtain a stable master clock from the VCO part.

The expected input frequency is selected via the bit field OSCCON.OSCVAL. The OSC_WDT checks for frequencies which are too low or too high.

The frequency that is monitored is f_{OSCREF} which is derived from f_{OSC}.

(8.1)

$$f_{OSCREF} = \frac{f_{OSC}}{OSCVAL + 1}$$

The divider value OSCCON.OSCVAL has to be selected in a way that f_{OSCREF} is 2.5 MHz.

Note: f_{OSCREF} has to be within the range of 2 MHz to 3 MHz and should be as close as possible to 2.5 MHz.

Before configuring the OSC_WDT function all the SMU Oscillator Watchdog alarm response options should be disabled in order to avoid unintended traps. Thereafter the value of OSCCON.OSCVAL can be changed. Then the OSC_WDT should be reset by setting OSCCON.OSCRES. This requests the start of OSC_WDT monitoring with the new configuration. When the expected positive monitoring results of OSCCON.PLLLV and / or OSCCON.PLLHV are set the input frequency is within the expected range. As setting OSCCON.OSCRES clears both bits OSCCON.PLLLV and OSCCON.PLLHV all both status flags will be set. Therefore both flags should be cleared before the SMU

alarm responses are enabled again. The trap disabling-clearing-enabling sequence should also be used if only bit OSCCON.OSCRES is set without any modification of OSCCON.OSCVAL.

The oscillator clock is selected as source for the watchdog by configuring CCUCON1.INSEL = 01_B.

8.1.1.2 Back-up Clock

A back-up clock source is available as alternate clock source. This clock source provides a stable but reliable clock source that can be used as clock for the system. It provides less accuracy than an external crystal or ceramic resonator. The back-up clock can not be enabled or disabled or anyhow else be controlled. Therefore no control bits beside the selection itself as source (CCUCON0.CLKSEL = 00_B as clock source for the clock distribution and CCUCON1.INSEL = 00_B as clock source for the PLL / PLL_ERAY) are available.

8.1.2 Clock Speed Upscaling

Typical CPU operating speeds are about 10 times higher than the speed of the used crystal as clock source. Therefore an upscaling of the clock frequency is required.

For the upscaling up to two Phase Lock Loop (PLLs) are provided.

8.1.2.1 Phase-Locked Loop (PLL) Module

The PLL can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. It allows the use of input and output frequencies of a wide range by varying the different divider factors.

The PLL also has fail-safe logic that detects degenerate external clock behavior such as abnormal frequency deviations or a total loss of the external clock. It can execute emergency actions if it loses its lock on the external clock.

Features

- VCO lock detection
- 4-bit input divider **P:** (divide by PDIV+1)
- 7-bit feedback divider **N**: (multiply by NDIV+1)
- 7-bit output divider **K1 or K2:** (divide by either by K1DIV+1 or K2DIV+1)
- 7-bit output divider **K3:** (divide by K3DIV+1)
- Oscillator Watchdog
  - Detecting too low input frequencies
  - Detecting too high input frequencies
- Different operating modes

  - Prescaler Mode
  - Freerunning Mode
  - Normal Mode
- VCO Power Down
- Glitchless switching between both K-Dividers
- Glitchless switching between Normal Mode and Prescaler Mode
- Frequency Modulation
- Jitter reduction for modulation jitter

PLL Functional Description

The following figure shows the PLL block structure.

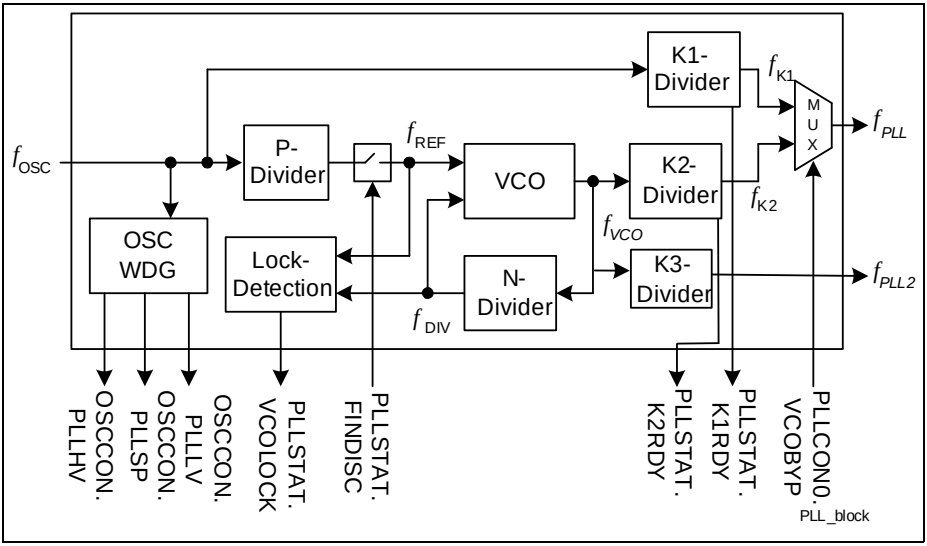

Figure 8-4 PLL Block Diagram

Mode Control

The PLL clock f_{PLL} and f_{PLL2} are generated from f_{OSC} in one of following software selectable modes:

- Normal Mode
- Prescaler Mode
- Freerunning Mode

Normal Mode

In Normal Mode the input frequency f_{OSC} is divided down by a factor P, multiplied by a factor N and then divided down by a factor K2 or K3.

The output frequency is given by

$$f_{PLL} = \frac{N}{P \cdot K2} \cdot f_{OSC} \quad (8.2)$$

$$f_{PLL2} = \frac{N}{P \cdot K3} \cdot f_{OSC} \quad (8.3)$$

Prescaler Mode

In Prescaler Mode the reference frequency f_{OSC} is only divided down by a factor K1.

The output frequency is given by

$$f_{PLL} = \frac{f_{OSC}}{K1} \quad (8.4)$$

Freerunning Mode

In Freerunning Mode the base frequency output of the Voltage Controlled Oscillator (VCO) $f_{PLLBASE}$ is only divided down by a factor K2 or K3.

The output frequency is given by

$$f_{PLL} = \frac{f_{PLLBASE}}{K2} \quad (8.5)$$

$$f_{PLL2} = \frac{f_{PLLBASE}}{K3} \quad (8.6)$$

Configuration and Operation of the Freerunning Mode

In Freerunning Mode, the PLL is running at its VCO base frequency and f_{PLL} / f_{PLL2} is derived from f_{VCO} only by the K2 / K3-Divider.

The Freerunning Mode is entered after each System Reset.

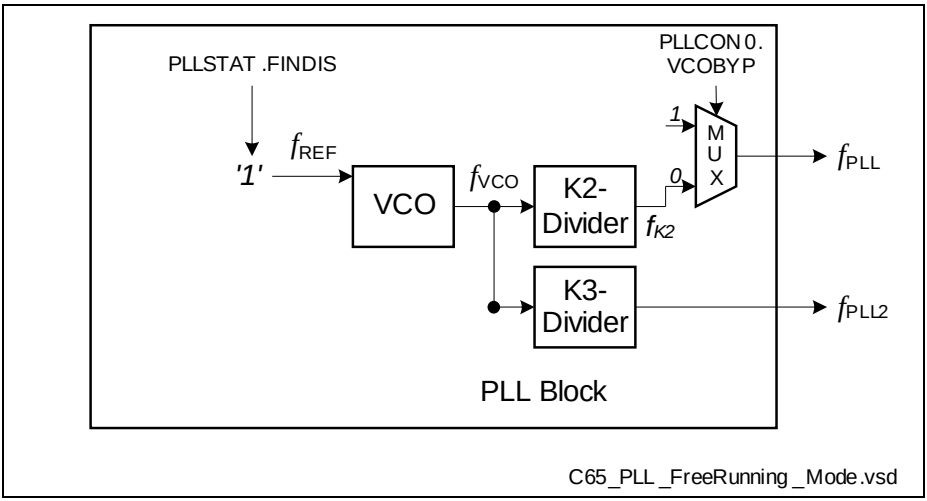

Figure 8-5 PLL Free-Running Mode Diagram

The output frequency is given by

$$f_{PLL} = \frac{f_{PLLBASE}}{K2} \quad (8.7)$$

$$f_{PLL2} = \frac{f_{PLLBASE}}{K3} \quad (8.8)$$

The Freerunning Mode is selected by the following settings

- PLLCON0.VCOBYP = 0
- PLLCON0.SETFINDIS = 1

The Freerunning Mode is entered when

- PLLSTAT.FINDIS = 1
- AND
- PLLSTAT.VCOBYST = 0

Operation on the Freerunning Mode does not require an input clock frequency of f_{OSC}. The Freerunning Mode is automatically entered on a PLL VCO Loss-of-Lock event if bit PLLCON0.OSCDISCDIS is cleared. This mechanism allows a fail-safe operation of the PLL as in emergency cases still a clock is available.

The frequency of the Freerunning Mode $f_{PLLBASE}$ is listed in the Data Sheet.

Note: Changing the system operation frequency by changing the value of the K2-Divider has a direct effect on the power consumption of the device. Therefore this has to be changed carefully to avoid excessive current steps.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface.

Configuration and Operation of the Prescaler Mode

In Prescaler Mode, the PLL is running at the external frequency f_{OSC} and f_{PLL} is derived from f_{OSC} only by the K1-Divider.

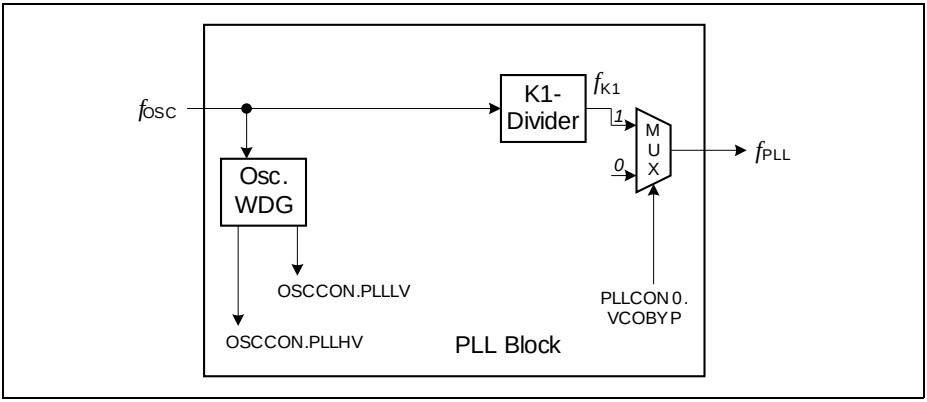

Figure 8-6 PLL Prescaler Mode Diagram

The output frequency is given by:

$$f_{PLL} = \frac{f_{OSC}}{K1} \quad (8.9)$$

The Prescaler Mode is selected by the following settings

- PLLCON0.VCOBYP = 1

The Prescaler Mode is entered when the following requirement isvalid:

- PLLSTAT.VCOBYST = 1

Operation on the Prescaler Mode does require an input clock frequency of f_{OSC}. Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

For the Prescaler Mode there are no requirements regarding the frequency of f_{OSC}.

The system operation frequency is controlled in the Prescaler Mode by the value of the K1-Divider. When the value of PLLCON1.K1DIV was changed the next update of this value should not be done before bit PLLSTAT.K1RDY is set.

Note: Changing the system operation frequency by changing the value of the K1-Divider has a direct coupling to the power consumption of the device. Therefore this has to be done carefully.

Depending on the selected divider value of the K1-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K1-divider values are defined in the Data Sheet.

The Prescaler Mode is requested from the Freerunning or Normal Mode by setting bit PLLCON.VCOBYP. The Prescaler Mode is entered when the status bit PLLSTAT.VCOBYST is set. Before the Prescaler Mode is requested the K1-Divider should be configured with a value generating a PLL output frequency f_{PLL} that matches the one generated by the Freerunning or Normal Mode as much as possible. In this way the frequency change resulting out of the mode change is reduced to a minimum.

The Prescaler Mode is requested to be left by clearing bit PLLCON.VCOBYP. The Prescaler Mode is left when the status bit PLLSTAT.VCOBYST is cleared.

Configuration and Operation of the Normal Mode

In Normal Mode, the PLL is running at the external frequency f_{OSC} divided down by a factor P, multiplied by a factor N and then divided down by a factor K2 / K3 resulting in f_{PLL} / f_{PLL2}.

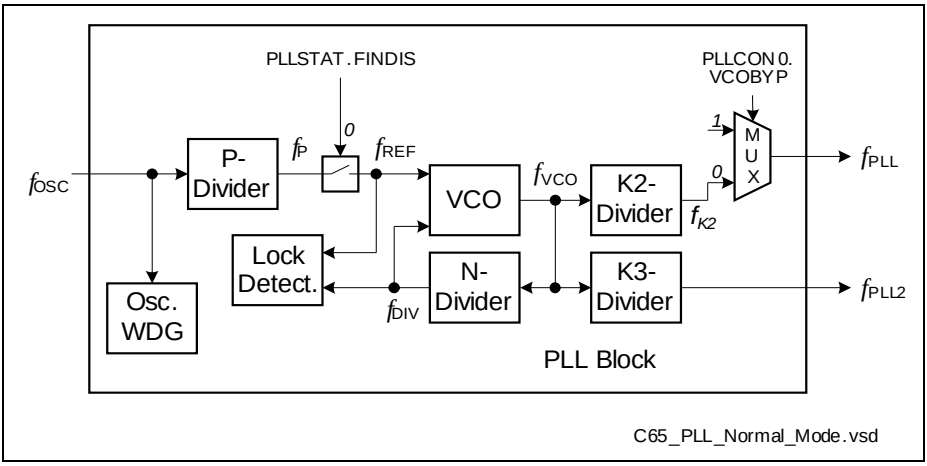

Figure 8-7 PLL Normal Mode Diagram

The output frequency is given by:

(8.10)

$$f_{PLL} = \frac{N}{P \cdot K2} \cdot f_{OSC}$$

(8.11)

$$f_{PLL2} = \frac{N}{P \cdot K3} \cdot f_{OSC}$$

The Normal Mode is selected by the following settings

- PLLCON0.VCOBYP = 0
- PLLCON0.CLRFINDIS = 1

The Normal Mode is entered when the following requirements are all together valid:

- PLLSTAT.FINDIS = 0
- PLLSTAT.VCOBYST = 0
- PLLSTAT.VCOLOCK = 1
- OSCCON.PLLLV = 1
- OSCCON.PLLHV = 1

Operation on the Normal Mode does require an input clock frequency of f_{OSC}. Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

The system operation frequency is controlled in the Normal Mode by the values of the three dividers: P, N, and K2 / K3. A modification of the two dividers P and N has a direct influence to the VCO frequency and could lead to a loss of the VCO Lock status. A modification of the K2 / K3-divider has no impact on the VCO Lock status but still changes the PLL output frequency.

Note: Changing the system operation frequency by changing the value of the K2-Divider has a direct coupling to the power consumption of the device. Therefore this has to be done carefully.

When the frequency of the Normal Mode should be modified or entered the following sequence should be followed:

First the Prescaler Mode should be configured and entered. For more details see the Prescaler Mode.

The SMU alarm generation for the VCO Loss of Lock should be disabled.

While the Prescaler Mode is used the Normal Mode can be configured and checked for a positive VCO Lock status. The first target frequency of the Normal Mode should be selected in a way that it matches or is only slightly higher as the one used in the Prescaler Mode. This avoids big changes in the system operation frequency and therefore power consumption when switching later from Prescaler Mode to Normal Mode. The P and N divider should be selected in the following way:

- Selecting P and N in a way that f_{VCO} is in the lower area of its allowed values leads to a slightly reduced power consumption but to a slightly increased jitter
- Selecting P and N in a way that f_{VCO} is in the upper area of its allowed values leads to a slightly increased power consumption but to a slightly reduced jitter

After the P, N, and K2 / K3 dividers have been updated on the first configuration, the indication of the VCO Lock status should be checked (PLLSTAT.VCOLOCK = 1).

Note: When configuring the PLL for the first time after a system reset it is recommended to disconnect the input clock f_{OSC} before configuring P and / or N and to connect f_{OSC} before checking for the lock status.

Note: It is recommended to reset the VCO Lock detection (PLLCON0.RESLD = 1) after the new values of the dividers are configured to get a defined VCO lock check time.

Note: Resetting the lock detection (PLLCON0.RESLD = 1) while PLLCON0.OSCDISCDIS = 0 when the PLL was already locked (PLLSTAT.VCOLOCK = 1) can lead to a disconnect of the input clock. In this case PLLCON0.OSCDISCDIS should be set before lock detection is reset. When the lock is thereafter is set again PLLCON0.OSCDISCDIS could be cleared again.

When this happens the switch from Prescaler Mode to Normal Mode can be done. Normal Mode is requested by clearing PLLCON.VCOBYP. The Normal Mode is entered when the status bit PLLSTAT.VCOBYST is cleared.

Now the Normal Mode is entered. The SMU status flag for the system PLL VCO Loss-of-Lock event should be cleared and then enabled again. The intended PLL output target frequency can now be configured by changing only the K2 / K3-Divider.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface.

This can result in multiple changes of the K2-Divider to avoid too big frequency changes. Between the update of two K2-Divider values 6 cycles of f_{PLL} should be waited.

PLL VCO Lock Detection

The PLL has a lock detection that supervises the VCO part of the PLL in order to differentiate between stable and instable VCO circuit behavior. The lock detector marks the VCO circuit and therefore the output f_{VCO} of the VCO as instable if the two inputs f_{REF} and f_{DIV} differ too much. Changes in one or both input frequencies below a level are not marked by a loss of lock because the VCO can handle such small changes without any problem for the system.

PLL VCO Loss-of-Lock Event

The PLL may become unlocked, caused by a break of the crystal / ceramic resonator or the external clock line. In such a case, an SMU alarm event is generated.

Additionally, the OSC clock input f_{OSC} is disconnected from the PLL VCO to avoid unstable operation due to noise or sporadic clock pulses coming from the oscillator circuit. Without a clock input f_{OSC}, the PLL gradually slows down to its VCO base frequency and remains there. This automatic feature can be disabled by setting bit PLLCON0.OSCDISCDIS. If this bit is set the OSC clock remains connected to the VCO.

VCO Power Down Mode

The PLL offers a VCO Power Down Mode. This mode can be entered to save power within the PLL. The VCO Power Down Mode is entered by setting bit PLLCON0.VCOPWD. While the PLL is in VCO Power Down Mode only the Prescaler Mode is operable. Please note that selecting the VCO Power Down Mode does not automatically switch to the Prescaler Mode. So before the VCO Power Down Mode is entered the Prescaler Mode must be active.

PLL Power Down Mode

The PLL offers a Power Down Mode. This mode can be entered to save power if the PLL is not needed at all. The Power Down Mode is entered by setting bit PLLCON0.PLLPWD. While the PLL is in Power Down Mode no PLL output frequency is generated.

Frequency Modulation

If the PLL operates in Normal Mode the output frequency f_{PLL} can additionally be modified by a low-frequency modulation. f_{VCO} is randomly modulated.

The modulation is enabled via bit PLLCON0.MODEN. The modulation itself variate the VCO frequency randomly with the range of the configured modulation amplitude. The modulation amplitude is selected via PLLCON2.MODCFG[9:0].

(8.12)

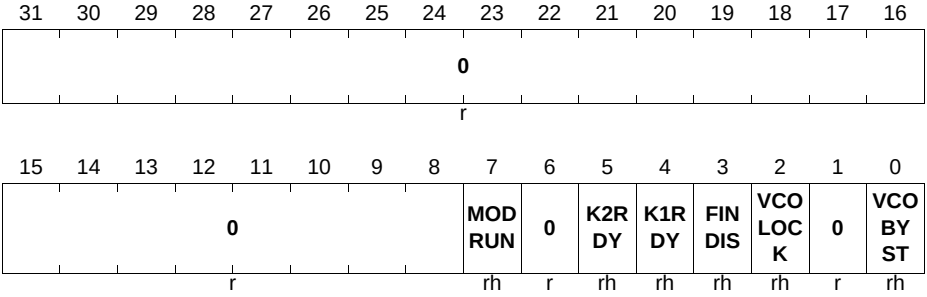
$$MA = \frac{f_{MV}}{f_{VCO} \times 2} \times MODCFG[9,0]$$

The modulation performed in a way that the resulting accumulated jitter added by the modulation stays below J_{MOD}. The modulation itself is monitored with f_{REF} and therefore the P-divider should by configured with the smallest possible value.

PLL Registers

These registers control the setting of the PLL.

PLLSTAT
PLL Status Register **(014_H)** **Reset Value: 0000 0038$_H$**



Field	Bits	Type	Description
VCOBYST	0	rh	**VCO Bypass Status** 0_B Freerunning / Normal Mode is entered 1_B Prescaler Mode is entered
VCOLOCK	2	rh	**PLL VCO Lock Status** 0_B The frequency difference of f_{REF} and f_{DIV} is greater than allowed. The VCO part of the PLL can not lock on a target frequency. 1_B The frequency difference of f_{REF} and f_{DIV} is small enough to enable a stable VCO operation. *Note: In case of a loss of VCO lock the f_{VCO} is keep on the previous constant frequency.*
FINDIS	3	rh	**Input Clock Disconnect Select Status** 0_B The input clock from the oscillator is connected to the VCO part 1_B The input clock from the oscillator is disconnected from the VCO part *Note: This bit can be set by setting bit PLLCON0.SETFINDIS.* *Note: This bit can be cleared by setting bit PLLCON0.CLRFINDIS.*

Field	Bits	Type	Description
K1RDY	4	rh	**K1 Divider Ready Status** This bit indicates if the K1-divider operates on the configured value or not. this is of interest if the values is changed. 0_B K1-Divider is not ready to operate with the new value 1_B K1-Divider is ready to operate with the new value
K2RDY	5	rh	**K2 Divider Ready Status** This bit indicates if the K2-divider operates on the configured value or not. this is of interest if the values is changed. 0_B K2-Divider is not ready to operate with the new value 1_B K2-Divider is ready to operate with the new value
MODRUN	7	rh	**Modulation Run** This bit indicates if the frequency modulation of the PLL is activated or not. 0_B Frequency modulation is not active 1_B Frequency modulation is active
0	1, 6, [31:8]	r	**Reserved** Read as 0; should be written with 0.

PLLCON0
PLL Configuration 0 Register **(018_H)** **Reset Value: 0001 C600$_H$**

0	[31:16]	rw	**Reserved** Have to be written with 0.

8.1.2.2 ERAY Phase-Locked Loop (PLL_ERAY) Module

The PLL_ERAY can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. It can execute emergency actions if it loses its lock on the external clock.

This module is a phase locked loop for integer frequency synthesis. It allows the use of input and output frequencies of a wide range by varying the different divider factors.

Features

- VCO lock detection
- 4-bit input divider **P:** (divide by PDIV+1)
- 5-bit feedback divider **N**: (multiply by NDIV+1)
- 7-bit output divider **K1 or K2:** (divide by either by K1DIV+1 or K2DIV+1)
- 7-bit output divider **K3:** (divide by K3DIV+1)

- Different operating modes
  - Prescaler Mode
  - Freerunning Mode
  - Normal Mode
- VCO Power Down (Sleep Mode)
- Glitchless switching between both K-Dividers
- Glitchless switching between Normal Mode and Prescaler Mode

PLL_ERAY Functional Description

The following figure shows the PLL_ERAY block structure.

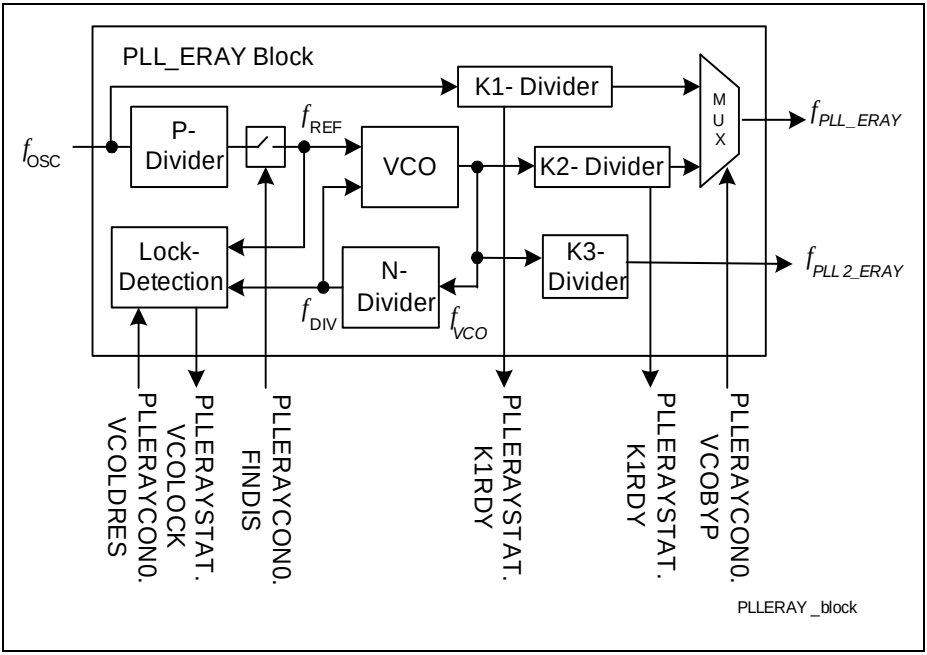

Figure 8-8 PLL_ERAY Block Diagram

Clock Source Control

The PLL_ERAY clocks f_{PLL_ERAY} / f_{PLL2_ERAY} are generated from f_{OSC} in one of three software selectable modes:

- Normal Mode
- Prescaler Mode
- Freerunning Mode

Normal Mode

In Normal Mode the input frequency f_{OSC} is divided down by a factor P, multiplied by a factor N and then divided down by a factor K2 / K3.

The output frequency is given by

$$f_{PLLERAY} = \frac{N}{P \times K2} \cdot f_{OSC} \quad (8.13)$$

$$f_{PLL2ERAY} = \frac{N}{P \times K3} \cdot f_{OSC} \quad (8.14)$$

Prescaler Mode

In Prescaler Mode the reference frequency f_{OSC} is only divided down by a factor K1.

The output frequency is given by

$$f_{PLLERAY} = \frac{f_{OSC}}{K1} \quad (8.15)$$

Freerunning Mode

In Freerunning Mode the base frequency output of the Voltage Controlled Oscillator (VCO) $f_{PLLBASEERAY}$ is only divided down by a factor K2 / K3.

The output frequency is given by

$$f_{PLLERAY} = \frac{f_{PLLBASEERAY}}{K2} \quad (8.16)$$

$$f_{PLL2ERAY} = \frac{f_{PLLBASEERAY}}{K3} \quad (8.17)$$

Configuration and Operation of the Freerunning Mode

In Freerunning Mode, the PLL_ERAY is running at its VCO base frequency and f_{PLL_ERAY} / f_{PLL2_ERAY} are derived from f_{VCO} only by the K2 / K3-Divider.

The Freerunning Mode is entered after each System Reset.

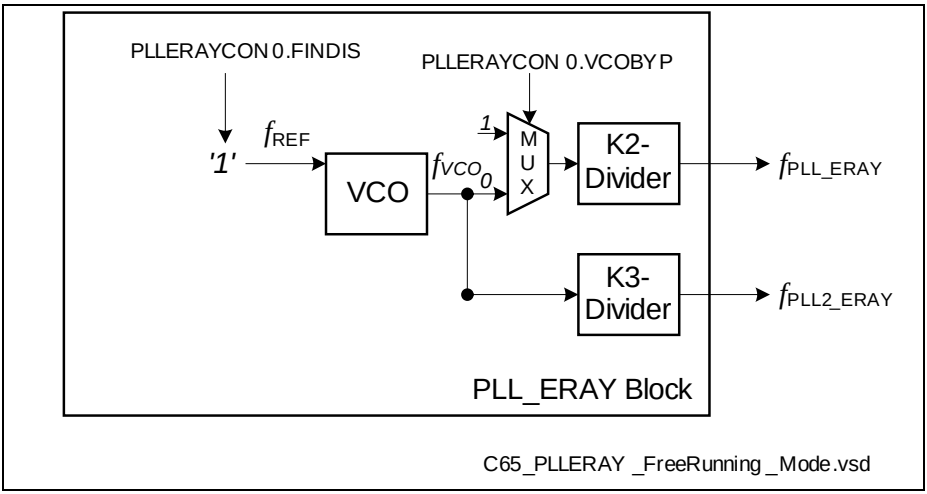

Figure 8-9 PLL_ERAY Free-Running Mode Diagram

The output frequency is given by

$$f_{PLLERAY} = \frac{f_{PLLBASEERAY}}{K2} \quad (8.18)$$

$$f_{PLL2ERAY} = \frac{f_{PLLBASEERAY}}{K3} \quad (8.19)$$

The Freerunning Mode is selected by the following settings

- PLLERAYCON0.VCOBYP = 0
- PLLERAYCON0.SETFINDIS = 1

The Freerunning Mode is entered when

- PLLERAYSTAT.FINDIS = 1
- AND
- PLLERAYSTAT.VCOBYST = 0

Operation on the Freerunning Mode does not require an input clock frequency of f_{OSC}. The Freerunning Mode is automatically entered on a PLL_ERAY VCO Loss-of-Lock event if bit PLLERAYCON0.OSCDISCDIS is cleared. This mechanism allows a fail-safe operation of the PLL_ERAY as in emergency cases still a clock is available.

The frequency of the Freerunning Mode $f_{PLLBASEERAY}$ is listed in the Data Sheet.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface.

Configuration and Operation of the Prescaler Mode

In Prescaler Mode, the PLL_ERAY is running at the external frequency f_{OSC} and f_{PLL_ERAY} is derived from f_{OSC} only by the K1-Divider.

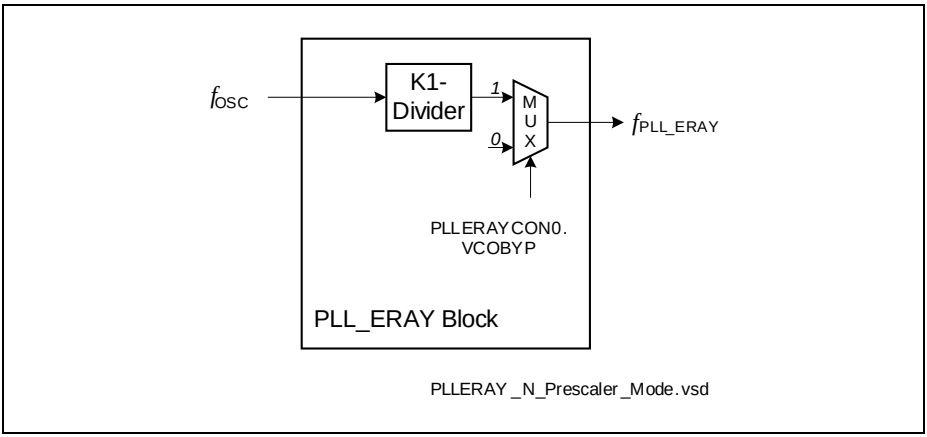

Figure 8-10 PLL_ERAY Prescaler Mode Diagram

The output frequency is given by:

$$f_{PLLERAY} = \frac{f_{OSC}}{K1} \quad (8.20)$$

The Prescaler Mode is selected by the following settings

- PLLERAYCON0.VCOBYP = 1

The Prescaler Mode is entered when the following requirement isvalid:

- PLLERAYSTAT.VCOBYST = 1

Operation on the Prescaler Mode does require an input clock frequency of f_{OSC}. Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

For the Prescaler Mode there are no requirements regarding the frequency of f_{OSC}.

The system operation frequency is controlled in the Prescaler Mode by the value of the K1-Divider. When the value of PLLERAYCON1.K1DIV was changed the next update of this value should not be done before bit PLLERAYSTAT.K1RDY is set.

Depending on the selected divider value of the K1-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K1-divider values are defined in the Data Sheet.

The Prescaler Mode is requested from the Freerunning or Normal Mode by setting bit PLLERAYCON.VCOBYP. The Prescaler Mode is entered when the status bit PLLERAYSTAT.VCOBYST is set. Before the Prescaler Mode is requested the K1-Divider should be configured with a value generating a PLL_ERAY output frequency f_{PLL_ERAY} that matches the one generated by the Freerunning or Normal Mode as much as possible. In this way the frequency change resulting out of the mode change is reduced to a minimum.

The Prescaler Mode is requested to be left by clearing bit PLLERAYCON.VCOBYP. The Prescaler Mode is left when the status bit PLLERAYSTAT.VCOBYST is cleared.

Configuration and Operation of the Normal Mode

In Normal Mode, the PLL is running at the external frequency f_{OSC} divided down by a factor P, multiplied by a factor N and then divided down by a factor K2 / K3 resulting in $f_{PLLERAY}$ / $f_{PLL2ERAY}$.

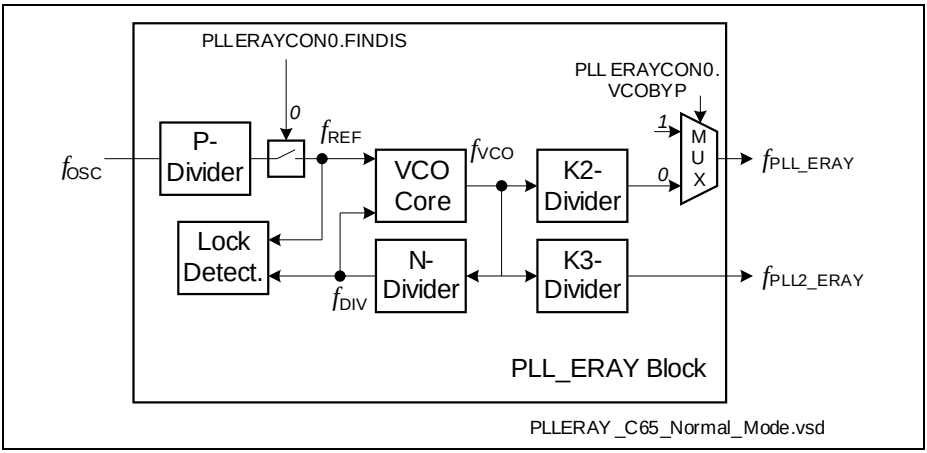

Figure 8-11 PLL_ERAY Normal Mode Diagram

The output frequency is given by:

(8.21)

$$f_{PLLERAY} = \frac{N}{P \times K2} \cdot f_{OSC}$$

(8.22)

$$f_{PLL2ERAY} = \frac{N}{P \times K3} \cdot f_{OSC}$$

The Normal Mode is selected by the following settings

- PLLERAYCON0.VCOBYP = 0
- PLLERAYCON0.CLRFINDIS = 1

The Normal Mode is entered when the following requirements are all together valid:

- PLLERAYSTAT.FINDIS = 0
- PLLERAYSTAT.VCOBYST = 0
- PLLERAYSTAT.VCOLOCK = 1
- OSCCON.PLLLV = 1
- OSCCON.PLLHV = 1

Operation on the Normal Mode does require an input clock frequency of f_{OSC}. Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

The system operation frequency is controlled in the Normal Mode by the values of the three dividers: P, N and K2 / K3. A modification of the two dividers P and N has a direct influence to the VCO frequency and could lead to a loss of the VCO Lock status. A modification of the K2 / K3-divider has no impact on the VCO Lock status but still changes the PLL_ERAY output frequency.

When the frequency of the Normal Mode should be modified or entered the following sequence should be followed:

First the Prescaler Mode should be configured and entered. For more details see the Prescaler Mode.

The SMU alarm generation for the VCO Loss of Lock should be disabled.

While the Prescaler Mode is used the Normal Mode can be configured and checked for a positive VCO Lock status. The first target frequency of the Normal Mode should be selected in a way that it matches or is only slightly higher as the one used in the Prescaler Mode. This avoids big changes in the system operation frequency and therefore power consumption when switching later from Prescaler Mode to Normal Mode. The N divider should be selected in the following way:

- Selecting P and N in a way that f_{VCO} is in the lower area of its allowed values leads to a slightly reduced power consumption but to a slightly increased jitter
- Selecting P and N in a way that f_{VCO} is in the upper area of its allowed values leads to a slightly increased power consumption but to a slightly reduced jitter

After the P, N and K2 / K3 dividers are updated for the first configuration the indication of the VCO Lock status should be await (PLLERAYSTAT.VCOLOCK = 1).

Note: When configuring the PLL the input clock f_{OSC} should be disconnected before configuring P and / or N and connected before checking for the lock status.

Note: It is recommended to reset the VCO Lock detection (PLLERAYCON0.RESLD = 1) after the new values of the dividers are configured to get a defined VCO lock check time.

Note: Resetting the lock detection (PLLERAYCON0.RESLD = 1) while PLLERAYCON0.OSCDISCDIS = 0 when the PLL_ERAY was already locked (PLLERAYSTAT.VCOLOCK = 1) can lead to a disconnect of the input clock. In this case PLLERAYCON0.OSCDISCDIS should be set before lock detection is reset. If the lock is subsequently set again PLLERAYCON0.OSCDISCDIS could be cleared again.

When this happens the switch from Prescaler Mode to Normal Mode can be done. Normal Mode is requested by clearing PLLERAYCON.VCOBYP. The Normal Mode is entered when the status bit PLLERAYSTAT.VCOBYST is cleared.

Now the Normal Mode is entered. The SMU alarm flag for the PLL_ERAY VCO Loss-of-Lock event should be cleared and then enabled again. The intended PLL_ERAY output target frequency can not be configured by changing only the K2-Divider.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. This can result in multiple changes of the K2-Divider to avoid too big frequency changes. Between the update of two K2-Divider values 6 cycles of f_{PLL_ERAY} should be waited.

PLL_ERAY VCO Lock Detection

The PLL_ERAY has a lock detection that supervises the VCO part of the PLL_ERAY in order to differentiate between stable and instable VCO circuit behavior. The lock detector marks the VCO circuit and therefore the output f_{VCO} of the VCO as instable if the two inputs f_{REF} and f_{DIV} differ too much. Changes in one or both input frequencies below a level are not marked by a loss of lock because the VCO can handle such small changes without any problem for the system.

PLL_ERAY VCO Loss-of-Lock Event

The PLL_ERAY may become unlocked, caused by a break of the crystal / ceramic resonator or the external clock line. In such a case, an SMU alarm event is generated.

Additionally, the OSC clock input f_{OSC} is disconnected from the PLL_ERAY VCO to avoid unstable operation due to noise or sporadic clock pulses coming from the oscillator circuit. Without a clock input f_{OSC}, the PLL_ERAY gradually slows down to its VCO base frequency and remains there. This automatic feature can be disabled by setting bit PLLERAYCON0.OSCDISCDIS. If this bit is cleared the OSC clock remains connected to the VCO.

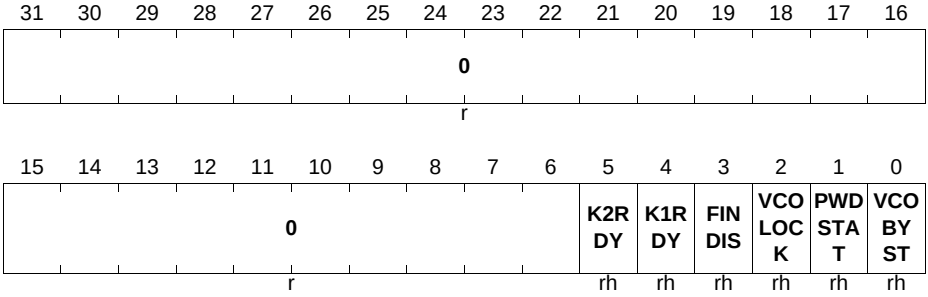
VCO Power Down Mode

The PLL_ERAY offers a VCO Power Down Mode. This mode can be entered to save power within the PLL_ERAY. The VCO Power Down Mode is entered by setting bit PLLCON0.VCOPWD. While the PLL_ERAY is in VCO Power Down Mode only the Prescaler Mode is operable. Please note that selecting the VCO Power Down Mode does not automatically switch to the Prescaler Mode. So before the VCO Power Down Mode is entered, the Prescaler Mode must be active.

PLL_ERAY Registers

These registers controls the setting of the PLL_ERAY.

PLLERAYSTAT
PLL_ERAY Status Register **(024_H)** **Reset Value: 0000 0038$_H$**



Field	Bits	Type	Description
VCOBYST	0	rh	**VCO Bypass Status** 0_B Freerunning / Normal Mode is entered 1_B Prescaler Mode is entered
PWDSTAT	1	rh	**PLL_ERAY Power-saving Mode Status** 0_B PLL_ERAY Power-saving Mode was not entered 1_B PLL_ERAY Power-saving Mode was entered
VCOLOCK	2	rh	**PLL VCO Lock Status** 0_B The frequency difference of f_{REF} and f_{DIV} is greater than allowed. The VCO part of the PLL_ERAY can not lock on a target frequency. 1_B The frequency difference of f_{REF} and f_{DIV} is small enough to enable a stable VCO operation. *Note: In case of a loss of VCO lock the f_{VCO} goes to the upper boundary of the VCO frequency if the reference clock input is greater than expected.* *Note: In case of a loss of VCO lock the f_{VCO} goes to the lower boundary of the VCO frequency if the reference clock input is lower than expected.*

Field	Bits	Type	Description
FINDIS	3	rh	**Input Clock Disconnect Select Status** 0_B The input clock from the oscillator is connected to the VCO part 1_B The input clock from the oscillator is disconnected from the VCO part *Note: This bit can be set by setting bit PLLERAYCON0.SETFINDIS.* *Note: This bit can be cleared by setting bit PLLERAYCON0.CLRFINDIS.*
K1RDY	4	rh	**K1 Divider Ready Status** This bit indicates if the K1-divider operates on the configured value or not. this is of interest if the values is changed. 0_B K1-Divider is not ready to operate with the new value 1_B K1-Divider is ready to operate with the new value
K2RDY	5	rh	**K2 Divider Ready Status** This bit indicates if the K2-divider operates on the configured value or not. this is of interest if the values is changed. 0_B K2-Divider is not ready to operate with the new value 1_B K2-Divider is ready to operate with the new value
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

PLLERAYCON0

PLL_ERAY Configuration 0 Register (028$_H$) **Reset Value: 0001 2E00$_H$**

8.1.3 Clock Distribution

Using the first two parts of the Clock System all clocks the system rely on for operation are defined. Now these different clocks need to be distributed to the single modules, CPU, and blocks in a way that these IPs can operate in best way in terms performance and power consumption.

For the clock distribution the system is split into several sub-clock domains where the clock speed could be configured individually but there are also several limitation for each sub-clock domain derived out of the internal interfaces.

Each sub-clock domain defines a logical unit from clocking perspective point of view.

The clock distribution is done via the Clock Control Unit (CCU). The CCU receives the clocks that are created by the two PLLs ($f_{PLL/PLL2}$ and f_{PLL_ERAY/PLL_ERAY2}), the back-up clock f_{Back}, and f_{OSC0}. These clock are either forwarded directly or divided in order to supply the sub-clock domains.

The following figure shows the structure of the TC21x/TC22x/TC23x clock system that shows the different sub-clock domains together with their clock inputs.

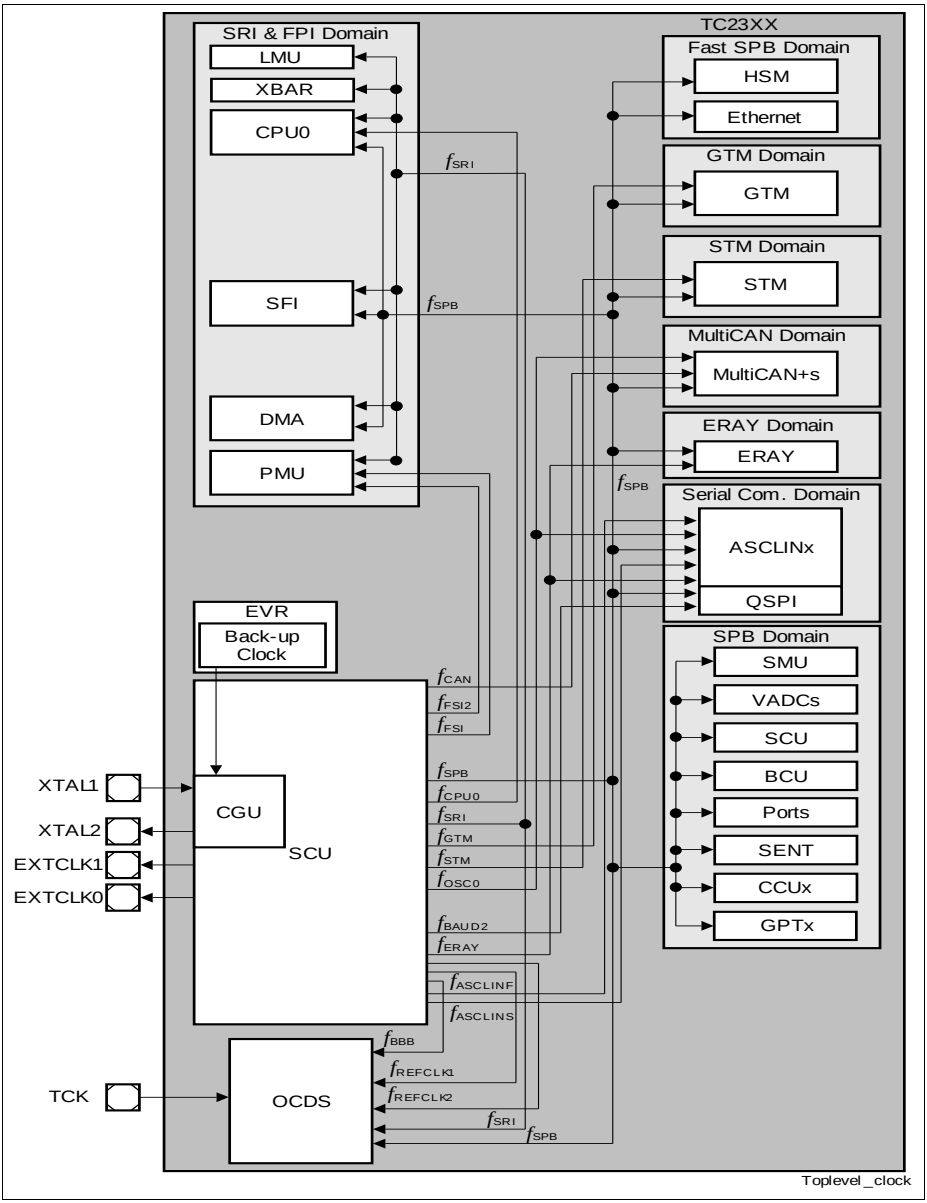

Figure 8-12 TC21x/TC22x/TC23x Clocking System

8.1.3.1 Clock Control Unit

The Clock Control Unit (CCU) receives the clocks that are created by the two PLLs ($f_{PLL/PLL2}$ and $f_{PLL\_ERAY/PLL2\_ERAY}$), the back-up clock f_{Back}, and f_{OSC0}.

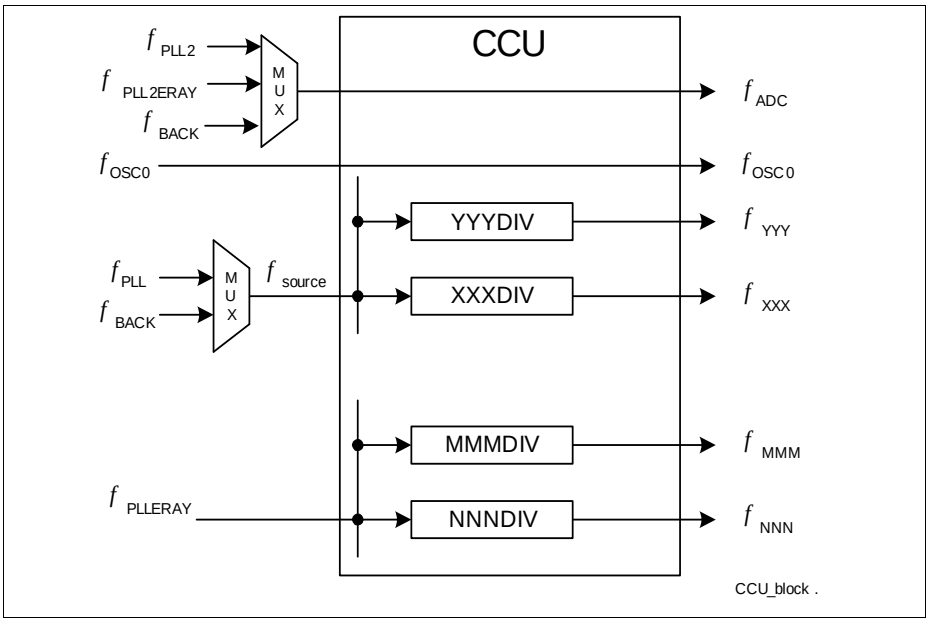

Figure 8-13 Clock Control Unit Overview

For most clocks a linear divider is provided to adapt the clock frequency to the application requirement. This divider is controlled by the bit field XXXDIV.

For the CPU clocks, more sophisticated dividers are implemented. This allows a better precision for the control in clock frequency changes of individual CPUs. This mechanism allows the adaptation of the frequency change to a specific current limit defined by the application.

There is also a fixed reference clock REFCLK1/2 for the debug block, which divides the master clock f_{PLL}/$f_{PLLERAY}$ by 24. This allows the OCDS to generate timestamps independently of the selected SRI and SPB clock speeds.

Basic Clock System Mechanisms

The clocking system offers a lot of options and a high amount of flexibility. Behind this complex clocking system a set of basic ideas is implemented in order to allow a configuration as close as possible to the given application needs.

The heart of the system is a synchronous block including all modules except the ERAY. The heartbeat here is defined by f_{MAX}. f_{MAX} is defined as the highest frequency used inside the system for any clock derived out of f_{SOURCE}.

For different IPs (CPUs, modules or module clusters) options are included to influence the application execution / performance via the clock control.

Following is a brief overview of the different clocks:

- System buses
  - f_{SRI} defines the operating performance of the SRI-Bus and therefore the data exchange rate between all connected masters and slaves
  - f_{SPB} defines the operating performance of the SPB-Bus and therefore the data exchange rate between all connected masters and slaves and the interrupt system
- CPU controls
  - f_{CPU0} defines the execution speed of CPU0
- PMU controls
  - f_{FSI2} defines the execution speed of the PFlash for reading operations
  - f_{FSI} defines the execution speed for all other flash operations
- Peripheral options
  - f_{STM} defines a basic frequency for the STMs independent of the rest of the system (beside the limitations listed in **Table 8-2**). This allows the STMs to operate on a constant frequency.
  - f_{GTM} defines a basic frequency for the GTM independent of the rest of the system (beside the limitations listed in **Table 8-2**). This allows the GTM to operate on a constant frequency.
  - f_{CAN} defines a basic frequency for the MultiCAN independent of the rest of the system (beside the limitations listed in **Table 8-2**). This allows the MultiCAN to operate on a constant baudrate (frequency).
  - $f_{ASCLINS}$ defines a basic frequency for the ASCLINs independent of the rest of the system (beside the limitations listed in **Table 8-2**). This allows the ASCLINs to operate on a constant baudrate (frequency).
- Debug system
  - As debugging should be non-intrusive to the application system, a separate clock f_{BBB} for dedicated debug resources is available. This allows debugging (trace generation) during changes of the other clock configurations. Please note that f_{BBB} needs to be faster than or equal to f_{SPB} for debug.

In addition several peripherals offer the option to operate on other clock sources. If frequency modulation is used, some peripherals should switch to a non-modulated clock.

Due to its unique requirements the ERAY module is implemented as an asynchronous domain with its own independent clock source.

Table 8-1 CCU Clock Options

CCU Clock Output	Clock Source			
	PLL	PLL_ERAY	Back-up	OSC_XTAL
f_{MAX}	✓	–	Default	–
f_{SRI}	✓	–	Default	–
f_{CPU0}	f_{SRI}	–	–	–
f_{SPB}	✓	–	Default	–
f_{FSI}	f_{SRI}	–	–	–
f_{FSI2}	f_{SRI}	–	–	–
$f_{REFCLK1/2}$	✓	✓	Default	–
f_{BBB}	✓	–	Default	–
f_{ERAY}	–	Default	–	–
f_{GTM}	✓	–	Default	–
f_{STM}	✓	–	Default	–
f_{BAUD2}	✓	–	Default	–
f_{CAN}	✓	–	Default	–
$f_{ASCLINF}$	✓	–	Default	–
$f_{ASCLINS}$	✓	–	Default	–

The complete system is based on a single clock (f_{SOURCE}) in order to achieve the performance advantage of a synchronous system. Therefore certain limitations have to be considered when configuring the clock control options.

Clock Divider Limitations

For the clock dividers which control the different sub-clock domains / modules the allowed values are limited and the following ratios have to be observed. The ratios are defined in the following way: clock A = f_{AAA}; clock B = f_{BBB} the allowed ratio is 1 : n where n has a defined range of values. Clock A is always faster or equal to clock B in this definition with f_{AAA} [MHz] = n * f_{BBB} [MHz].

In addition the divider values are limited by the resulting maximum frequencies . These allowed max. frequencies are defined in the Target Data Sheet / ACDC Target Specification.

Table 8-2 CCU allowed Clock Ratios

Clock A	Clock B	Allowed Ratios [1]	Recommended Default
f_{SRI}	f_{SPB}	1 : n; n = 1, 2, 3, 4, 5, 6	n = 2
f_{SRI}	f_{FSI}	1 : n; n = 1, 2	n = 2
f_{SRI}	f_{FSI2}	1 : n; n = 1, 2	n = 1
f_{FSI2}	f_{FSI}	1 : n; n = 1, 2	n = 2
f_{GTM}	f_{SPB}	1 : n [2]; n = 1, 2, 3, 4, 5,...	n = 1
f_{SPB}	f_{GTM}	1 : n [2]; n = 1, 2, 3, 4, 5,...	n = 1
f_{SPB}	f_{STM}	1 : n [3]; n = 1, 2, 3, 4, 5,...	n = 1
f_{STM}	f_{SPB}	1 : n [3]; n = 1, 2, 3, 4, 5,...	n = 1
f_{SRI}	f_{BBB} [4]	1 : n; n = 1, 2	n = 2
f_{BAUD2}	f_{SPB}	1 : n [5]; n = 1, 2, 3, 4, 5,...	n = 2
f_{SPB}	f_{BAUD2}	1 : n [5]; n = 1, 2, 3, 4, 5,...	-
f_{CAN}	f_{SPB}	1 : n [6]; n = 1, 2, 3, 4, 5,...	n = 1
f_{SPB}	f_{CAN}	1 : n [6]; n = 1, 2, 3, 4, 5,...	-
$f_{ASCLINF}$	f_{SPB}	1 : n [7]; n = 1, 2, 3, 4, 5,...	n = 2
f_{SPB}	$f_{ASCLINF}$	1 : n [7]; n = 1, 2, 3, 4, 5,...	-
$f_{ASCLINS}$	f_{SPB}	1 : n [8]; n = 1, 2, 3, 4, 5,...	n = 1
f_{SPB}	$f_{ASCLINS}$	1 : n[8]; n = 1, 2, 3, 4, 5,...	-

1) Configuring the registers CCUCON0, CCUCON1 and CCUCON2 to values that result in a violation of the allowed ratios are not allowed even if a single configuration entery for a bit field is with the allowed register bit field description.

2) f_{GTM} can be faster, slower, or equal to f_{SPB}

3) f_{STM} can be faster, slower, or equal to f_{SPB}

4) f_{BBB} has to be faster, or equal to f_{SPB}

5) f_{BAUD2} can be faster, slower, or equal to f_{SPB}

6) f_{CAN} can be faster, slower, or equal to f_{SPB}

7) $f_{ASCLINF}$ can be faster, slower, or equal to f_{SPB}

8) $f_{ASCLINS}$ can be faster, slower, or equal to f_{SPB}

Note: Recommended values did not necessarily reflect the default configuration after a reset event. Instead they should give a hint how the configure the system for a optimal performance configuration.

CCU Registers

*Note: The relation in between the described CCUCONx.yyyDIV bit fields is described in the table **CCU allowed Clock Ratios**.*

8.1.4 Individual Clock Generation

Each module provides some individual clock control options. Most modules provide a Clock Control (CLC) Register for this purpose. Some modules provide in addition more options to control the clocks. For more details please see the dedicated module chapters.

Modules can have in addition other registers controlling sub-clock domains e.g. for baud rate generation. These registers are always defined in the module chapters.

8.1.4.1 Clock Control Register CLC

All CLC registers have basically the same bit and bit field layout. However, not all CLC register functions are implemented for each peripheral module. **Table 8-3** defines in detail which bits and bit fields of the CLC registers are implemented for each clock control register.

The following functions for the module are associated with the CLC register:

- Peripheral clock static on/off control
- Module clock behavior in Sleep Mode

Module Enable/Disable Control

If a module is not used at all by an application, it can be completely shut off by setting bit DISR in its CLC register. For peripheral modules with a run mode clock divider field RMC, a second option to completely switch off the module is to set bit field RMC to 00_H. This also disables the module's operation.

The status bit DISS always indicates whether a module is currently switched off (DISS = 1) or switched on (DISS = 0).

Write operations to the non CLC registers of disabled modules are not allowed. However, the CLC of a disabled module can be written. An attempt to write to any of the other writable registers of a disabled module except CLC will cause the corresponding Bus Control Unit (BCU) to generate a bus error.

A read operation of registers of a disabled module is allowed and does not generate a bus error.

When a disabled module is switched on by writing an appropriate value to its MOD_CLC register (DISR = 0 and RMC (if implemented) > 0), status bit DISS changes from 1 to 0. During the phase in which the module becomes active, any write access to corresponding module registers (while DISS is still set) will generate a bus error. When enabling a disabled module, application software should read back the CLC register once, to check that DISS is cleared, before writing to any module register (including the CLC register).

Sleep Mode Control

The EDIS bit in the CLC register controls whether or not a module is stopped during Sleep Mode. If EDIS is 0, a Sleep Mode request can be recognized by the module and, when received, its clock is shut off.

If EDIS is set to 1, a Sleep Mode request is disregarded by the module and the module continues its operation.

Entering Disabled Mode

Software can request that a peripheral unit be put into Disabled Mode by setting DISR. A module will also be put into Disabled Mode if the Sleep Mode is requested and the module is configured to allow Sleep Mode.

In Secure Shut-off Mode, a module first finishes any operation in progress, then proceeds with an orderly shut down. When all sub-components of the module are ready to be shut down, the module's clock control unit turns off the clock. The status bit DISS is updated by the peripheral unit accordingly.

Module Clock Divider Control

Peripheral modules of the TC21x/TC22x/TC23x can have a RMC control bit field in their CLC registers. This Run Mode Clock control bit field makes it possible to slow down the CLC clock via a programmable clock divider circuit.

A value of 00_H in RMC disables the clock signals to these modules (CLC clock is switched off). If RMC is not equal to 00_H, the clock for a module register (f_{CLC}) accesses is generated as

(8.23)

$$f_{CLC} = \frac{f_{SPB}}{RMC}$$

where RMC is the content of its CLC register RMC field with a range of 1 to 255. If RMC is not available in a CLC register, the CLC clock frequency f_{CLC} is always equal to the frequency of f_{SPB}.

Note: The number of module clock cycles (wait states) that are required for a "destructive read" access (means: flags/bits are set/cleared by a read access) to a module register of a peripheral unit depends on the selected CLC clock frequency.
Therefore, a slower CLC clock (selected via bit field RMC in the CLC register) may result in a longer read cycle access time on the SPB for peripheral units with "destructive read" access.

Module Clock Register Implementations

Table 8-3 shows which of the CLC register bits/bit fields are implemented for each peripheral module in the TC21x/TC22x/TC23x.

Table 8-3 Clock Generation Implementation of the TC21x/TC22x/TC23x Peripheral Modules

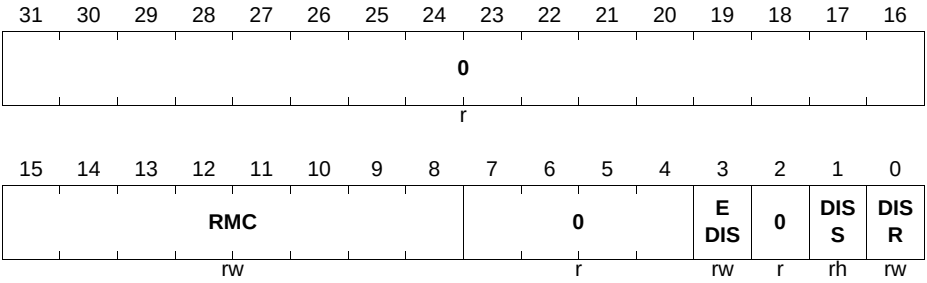
Module CLC Register

MOD_CLC
Clock Control Register **(00_H)** **Reset Value: Module-specific**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested 1_B Module disable is requested
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module 0_B Module is enabled 1_B Module is disabled If the RMC field is implemented and if it is 0, DISS is set automatically.
EDIS	3	rw	**Sleep Mode Enable Control** Used for module Sleep Mode control. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered on a request.
RMC	[15:8]	rw	**8-Bit Clock Divider Value in RUN Mode** This is a maximum 8-bit divider value for clock f_{SPB}. If RMC is set to 0 the module is disabled.
0	2, [7:4], [31:16]	r	**Reserved** Read as 0; should be written with 0.

8.1.5 Clock Monitors

For safety reasons clock monitors are available. For the following safety relevant clocks in the system monitors are present:

f_{PLL}
f_{PLL_ERAY}
f_{SRI}
f_{SPB}
f_{GTM}
f_{STM}

Each of these clocks is monitored by its own counter.

As reference clock the back-up clock is used as diverse clock source.

The divider has to be set in a way that the monitored frequency is one of the possible frequencies of **Table 8-4**.

Operating the Clock Monitors

The clock monitors are implemented in a way that safety system requirements are supported for a flexible system configuration of the clock system. So it is possible to adapt the monitor configuration to the application configuration of the clock system.

For each clock monitor two bit fields are available, either in register CCUCON3 or CCUCON4 depending on the monitor.

For each monitor a divider bit field and a select bit field are available for the configuration.

The CCUCONy.SELXXX bit filed defines one target frequency out of four predefined options.

Bit field CCUCONy.DIVXXX is used to divide the real clock frequency down to the selected target frequency.

Example: if the SPB is configured to operate at 100 MHz and needs to be monitored, CCUCON3.SBPDIV should be written with 0x14 and CCUCON3.SBPSEL with 00_B. This selects a target monitoring frequency of 5 MHz and divides the SPB clock by 20 resulting also in 5 MHz. If the SPB is configured to operate at 20 MHz and needs to be monitored, CCUCON3.SBPDIV should be written with 0x04 and CCUCON3.SBPSEL with 00_B.

The four target frequencies are selected in a way that all normally used frequency in a system can be covered. This means that frequencies like 66 MHz, 120 MHz, 130 MHz, 133 MHz, ... can be monitored.

Goal of the clock monitoring is to detect and signal clock malfunctions before these errors lead to not longer working system. Therefore the back-up clock is trimmed automatically and operated on f_{BACKT}. This setup guarantees that error are detected before the system could not react anymore

Table 8-4 Target trimmed Check limits

Target Frequency	LOWER value	UPPER value	SELXXX	Error can be detected for min. deviation	Error is detected for min. deviation
7.5 MHz	0x24	0x27	11_B	-1.23% +1.56%	-8.56% +9.44%
$6.\overline{6}$ MHz	0x20	0x23	10_B	-0.9% +2.38%	-8.59% +11.11%
6 MHz	0x1C	0x1F	01_B	-3.23% +1.56%	-11.13% +10.11%
5 MHz	0x17	0x1A	00_B	-3.9% +2.83%	-12.41% +12.11%

An error is detected if the reference counter has an overflow and the monitor counter of the dedicated clock is either below the lower limit (clock too slow) or greater as the upper limit (clock too fast). Errors are signaled to the SMU where the further reaction can be configured.

In addition there is a fast upper limit checking for the SPB frequency available. This limit checking checks only for high SPB compared to the maximum allowed value. A violation generates a trigger.

An error is detected when the reference counter generates an overflow AND:

- Counter_value - UPPER > 0 for the upper limit
- OR
- LOWER - Counter_value > 0 for the upper limit

Note: This feature is supported by the Infineon safety driver [safTlib] and there is no additional customer software required.

8.1.5.1 Clock Monitor Registers

These registers can be accessed by all CPUs in the system. Anyway it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU after each reset this is the best choice.

CCUCON3
CCU Clock Control Register 3

(044_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LCK	UP	SLCK	0					SRISEL		SRIDIV					
rh	w	rw	r					rw		rw					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PLLERAYSEL		PLLERAYDIV						PLLSEL		PLLDIV					
rw		rw						rw		rw					

Field	Bits	Type	Function
PLLDIV	[5:0]	rw	**PLL Divider Value** The resulting monitoring frequency is configured to $f_{PLLMON} = f_{PLL}$ / PLLDIV. For PLLDIV = 0000_B the monitoring is disabled.
PLLSEL	[7:6]	rw	**PLL Target Monitoring Frequency Selection** 00_B 5 MHz is selected as target monitoring frequency 01_B 6 MHz is selected as target monitoring frequency 10_B 6.6 MHz is selected as target monitoring frequency 11_B 7.5 MHz is selected as target monitoring frequency
PLLERAYDIV	[13:8]	rw	**PLL_ERAY Divider Value** The resulting monitoring frequency is configured to $f_{PLLERAYMON} = f_{PLLERAY}$ / PLLERAYDIV. For PLLERAYDIV = 0000_B the monitoring is disabled.

Field	Bits	Type	Function
PLLERAYSEL	[15:14]	rw	**PLL_ERAY Target Monitoring Frequency Selection** 00_B 5 MHz is selected as target monitoring frequency 01_B 6 MHz is selected as target monitoring frequency 10_B 6.$\overline{6}$ MHz is selected as target monitoring frequency 11_B 7.5 MHz is selected as target monitoring frequency This bit field is not link to the update handshake defined by bits UP and LCK. Always a new value (different number) is written to this bit field an update is done. If the same value is written again no update is started.
SRIDIV	[21:16]	rw	**SRI Divider Value** The resulting monitoring frequency is configured to $f_{SRIMON} = f_{SRI}$ / SRIDIV. For SRIDIV = 0000_B the monitoring is disabled.
SRISEL	[23:22]	rw	**SRI Target Monitoring Frequency Selection** 00_B 5 MHz is selected as target monitoring frequency 01_B 6 MHz is selected as target monitoring frequency 10_B 6.$\overline{6}$ MHz is selected as target monitoring frequency 11_B 7.5 MHz is selected as target monitoring frequency
UP	30	w	**Update Request** This bit triggers the update for the CCU, beside CCUCON3.PLLERAY. Please note that setting this bit request a CCU update based on both registers (CCUCON3 and CCUCON4), so only one UP bit have to be set. 0_B No action 1_B A new complete parameter set is transferred to the CCU. Both registers CCUCON3 and 4 content is taken by CCU. This bit always read as zero.

Field	Bits	Type	Function
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and can not be updated
0	[28:24]	r	**Reserved** Read as 0; should be written with 0.

CCUCON4
CCU Clock Control Register 4

(048_H) **Reset Value: 0000 0000$_H$**

Field	Bits	Type	Function
SPBDIV	[5:0]	rw	**SPB Divider Value** The resulting monitoring frequency is configured to $f_{SPBMON} = f_{SPB}$ / SPBDIV. For SPBDIV = 0000_B the monitoring is disabled.
SPBSEL	[7:6]	rw	**SPB Target Monitoring Frequency Selection** 00_B 5 MHz is selected as target monitoring frequency 01_B 6 MHz is selected as target monitoring frequency 10_B 6.$\overline{6}$ MHz is selected as target monitoring frequency 11_B 7.5 MHz is selected as target monitoring frequency

Field	Bits	Type	Function
GTMDIV	[13:8]	rw	**GTM Divider Value** The resulting monitoring frequency is configured to $f_{GTMMON} = f_{GTM}$ / GTMDIV. For GTMDIV = 0000_B the monitoring is disabled.
GTMSEL	[15:14]	rw	**GTM Target Monitoring Frequency Selection** 00_B 5 MHz is selected as target monitoring frequency 01_B 6 MHz is selected as target monitoring frequency 10_B 6.$\overline{6}$ MHz is selected as target monitoring frequency 11_B 7.5 MHz is selected as target monitoring frequency
STMDIV	[21:16]	rw	**STM Divider Value** The resulting monitoring frequency is configured to $f_{STMMON} = f_{STM}$ / STMDIV. For STMDIV = 0000_B the monitoring is disabled.
STMSEL	[23:22]	rw	**STM Target Monitoring Frequency Selection** 00_B 5 MHz is selected as target monitoring frequency 01_B 6 MHz is selected as target monitoring frequency 10_B 6.$\overline{6}$ MHz is selected as target monitoring frequency 11_B 7.5 MHz is selected as target monitoring frequency
UP	30	w	**Update Request** This bit triggers the update for the CCU, beside CCUCON3.PLLERAY. Please note that setting this bit request a CCU update based on both registers (CCUCON3 and CCUCON4), so only one UP bit have to be set. 0_B No action 1_B A new complete parameter set is transferred to the CCU. Both registers CCUCON3 and 4 content is taken by CCU. This bit always read as zero.

Field	Bits	Type	Function
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and can not be updated
0	[28:24]	r	**Reserved** Read as 0; should be written with 0.

8.1.6 Clock Emergency Behavior

In case of a clock error the CCU switches to the back-up clock f_{BACK} as clock source. The only exception here is the ERAY clock f_{ERAY} that stays operating on the PLL_ERAY. A clock error is defined by a loss of lock event of the PLL (not PLL_ERAY) while operating in Normal Mode or by an error of the PLL clock monitor.

*Note: After a clock emergency bit field CCUCON0.CLKSEL has to be re-written following a reconfigfuration of the clock system (see also **Page 8-79**) when the root cause for the clock error disappears.*

*Note: After a clock emergency bit field PLLCON0.SETFINDIS / PLLERAYCON0.SETFINDIS has to be set following by PLLCON0.CLRFINDIS / PLLERAYCON0.CLRFINDIS clear before a reconfiguration of the clock system (see also **Page 8-79**) when the root cause for the clock error disappears.*

8.1.7 External Clock Output

Two external clock outputs are provided via pins EXTCLK0 and $\overline{\text{EXTCLK1}}$. These external clocks can be enabled/disabled via bits EXTCON.EN0 for EXTCLK0 and EXTCON.EN1 for EXTCLK1. Each of the clocks that defines a clock domain can individually be selected to be seen at pins EXTCLK0 or EXTCLK1, this is configured via bit field EXTCON.SEL0/1. Changing the content of bit field EXTCON.SEL0/1 can lead to spikes at pins EXTCLK0/1.

8.1.7.1 Programmable Frequency Output for EXTCLK0

This section describes the external clock generation using the Fractional Divider.

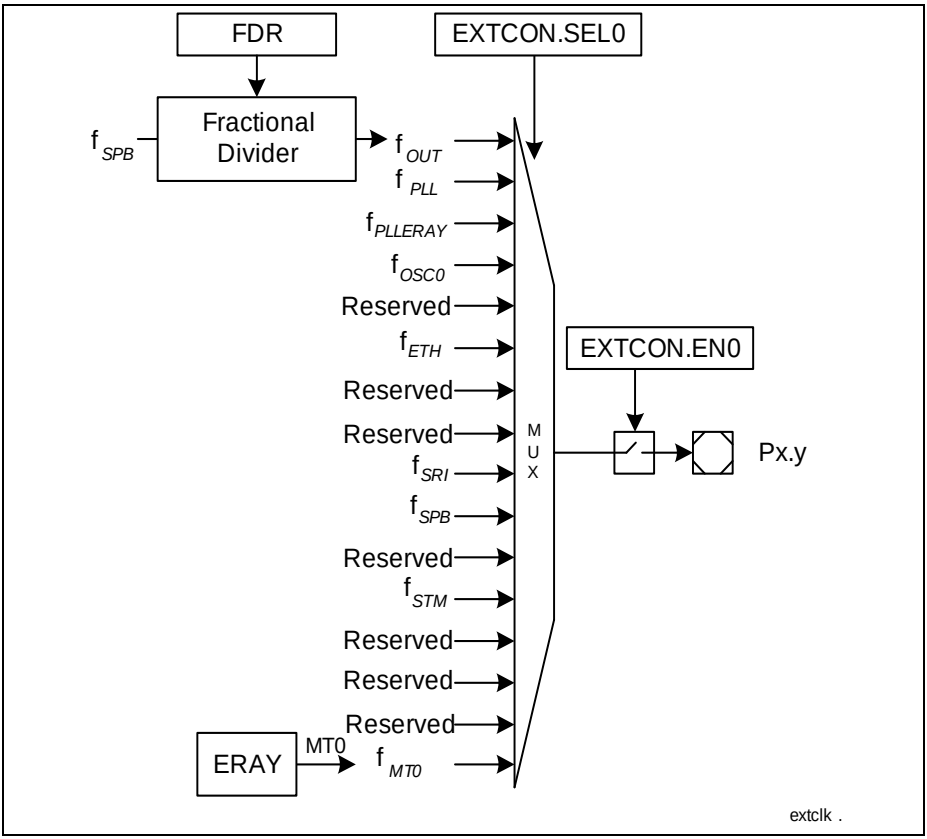

Figure 8-14 EXTCLK0 Generation

Overview

The fractional divider makes it possible to generate a external clock from the SPB clock using a programmable divider. The fractional divider divides the input clock f_{SPB} either by the factor 1/n or by a fraction of n/1024 for any value of n from 0 to 1023. This clock is thereafter divided additionally by a factor of two to guarantee a 50% duty cycle and outputs the clock, f_{OUT}. The fractional divider is controlled by the FDR register. **Figure 8-15** shows the fractional divider block diagram.

The adder logic of the fractional divider can be configured for two operating modes:

- Reload counter (addition of +1), generating an output clock pulse on counter overflow
- Adder that adds a STEP value to the RESULT value and generates an output clock pulse on counter overflow

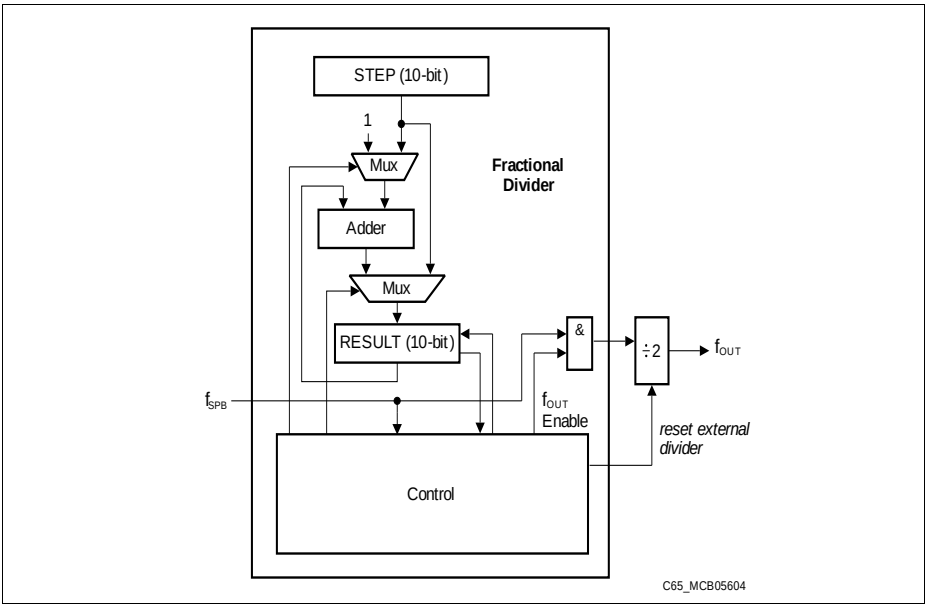

Figure 8-15 Fractional Divider Block Diagram

The adder logic of the fractional divider can be configured for two operating modes:

- **Normal Mode:** Reload counter (RESULT = RESULT + 1), generating an output clock pulse on counter overflow.
- **Fractional Divider Mode:** Adder that adds a STEP value to the RESULT value and generates an output clock pulse on counter overflow.

Fractional Divider Operating Modes

The fractional divider has two operating modes:

- Normal Divider Mode
- Fractional Divider Mode

Normal Divider Mode

In Normal Divider Mode (FDR.DM = 01_B), the fractional divider behaves as a reload counter (addition of +1) that generates an output clock pulse on the transition from $3FF_H$ to 000_H. FDR.RESULT represents the counter value and FDR.STEP determines the reload value.

The output frequencies in Normal Divider Mode are defined according to the following formulas:

$$f_{OUT} = \frac{f_{SPB} \times \frac{1}{n}}{2}, \text{ with } n = 1024 - STEP \quad (8.24)$$

In order to get $f_{OUT} = f_{SPB}/2$ STEP must be programmed with $3FF_H$.

Fractional Divider Mode

When the Fractional Divider Mode is selected (FDR.DM = 10_B), the output is derived from the input clock f_{SPB} by division of a fraction of n/1024 for any value of n from 0 to 1023 followed by the division of two. In general, the Fractional Divider Mode makes it possible to program the average output clock frequency with a higher accuracy than in Normal Divider Mode.

In Fractional Divider Mode, a pulse is generated depending on the result of the addition FDR.RESULT + FDR.STEP. If the addition leads to an overflow over $3FF_H$, a pulse is generated for the divider by two. Note that in Fractional Divider Mode the clock f_{OUT} can have a maximum period jitter of one f_{SPB} clock period.

The output frequencies in Fractional Divider Mode are defined according to the following formulas:

$$f_{OUT} = \frac{f_{SPB} \times \frac{n}{1024}}{2}, \text{ with } n = FDR.STEP = 0\text{-}1023 \quad (8.25)$$

8.1.7.2 Programmable Frequency Output for EXTCLK1

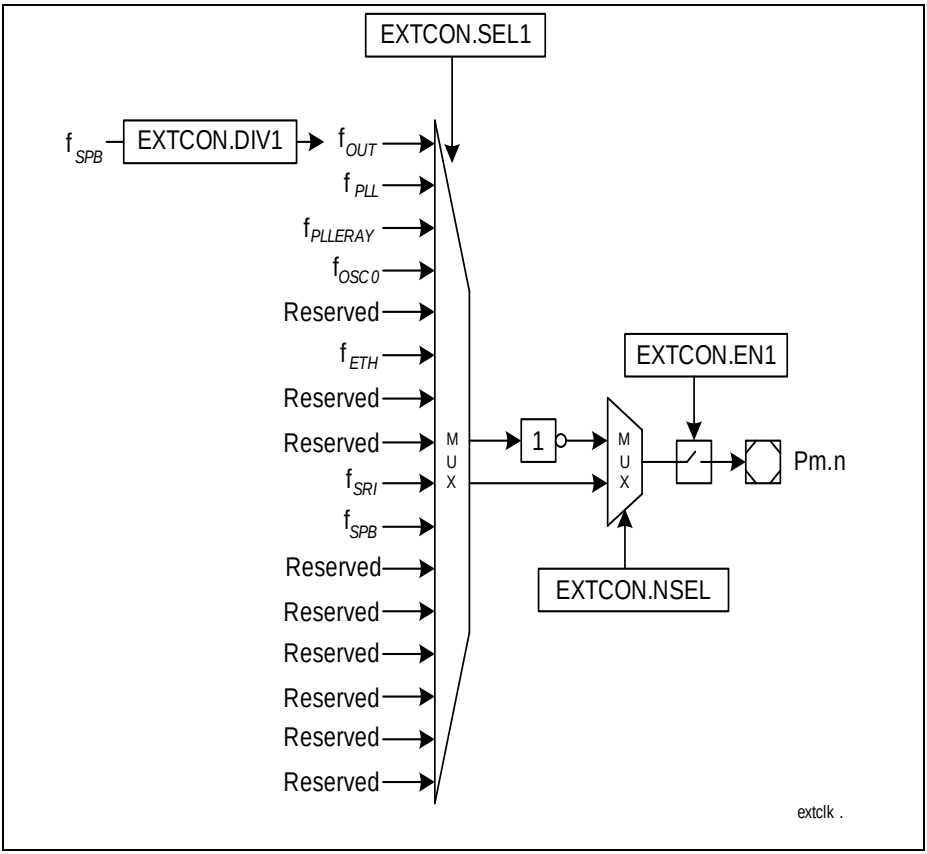

Figure 8-16 EXTCLK1 Generation

Clock f_{OUT} is generated via a counter, so the output frequency can be selected in small steps.

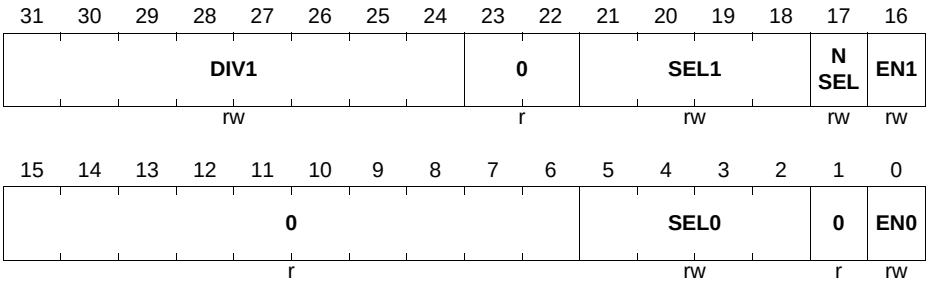
f_{OUT} always provides complete output periods.

Register EXTCON provides control over the output generation (frequency, activation).

8.1.7.3 Clock Output Control Register

These registers can be accessed by all CPUs in the system. Anyway it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU after each reset this is the best choice.

EXTCON
External Clock Control Register ($03C_H$) Reset Value: $0000\ 0000_H$

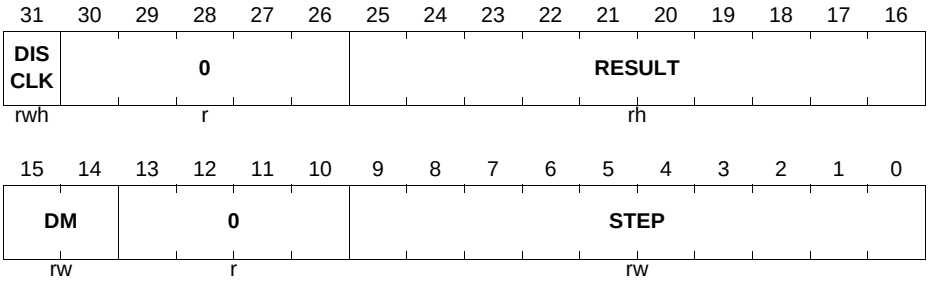


Field	Bits	Type	Description
EN0	0	rw	**External Clock Enable for EXTCLK0** 0_B No external clock is provided 1_B The configured external clock is provided

Field	Bits	Type	Description
SEL0	[5:2]	rw	**External Clock Select for EXTCLK0** This bit field defines the clock source that is selected as output for pin EXTCLK0. 0000_B f_{OUT} is selected for the external clock signal 0001_B f_{PLL} is selected for the external clock signal 0010_B $f_{PLLERAY}$ is selected for the external clock signal 0011_B f_{OSC0} is selected for the external clock signal 0100_B Reserved, do not use this combination 0101_B Reserved, do not use this combination 0110_B Reserved, do not use this combination 0111_B Reserved, do not use this combination 1000_B f_{SRI} is selected for the external clock signal 1001_B f_{SPB} is selected for the external clock signal 1010_B Reserved, do not use this combination 1011_B f_{STM} is selected for the external clock signal 1100_B Reserved, do not use this combination 1101_B Reserved, do not use this combination 1110_B Reserved, do not use this combination 1111_B f_{MT0} from the ERAY module is selected for the external clock signal
EN1	16	rw	**External Clock Enable for $\overline{\text{EXTCLK1}}$** 0_B No external clock is provided 1_B The configured external clock is provided
NSEL	17	rw	**Negation Selection** 0_B The external clock is inverted 1_B The external clock is not inverted

Field	Bits	Type	Description
SEL1	[21:18]	rw	**External Clock Select for EXTCLK1** This bit field defines the clock source that is selected as output for pin EXTCLK1. 0000_B f_{OUT} is selected for the external clock signal 0001_B f_{PLL} is selected for the external clock signal 0010_B $f_{PLLERAY}$ is selected for the external clock signal 0011_B f_{OSC0} is selected for the external clock signal 0100_B Reserved, do not use this combination 0101_B f_{ETH} is selected for the external clock signal 0110_B Reserved, do not use this combination 0111_B Reserved, do not use this combination 1000_B f_{SRI} is selected for the external clock signal 1001_B f_{SPB} is selected for the external clock signal 1010_B Reserved, do not use this combination 1011_B Reserved, do not use this combination 1100_B Reserved, do not use this combination 1101_B Reserved, do not use this combination 1110_B Reserved, do not use this combination 1111_B Reserved, do not use this combination
DIV1	[31:24]	rw	**External Clock Divider for EXTCLK1** This value defines the reload value of the divider that generates f_{OUT} out of f_{SPB} ($f_{OUT} = f_{SPB}/(DIV1+1)$). The divider itself is cleared each time bit EN1 is cleared.
0	1, [15:6], [23:22]	r	**Reserved** Read as 0; should be written with 0.

FDR
Fractional Divider Register **(038_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** In Normal Divider Mode, STEP contains the reload value for RESULT. In Fractional Divider Mode, this bit field determines the 10-bit value that is added to RESULT with each input clock cycle.
DM	[15:14]	rw	**Divider Mode** This bit fields determines the functionality of the fractional divider block. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** In Normal Divider Mode, RESULT acts as reload counter (addition +1). In Fractional Divider Mode, this bit field contains the result of the addition RESULT + STEP. If DM is written with 01_B or 10_B, RESULT is loaded with $3FF_H$.
DISCLK	31	rwh	**Disable Clock** 0_B Clock generation of f_{OUT} is enabled according to the setting of bit field DM. 1_B Fractional divider is stopped. No change except when writing bit field DM.
0	[13:10], [30:26]	r	**Reserved** Read as 0; should be written with 0.

8.1.8 Clock Generation Unit

The Clock Generation Unit (CGU) allows a very flexible clock generation for the TC21x/TC22x/TC23x. During user program execution the frequency can be programmed for an optimal ratio between performance and power consumption.

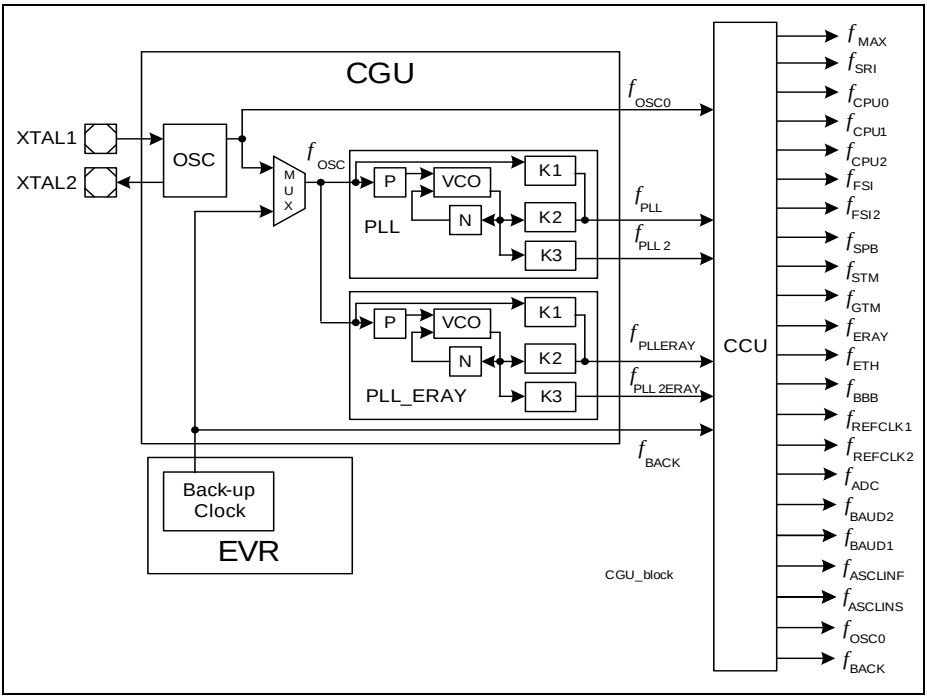


Figure 8-17 Clock Generation Unit Block Diagram

The CGU includes the clock source generation, the clock upscaling beside the clock distribution.

8.1.8.1 Example Sequence

The following sequence give an example for the clock ramp-up.

Goal for normal target setting is that system clock is based on PLL with external crystal.

- After power-on and system reset:
  - the system operates on the back-up clock
  - the oscillator (OSC) needs to be enabled via software or was enabled by firmware via BMI settings
- Fast clocks (SRI-Bus and CPUs) run with approximately 100 MHz

- Peripherals and SPB-Bus run with approximately 50 MHz
- Step 1: If f_{OSC0} is to be used but is not running, enable the oscillator to wait until it is providing a stable clock
- Step 2: Initialize the PLL to target f_{VCO} and f_{PLL} frequency
  - Select PLL input clock via CCUCON1.INSEL
  - Disconnect input clock from VCO; set PLLCON0.SETFINDIS
  - Select P, K2 / K3, and N divider for final target VCO and PLL frequency
  - 1) Select P as small as possible
  - 2) Select N (VCO) as high as possible
  - Connect input clock to VCO; set PLLCON0.CLRFINDIS
  - Configure resulting K2
- Step 3: Wait for PLL lock to be set
- Step 4: Configure CCUCON0, CCUCON1 and CCUCON5 to first target setting
  - Hint: both registers CCUCON0 and CCUCON1 can be reprogrammed without changing the clocking. Only setting the UP bit in one of the two registers transfers the values for both registers and lead to changes in the clock system.
  - Register CCUCON2 has its own UP bit
  - Bit fields CCUCON1.ERAY and CCUCON1.ETH are excluded from the update via UP in CCUCON0 or CCUCON1 and are always updated when a new value is programmed
- Step 5: Switch CCU input clock f_{SOURCE} to PLL via CCUCON0.CLKSEL
- Step 6: After setting CCU f_{SOURCE} to f_{PLL}, frequency has to be increased step by step to target frequency

Important hints for steps 4 and 5;

- Select CCUCON1 and CCUCON0 register settings in a way that the current consumption of the 1.3 V domain does not change more than the desired target value of the application, e.g. 50 mA.

- After every frequency programming step a wait time is recommended until supply ripple caused by supply current transient is faded away.

Note: The wait time between frequency steps depends on the supply and block concept.

- Continue these CCUCON1 and CCUCON0 update steps until the target system frequency is reached.

8.1.9 CCU Register Address

Table 8-5 Registers Address Spaces - CCU Registers

Module	Base Address	End Address	Note
SCU	$F003\ 6000_H$	$F003\ 63FF_H$	-

8.1.10 CCU Kernel Registers

This section describes the CCU kernel registers of the SCU module. Most of CCU kernel register names described in this section will be referenced in other parts of the TC21x/TC22x/TC23x User's Manual by the module name prefix "SCU_".

CCU Kernel Register Overview

Module Base Address + Offset Address (shown in this column)

8.2 Reset Control Unit (RCU)

The Reset Control Unit (RCU) of the TC21x/TC22x/TC23x contains the following functional sub-blocks:

- Basic Reset Operation (see **Section 8.2.1**)
- External Reset sources and indications (see **Section 8.2.2**)
- Software Boot Support (see **Section 8.2.3**)
- NMI Trap Generation (see **Section 8.2.4**)
- RCU register overview table (see **Table 8-17**)

8.2.1 Reset Operation

This section describes the conditions under which the TC21x/TC22x/TC23x will be reset and the reset operation configuration and control.

8.2.1.1 Overview

The following reset request triggers are available:

- Supply monitor (SWD) triggers a power-on reset (cold reset)
- 1.3V EVR monitor triggers a power-on reset (cold reset)
- Standby EVR (STBYR) monitor triggers a power-on reset (cold reset)
- External active low hardware “power-on” reset request trigger; $\overline{\text{PORST}}$ (can be either a warm reset or to extend a cold reset)
- External System Request reset trigger pins; $\overline{\text{ESR0}}$ and ESR1 (warm reset)
- Safety Management Unit (SMU) alarm reset request trigger, (warm reset)
- Software reset (SW), (warm reset)
- System Timer (STMx) trigger (warm reset)
- Resets via the JTAG interface
- JTAG resets (special reset)
- Software triggered module reset
-
-
-

Note: The JTAG resets are described in the OCDS chapter.

8.2.1.2 Reset Types

The following list describes the different reset types.

- Power-on Reset :
  This reset results in initialization of the complete system into a defined state. A Power-on Reset also generates a Debug Reset and a System Reset (and therefore also an Application Reset).
- System Reset :
  This reset leads to a initialization into a defined state of the complete system but without a reset of the power subsystem, debug subsystem or reset configuration registers.
  A System Reset also generates an Application Reset.
- Debug Reset :
  This reset leads to a initialization into a defined state of the complete debug system.
- Application Reset:
  This reset leads to a initialization into a defined state of the complete application system with the following parts: all peripherals, the CPUs and parts of the SCU.

- Module Resets:
  Module resets result in individual modules being initialized into a defined state without any impact on the rest of the system.

8.2.1.3 Reset Sources Overview

The connection of the reset sources and the activated reset signals/domains are shown in **Table 8-7**.

Table 8-7 Effect of Reset Triggers

Reset Request Trigger	Application Reset	Debug Reset	System Reset
$\overline{\text{PORST}}$	Activated	Activated	Activated
$\overline{\text{STBYR}}$	Activated	Activated	Activated
$\overline{\text{SWD}}$	Activated	Activated	Activated
$\overline{\text{EVR13}}$	Activated	Activated	Activated
$\overline{\text{ESR0}}$	Configurable	Not Activated	Configurable
$\overline{\text{ESR1}}$	Configurable	Not Activated	Configurable
SMU	Configurable	Not Activated	Configurable
STM0	Configurable	Not Activated	Configurable
SW	Configurable	Not Activated	Configurable
Cerberus RSTCL0[1)]	Activated	Not Activated	Activated
Cerberus RSTCL1[2)]	Not Activated	Activated	Not Activated
Cerberus RSTCL3[3)]	Activated	Not Activated	Not Activated
Module Resets[4)]	Not Activated	Not Activated	Not Activated

1) Cerberus resets may be triggered by CBS_OCNTRL or CBS_OJCONF
2) Cerberus resets may be triggered by CBS_OCNTRL or CBS_OJCONF
3) Cerberus resets may be triggered by CBS_OCNTRL or CBS_OJCONF
4) Module Resets (via MOD_KRSTx.RST register bits in some modules) have no effect on chip-level reset system. The scope of a module reset is limited to the module itself.

8.2.1.4 Warm and Cold Resets

A cold “power-on” reset is a reset which is triggered for the first time during a system power-up or in response to a temporary power failure. During the power-up the EVR primary undervoltage monitors will trigger a complete reset of the system, placing the system into a known state. The $\overline{\text{PORST}}$ pin can be used to extend this reset phase and control the timing of its release. The pins and internal states are placed immediately into their reset state when the trigger is asserted.

A warm reset is a reset which is triggered while the system is already operational and the supplies remain stable. It is used to return the system to the same known state. On a warm reset request, any reset of pin states will take place immediately, but the internal circuitry will only be reset after the system has been brought into a state where memory contents and debug trace data will not be corrupted and the current consumption has been ramped down. Note that $\overline{\text{PORST}}$ may be asserted as a warm reset.

8.2.1.5 EVR Resets and PORST

The $\overline{\text{PORST}}$ pin is a bidirectional reset in/output intended for external triggering of power-related resets. If this pin is left open then the default behavior shall be that the device remains in a reset state. If the $\overline{\text{PORST}}$ pin remains asserted after a power event then the reset will be extended until it is deasserted. This does not replace the ESR pins functional reset.

8.2.1.6 Module Reset Behavior

Table 8-8 lists how the various functions of the TC21x/TC22x/TC23x are affected by each reset type. An “X” means that this block has at least some register/bits that are affected by the corresponding reset.

Table 8-8 Effect of Reset on Device Functions

Module / Function	Application Reset	Debug Reset	System Reset	Warm “Power-on” Reset	Cold Power-on Reset
All TriCore CPU Core	X	X	X	X	X
Peripherals (except SCU)	X	X	X	X	X

Other	Not affected, reliable	Not affected, reliable	Not affected, reliable	Not affected, reliable	Uninitialized

1) Reliable here means that also the redundancy is not affected by the reset.

2) DSPR is partially used as a scratchpad by the startup firmware. Previous data stored in the upper 32kB will be overwritten on start-up. Auto-initialization on reset can be optionally configured by PROCOND.RAMIN and PROCOND.RAMINSEL. Auto-initialization is disabled for CPU0 DSPR if the standby RAM is enabled.

3) Depending upon PROCOND.RAMIN and RAMINSEL setting, these memories may be automatically erased on cold or warm resets.

4) Tag memories are invalidated by hardware at reset. Depending upon PROCOND.RAMIN setting, cache content may also be automatically erased at reset (See MTU chapter for details).

5) Depending upon PROCOND.RAMIN and RAMINSEL setting, these memories may be automatically erased on cold or warm resets.

8.2.1.7 General Reset Operation

A reset is generated if an enabled reset request trigger is asserted. Most reset triggers can be configured to initiate different types of reset. No action (disabled) is a valid

configuration which is selected by setting the corresponding bit field in the Reset Configuration Register to 00_B.

A Debug Reset can only be requested by dedicated reset request triggers and can not be selected via a Reset Configuration Register . For more information see also register RSTCON.

8.2.1.8 Reset Generation

The figure below shows the RCU controlling the reset generation for the complete device, with the exception of the JTAG reset domain.

Note: The JTAG reset domain is controlled by the $\overline{TRST}$ pin.

The RCU detects the different reset requests, schedules a shutdown of the system, and then generates the appropriate internal reset pulse(s).

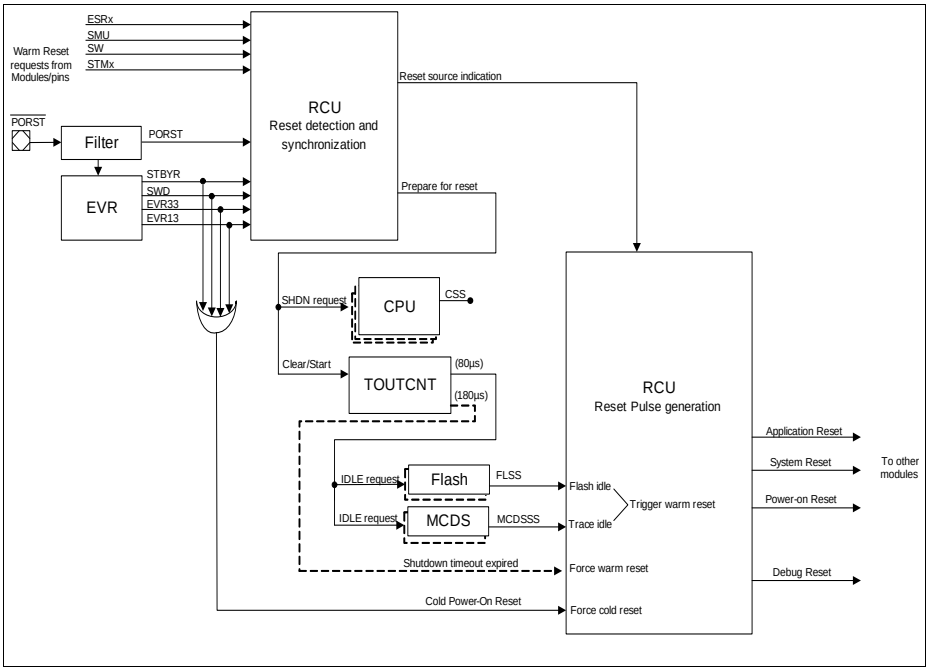

Figure 8-18 Reset Overview

8.2.1.9 Shutdown and Reset Delay Timeout Counter (TOUTCNT)

The system is automatically brought to a stable state before the internal reset(s) are applied so that the RAM content may be reliably reused after a warm reset

On detection of a warm Application Reset, System Reset or Power-On Reset trigger, a Shutdown Trap request is sent by the RCU to the CPU(s). This request causes the CPU(s) which are not already in a halt or idle state to unconditionally execute a ROM shutdown routine which executes a controlled rampdown of the device power consumption (to prevent current jumps which might trigger EVR reset). At the end of this routine each CPU executes a WAIT instruction and stalls, to ensure that all ongoing write transactions have been completed. Interrupts and NMI to the CPUs during the shutdown routine will not reawaken CPUs.

The internal reset starts when all relevant system modules are Idle. If timeout counter TOUTCNT exceeds a timeout period (180 microseconds) before the system become idle then the reset is started regardless. This timeout ensures that a reset would still occur in the case of an internal deadlock.

The RSTCON2.CSS bits indicate whether each CPU successfully flushed its write buffers and reached an idle state before the previous reset. These bits can therefore be used to determine whether RAM content integrity can be trusted after the previous reset cycle.

8.2.1.10 Reset Triggers

There are two types of reset triggers for the reset control logic:

- Triggers that lead to a specific reset
- Triggers that lead to a configurable reset

Specific Reset Triggers

Assertion of these triggers leads to a predefined reset type. These triggers can not be enabled / disabled. All specific reset triggers are listed in **Table 8-9**.

Table 8-9 Specific Reset Triggers

Reset Trigger	Reset Type Request
Cerberus 0 (CB0)	SystemReset
Cerberus 1 (CB1)	DebugReset
Cerberus 3 (CB3)	ApplicationReset
STBYR	Power-on Reset
SWD	Power-on Reset
EVR13	Power-on Reset

Configurable Reset Triggers

Assertion of these triggers leads to a configurable reset type. These triggers can be enabled / disabled. The result of the reset triggers is defined by the corresponding bit field in register RSTCON.

Prevention of Double SMU Resets

After boot firmware initialization, the default behaviour of the SMU/RCU is that a Watchdog timeout would result in an NMI followed by an Application Reset. If an SMU-induced Application Reset occurs twice, a severe system malfunction is assumed and the TC21x/TC22x/TC23x is held in permanent Application Reset until a Power-On or System Reset occurs. This prevents the device from being periodically reset if the application fails to service the watchdog correctly and the watchdog repeatedly times out.

An internal flag is set when the first SMU reset is requested. If a second reset is also requested by the SMU when the internal flag is already set, the double SMU reset event has occurred and a permanent reset request is automatically generated. This internal flag is only reset by a System Reset or when bit WDTSCON1.CLRIRF is set and bit WDTSCON0.ENDINIT has also been set. A correct service of the WDT does not automatically clear this flag.

If this behaviour is undesirable, then the CLRIRF bit should be written by the application during initialization (before the watchdog times out), to clear the flag and prevent any subsequent occurrence of a permanent reset.

Note: If for any reason random code is executed bit field RSTCON.SMU can be updated unintentionally. This can result in an SMU alarm not leading to a reset. To avoid this after the SSW is finished this bit field should be checked and the Safety WDT ENDINIT protection enabled.

8.2.1.11 Debug Reset Specific Behavior

For safety reasons it is required by the debugger that if the OCDS system is disabled a DebugReset is also asserted every time an Application Reset is asserted.

8.2.1.12 Module Resets

Many modules within TC21x/TC22x/TC23x can be reset individually. The module reset has no effect outside the module itself. A module reset can only be triggered by writing ‘1’ into both of the module reset registers MOD_KRST1.RST and register MOD_KRST0.RST.

The Module Reset register bits may only be written by those masters which have been explicitly configured to have module access (See module ACCEN register). In addition, it is only possible to write to these reset bits during the short time window after a correct

ENDINIT password unlock sequence (See Watchdog chapter for details). This prevents accidental module resets by rogue software.

The table below shows the modules which have Module Reset capability

Table 8-10 Module Resets

Module	Module Reset capability
CAN	Module reset implemented in CAN
ASCLIN	Module reset implemented in ASCLIN
Flexray	Module reset implemented in ERAY
QSPI	Module reset implemented in QSPI
ETHERMAC	Module reset implemented in ETHERMAC
SENT	Module reset implemented in SENT
VADC	Module reset implemented in VADC
CCU6	Module reset implemented in CCU6
GPT12	Module reset implemented in GPT12
SMU	Module reset implemented in SMU
STM	Module reset implemented in STM
DMA	Per channel reset implemented in DMA
SCU, RCU, PMC, CCU	No module reset capability
PMU, Flash	No module reset capability
LMU	No module reset capability
PORTS	No module reset capability
IR	No module reset capability
IOM	Module reset implemented in IOM

8.2.1.13 Reset Controller Registers

Status Registers

After a chip level reset has been executed, the Reset Status registers provide information on the trigger of the last reset(s). Warm reset status bits are updated upon each reset cycle. A reset cycle is finished when all resets are de-asserted. Within a reset cycle the status flags are used as sticky flags. Module level resets have no effect on the Reset Status register. Bits which may indicate a cold reset trigger (SWD, PORST and EVR13) provide useful information to the application and are not cleared automatically. The application may clear these bits by writing to bit RSTCON2.CLRC.

RSTSTAT

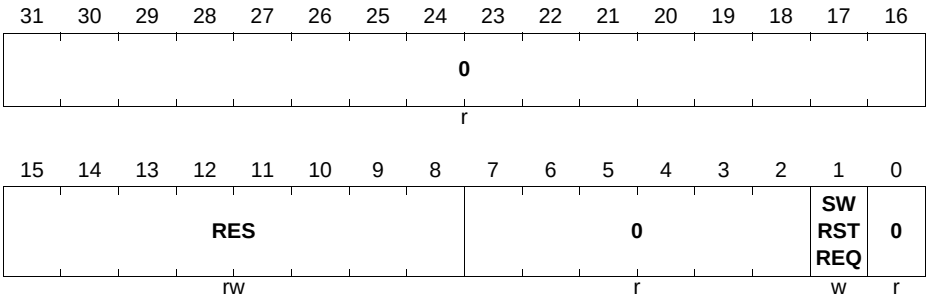
SW Reset Configuration Register

This register controls the SW Reset operation.

As for other kernel registers, write access to the SWRSTCON register is configurable via SCU_ACCEN0 and additionally is temporally restricted by Safe ENDINIT. These restrictions can be used to provide protection against accidental reset by unauthorised CPUs or system bus masters.

SWRSTCON
Software Reset Configuration Register

(060_H) **Reset Value: 0000 XX00$_H$**

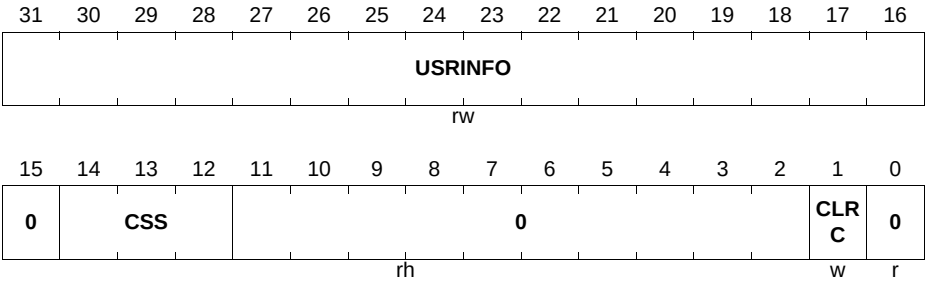


Field	Bits	Type	Description
0	0	rw	**Reserved** Read as 0; should be written with 0.
SWRSTREQ	1	w	**Software Reset Request** 0_B No SW Reset is requested 1_B A SW Reset request trigger is generated This bit is automatically cleared and read always as zero.
RES	[15:8]	rw	**Reserved** Should be written with original content.
0	[7:2], [31:16]	r	**Reserved** Read as 0; should be written with 0.

Additional Reset Control Register

RSTCON2
Additional Reset Control Register

(064_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
USRINFO	[31:16]	rw	**User Information** User data register (Cleared only on Power-on reset).
Reserved	[11:2], 15	r	**Reserved** Internal use only. Bits may read as 0 or 1. Writes have no effect.
CSS2	14	r	**Reserved in this product** Bit reads as ‘1’ after warm reset
CSS1	13	r	**Reserved in this product** Bit reads as ‘1’ after warm reset
CSS0	12	rh	**CPU0 Safe State Reached** The state of CPU0 before the last warm reset If any bit is zero after an Application Reset (or higher) then it is possible that SRAM content could have been corrupted by the reset 0_B CPU0 safe state not achieved prior to last reset 1_B CPU0 in safe state at last reset

Field	Bits	Type	Description
CLRC	1	w	**Clear Cold Reset Status** This bit simultaneously clears the sticky status bits which may indicate any previous cold reset (i.e. RSTSTAT.STBYR, RSTSTAT.SWD, RSTSTAT.EVR33, RSTSTAT.EVR13 and RSTSTAT.PORST). 0_B No effect 1_B Clear cold reset RSTSTAT status bits
0	0	r	**Reserved** Bits read as 0. Should only be written as 0.

8.2.2 External Reset Sources and Indications

ESR interface pins are provided to give an external indication of internal resets, and to provide a mechanism for external sources to trigger internal resets:

ESR pin functions:

- Reset request trigger
- Wakeup trigger
- Reset indication output
- Trap request trigger

8.2.2.1 External Service Requests ($\overline{\text{ESR}}$x)

The ESR pins can be used in various ways:

- ESR inputs can trigger a reset
- ESR outputs can provide a reset indication
- ESR inputs can trigger a trap (NMI)
- ESR pins can be used as general data I/O pins
- ESR inputs can trigger a wake-up from standby mode

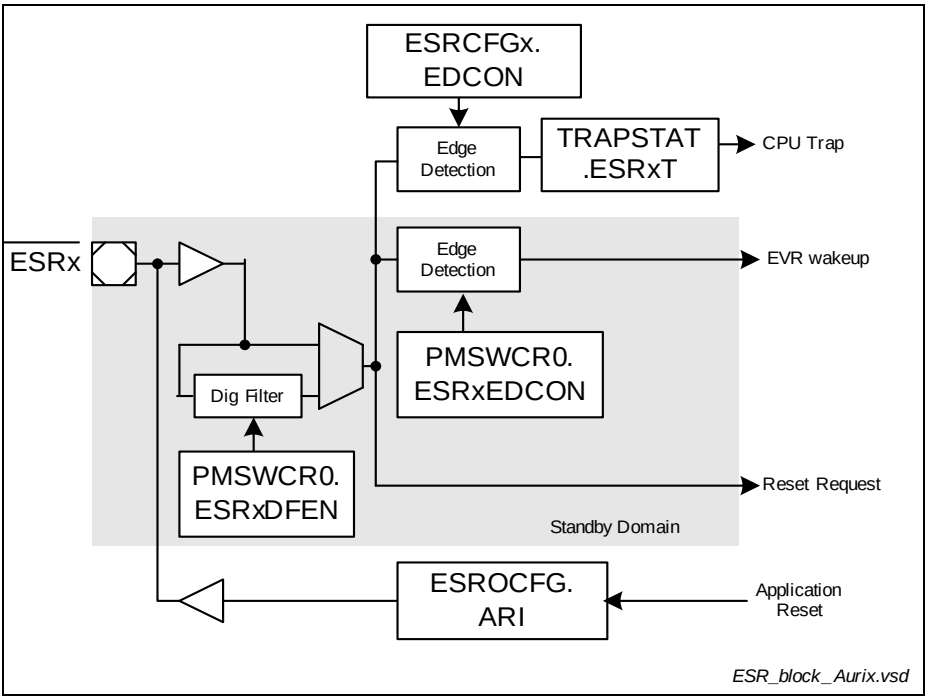


Figure 8-19 ESR Operation

ESRx as Reset Request Trigger

An $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ pin reset request trigger can lead to a Systemor Application Reset. The type of the reset is configured via RSTCON.ESRx.

The input signals $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ can be filtered. The filter can be disabled by register bit PMSWCR0.ESRxDFEN.

If the digital filter is enabled then pulses less than 20ns cannot trigger a reset and pulses longer than 100ns will always result in a trigger..

The behavior of $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ pins can be configured by programming registers ESRCFG0/1. The pad control functionality can be configured independently for each pin. The configuration comprises:

- Selection of driver type (open-drain or push-pull)
- Enable of the output driver (input and/or output capability)
- Enable of internal pull-up or pull-down resistance

ESRx as Reset Output

The external pins $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ can provide a reset output indication (open drain) for Application Resets .

Register ESROCFG.ARI determines the output of the ESR pin(s) when one or more are configured as functional reset outputs. ARI is set automatically when any Application Reset starts and cleared by Boot or Application software (Note that an Application Reset also occurs on a System Reset or Power-On Reset). While the ARI bit is set, the configured ESR pin(s) drive active low. A subsequent write to ESROCFG.ARC clears the ARI bit, which deasserts the ESR output(s). The exact duration of the ESR pulse is determined by the value of the Flash Config Sector setting “ESR0CNT” which is copied by Boot Code into FLASH0_PROCOND.ESR0CNT on a cold power-on reset. The effect of this value is shown in **Table 8-11**. When the same ESR pin is configured as a PORT output, its state can instead be controlled directly by application software so that the application has the possibility to reset external devices.

Do not configure ESR pin to be used as both an output (reset indication or general purpose port) and a reset trigger input simultaneously.

Table 8-11 ESRx Reset Indication Options

ESR0CNT value	ESR Reset Indication Behaviour
0000 0000h	ESR0 deasserted as soon as possible after start of Boot Code execution
> 0000 0000h and < FFFh	ESR0 deasserted after programmed delay (by Boot Code). Boot Code may be extended and Application start may be delayed if programmed delay exceeds the normal Boot Code execution time. Programmed delay is ESR0CNT * 10 microseconds
FFFh	ESR0 not deasserted by Boot Code. Application code must deassert ESROCFG.ARI bit or PORT output to deassert ESRx pin(s).

An external device may extend an existing reset condition by holding the ESR pin active.

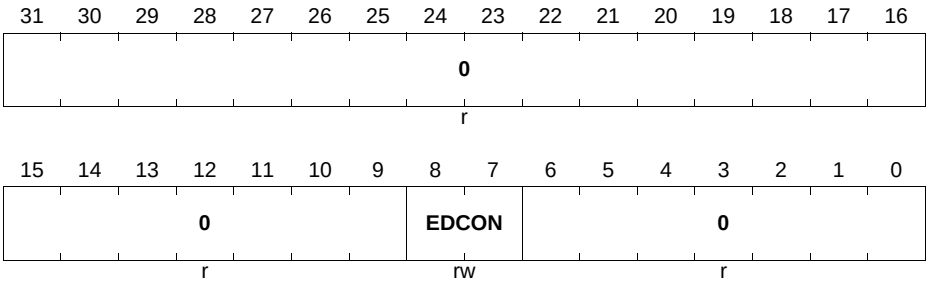
ESR Registers

ESRCFG0
ESR0 Input Configuration Register

(070_H) **Reset Value: $0000\ 0100_H$**

ESRCFG1
ESR1 Input Configuration Register

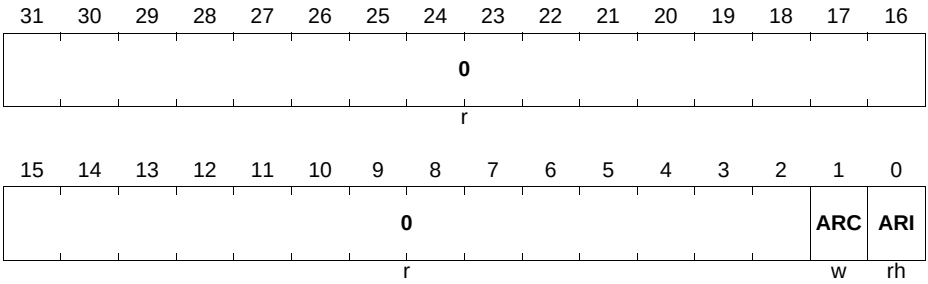
(074_H) **Reset Value: $0000\ 0100_H$**



Field	Bits	Type	Description
0	[6:0]	r	**Reserved** Read as 0; should be written with 0.
EDCON	[8:7]	rw	**Edge Detection Control** This bit field defines the edges that lead to an ESRx trigger of the synchronous path. 00_B No trigger is generated 01_B A trigger is generated upon a rising edge 10_B A trigger is generated upon a falling edge 11_B A trigger is generated upon a rising OR falling edge
0	[31:9]	r	**Reserved** Read as 0; should be written with 0.

ESROCFG
ESR Output Configuration Register

(078_H) **Reset Value: 0000 000X$_H$**

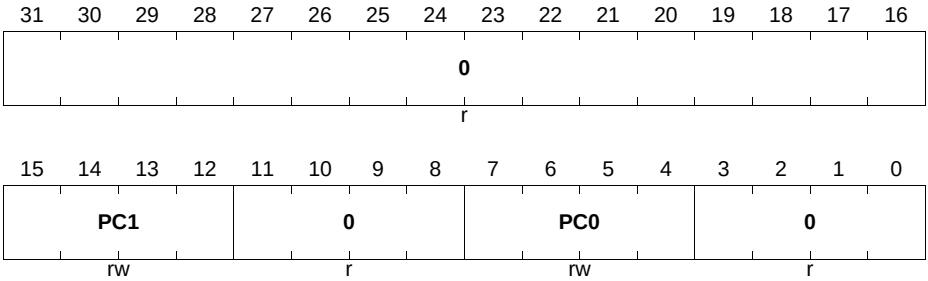


Field	Bits	Type	Description
ARI	0	rh	**Application Reset Indicator** This bit is set when an Application Reset request trigger occurs and cleared by writing to ARC. 0_B No application reset trigger detected (since last clear) 1_B Application reset trigger detected (since last clear) When the ARI bit is set and an ESR pin is configured as a reset output, the corresponding ESR input will not re-trigger a reset. This prevents feedback of the reset indication causing a new reset request. Extension of the reset by an external ESR source is handled by SSW. *Note: Observed reset value after boot will depend upon ARI mode, see **Table 8-11***
ARC	1	w	**Application Reset Indicator Clear** 0_B No effect 1_B Clear Application Reset Indicator (ARI) Read as 0
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

The input/output control registers select the digital output and input driver functionality and characteristics of the pin. Direction (input or output), pull-up or pull-down devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-1).

IOCR

Input/Output Control Register ($0A0_H$) Reset Value: 0000 $20E0_H$



Field	Bits	Type	Description
PC0, PC1	[7:4], [15:12]	rw	**Control for ESR Pin x** This bit field defines the ESR x functionality according to the coding tables (see **Table 8-12** and **Table 8-13**).
0	[3:0], [11:8], [31:16]	r	**Reserved** Read as 0; should be written with 0.

Pad Control Coding

Table 8-12 describes the coding of the PC0 bit field that determine the port line functionality.

Table 8-12 PC0 Coding

PC0[3:0]	I/O	Output Characteristics	Selected Pull-up/Pull-down/ Selected Output Function
$0X00_B$	Input is active and not inverted; Output is inactive		No input pull device connected
$0X01_B$			Input pull-down device connected
$0X10_B$			Input pull-up device connected
$0X11_B$			No input pull device connected
1000_B	Input is active and not inverted; Output is active	Push-pull	General-purpose Output
1001_B			Output drives a 0 for System Resets until ESROCFG.ARI is cleared, a weak pull-up is active otherwise
1010_B			Reserved, do not use this combination
1011_B			Reserved, do not use this combination
1100_B	the input is active and not inverted; Output is active	Open-drain	General-purpose Output
1101_B			Output drives a 0 for System Resets until ESROCFG.ARI is cleared , a weak pull-up is active otherwise
1110_B			Output drives a 0 for Application Resets until ESROCFG.ARI is cleared, a weak pull-up is active otherwise
1111_B			Reserved, do not use this combination

Pad Control Coding

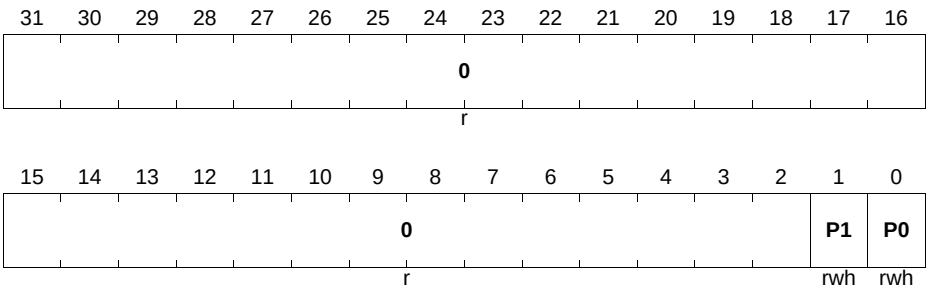
Table 8-13 describes the coding of the PC1 bit field that determine the port line functionality.

Table 8-13 PC1 Coding

PC1[3:0]	I/O	Output Characteristics	Selected Pull-up/Pull-down/ Selected Output Function
$0X00_B$	Input is active and not inverted; Output is inactive		No input pull device connected
$0X01_B$			Input pull-down device connected
$0X10_B$			Input pull-up device connected
$0X11_B$			No input pull device connected
1000_B	Input is active and not inverted; Output is active	Push-pull	General-purpose Output
1001_B			Reserved, do not use this combination
1010_B			Reserved, do not use this combination
1011_B			Reserved, do not use this combination
1100_B	the input is active and not inverted; Output is active	Open-drain	General-purpose Output
1101_B			Reserved, do not use this combination
1110_B			Output drives a 0 for Application Resets until ESROCFG.ARI is cleared, a 'Z' otherwise
1111_B			Reserved, do not use this combination

The output register determines the value of a GPIO pin when it is selected by IOCR as output. Writing a 0 to a OUT.Px (x = 0-1) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that each single bit or group of bits of OUT.Px can be set/cleared by writing appropriate values into the output modification register OMR.

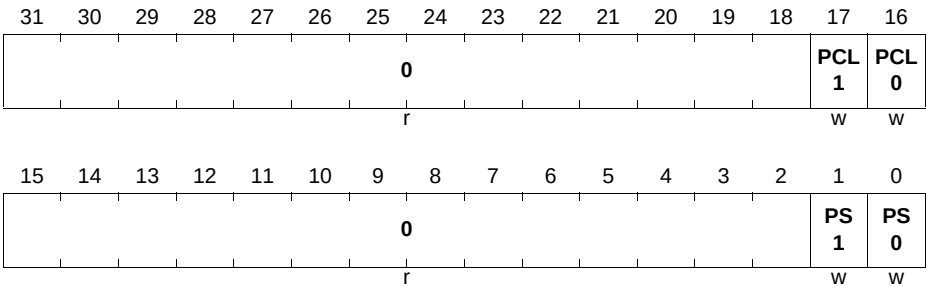
OUT
ESR Output Register **($0A4_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
Px **(x = 0-1)**	x	rwh	**Output Bit x** This bit determines the level at the output pin $\overline{ESR}$x if the output is selected as GPIO output. 0_B The output level of $\overline{ESR}$x is 0 1_B The output level of $\overline{ESR}$x is 1 Px can also be set/cleared by control bits of the OMR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

The output modification register contains control bits that make it possible to individually set, clear, or toggle the logic state of a single pad by manipulating the output register.

OMR
ESR Output Modification Register **($0A8_H$)** **Reset Value: 0000 0000$_H$**



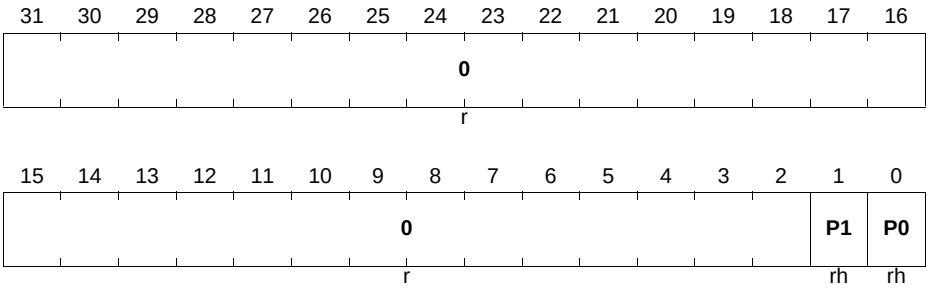
Field	Bits	Type	Description
PSx (x = 0-1)	x	w	**ESRx Pin Set Bit x** Setting this bit will set or toggle the corresponding bit in the output register OUT. The function of this bit is shown in **Table 8-14**. Reading this bit returns 0.
PCLx (x = 0-1)	x + 16	w	**ESRx Pin Clear Bit x** Setting this bit will clear or toggle the corresponding bit in the port output register OUT. The function of this bit is shown in **Table 8-14**. Reading this bit returns 0.
0	[15:2], [31:18]	r	**Reserved** Read as 0; should be written with 0.

Table 8-14 Function of the Bits PCLx and PSx

PCLx	PSx	Function
0	0	Bit OUT.Px is not changed
0	1	Bit OUT.Px is set
1	0	Bit OUT.Px is cleared
1	1	Bit OUT.Px is toggled

The logic level of a GPIO pin can be read via the read-only port input register IN. Reading the IN register always returns the current logical value at the GPIO pin independently whether the pin is selected as input or output.

IN
ESR Input Register **($0AC_H$)** **Reset Value: $0000\ 000X_H$**



Field	Bits	Type	Description
Px **(x = 0-1)**	x	rh	**Input Bit x** This bit indicates the level at the input pin $\overline{ESR}$x. 0_B The input level of ESRx is 0 1_B The input level of ESRx is 1
0	[31:2]	r	**Reserved** Read as 0.

Pad Disable Control Register

The pad structure of the TC21x/TC22x/TC23x GPIO lines offers the possibility to disable pad. This feature can be controlled by individual bits in the pad disable control register PDISC.

PDISC
Pad Disable Control Register **($18C_H$)** **Reset Value: 0000 0000$_H$**

0	[31:8]	rw	**Reserved**

8.2.3 Boot Software Interface

In order to determine the correct starting point of operation for the software a minimum amount of hardware support is required. As much as possible is done via software. Some decisions have to be made in hardware because they must be known before any software is operational.

For a startup operation there are two general cases that have to be handled:

- Differentiation between Test Mode and Normal Mode for each Power-on Reset event (see **Section 8.2.3.1**)
- Configuration of the boot option for each Application Reset event (see **Section 8.2.3.2**)

8.2.3.1 Configuration done with Start-up

At device power-on some basic operating mode selection has to be done. The first decision that has to be made is whether the device should operate in Test Mode or in Normal (Customer) Mode. The Test Mode is only for Infineon internal device testing, it is not intended for any customer and is not related to debug.

If the Normal Mode was selected the next decision is which debug interface type issued for debugging for this session (until the next power-on event).

Table 8-15 Normal Mode / Test Mode Input Selection

Field	Description
TESTMODE	**Latched TESTMODE Signal** 0 A Test Mode can be selected 1 Normal Mode is selected
$\overline{\text{TRST}}$	**Latched $\overline{\text{TRST}}$ Signal** 0 The JTAG interface is active. 1 The DAP interface is active.

After these two decisions were made the detailed decision has to be made to define the real startup configuration. Most is made via the software and can be supported by some hardware selections depending on the startup configuration that should be selected.

8.2.3.2 Start-up Configuration Options

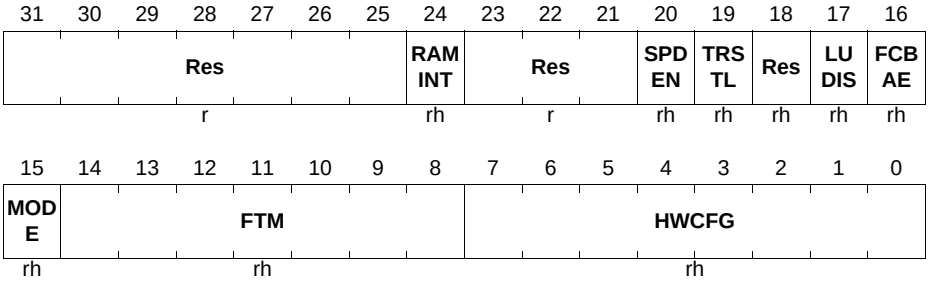
The states of the HWCFG port pin inputs are latched on the rising edge of an Application Reset and stored in register STSTAT.HWCFG. The update of bit field STSTAT.HWCFG with the latched value is only done if bit STSTAT.LUDIS is cleared. If bit STSTAT.LUDIS is set then the value of STSTAT.HWCFG is not updated.

8.2.3.3 Status Registers

Startup Status Registers

Register STSTAT contains the information used by the boot firmware to identify the start-up settings.

STSTAT
Start-up Status Register **($0C0_H$)** **Reset Value: $000X\ 80XX_H$**



Field	Bits	Type	Description
HWCFG	[7:0]	rh	**Hardware Configuration Setting** This bit field contains the value that is used by the boot software. This bit field is updated in case of an ApplicationReset with the content of the latches of the HWCFG port pins if bit STSTAT.LUDIS is cleared. This bit field is left unchanged in case of an ApplicationReset and is not updated with the content of the latches of the HWCFG port pins if bit RSTSTAT.SW are cleared and bit STSTAT.LUDIS is set. This bit field is updated with the value written to bit field STCON.HWCFG on a software write action. *Note: The observed reset value after boot depends upon the state of the HWCFG pins*

Field	Bits	Type	Description
FTM	[14:8]	rh	**Firmware Test Setting** In Normal Mode this bit field is updated with 0000000_B and should be ignored by the boot software.
MODE	15	rh	**MODE** This bit indicates if the Test Mode is entered or not. 0_B A Test Mode can be selected 1_B Normal Mode is selected
FCBAE	16	rh	**Flash Config. Sector Access Enable** 0_B Flash config sector is not accessible. Instead the flash memory area is accessed. 1_B Flash config sector is accessible. The flash memory area can not be accessed. This bit can be cleared by setting bit STCON.CFCBAE. This bit can be set by setting bit STCON.SFCBAE. *Note: Reset value of this bit is 0*
LUDIS	17	rh	**Latch Update Disable** 0_B Bit field STSTAT.HWCFG is automatically updated with the latched value of the HWCFG input pins 1_B Bit field STSTAT.HWCFG is not updated with the latched value of the HWCFG input pins This bit can be set by setting bit SYSCON.SETLUDIS. *Note: Reset value of this bit is 0*
Res	18	rh	**Reserved** **Read as 0; should be written with 0.**
TRSTL	19	rh	**TRSTL Status** This bit simply displays the value of TRSTL.
SPDEN	20	rh	**Single Pin DAP Mode Enable** 0_B Single Pin DAP Mode is disabled 1_B Single Pin DAP Mode is enabled
Res	[23:21]	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
RAMINT	24	rh	**RAM Content Security Integrity** In normal operation this bit can be set or cleared by the application (via SYSCON). If a test boot mode is entered, the bit is automatically cleared (and cannot be set again in test mode) because the content may have been altered 0_B RAM Security Integrity cannot be guaranteed 1_B RAM Security Integrity maintained Note: This bit is reset only by a cold power-on reset.
Res	[31:25]	r	**Reserved** Read as 0; should be written with 0.

8.2.4 NMI Trap Generation

The NMI trap structure is shown in **Figure 8-20**. The trap request trigger or the corresponding trap set bit (in register TRAPSET) can trigger the NMI trap generation. An NMI trap is always issued simultaneously to all CPUs in the system. The trap flag can be cleared by software by writing to the corresponding bit in register TRAPCLR. A NMI request is only generated if the trap source was not disabled. Otherwise only the trap status flag is set but no NMI request is generated.

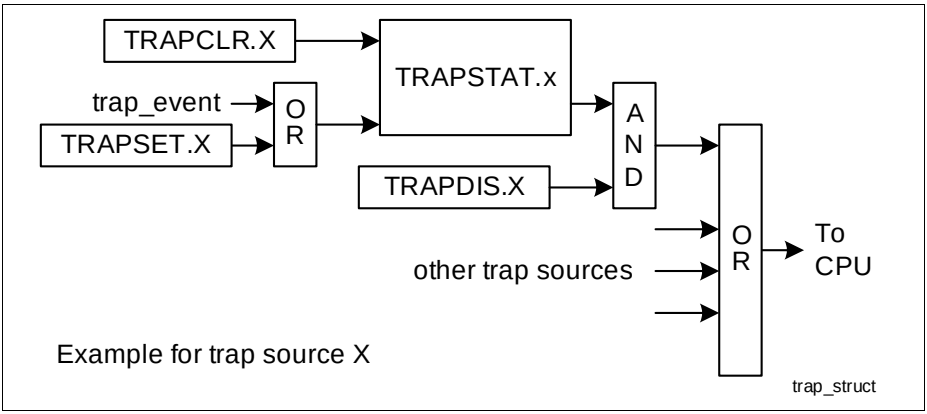


Figure 8-20 NMI Trap Generation

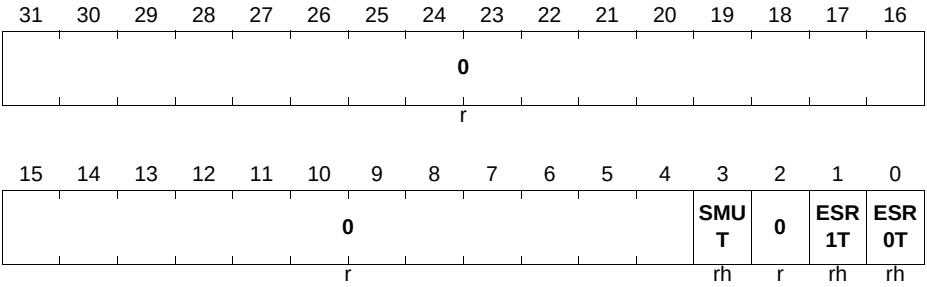
Handling NMI Traps

As an NMI trap is generated while the trap source is enabled AND the trap status flag is set, it is recommended to clear the trap status flag before the trap source is enabled. The trap status flag can be set before the trap source is enabled and simply enabling the trap source can result in unintended NMI traps. At the end of a NMI trap handling routine the trap status flag should be cleared.

8.2.4.1 Trap Control Registers

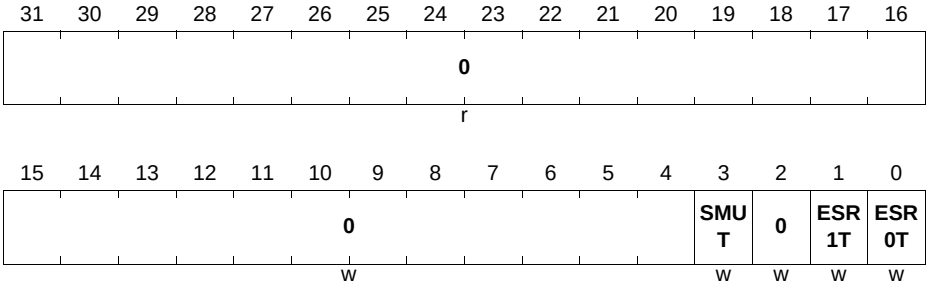
TRAPSTAT
Trap Status Register **(124_H)** **Reset Value: 0000 000X$_H$**



Field	Bits	Type	Description
ESR0T	0	rh	**ESR0 Trap Request Flag** This bit is set if an $\overline{\text{ESR0}}$ event is triggered. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.ESR0T. This bit can be set by setting bit TRAPSET.ESR0T. *Note: Observed reset value after boot will depend upon ARI mode because of ESR pin transition, see **Table 8-11***
ESR1T	1	rh	**ESR1 Trap Request Flag** This bit is set if an $\overline{\text{ESR1}}$ event is triggered. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.ESR1T. This bit can be set by setting bit TRAPSET.ESR1T. *Note: Reset value of this bit is 0*

Field	Bits	Type	Description
SMUT	3	rh	**SMU Alarm Trap Request Flag** This bit is set if an SMU Alarm is indicated . 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.SMUT. This bit can be set by setting bit TRAPSET.SMUT. *Note: Reset value of this bit is 0*
0	2, [31:4]	r	**Reserved** Read as 0.

TRAPSET
Trap Set Register **(128_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
ESR0T	0	w	**Set Trap Request Flag ESR0T** Setting this bit sets bit TRAPSTAT.ESR0T. Clearing this bit has no effect. Reading this bit returns always zero.
ESR1T	1	w	**Set Trap Request Flag ESR1T** Setting this bit sets bit TRAPSTAT.ESR1T. Clearing this bit has no effect. Reading this bit returns always zero.

Field	Bits	Type	Description
SMUT	3	w	**Set Trap Request Flag SMUT** Setting this bit sets bit TRAPSTAT.SMUT. Clearing this bit has no effect. Reading this bit returns always zero.
0	2, [31:4]	r	**Reserved** Read as 0; should be written with 0.

TRAPCLR
Trap Clear Register **(12C$_H$)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.3 Power Supply & Power Management Controller (PMC)

This chapter describes the Power Supply of the TC21x/TC22x/TC23x and the Power Management Controller (PMC).

This is described in the following sections:

- Power Supply and Control (see **Section 8.3.1**)
- Power Management (see **Section 8.3.2**)
- Power Supply and Power Management Registers (see **Table 8-24**)

8.3.1 Power Supply and Control

8.3.1.1 Introduction

On-chip linear and switch mode voltage regulators are implemented in TC21x/TC22x/TC23x thereby enabling a single source power supply concept. The external nominal system supply is 3.3 V. The Embedded Voltage Regulator (EVR13) in turn generate the 1.3 V supply required internally for the core, flash and port domains. Linear Drop Out (LDO) or Switch Mode Power Supply (SMPS) mode may be selected for the EVR13 regulator.

Depending on the chosen EVR mode, the actual power consumption, EMC requirements and thermal constraints of the system; additional external components may be required. It is also possible to supply the 1.3 V supply voltage externally thus ensuring compliance to the legacy supply concept.

All supply and generated voltages are monitored internally against overshoot and brownout conditions based on programmable thresholds. In case these thresholds are violated, either a cold power on reset is triggered or an alarm is provided to the SMU.

All internal supplies except analog domain (V_{AREF} & V_{DDM}) are supplied by the EVRs. The analog supply domain is separated from the main EVR supply domain and can be supplied by separate external regulators or trackers. It is possible to have a unified supply scheme with a 3.3V ADC domain (V_{DDM} / V_{AREFx} = 3.3 V) and the remaining system also running on 3.3 V supply (V_{DDP3} = 3.3 V). Alternatively it is also possible to have a mixed supply scheme with a 5 V ADC domain (V_{DDM} / V_{AREFx} = 5 V) and the remaining system running on 3.3 V supply (V_{DDP3} = 3.3 V).

8.3.1.2 Supply Mode and Topology Selection

The choice of the supply scheme at startup is based on the latched status of HWCFG[0] and HWCFG[2] pins before PORST release and is indicated by **PMSWSTAT**.HWCFGEVR [0,2] status flags. Following supply modes are supported and are further enumerated in **Table 8-18**.

- Single source 3.3 V supply level is supported in following topologies.
  - EVR13 in SMPS mode with external switch capacitors. (TC23x only)
  - EVR13 in LDO mode with internal pass devices. (TC23x & TC22x)
- Supplies are provided externally and the EVR is in disabled state.
  - 3.3 V and 1.3 V are supplied externally.(TC23x & TC22x)

EVR13 is enabled or disabled at startup via the HWCFG[2] configuration pin. The selection between LDO or SMPS topology for EVR13 is decided via HWCFG[0] configuration pin. In case EVR13 SMPS mode is selected, V_{CAP0} and V_{CAP1} pins shall be connected to an external switch capacitor as shown **Figure 8-24**. In case EVR13 LDO mode is selected, V_{CAPx} pin shall be left unconnected.

In case of smaller devices and packages, HWCFG[0,2] configuration pins may be absent and the EVR is active at startup in LDO mode with internal pass devices. In case of TC22x, SC SMPS EVR13 regulator is absent and 1.3 V supply may only be generated using internal LDO pass devices. EVR13 may be disabled via **EVR13CON**.EVR13OFF bit if required. The current state of EVR13 are reflected in **EVRSTAT**.EVR13 flags.All supplies must be available and be stable with the release of the PORST signal.

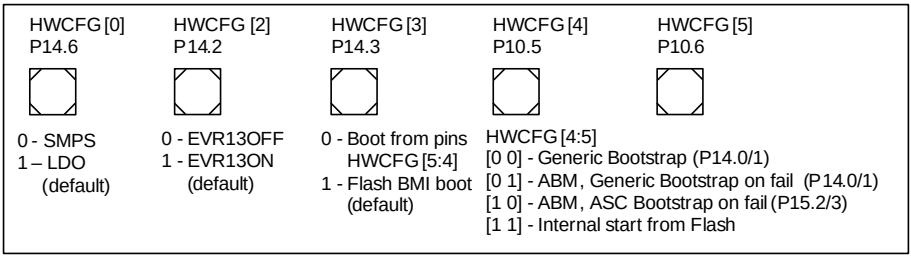
Table 8-18 Supply Mode and Topology selection

No.	HWCFG [0,2][1)]	VCAP0 VCAP1[2)]	Supply Pin Voltage Level / Source[3)]	Selected Supply Scheme
e.)	$0,1_B$	V_{CAP0}/V_{CAP1} pins connected to external flying capacitor.	V_{DDP3}= 3.3V V_{DDM}/V_{AREFx} = 5V / 3.3V V_{DD} = EVR13 SMPS $V_{SS}/V_{SSM}/V_{AGND}$ = 0 V	3.3 V single source supply. EVR13 in SMPS mode with external switch capacitor. 5 V or 3.3 V ADC domain. Standby Mode supported.
f.)	$1,1_B$	V_{CAP0}/V_{CAP1} pins may be left open.	V_{DDP3}= 3.3V V_{DDM}/V_{AREFx} = 5V / 3.3V V_{DD} = EVR13 LDO $V_{SS}/V_{SSM}/V_{AGND}$ = 0 V	3.3 V single source supply. EVR13 in LDO mode with internal pass devices. 5 V or 3.3 V ADC domain. Standby Mode supported.
h.)	$X,0_B$	V_{CAP0}/V_{CAP1} pins shall be left open.	V_{DDP3}= 3.3V V_{DDM}/V_{AREFx} = 5V / 3.3V V_{DD} = 1.3 V $V_{SS}/V_{SSM}/V_{AGND}$ = 0 V	3.3 V and 1.3 V are supplied externally. EVR13 inactive. 5 V or 3.3 V ADC domain. Standby Mode supported and 1.3V supply shall be switched off by external regulator after Standby state is entered.

1) HWCFG[0,2] pins are configured as inputs with weak pull-up after reset, therefore if pins are left unconnected, it is ensured that EVR13 LDO is active by default. These pads have default pull-up during reset unlike the normal port pads which are predominantly in tristate during reset.

2) VCAPx pins are dedicated for SMPS Switch capacitor SMPS mode and cannot be used as port pins, In SMPS mode, the VCAPx shall be connected with a flying capacitor between the pins. Incase of LDO mode, the VCAP pins may be left open or may be connected with a small decoupling capacitor. VCAP pins shall not be connected to ground as ESD diodes start conducting.

3) It shall be ensured that all VDD pins are connected together on PCB level. Likewise It shall be ensured that all VDDP3 pins are connected together on PCB level.



1.) In QFP100 and smaller packages, HWCFG [2] pin is absent and pulled high ensuring EVR13 is active.

2.) Incase HWCFG pins are left unconnected, EVR13 LDO mode is selected owing to default pull-up state.

3.) HWCFG [0:2] pins are latched during supply ramp-up (VDDP3 < 2.97V) and stored in PMSWSTAT.HWCFGEVR & TRIST register bits. The remaining HWCFG pins are latched on internal reset release (between 100us – 180us after reset assertion) and stored in STSTAT register.

Figure 8-21 Hardware Configuration (HWCFG) pins

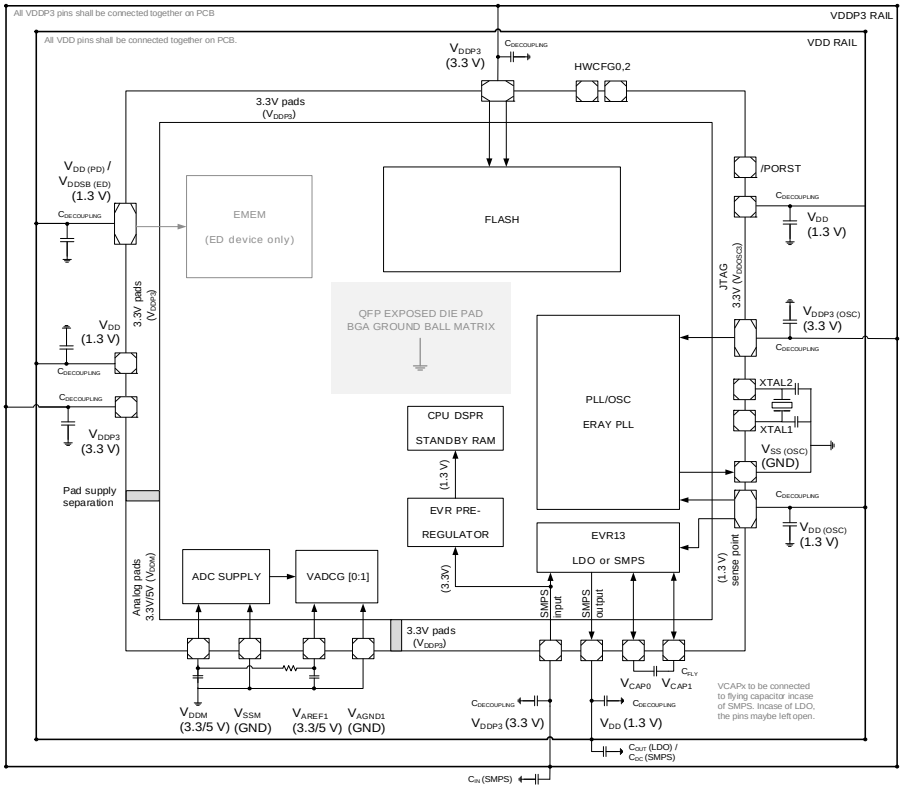


Figure 8-22 Supply Routing

8.3.1.3 Linear Regulator Mode

The LDO part of the EVR is composed of

- Infrastructure components : EVR internal pre-regulator, bandgaps and clock sources
- EVR13 main LDO regulator

The EVR13 regulator supplies mainly the core domain including RAMs. The EVR constitutes a digital regulator, a pass device control unit and a voltage feedback loop. The pass device outputs are appropriately buffered by capacitors to handle load transients so as not to violate the operating voltage limits. The EVR can be individually disabled via HWCFG[2] pin as described in **Chapter 8.3.1.2**. The EVR13 can also be disabled via **EVR13CON**.EVR13OFF protected register bit .

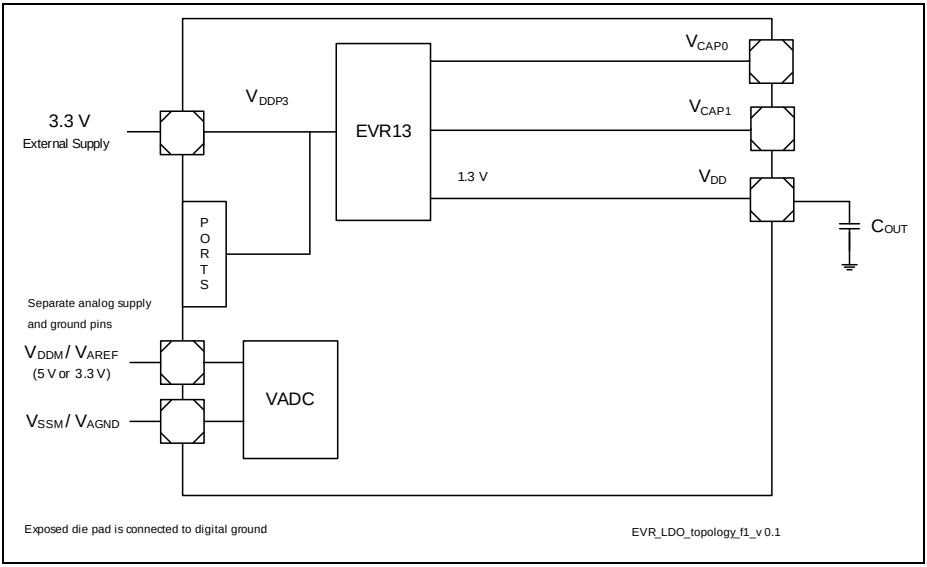

Figure 8-23 EVR LDO topology (f) - 3.3 V single supply with int. pass device

8.3.1.4 Switch Capacitor Regulator Mode

The **S**witch **C**apacitor SMPS regulator provides a higher efficiency of power conversion compared to the linear voltage regulator concept. However it requires additional external components and injects more switching noise into the system. The integrated switch capacitor regulator modulates internal switches to buffer the energy in capacitors in order to generate a regulated core supply. A flying capacitor and a buffer capacitor is required as shown in **Figure 8-24** .

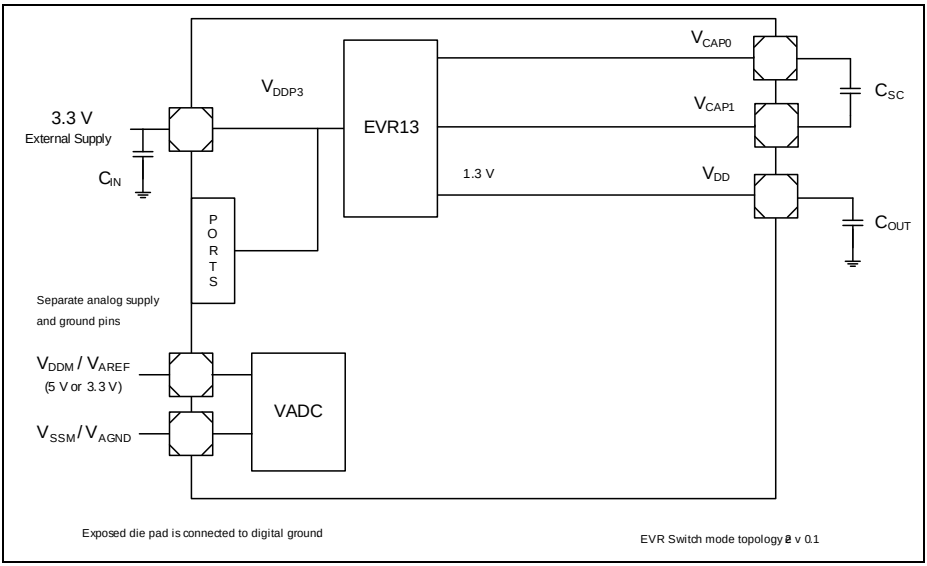

Figure 8-24 EVR Switch mode topology (e) - 3.3 V single supply

The control strategy involves synchronous switching of the 4 switches at a defined switching frequency in conductance modulation mode thus charging and discharging the switch capacitor network. The charge and discharge time are programmable via **EVRSDCTRL1**.TON and TOFF fields which inturn determine the switching frequency. The output voltage is measured via the SMPS ADC module and based on the deviation to the reference voltage the controller modulates the conductance value for the next charge / discharge period. The nominal efficiency of conversion is approximately 75 %. The efficiency of conversion varies within 70 % - 85 % as the input supply varies within the V_{DDP3} +- 10% operation range.

During the start-up phase, a soft-startup control strategy is used in order to avoid an overshoot of the output voltage and the charging of the buffer capacitor takes place gradually. During the initial switching periods a different set of coefficients are used. The start phase ends when the ADC indicates that the output voltage has reached the target value. At this point the PI controller is re-configured and the normal closed loop operation begins. After a voltage transient (typically an overshoot), EVR13 is ready. The step-down regulator and the associated bandgaps are trimmed later to achieve a more accurate output voltage.

In case frequency spreading is activated, the charge and discharge times are appended with a uniform random offset once per switching period. This allows to randomize the switching frequency of the SC DCDC regulator within a maximum value. The maximum random offset can be programmed via **EVRSDCTRL1**.SDFREQSPRD register. It is

possible to synchronize an external step-down regulator which may run at much lower switching frequencies than the internal regulator. A scaled synchronisation clock output is provided and routed to an external pin (P33.11 pin - DCDCSYNC output).

In case the current consumption in SC SMPS mode exceeds the switching regulator capabilities as indicated in the datasheet and the maximum conductance limit is reached, a switch of the switch capacitor mode takes place from 2 : 1 to 1 : 1 mode. A consequent interrupt (SRC_EVRSCDC) is issued to the system. The switch from the SC 2:1 mode (SCMOD = 01b) to SC 1:1 mode (SCMOD = 00b) is also indicated via **EVRSTAT**.SCMOD status bits. The lower bit of **EVRSTAT**.SCMOD[12] signal is used to generate the interrupt on SRC_EVRSCDC interrupt node on a transition from 1 to 0.

It shall be ensured that all the VDD pins are connected together when using SC DCDC regulator. The VDD output pin adjacent to the VCAP pins is separated from the VDD feedback sense pin as shown **Figure 8-22** and needed to be connected together for proper functioning of regulator closed loop.

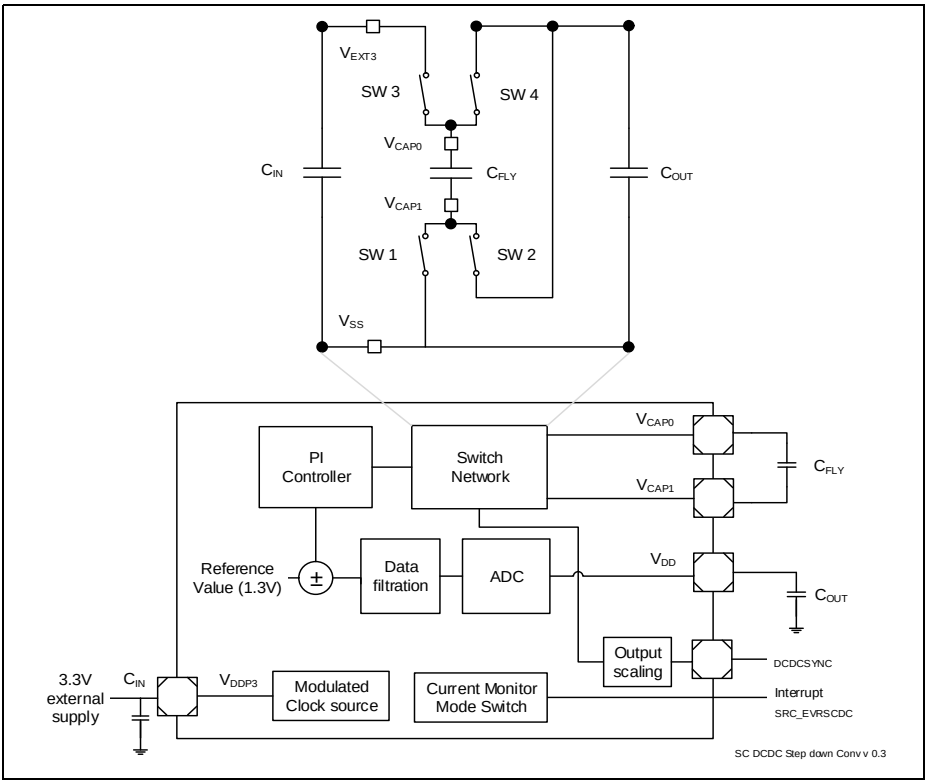

Figure 8-25 Switch Capacitor SMPS regulator

8.3.1.5 External Supply Mode

The external supply mode involves deactivating EVR13 and providing both 3.3 V and 1.3 V supply externally. In this mode, EVR13 is disabled via the HWCFG[2] configuration pin .

Following external supply modes are supported.

- 3.3 V and 1.3 V supplied externally as shown in **Figure 8-26** .

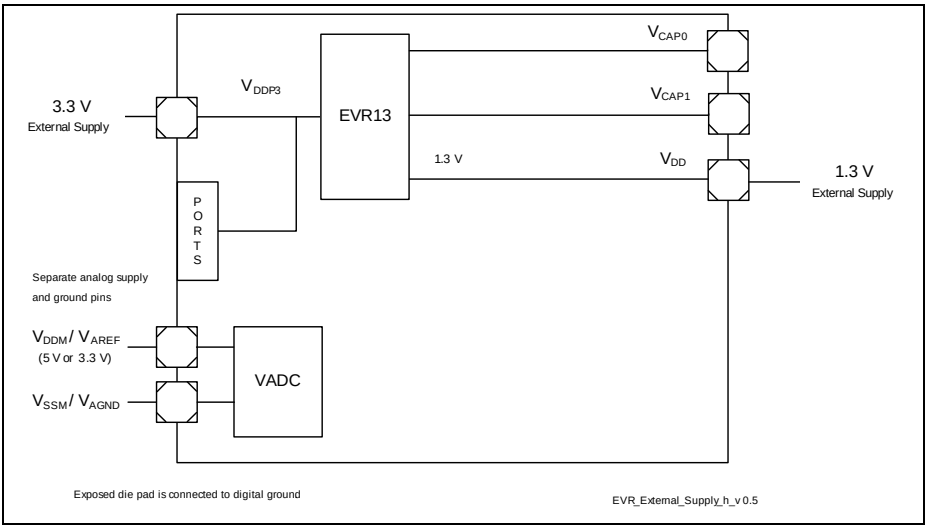

Figure 8-26 External Supply mode (h) - 3.3 V and 1.3 V externally supplied

8.3.1.6 Components and Layout

The efficiency of EVR is influenced by the characteristics of the selected components and also the placement and routing of the components on the PCB. In case of EVR13 LDO regulator, an appropriate buffer capacitor is required at the 1.3 V V_{DD} regulator supply output to handle load and line jump and regulation requirements based on application needs. The additional external components for the SC SMPS regulator constitute a flying capacitor (1 uF) and a buffer capacitor (10 uF). An input capacitor (4,7 uF) is required in case of SC SMPS mode to limit the input current ripple. The trace impedances and distances to the external components should be in principle as small as possible. The component requirements are documented in the datasheet and recommendations are also provided in application notes.

In case of usage of Emulation devices, it should be taken care that the component choice also considers the current additionally drawn by ED RAM and EEC part.

8.3.1.7 Voltage Monitoring

The PMC module implements a staggered voltage monitoring build upon a primary and a secondary monitor. The primary monitor ensures that the microcontroller is put into a reset state when the lowest operational threshold is violated. The secondary monitor serves as an additional safety monitor providing over- and under-voltage alarms.

Primary under-voltage monitoring of the external V_{DDP3} supply and V_{DD} / EVR13 supplies are inherently carried out to ensure proper functioning of the system. The EVR control loop as well as the under-voltage monitors are based on a primary bandgap reference. The thresholds for the basic monitoring are non-configurable and represents the lowest possible thresholds for the correct functioning of the system. In case of violation of these thresholds, cold $\overline{\text{PORST}}$ is activated and $\overline{\text{PORST}}$ pin is pulled low (strong current sink). Following the reset release and firmware boot, it can be inferred from STBYR, EVR13 or SWD bits in RSTSTAT register as to whether the violation of these thresholds led to the previous reset. The primary under-voltage monitoring is kept active even if the respective EVR has been disabled and the supply is provided externally as shown in **Table 8-19**.

The primary Supply WatchDog (SWD monitor) monitors the ramp-up of external supply voltage and keeps the microcontroller in cold Power On Reset state as long as the supply has not reached the operational range. Likewise, it also detects ramp-down or brown out condition of external supply and sets the device into a cold Power On Reset state when the voltage has dropped below the lowest operational threshold. Nevertheless, It is recommended to monitor externally all supplies generated external to the microcontroller and to assert $\overline{\text{PORST}}$ reset pin in case of violation of the lowest operational limits.

The violation of the primary under-voltage thresholds of EVR13 and EVR33 is communicated to the HSM module. HSM module may lock access to EVR registers via SLCK bit so that supply generation cannot be influenced by other masters. This is to ensure that trojan programs do not manipulate the supplies to gain access to the system.

The external V_{DDP3} supply and V_{DD} / EVR13 supplies are measured by 8 bit analog converters and the measured value is indicated in **EVRADCSTAT** register. This may be used to do a plausibility check of external regulator supplies during runtime.To support safety startup tests including the EVR monitoring mechanism, it shall be possible to measure the EVR HPBG bandgap voltage (G0CH12), V_{DDP3} /2 (G1CH13) and V_{DD} / EVR13 (G1CH12) supplies using VADC converter channels. This may be used to also to do a plausibility check of the internal EVR bandgap voltage against the external VAREF / VAGND reference supplies.

Additional secondary over-voltage and under-voltage monitoring against programmable thresholds is provided for all supplied and generated voltages using a secondary bandgap reference. This includes the external supply voltage and the internally generated EVR13 output voltages as shown in **Figure 8-28**. The secondary voltage monitors are kept active even if the respective EVRs have been disabled and the supply is provided externally as shown in **Table 8-19**. In case of a threshold violation, an SMU alarm event is generated.

The secondary monitor violation is notified depending on the direction of voltage transition as programmed in **EVRMONCTRL** register. The appropriate thresholds for voltage monitoring can be programmed in the **EVROVMON** and **EVRUVMON** registers. In case of an active monitoring violation, respective status flags are set in the **EVRSTAT** register. It can be inferred from OV13 or OVSWD bits in **EVRSTAT** register as to whether over-voltage thresholds for the respective voltage domains were violated. Likewise, It can be inferred from UV13 or UVSWD bits in **EVRSTAT** register as to whether under-voltage thresholds were violated. It is also possible to deactivate the generation of SMU alarms from secondary monitors in **EVRMONCTRL** register.

The primary bandgap is compared with a secondary bandgap to detect bandgap drifts as reflected in **EVRSTAT**.BGPROK register bit. The bandgap BIST is only carried out during a supply ramp-up.

In case of primary monitor violation, respective status bits are set to indicate the event as shown in **Table 8-19**. These bits maybe evaluated during consequent start-up after cold power-fail reset to recognize which among the supply rails had the power-fail. Likewise for secondary monitor violation, the respective status bits may be evaluated to discriminate between an overvoltage or an undervoltage event and to recognize which supply rail had triggered the alarm event to SMU.

Table 8-19 Voltage Monitoring

Supply Pin / Rail	Primary Under-voltage monitor State (ON/OFF)	Secondary Over & Under-voltage Monitor State (ON/OFF)	Supply Range V	Is the Pin supplied
RUN or SLEEP system mode during supply modes e-h.				
V_{DDP3}	ON. RSTSTAT.SWD RSTSTAT.STBYR	ON **EVRSTAT**.OVSWD **EVRSTAT**.UVSWD	2.97–3.63 V	External 3.3V Supply to be provided
V_{DDM}	-	-	2.97–5.50 V	External Supply to be provided
V_{DD}	ON RSTSTAT.EVR13	ON **EVRSTAT**.OV13 **EVRSTAT**.UV13	1.17–1.43 V	EVR13 active or external 1.3V supply to be provided
STANDBY system mode during supply modes e-h.				
V_{DDP3}	ON RSTSTAT.STBYR	OFF	2.97–3.63 V	External 3.3V Supply to be provided
V_{DDM}	-	-	0–5.50 V	ON or OFF
V_{DD}	OFF	OFF	0 V	OFF

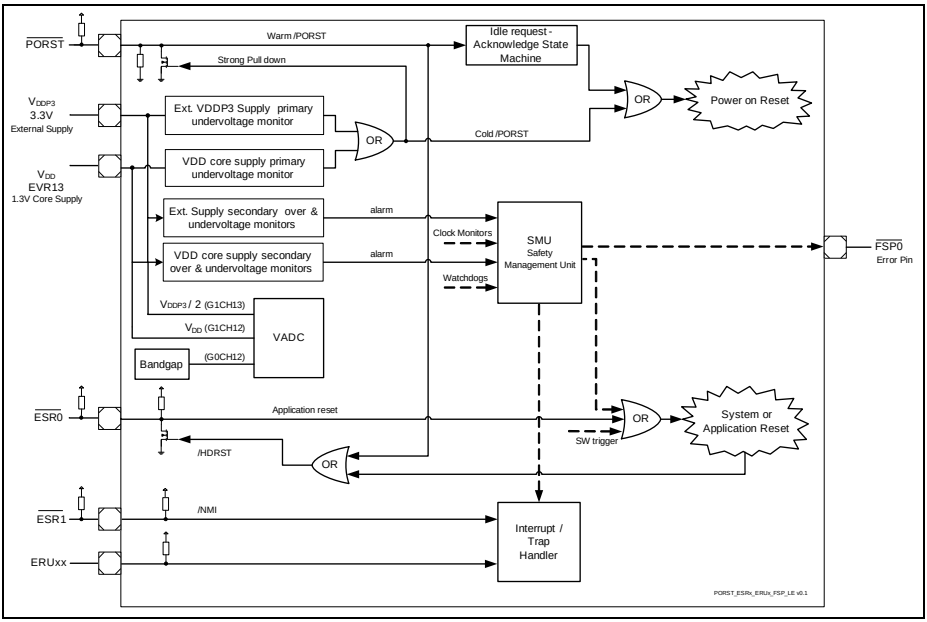

Figure 8-27 Monitoring and Reset

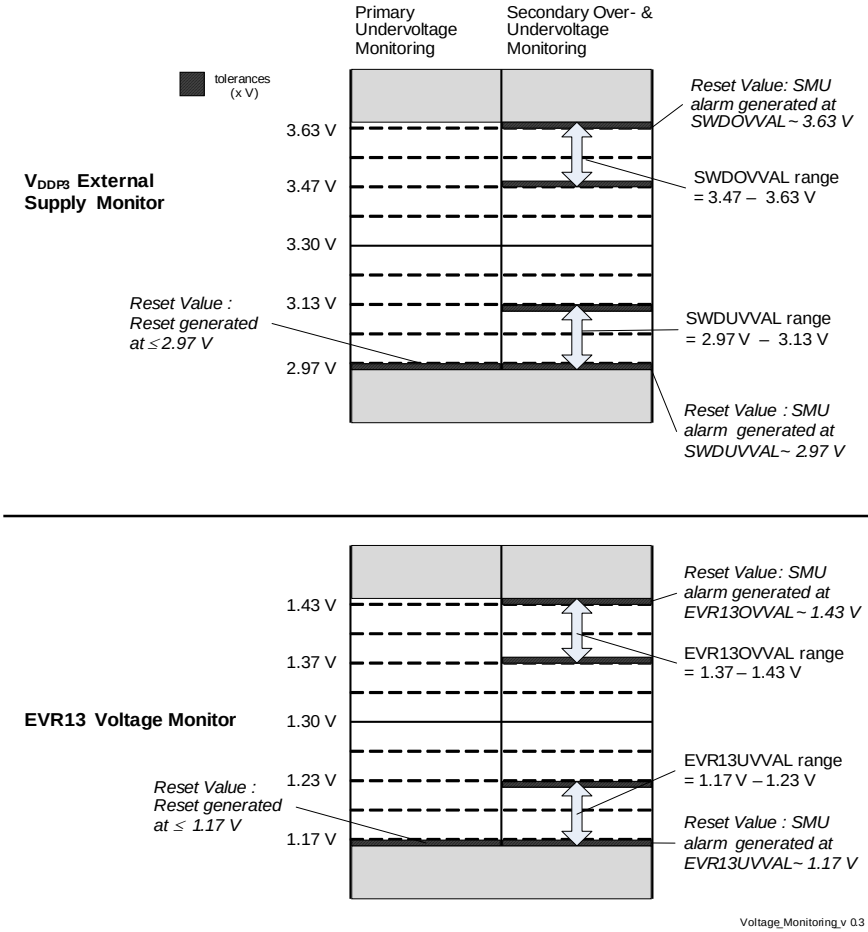

Monitoring tolerances and levels are specified in datasheet section EVR : Supply monitoring

Figure 8-28 Voltage Monitoring

8.3.1.8 Sequence during Power-up and Power-down

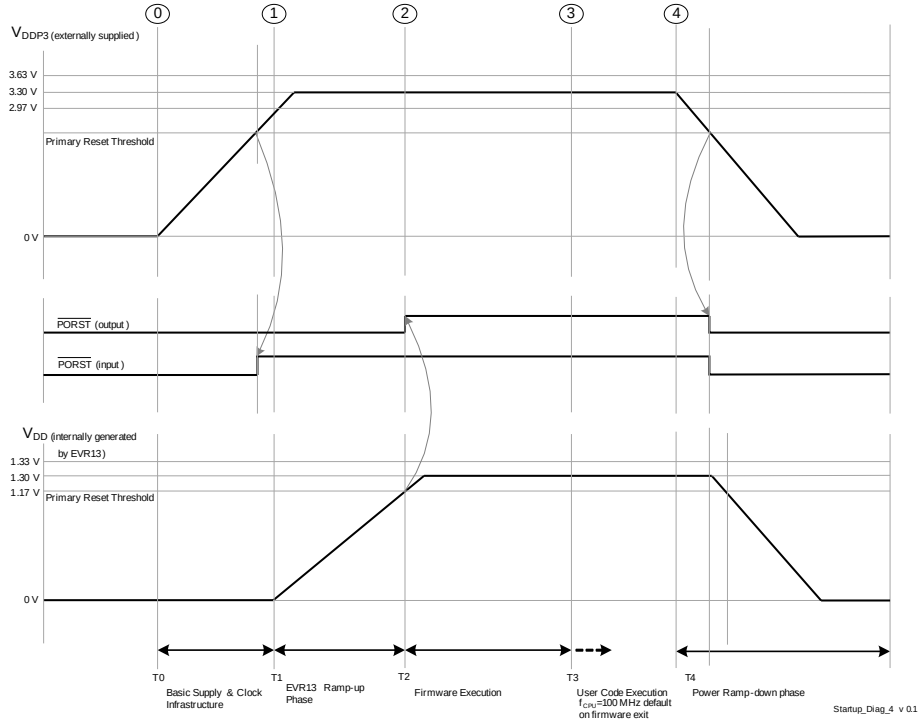

Figure 8-29 Single Supply mode (e & f) - 3.3 V single supply

Single Supply mode (e & f)

3.3 V single supply mode. 1.3 V is generated internally by the EVR13 regulator.

- The rate at which current is drawn from the external regulator (dI_{DDP3} /dt) is limited during the basic infrastructure and EVR13 regulator start-up phase (T0 upto T2) to a maximum of 100 mA/100 us. EVR13 is also robust against a voltage ramp-up starting from a residual voltage between 0 - 1 V. Start-up slew rates for supply rails should comply to datasheet values.
- Furthermore it is also ensured that the current drawn from the external regulator (dI_{DDP3} /dt) is limited during the Firmware start-up phase (T2 upto T3) to a maximum of 100 mA/100 us.
- PORST is active/ asserted when either PORST (input) or PORST (output) is active/ asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until the external supply is above the respective primary reset threshold.
- PORST (output) active means that µC asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the µC when atleast one among the two supply domains (1.3 V or 3.3 V) violate their primary under-voltage reset thresholds.The PORST (output) is deasserted by the µC when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available.
- The power sequence as shown in **Figure 8-29** is enumerated below
  - T1 refers to the point in time when basic supply and clock infrastructure is available as the external supply ramps up. The supply mode is evaluated based on the HWCFG[0,2] pins and consequently a soft start of EVR13 regulator is initiated.
  - T2 refers to the point in time when all supplies are above their primary reset thresholds. EVR13 regulator has ramped up. PORST (output) is deasserted and HWCFG[3:5] pins are latched on PORST rising edge. Firmware execution is initiated.
  - T3 refers to the point in time when Firmware execution is completed. User code execution starts with a default frequency of 100 MHz.
  - T4 refers to the point in time during the Ramp-down phase when atleast one of the externally provided or generated supplies (1.3 V or 3.3 V) drop below their respective primary under-voltage reset thresholds.

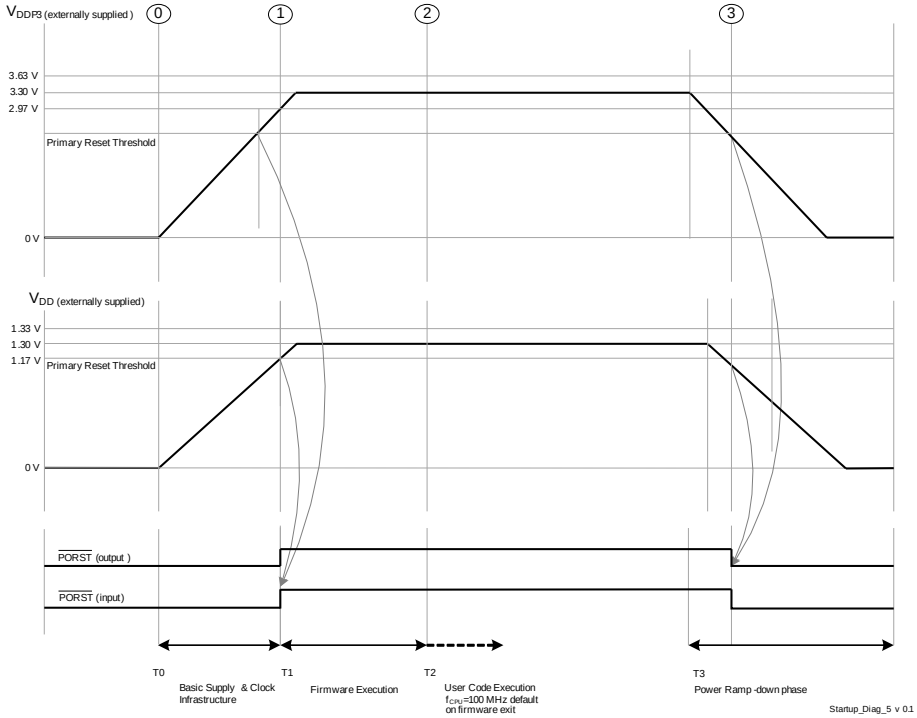

Figure 8-30 External Supply mode (h) - 3.3 V and 1.3 V external supply

External Supply mode (h)

All supplies, namely 3.3 V & 1.3 V, are externally supplied.

- External supplies V_{DDP3} & V_{DD} may ramp-up or ramp-down independent of each other with regards to start, rise and fall time(s). The supply system is also robust against a voltage ramp-up starting from a residual voltage between 0 - 1 V. Start-up slew rates for supply rails should comply to datasheet values.
- The rate at which current is drawn from the external regulator (dI_{DDP3} /dt, dI_{DD} /dt) is limited in the Start-up phase to a maximum of 100 mA/100 us.
- PORST is active/ asserted when either PORST (input) or PORST (output) is active/ asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until all the external supplies are above their primary reset thresholds.
- PORST (output) active means that µC asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the µC when atleast one among the two supply domains (1.3 V or 3.3 V) violate their primary under-voltage reset thresholds.The PORST (output) is deasserted by the µC when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available.
- The power sequence as shown in **Figure 8-30** is enumerated below
  - T1 refers to the point in time when all supplies are above their primary reset thresholds and basic clock infrastructure is available. The supply mode is evaluated based on the HWCFG[0,2] pins. PORST (output) is deasserted and HWCFG[3:5] pins are latched on PORST rising edge. Firmware execution is initiated.
  - T2 refers to the point in time when Firmware execution is completed. User code execution starts with a default frequency of 100 MHz.
  - T3 refers to the point in time during the Ramp-down phase when atleast one of the externally provided supplies (1.3 V or 3.3 V) drop below their respective primary under-voltage reset thresholds.

8.3.1.9 EVR Control Registers

All EVR registers with LCK bits have corresponding shadow registers in the EVR Standby domain. When writing consecutive EVR registers with LCK bits, it need to be ensured that the consecutive register is written only when the respective LCK bit is in unlocked state. This is because all EVR shadow registers are addressed using a shared bus across multiple clock domains and power isolation. An ongoing write will block the complete bus inhibiting parallel or consecutive writes on other registers until LCK bit is released. After a cold PORST, warm and system resets these registers may return a value 0 or the updated value by the Firmware. The reset value reflects the default isolation value in the shadow register. Otherwise, a read will provide the value of the most recent write operation. The status registers **EVRSTAT** and **EVRADCSTAT** are updated during Start-up and after every EVR measurement cycle and the reset value is dependent on the EVR topology. Therefore the value read from register may differ from the documented reset value.

EVRSTAT
EVR Status Register **($0B0_H$)** **Reset Value: $0000\ 1400_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r		rh		r	rh	r	r	rh	r	rh	rh	r		rh	rh

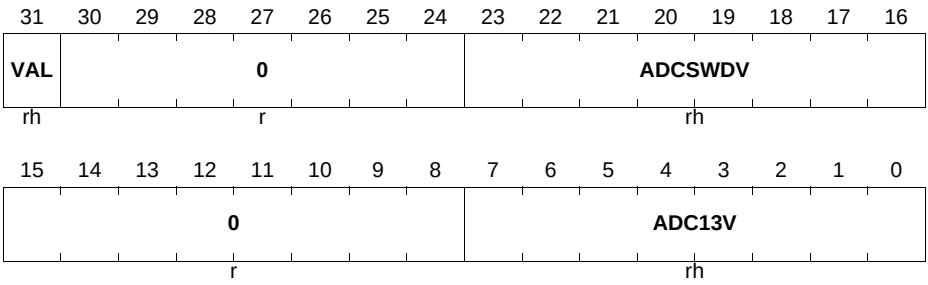
Field	Bits	Type	Description
EVR13	0	rh	**EVR13 status** This bit is set if the internal EVR13 LDO or SMPS regulator is active. EVR13 is activated if HWCFG[2] pin level is latched high during start-up phase. 0_B EVR13 is inactive. 1_B EVR13 is active.

Field	Bits	Type	Description
OV13	1	rh	**EVR13 Regulator Over-voltage event flag** This bit is set if EVR13 secondary voltage monitor recognises a 1.3 V over-voltage event. An alarm is raised to the SMU. 0_B No over-voltage condition happened. 1_B EVR13 Over-voltage event indication as configured in EVROVMON register.
OVSWD	4	rh	**Supply Watchdog (SWD) Over-voltage event flag** This bit is set if V_{DDP3} secondary voltage monitor recognises an over-voltage event. An alarm is raised to the SMU. 0_B No over-voltage condition happened. 1_B SWD Over-voltage event indication as configured in EVROVMON register.
UV13	5	rh	**EVR13 Regulator Under-voltage event flag** This bit is set if EVR13 secondary voltage monitor recognises a 1.3 V under-voltage event. An alarm is raised to the SMU. 0_B No under-voltage condition happened. 1_B EVR13 Under-voltage event indication as configured in EVRUVMON register.
UVSWD	7	rh	**Supply Watchdog (SWD) Under-voltage event flag** This bit is set if V_{DDP3} secondary voltage monitor recognises an under-voltage event. An alarm is raised to the SMU. 0_B No under-voltage condition happened. 1_B SWD Under-voltage event indication as configured in EVRUVMON register.
BGPROK	10	rh	**Primary Bandgap status** This bit is set after any reset and indicates that the primary bandgap voltage is in operational range. In case primary bandgap is not ok, we remain in cold reset state. On a Cold PORST release, this bit would be set to 1. 0_B Primary bandgap not ok. 1_B Primary bandgap is ok.

Field	Bits	Type	Description
SCMOD	[13:12]	rh	**Switch Capacitor SMPS Mode** If Switch Capacitor SMPS regulator is selected via HWCFG [0] pin, this bitfield indicates the conversion mode of the SC regulator. 00_B Mode 1/1 SC DCDC mode. 01_B Mode 1/2 SC DCDC mode. In case the current drive capabilities of the SC DCDC mode is exceeded, a switch from mode 2:1 to 1:1 takes place and an interrupt is issued.This bitfield shall be ignored incase EVR13 LDO mode is selected and is intended to be used only incase of EVR13 SCDCDC mode is selected.
0	[31:14], 11,9,6,3 ,2	r	**Reserved** Read as 0.

The over-voltage and under-voltage status signals are reported to SMU.EMM unit. An alarm for the upper and lower bound is supported in the SMU.EMM unit.

EVRADCSTAT
EVR ADC Status Register **($19C_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
ADC13V	[7:0]	rh	**ADC 1.3 V Conversion Result** This bit field contains the last conversion result of the ADC measurement of the V_{DD} / EVR13 supply . VIN = [LSB * (ADC13V-1)] ; LSB = 5.77 mV Eg. 1.3 V – $E2_H$ – 226_D

Field	Bits	Type	Description
ADCSWDV	[23:16]	rh	**ADC External Supply Conversion Result** This bit field contains the last conversion result of the ADC measurement of the external V_{DDP3} supply. VIN = [LSB * (ADCSWDV-1)] ; LSB = 23.0 mV Eg. 3.3 V – 90_H – 144_D
VAL	31	rh	**Valid Status** This bit indicates if the register is being updated with a new value. Values are updated every EVR cycle. 0_B The register is not being updated 1_B The register is being updated
0	[30:24], [15:8]	r	**Reserved** Read as 0.

EVRRSTCON
EVR Reset Control Register ($06C_H$) Reset Value: 007E 00C5$_H$

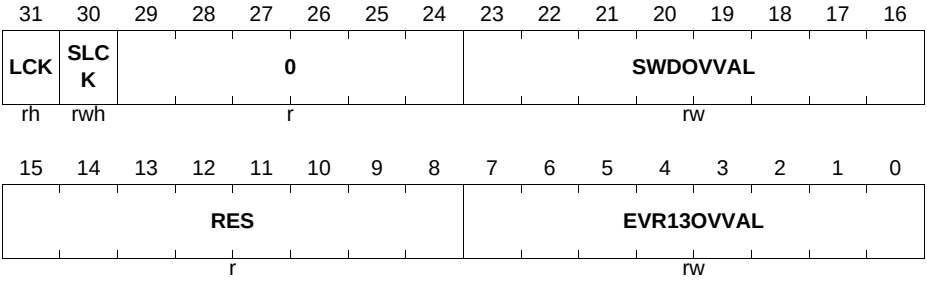
Field	Bits	Type	Description
RSTSWDOFF	28	rw	**EVR SWD Reset Enable** 0_B A reset trigger signal is generated and forwarded to the SCU by the external supply monitoring block depending on the selected reset trim value. 1_B No reset trigger signal is generated and forwarded to the SCU by the external supply monitoring block depending on the selected reset trim value. This bit can only be changed if bit BPRSTSWDOFF is set in parallel.
BPRSTSWDOFF	29	w	**Bit Protection RSTSWDOFF** Setting this bit enables that bit RSTSWDOFF can be changed in this write operation. This bit is read as zero.
RES	[27:0]	r	**Reserved** These bits should not be written. Writes to other bitfields must ensure that these bits are not changed.
SLCK	30	rwh	**HSM Security Lock** 0_B No lock active 1_B Lock is active If this bit is set, all other bits in this register can no longer be written. Write requests to other bits when SLCK is set will cause a bus access error. SLCK bit can only be set by an access from the HSM master (TAG = 001101_B). A set operation performed by any other master or software is ignored and the bit is kept as cleared.
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and cannot be updated

EVROVMON

EVR Over-voltage Configuration Register(1A4$_H$) **Reset Value: 00F1 9EFD$_H$**



Field	Bits	Type	Description
EVR13OVVAL	[7:0]	rw	**1.3 V Regulator Over-voltage threshold** This field defines the over-voltage monitoring threshold level of the EVR13 regulator. 1.30 V – $E2_H$ – 226_D (refer datasheet) Threshold = [(VIN / LSB) + 1] LSB = 5.7692 mV
SWDOVVAL	[23:16]	rw	**Supply monitor (SWD) Over-voltage threshold value** This field defines the over-voltage threshold level of the external V_{DDP3} supply monitor. 3.3 V external supply 3.29 V – 90_H – 144_D (refer datasheet) Threshold = [(VIN / LSB) + 1] LSB = 23.077 mV The reset value of register is $F1_H$. Firmware later programs $9E_H$ to set the threshold to 3.3 V+10%.
SLCK	30	rwh	**HSM Security Lock** 0_B No lock active 1_B Lock is active If this bit is set, all other bits in this register can no longer be written. Write requests to other bits when SLCK is set will cause a bus access error. SLCK bit can only be set by an access from the HSM master (TAG = 001101_B). A set operation performed by any other master or software is ignored and the bit is kept as cleared.

Field	Bits	Type	Description
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and cannot be updated
0	[29:24],[15:8]	r	**Reserved** Read as 0; should be written with 0.

A configurable threshold with upper and lower voltage bounds can be defined in EVROVMON and EVRUVMON registers for monitoring external supply and EVR13 regulator output. It need to be considered that after a system reset, Firmware overwrites the register values.

The EVROVMON and EVRUVMON registers can be configured to trigger SMU alarms via software. It is also possible to activate alarms via software in the SMU unit.

EVRUVMON

EVR Under-voltage Configuration Register(1A0$_H$) **Reset Value: 00D0 89D6$_H$**

Field	Bits	Type	Description
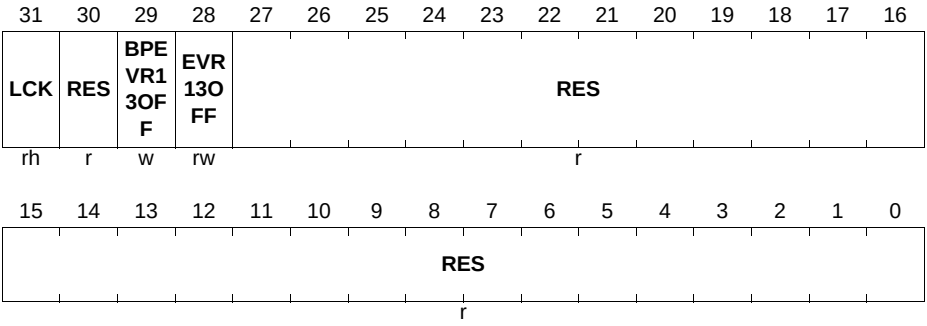
0	2,3, [6:15], 18,19, [29:22], 31	r	**Reserved** Read as 0; should be written with 0.

The default setting after reset is that over-voltage indication is notified via an SMU alarm when the overvoltage threshold is crossed in a lower to higher voltage transition.

The default setting after reset is that under-voltage indication is notified via an SMU alarm when the under-voltage threshold is crossed in a higher to lower voltage transition.

It can be configured in EVRMONCTRL register to generate an interrupt when the over-under-voltage thresholds are crossed in either direction. This may be used to notify when the violation condition disappears with respect to secondary voltage monitoring.

EVR13CON
EVR13 Control Register **($0B8_H$)** **Reset Value: 0380 0380_H**



Field	Bits	Type	Description
EVR13OFF	28	rw	**EVR13 Regulator Enable** 0_B The EVR13 regulator module is enabled 1_B The EVR13 regulator module is disabled/switched off. The device may be operating in standby or with external 1.3V supply. This bit can only be changed if bit BPEVR13OFF is set in parallel.

Field	Bits	Type	Description

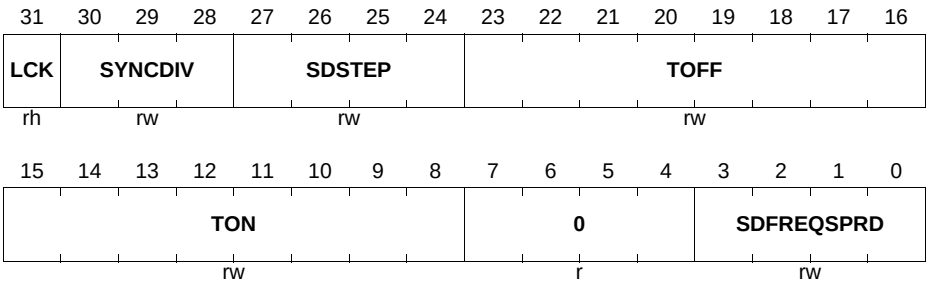
EVRSDCTRL1
EVR13 SD Control Register 1 ($1B0_H$) Reset Value: $0829\ 2901_H$



Field	Bits	Type	Description
SDFREQSPRD	[3:0]	rw	**Frequency Spread Mode** This bit field activates frequency spreading for the SC SMPS regulator. The charge and discharge times are calculated every switching period as programmed in the TON and TOFF bitfields plus a uniform random offset. The maximum random offset clock cycles is defined by SDFREQSPRD field. 0_H No frequency spreading activated (default) 1_H 0 to 1 clock cycle is added in a random manner to both TON or TOFF switching periods (50% probability). 2_H 0 to 2 clock cycles are added. 3_H 0 to 4 clock cycles are added. 4_H 0 to 8 clock cycles are added. 5_H 0 to 16 clock cycles are added. All other values are reserved.
TON	[15:8]	rw	**Charge Phase length** The charge phase length in nominal 100 MHz clock cycles. Switching period = TON + TOFF + (16+2) cycles 1 MHz = 100 clock cycles 1.85 Mhz = 54 clock cycles
TOFF	[23:16]	rw	**Discharge Phase length** The discharge phase length in clock cycles. Switching period = TON + TOFF + (16+2) cycles 1 MHz = 100 clock cycles 1.85 Mhz = 54 clock cycles
SDSTEP	[27:24]	rw	**Droop Voltage Step** This bit field defines the voltage offset for droop compensation on a load jump.

Field	Bits	Type	Description
SYNCDIV	[30:28]	rw	**Clock Divider Ratio for external DCDC SYNC signal** This bitfield defines the divider factor for the clock signal to synchronise external regulator to the internal SC SMPS EVR13 regulator. 000_B $f_{DCDCSYNC} = f_{DCDC}$ 001_B $f_{DCDCSYNC} = f_{DCDC}/2$ 010_B $f_{DCDCSYNC} = f_{DCDC}/4$ 011_B $f_{DCDCSYNC} = f_{DCDC}/8$ 100_B $f_{DCDCSYNC} = f_{DCDC}/16$ 101_B $f_{DCDCSYNC} = f_{DCDC}/32$ All other combinations are reserved.
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and cannot be updated
0	[7:4]	r	**Reserved** Read as 0; should be written with 0.

SD33I	[11:8]	rw	**I Coefficient** I control parameter for the PI regulator (3.3V external supply).
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and cannot be updated
0	[30:12], [7:4]	r	**Reserved** Read as 0; should be written with 0.

8.3.2 Power Management

8.3.2.1 Power Management Overview

The Power Management scheme allows activation of power down modes so that the system operates with the minimum required power for the corresponding application state. A progressive reduction in power consumption is achieved by invoking Idle, Sleep or Standby modes respectively. The Idle mode is specific to each CPU where as Sleep and Standby modes influence the complete system.

As shown in **Table 8-20**, there are two power modes available for each CPU:

- CPU Run Mode
- CPU Idle Mode

Table 8-20 CPU Power Management

Mode	Description
Run Mode	The CPU clock is active and code is being executed.
Idle Mode	CPU may enter Idle Mode on following events: • On a SW Idle request issued by setting register bits **PMCSR0**.REQSLP = 01b when CPU has no active tasks to perform. • On a SMU Idle request in case CPU faults are detected triggering safety alarms which are configured in SMU to set CPU into Idle state. The CPU code execution is halted and CPU clock is disabled in Idle state. The peripherals continue to remain active.CPU RAM memories (PSPR / DSPR) are accessible to other bus masters and peripherals. CPU may exit Idle mode on following events: • When an interrupt occurs on a CPU returning the CPU to Run Mode. • When a trap occurs like an NMI trap event. • When the CPU watchdog or Safety watchdog timer overflow events trigger an SMU alarm in turn leading to a CPU interrupt. • When a MSB bit wrap of the CPU Watchdog counter takes place. • When an Application reset, System reset or any higher reset occurs.

As shown in **Table 8-21**, there are three main power modes available for the system:

- System Run Mode
- System Sleep Mode
- System Standby Mode

Table 8-21 System Power Management

Mode	Description
Run Mode	CPU has not requested Sleep Mode or Standby mode and is in Run mode. All peripheral modules are active.
Sleep Mode	System may enter Sleep Mode on following events: • On a SW Sleep request issued by setting **PMCSR0**.REQSLP = 10_B by the CPU. CPU code execution is halted and CPU Idle state is entered. Peripherals are set into sleep state if so configured in the respective CLCx.EDIS bit. Ports retain their earlier programmed state. System may exit Sleep mode on following events: • When an interrupt or trap is issued to a CPU. • When an NMI trap event takes place. • When the CPU watchdog or Safety watchdog timer overflow events trigger an SMU alarm leading in turn to a CPU interrupt. • When a MSB bit wrap of CPU Watchdog counter takes place. • When an Application reset, System reset or any higher reset occurs.
Standby Mode	System may enter Standby Mode on following events if so configured: • On a SW Standby request issued by setting **PMCSR0**.REQSLP= 11_B by the CPU. • On an NMI / $\overline{\text{ESR1}}$ assertion event. The Standby domain constituting the Standby RAM, the Wake-Up Timer, shared ports and the wake-up unit remain actively supplied. The power to the rest of the chip is completely switched off. System may exit Standby mode on following events in case V_{DDP3} remains supplied during Standby state: • when a wake-up edge is detected on selected pins / $\overline{\text{ESR1}}$. • when a wake-up request is issued by the Wake-Up Timer. • when $\overline{\text{PORST}}$ assertion is detected.

Furthermore, flexible reduction of power consumption is possible through following measures:

- Reduction of specific CPU power consumption by means of CPU throttling.
- Disabling the module clock by setting bit DISR in module CLC register.
- Reducing the system frequency without changing individual peripheral clocks.
- Reducing peripheral clock frequency without changing system clock frequency.

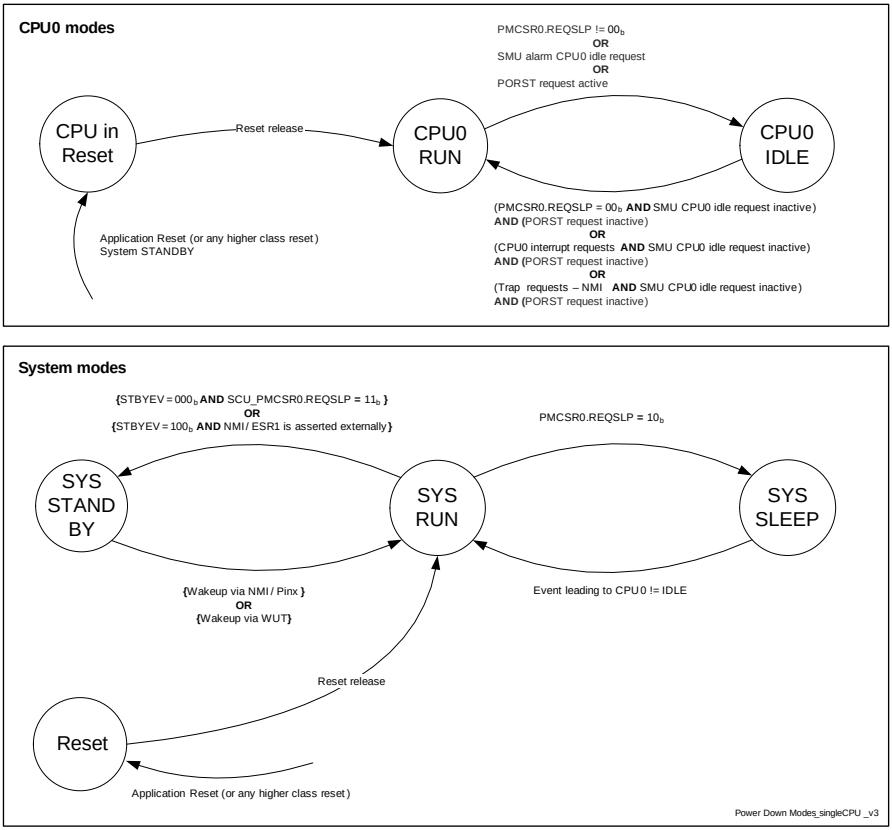

Figure 8-31 Power down modes and transitions

8.3.2.2 Idle Mode

In case there are no active tasks to perform, CPU may be requested to enter Idle mode during runtime by writing to the **PMCSR0** register and setting the bitfield REQSLP = 01_B.

Entering Idle Mode :

Following events can invoke a CPU Idle request

- CPUx setting itself in Idle by writing its own **PMCSR0** register: The **PMCSR0** register shall be accessed by setting CPUx ENDINIT = 0_B and consequently writing the bitfield REQSLP = 01_B. The Idle transition takes place only when CPUx ENDINIT = 1_B is set back again. This ensures that a CPUx does not enter Idle mode when it's WDTx is in Time-Out mode and ENDINITx = 0_B to avoid wake-up on a consequent WDT time-out. Safety ENDINIT mechanism shall not be used by a CPU to set itself into Idle to avoid wake-up on a Safety WDT time-out. It is to be noted that CPU is set into Idle state during entry into SLEEP (REQSLP = 10_B) mode as well. In STANDBY mode (REQSLP = 11_B), CPU is set first into Idle state before power is switched off.
- CPUx being set into Idle by SMU alarm: Idle mode may be requested by an SMU alarm in case of detected CPU faults thus setting the faulty CPU in Idle without initiating a full application reset.

The CPU watchdog may be disabled or slowed down by reprogramming the timers before triggering Idle request via Software. On an Idle request, the CPU finishes its current operations and sends an acknowledge back to the Power Management unit. It then enters an inactive state in which the CPU and the respective DMI and PMI memory units are shut off. The respective CPU clocks may be reduced via CPUxDIV register bitfield before issuing Idle request for further load jump reduction.

State during Idle mode

During Idle Mode, memory accesses to the DMI and PMI from other bus masters cause these units to wake-up automatically to handle these transactions. When memory transactions are complete, the DMI and PMI return to Idle state again. Once Idle Mode is entered, the state is reflected in **PMCSR0**.PMST status bits. CPU Idle request from the SMU is reflected in **PMCSR0**.SMUSLP bit.

Exiting Idle mode

In Idle mode, if there is no outstanding SMU Idle request to the CPU, the CPU will return to Run mode in response to the following events:

- An interrupt / trap received from an interrupt / trap source mapped to the CPU.
- An NMI trap request is received to wake-up the CPU.
- A MSB bit wrap of the corresponding CPU Watchdog counter occurs.
- Setting the register bits **PMCSR0**.REQSLP = 00_B to set the CPUx into Run mode.

If there is an outstanding SMU Idle request to the CPU, then the CPU may only return to Run mode after an application reset or any higher reset. The system enters reset state on an Application, System reset or any higher reset. If it is woken by a watchdog timer overflow event routed via the SMU to the CPU or by an NMI or by an interrupt, the CPU will immediately vector to the appropriate interrupt / trap handler.

8.3.2.3 Sleep Mode

System may be requested to enter Sleep mode by writing to the **PMCSR0** register and setting the bitfield REQSLP = 10_B.

The **PMCSR0** register shall be accessed by setting CPUx ENDINIT = 0_B. The Sleep request is issued only after CPUx ENDINIT bit is set back again. Safety ENDINIT mechanism shall not be used by a CPUx to issue Sleep request.

Entering Sleep Mode

It should be ensured to select individual clocks from Clock Control Unit for peripherals which need to remain active during Sleep mode. This allows the reduction of system clock frequencies , namely SRI and SPB clocks, to the minimum possible values via the low power divider. Low power modes for Analog and Flash modules may also be requested. The CLCx.EDIS register bit is cleared for all peripherals intended to be inactive in Sleep mode. The watchdogs may be disabled or slowed down before issuing a Sleep request.

State during Sleep Mode

Sleep Mode is disabled for a unit if CLCx.EDIS bit is set. The sleep request is ignored in this case and the corresponding unit continues normal operation as intended. If CLCx.EDIS is cleared, the clock of the module is gated. The exact sequence used for entering Sleep Mode is determined for each module by the setting of register field OCSx.SUS. CPU Idle state is entered as described in the previous section. All ports retain their earlier programmed state.

Exiting Sleep Mode

The system will exit Sleep mode on any wakeup event that causes the CPU to exit Idle Mode. The CPU would be set into Run mode (REQSLP = RUN, PMST = RUN). An NMI trap event will wake-up the system. A MSB bit wrap of the CPU Watchdog counter would also wake-up the CPU. The response of the CPU to being woken up from Sleep Mode is also the same as for Idle Mode. Peripheral units that have entered Sleep Mode will switch back to their selected Run Mode operation.

8.3.2.4 Standby Mode

The Standby domain constitutes the Standby RAM, the **W**ake**U**p **T**imer, the power management unit, the wake-up unit, the V_{DDP3} monitor and some basic infrastructure components. The Standby domain is supplied by the EVR pre-regulator and is by default clocked by the 100 KHz internal clock in Standby Mode.

Following events may trigger Standby mode entry based on **PMSWCR1**.STBYEV bits.

- Standby entry on SW request (**PMCSR0**.REQSLP = 11_B).
- Standby entry on ESR1 / NMI edge event.

Following events may trigger wake-up from Standby mode.

- Wake-up via NMI / Pinx: Wake-up on rising, falling or any edge of NMI / ESR1, Pin A or Pin B pins. Standby domain is supplied via V_{DDP3} supply pins which in turn is supplied by an external regulator with Standby support.
- Wake-up via WUT: Wake-up is triggered by the WakeUp Timer.

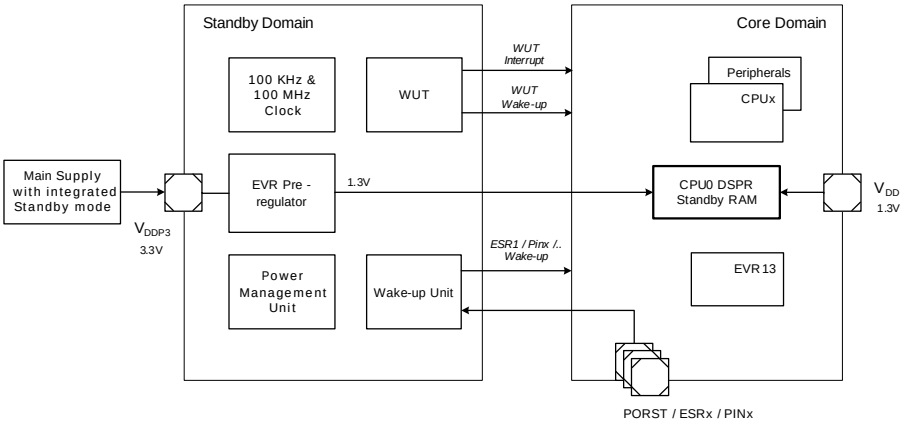

Figure 8-32 Standby domain

The Standby RAM constitutes a single block of ECC protected DSPR RAM of CPU0. The RAM remains supplied during Standby mode if configured in **PMSWCR0**.STBYRAMSEL bits. On wake-up, the status of the Standby RAM is reflected in **PMSWSTAT**.STBYRAM bits. On Standby request, the supply to the Standby RAM is immediately switched from EVR13 / V_{DD} supply to EVR Pre-regulator before Standby shut-off sequence is issued.

External events may be mapped to ESRx / PINx pins in turn acting as wake-up signals for the system. In Run Mode, NMI / ESR1 pin may be used as fault or functional interface for external devices. In Standby Mode, an edge event on the NMI / ESR1 pin may be configured to trigger wake-up of the main core domain via **PMSWCR0**.ESR1WKEN bit and is reflected in **PMSWSTAT**.ESR1WKEN status flag. It can be configured to trigger

a wake-up on rising, falling or both edges via **PMSWCR0**.ESR1EDCON bit. Glitches on ESR1 input are filtered out by activating the filter via **PMSWCR0**.ESR1DFEN bit. Additional pins (PINA - P14.1 and PINB - P15.1) may likewise be configured to trigger wake-up via **PMSWCR0**.xEDCON, xDFEN & xWKEN bits. On wake-up, **PMSWSTAT**.ESR1WKP or PINxWKP event flags provide information as to the wake-up source. It should be taken care after wake-up to clear the event flags via **PMSWSTATCLR** register. In case new wake-up events are captured while **PMSWSTAT**.xWKP flags are still set, then **PMSWSTAT**.xOVRRUN flags are set to indicate an overrun state owing to consecutive unserviced wake-up events.

Entering Standby Mode (ESR1 / Pin or WUT Wake-up configuration)

The Standby Mode entry may be requested by writing to **PMCSR0** register to set bitfield REQSLP = 11_B or via NMI / ESR1 assertion as configured in **PMSWCR1**.STBYEV bits.

Before entering standby mode, various modules should be sequentially shut off in a sequence mainly to avoid large current jump on standby entry.

- Peripheral module clocks are switched off in respective CLC.DISR registers. CPU watchdogs may be disabled or reconfigured for slower modes.
- CPU frequency reduction in steps compliant to load jump constraints.
- CPU code execution is switched from Flash to PSPR RAM. Flash modules are deactivated via FCON register.
- System Clock is switched to the internal 100 MHz clock source. System PLL & E-Ray PLL are switched off. Clock dividers are programmed to lower values.
- Clear **PMSWCR1**.IRADIS bit to disable Idle Request Acknowledge sequence activation for fast Standby Mode entry. This ensures that standby request is not blocked by a pending reset request / sequence.
- Select the Standby RAM block via **PMSWCR0**.STBYRAMSEL bits. Copy Standby RAM redundancy data (16 words in size) to DSPR0 starting at 0xD000 2000h. The procedure is also described in Boot ROM chapter in section “Preparation before to enter Standby mode”. Dcache write back to be executed before Standby entry.
- Select the clock source which need to be active on entry into Standby Mode via **PMSWCR0**.SCRCLKSEL bits.
- Configure the wake-up signals which should trigger exit from Standby Mode. Edge detection and filter activation is appropriately configured via **PMSWCR0**.xxxEDCON and **PMSWCR0**.xxxDFEN bits.
- Configure pad state via **PMSWCR0**.TRISTREQ bit. All pads may either be in tristate or have pull-up devices active. Configure **PMSWCR0**.ESR0TRIST bit to configure ESR0 behavior as reset output or tristate during Standby and on wake-up. In case HWCFG[2:5] pins are read by Firmware, it should be ensured to tie them to external pull devices.
- Enable ESR1 or PINx pins for wake-up via **PMSWCR0**.xxxWKEN bits.The wake-up from WUT should be activated via xxx bit. WUT should be running before entering the Standby state in case used.
- Configure Standby Entry event in **PMSWCR1**.STBYEV register bits.
- Standby request issued. An orderly shut down of various sub-systems is triggered to enter Standby mode.

State during Standby Mode

The Standby RAM (DSPR RAM of CPU0), the **W**ake**U**p **T**imer, the shared ports and the wake-up logic are kept alive in this mode. PORST pin serves as a wakeup source when asserted and shall be held high externally to remain in Standby state.

Exiting Standby Mode - Wake-up

The wake-up event may happen on

- ESR1 edge transition (NMI trap)
- Pin A or Pin B edge transition (P14.1 or P15.1)
- Wake-up on a WUT underflow

The main EVR13 regulators are ramped up on wake-up based on the configuration in **PMSWSTAT**.HWCFGEVR register bits. Firmware is executed thereafter including installation of RAM redundancy data. If Standby RAM was supplied during Standby state, it is indicated in **PMSWSTAT**.STBYRAM register bits. Additional RAM integrity checks may be carried out. RSTSTAT.STBYR bit indicates that the supply was reliable during Standby. The wake-up and over-run status flags are set in **PMSWSTAT** register and shall be cleared by **PMSWSTATCLR** register.

Exiting Standby mode - Power Fail or $\overline{\text{PORST}}$ assertion

The $\overline{\text{PORST}}$ pin triggers a wakeup from Standby if asserted low during Standby state. The device boots up ramping up the regulators followed by firmware execution similar to a normal device start-up.

The Standby RAM contents are kept intact after PORST assertion provided Firmware is not configured to re-initialize the Standby RAM depending on Flash configuration. Reset is propagated to external devices via the ESR0 pin on exit from Standby mode depending on **PMSWCR0**.ESR0TRIST configuration. Firmware may elongate ESR0 reset output depending on Flash configuration.

A power fail event of the Standby supply during Standby mode will inevitably result in the loss of Standby RAM contents. Consequently, a cold PORST event is issued and the Standby domain is set into reset. EVR Pre- regulator under-voltage violation is indicated in RSTSTAT.STBYR flag.

8.3.2.5 Wake-up Timer (WUT)

The Wake-up Timer is a basic low power counter which may be used to wake-up the system periodically from Standby mode. The timer may also be used during Run, Idle or Sleep modes. The following list enumerates the salient features.

- 24 bit counter running on 100 KHz clock source with programmable reload value.
- 24 bit counter status register providing the current count value.
- Timer resolution of 100 KHz or (100 KHz / 2^{10}) configured via a clock divider.
  - 10 us resolution : 10 us - 168 s range.
  - 10 ms resolution : 10 ms - 1.9 days range.
- 2 operating modes :
  - Auto Reload mode - WUT is started and stopped via Software. Automatic reload on counter underflow.
  - Standby Auto Stop mode - Counter starts counting down from reload value on Standby entry. Counter stops on underflow and triggers a system wake-up.
- Events on WUT counter underflow
  - Interrupt request on SRC_EVRWUT interrupt node on counter underflow during Run, Idle or Sleep mode.
  - Wake-up trigger on counter underflow during Standby mode.
  - Capture trigger on counter underflow to CCU6x_CC60IND for trimming purpose.
- Over-run indication of consecutive unserviced wake-up triggers.

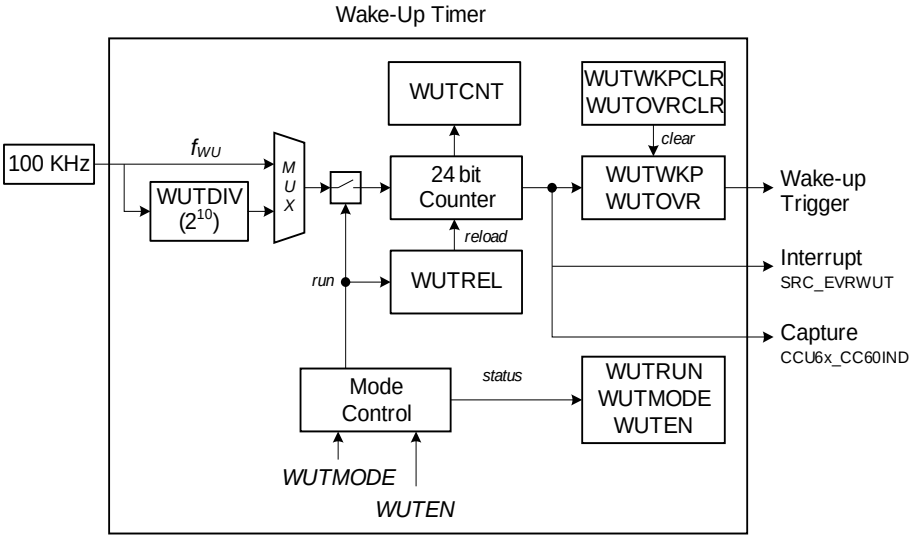

Figure 8-33 Wake-up Timer (WUT)

Wake-up Timer Operation

Wake-up Timer may be operated in following modes :

Table 8-22 Wake-up Timer Operation

WUT EN	WUT MODE	Mode Description
0B	XB	WUT is disabled and counter is stopped. **PMSWCR3**.WUTREL reload value may be updated. **PMSWSTAT**.WUTCNT,WUTRUN,WUTWKP & WUTOVR flags read 0.

Table 8-22 Wake-up Timer Operation

WUT EN	WUT MODE	Mode Description
1B	0B	Software Auto Reload mode : WUT starts running when **PMSWCR3**.WUTEN = 1 & WUTMODE = 0 is set. **PMSWSTAT**.WUTRUN bit is set indicating that WUT timer is currently running. **PMSWUTCNT**.WUTCNT bitfield indicates the actual counter value. On counter underflow, WUT is automatically reloaded with WUTREL value. During Standby, WUT underflow triggers system wake-up and **PMSWSTAT**.WUTWKP flag is set. During Run, Sleep or Standby modes, WUT underflow triggers an interrupt request and **PMSWSTAT**.WUTWKP flag is set. WUTREL reload value shall not be updated in this state. On wake-up, the **PMSWSTAT**.WUTWKP flag shall be cleared by **PMSWSTATCLR**.WUTWKPCLR bit.In case of unserviced consecutive counter underflow events, **PMSWSTAT**.WUTOVRUN flag is set to indicate an over-run wake-up event. Interrupt over-run event can be detected via SRC.IOV bit during RUN mode.
1B	1B	Standby Auto Stop mode: The mode is selected by setting **PMSWCR3**.WUTEN = 1 & WUTMODE = 1. WUT starts running only when Standby mode is entered.On counter underflow, WUT stops running and the wake-up of system is triggered and **PMSWSTAT**.WUTWKP flag is set. WUT starts running again on the next Standby mode entry. The intention is to have the timer running only during the Standby state. **PMSWUTCNT**.WUTCNT, **PMSWSTAT**.WUTRUN reads 0 after a wake-up.WUTREL reload value shall not be updated in this state. On wake-up, the **PMSWSTAT**.WUTWKP flag shall be cleared by **PMSWSTATCLR**.WUTWKPCLR bit. In case system was woken up by other wake-up triggers while WUT was still running, an interrupt request is generated on WUT underflow. In case of unserviced consecutive counter underflow events, **PMSWSTAT**.WUTOVRUN flag is set to indicate an over-run wake-up event. Interrupt over-run event can be detected via SRC.IOV bit during RUN mode.

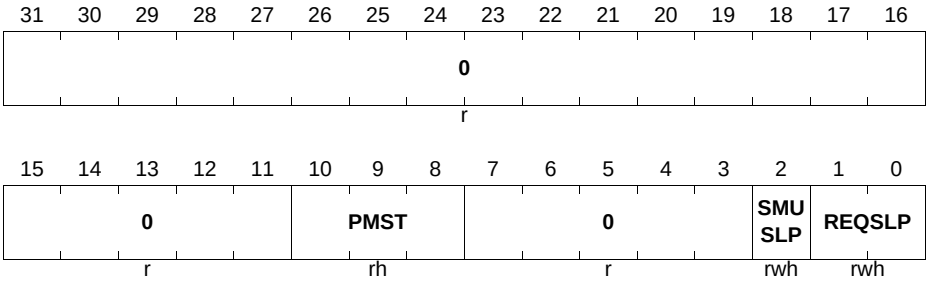
In case of timer overflow, an interrupt is issued on the interrupt node SRC_EVRWUT. Wake-up Timer reload value maybe trimmed during Run mode by comparing the time stamp on a WUT underflow captured by a GTM-TIM or CCU60 based on a more precise clock. This allows to compensate the 100 KHz (f_{WU}) clock source variations owing to technology and temperature.

8.3.2.6 Power Management Registers

Power Management Control and Status Register

The set of registers used for Power Management control the issue of power modes, manage wake-up configuration and provide status information on mode transitions. The request for Idle, Sleep or Standby mode is issued via **PMCSR0** register.

PMCSR0
Power Management Control and Status Register
($0D4_H$) **Reset Value: $0000\ 0100_H$**



Field	Bits	Type	Function
REQSLP	[1:0]	rwh	**Idle Mode and Sleep Mode Request** 00_B Request CPU Run Mode 01_B Request CPU Idle Mode 10_B Request System Sleep Mode 11_B Request System Standby Mode In Idle Mode or Sleep Mode, these bits are cleared in response to an interrupt for the CPU, or when bit 15 of the corresponding CPU Watchdog Timer register (bit WDTCPUxSR.TIM[15]) changes from 0 to 1. In Standby Mode, these bits are cleared on wake-up. REQSLP maybe written only when either CPU or Safety ENDINIT bits are reset to 0. Only after CPU or Safety ENDINIT bit is set back after REQSLP is written would the REQSLP take effect.

Field	Bits	Type	Function
SMUSLP	2	rwh	**SMU CPU Idle Request** 0_B No SMU Alarm request for CPU Idle Mode 1_B SMU Alarm requested CPU Idle Mode This bit is set to '1' when an SMU Alarm requests that the CPU is put into Idle Mode. This bit is NOT cleared in response to an interrupt to the CPU, or when bit 15 of the CPU Watchdog Timer register (bit WDTCPUxSR.TIM[15]) change from 0 to 1. It is cleared only by reset or by a write of '0' to this register. An attempt to write '1' has no effect.
0	3	r	**Reserved** Read as 0; should be written with 0.
PMST	[10:8]	rh	**Power management Status** This bit field reflects the current status of the CPU. 000_B Reserved, do not use this combination 001_B Normal Run Mode[1)] 010_B CPU Idle Mode requested 011_B CPU Idle Mode acknowledged 100_B Sleep Mode requested 101_B Reserved, do not use this combination 110_B Standby Mode requested 111_B Reserved, do not use this combination
0	[7:4], [31:11]	r	**Reserved** Read as 0; should be written with 0.

1) After a reset, all CPUs are in "Normal Run Mode", but this does not mean that all CPUs are executing code. This mode also includes the CPU "halt" mode which is the start-up default for all except CPU0.

Standby and Wake-up Control Registers

PMSWCR0

Standby and Wake-up Control Register 0 ($0C8_H$) **Reset Value: 0000 $02D0_H$**

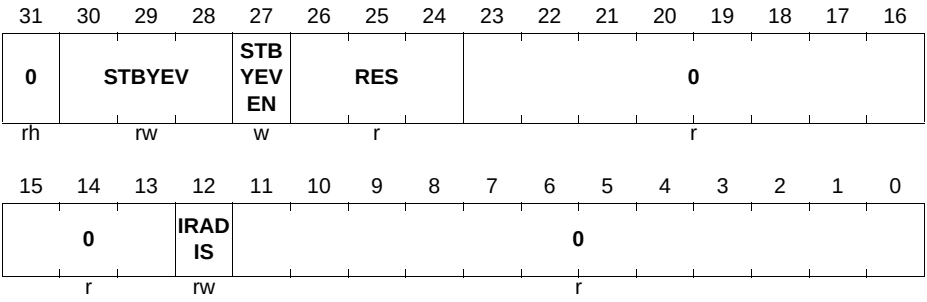
PMSWCR1
Standby and Wake-up Control Register 1 ($0E8_H$) **Reset Value: $0100\ 0000_H$**

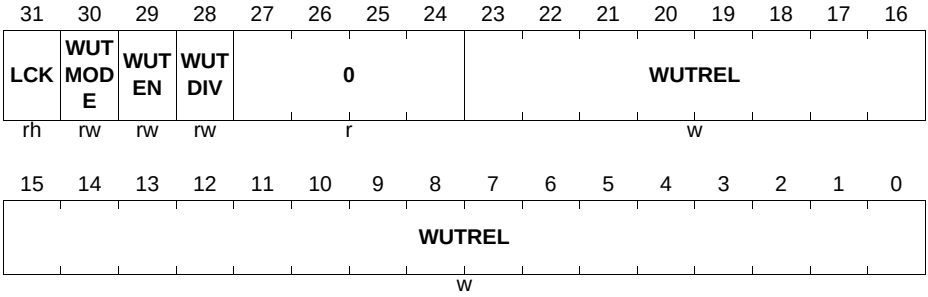


Field	Bits	Type	Description
0	[11:0]	r	**Reserved** Read as 0; should be written with 0.
IRADIS	12	rw	**Idle-Request-Acknowledge Sequence Disable** This bit enables SCU Idle Request Acknowledge sequence to all modules on Standby entry. This contributes an additional delay of 180us. 0_B Idle-Request-Acknowledge Sequence skipped on Standby entry. 1_B Idle-Request-Acknowledge Sequence issued on Standby entry. This bit shall be set before Standby entry to disable Idle request acknowledge sequence so that standby request is not blocked by a pending reset request / sequence.
0	[23:13]	r	**Reserved** Read as 0; should be written with 0.
RES	[26:24]	r	**Reserved** These bits shall not be written. When other bitfields are updated, it shall be ensured that these bits are not changed.
STBYEVEN	27	w	**Standby Entry Event configuration enable** 0_B Bit STBYEV is not updated. 1_B Bit STBYEV can be updated.
STBYEV	[30:28]	rw	**Standby Entry Event Configuration** 000_B Standby Entry triggered by setting **PMCSR0**.REQSLP register bit (Default). 100_B Standby Entry triggered on $\overline{\text{ESR1}}$/NMI assertion. *Note: All other bit combinations are reserved.*
0	31	r	**Reserved** Read as 0; should be written with 0.

Additional $\overline{\text{PORST}}$ digital filter activated via PMSWCR0.PORSTDF bit provides additional filtering of atleast 500 ns to provide enhanced immunity against spurious spikes. This is in addition to the inherent analog $\overline{\text{PORST}}$ filter delay of the PORST pad / pin as documented in the datasheet. After cold $\overline{\text{PORST}}$ this delay is by default inactive.

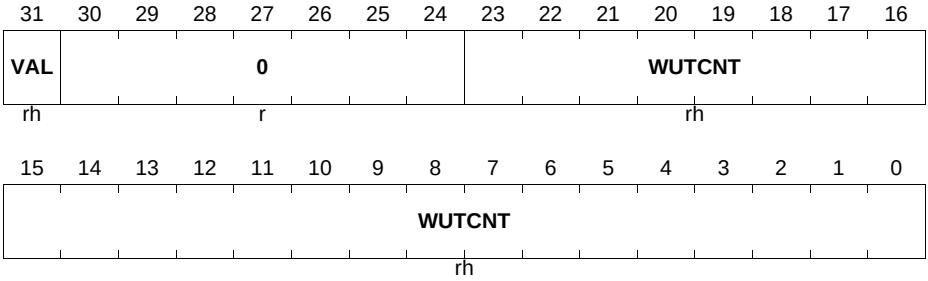
PMSWCR3

Standby and Wake-up Control Register 3(300_H) **Reset Value: $0000\ 0000_H$**



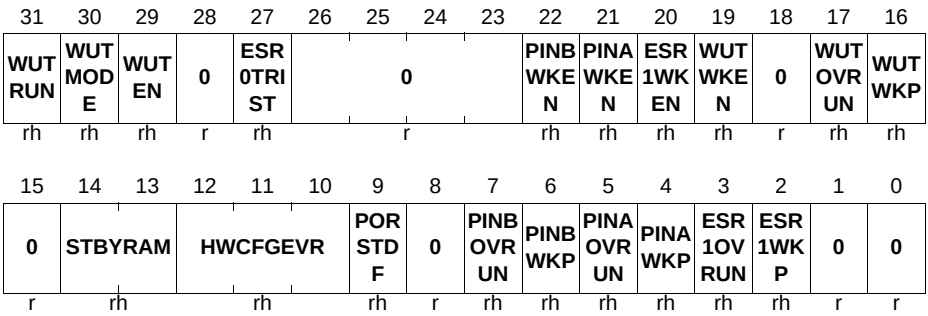
Field	Bits	Type	Description
WUTREL	[23:0]	rw	**WUT reload value.** The counter starts counting down from WUTREL value.
WUTDIV	28	rw	**WUT clock divider** 0_B WUT clock = f_{WU} = 100 KHz clock. 1_B WUT clock = f_{WU} (100 KHz) / 2^{10}.
WUTEN	29	rw	**WUT enable** This bit enables the Wake-up Timer. 0_B WUT is disabled. 1_B WUT is enabled.
WUTMODE	30	rw	**WUT mode selection** This bit selects the Wake-up Timer operation mode. 0_B WUT auto reload mode selected 1_B WUT auto stop mode selected.
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and cannot be updated
0	[27:24]	r	**Reserved** Read as 0; should be written with 0.

PMSWUTCNT
Standby WUT Counter Register (1DC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
WUTCNT	[23:0]	rh	**WUT counter value.** The current WUT counter value is updated every 100 KHz.
VAL	31	rh	**Valid Status** This bit indicates if the register is being updated with a new value. Values are updated every EVR cycle. 0_B The register is not being updated 1_B The register is being updated
0	[30:24]	r	**Reserved** Read as 0; should be written with 0.

PMSWSTAT
Standby and Wake-up Status Flag Register(0CC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	[1:0]	r	**Reserved** Read as 0; should be written with 0.
ESR1WKP	2	rh	**ESR1 Wake-up flag** 0_B No wake-up event detected on ESR1 input. 1_B An event as defined by PMSWCR0. ESR1EDCON detected on ESR1 input.
ESR1OVRUN	3	rh	**ESR1 Overrun status flag** This flag indicates that an ESR1 wake-up event occurred while the last one was not yet serviced. 0_B No overrun condition detected on ESR1 input. 1_B An overrun condition detected on ESR1 input.
PINAWKP	4	rh	**Pin A (P14.1) Wake-up flag** 0_B No wake-up event detected on Pin A input. 1_B An event as defined by PMSWCR0. PINAEDCON detected on Pin A input.
PINAOVRUN	5	rh	**Pin A Overrun status flag** This flag indicates that an PIN A wake-up event occurred while the last one was not yet serviced. 0_B No overrun condition detected on Pin A input. 1_B An overrun condition detected on Pin A input.
PINBWKP	6	rh	**Pin B (P15.1) Wake-up flag** 0_B No wake-up event occurred on the Pin B input. 1_B An event as defined by PMSWCR0. PINBEDCON detected on Pin B input.
PINBOVRUN	7	rh	**Pin B Overrun status flag** This flag indicates that an PIN B wake-up event occurred while the last one was not yet serviced. 0_B No overrun condition detected on Pin B input. 1_B An overrun condition detected on Pin B input.
0	8	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
PORSTDF	9	rh	**PORST Digital Filter status** This bit field indicates whether additional PORST digital filter is activated. This bit is updated when PMSWCR0.PORSTDF is updated. 0_B PORST recognition delay = Analog PORST pad filter delay (default reset state). 1_B PORST recognition delay = Analog PORST pad filter delay + Digital filter delay.
HWCFGEVR	[12:10]	rh	**EVR Hardware Configuration** This bit field indicates the supply configuration latched by the EVR from HWCFG[2,0] during a cold startup. The latched configuration is used during STANDBY-RUN transition to reselect EVR mode. In TC22x HWCFGEVR[0] bit is set to 1 by default as SMPS mode is not available in TC22x unlike TC23x. .
STBYRAM	[14:13]	rh	**Standby RAM Supply status** This bit field indicates whether Standby RAM is supplied during Standby Mode and to infer status after a wake-up event. This bit is updated when PMSWCR0.STBYRAMSEL is updated. 00_B Standby RAM is not supplied. 01_B Standby RAM (CPU0 DMI) is supplied. $1x_B$ Reserved, do not use this combination.
WUTWKP	16	rh	**WUT Wake-up flag** 0_B No wake-up event detected due to WUT underflow. 1_B A wake-up event was detected due to WUT underflow.
WUTOVRUN	17	rh	**WUT Overrun status flag** This flag indicates that a WUT wake-up event occurred while the last one was not yet serviced. 0_B No overrun condition detected of WUT events. 1_B An overrun condition detected of WUT events.
0	[19:18], 15	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
WUTWKEN	19	rh	**WUT Wake-up enable status** This bit indicates that WUT is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.WUTWKEN bit is updated. Due to synchronization to 100 KHz WUT clock, setting of flag may take upto 30 us. 0_B Wake-up from Standby via WUT is disabled. 1_B Wake-up from Standby via WUT is enabled.
ESR1WKEN	20	rh	**ESR1 Wake-up enable status** This bit indicates that ESR1 is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.ESR1WKEN bit is updated. 0_B Wake-up from Standby via ESR1 is disabled. 1_B Wake-up from Standby via ESR1 is enabled.
PINAWKEN	21	rh	**Pin A Wake-up enable status** This bit indicates that PINA is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.PINAWKEN bit is updated. 0_B Wake-up from Standby via PINA is disabled. 1_B Wake-up from Standby via PINA is enabled.
PINBWKEN	22	rh	**Pin B Wake-up enable status** This bit indicates that PINB is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.PINBWKEN bit is updated. 0_B Wake-up from Standby via PINB is disabled. 1_B Wake-up from Standby via PINB is enabled.
0	[26:23]	r	**Reserved** Read as 0; should be written with 0.
ESR0TRIST	27	rh	**ESR0 pin status during Standby** This bit indicates if ESR0 pin is configured as reset output or tristate during Standby mode & transitions.This bit is updated when PMSWCR0. ESR0TRIST is updated. 0_B ESR0 configured as reset output and is held low during Standby state (default reset state) 1_B ESR0 in tristate during Standby state.
0	28	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
WUTEN	29	rh	**WUT Enable status** This bit indicates whether WUT is enabled. This bit is updated when PMSWCR3.WUTEN bit is updated. Due to synchronization to 100 KHz WUT clock, setting of flag may take upto 30 us. 0_B Wake-up timer is disabled. 1_B Wake-up timer is enabled.
WUTMODE	30	rh	**WUT Mode status** This bit indicates the current WUT mode. This bit is updated when PMSWCR3.WUTMODE bit is updated. Due to synchronization to 100 KHz WUT clock, setting of flag may take upto 30 us. 0_B WUT auto reload mode is selected 1_B WUT auto stop mode is selected.
WUTRUN	31	rh	**WUT Run status** This bit indicates whether WUT is currenly running. Due to synchronization to 100 KHz WUT clock, setting of flag may take upto 30 us. 0_B Wake-up timer is inactive. 1_B Wake-up timer is currently running.

PMSWSTATCLR

Standby and Wake-up Status Clear Register($0D0_H$) **Reset Value: $0000\ 0000_H$**

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

2) All EVR registers excluding status registers have corresponding shadow registers in the EVR Standby domain. After a cold PORST, a read of these registers may return the reset value or the value updated by the Firmware. The reset value reflects the default isolation value in the shadow register. Otherwise, a read will provide the value of the most recent write operation.

3) The address does not generate a bus error on read/write access.

8.4 System Control Unit (SCU)

The System Control Unit (SCU) of the TC21x/TC22x/TC23x contains miscellaneous control registers associated with other system functions.

This includes:

- External Request and Cross-triggering Unit (ERU) (see **Section 8.4.1**)
- CPU Lockstep Comparator Logic (LCL) (see **Section 8.4.2**)
- Die Temperature Sensor (DTS) (see **Section 8.4.3**)
- Watchdog Timers (WDTx) (see **Section 8.4.4**)
- Emergency Stop (EMS) (see **Section 8.4.5**)
- Logic Built-in-Self-Test (LBIST) (see **Section 8.4.6**)
- Overlay Control (OVC) (see **Section 8.4.7**)
- Miscellaneous System Control Registers (see **Section 8.4.8**)
- SCU register overview table (see **Table 8-29**)

8.4.1 External Request Unit (ERU)

The External Request Unit (ERU) is a versatile event and pattern detection unit. Its major task is the **generation of interrupts based on selectable trigger events at different inputs**, e.g. to generate external interrupt requests if an edge occurs at an input pin. The detected events can also be used by other modules to trigger or to gate module-specific actions.

8.4.1.1 Introduction

The ERU of the TC21x/TC22x/TC23x can be split in three main functional parts:

- 8 independent **Input Channels x** for input selection and conditioning of trigger or gating functions
- Event distribution: A **Connecting Matrix** defines the events of the Input Channel x that lead to a reaction of an Output Channel y.
- 8 independent **Output Channels y** for combination of events, definition of their effects and distribution to the system (interrupt generation, ...)

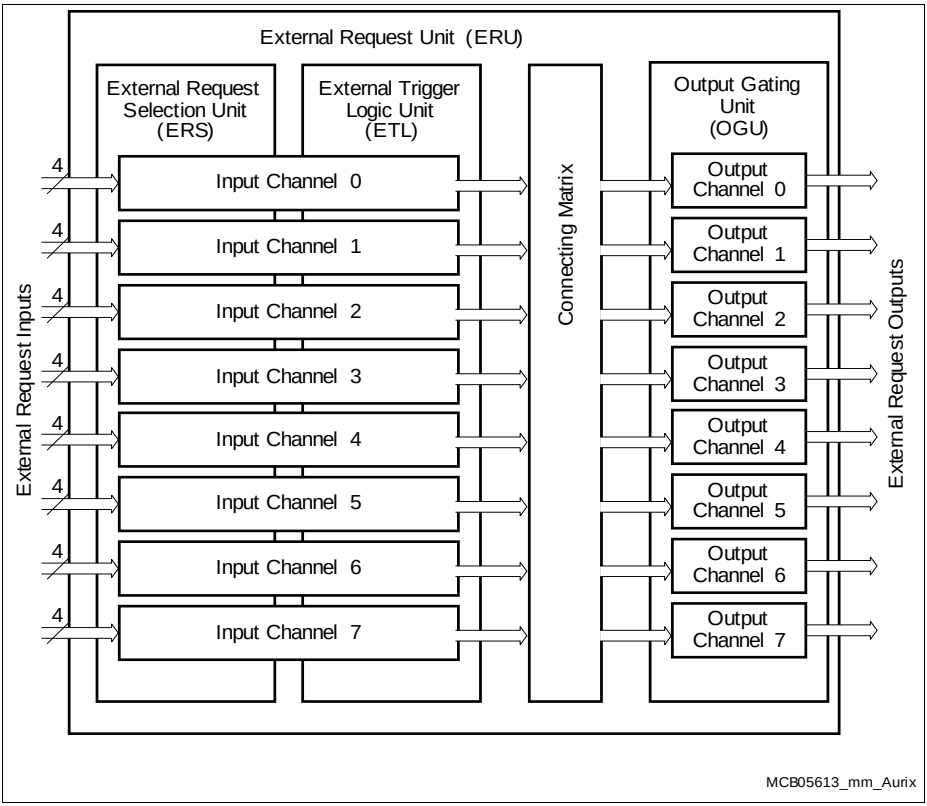

Figure 8-34 External Request Unit Overview

These tasks are handled by the following building blocks:

- An **External Request Select Unit (ERSx)** per Input Channel allows the selection of one input vector out of the 4 possible available inputs.
- An **Event Trigger Logic (ETLx)** per Input Channel allows the definition of the transition (edge selection, or by software) that lead to a trigger event and can also store this status. Here, the input levels of the selected signals are translated into events (event detected = event flag becomes set, independent of the polarity of the original input signals).
- The **Connecting Matrix** distributes the events and status flags generated by the Input Channels to the Output Channels.
- An Output Gating Unit (OGUy) per Output Channel that combines the available trigger events and status information from the Input Channels. An event of one Input Channel can lead to reactions of several Output Channels, or also events of several

Input Channels can be combined to a reaction of one Output Channel (pattern detection).
Different types of reactions are possible, e.g. interrupt generation (based on signals ERU_IOUTy).

8.4.1.2 ERU Input Pin Connections

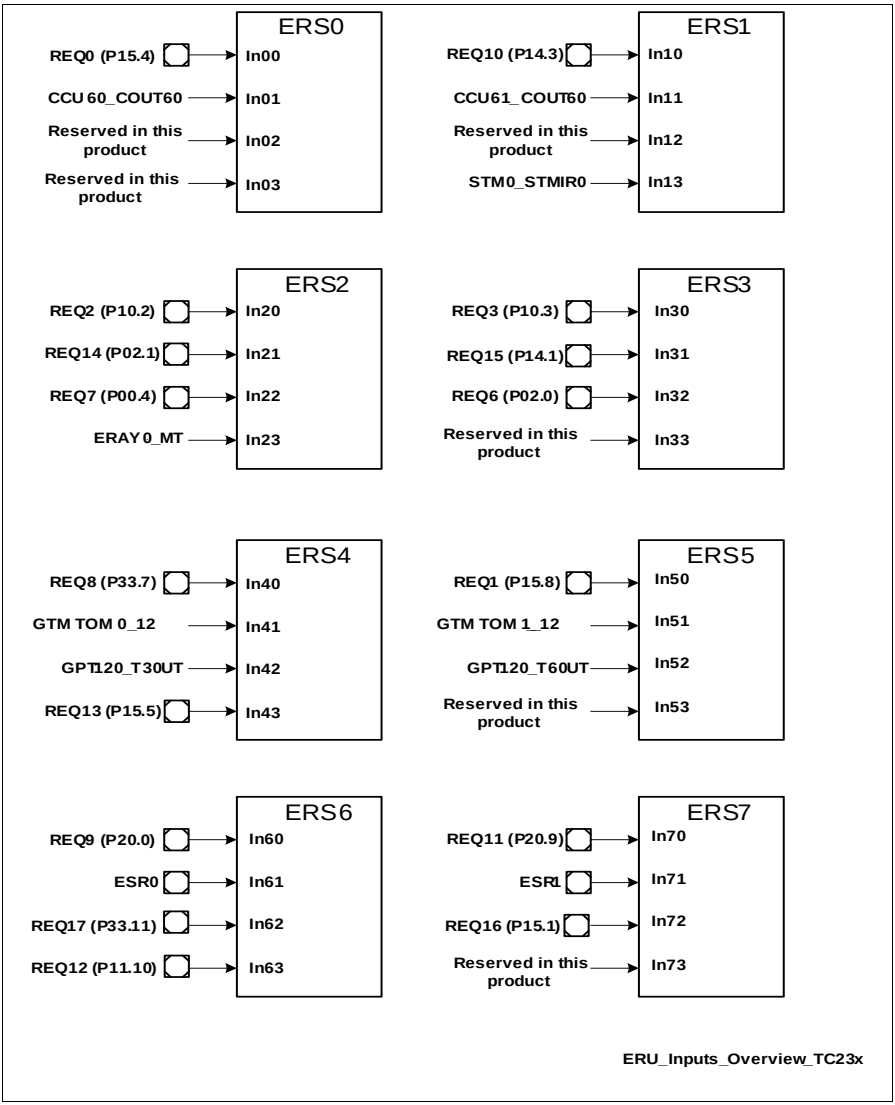

Figure 8-35 External Request Unit Input Connections for TC22x/TC23x

The inputs to the ERU can be selected from a large number of input signals. 16 of these inputs come directly from input REQx ports, but other inputs come from various peripheral module status signals. Usually, such inputs would be selected for an ERU function when the module input function is not used by the application, or when the module is not used at all. However, it is also possible to select an input which is also used by the other module, to also be used in the ERU as a trigger or to be combined with other signals (e.g. to generate an interrupt trigger when a start-of-frame is detected on a selected communication interface input).

8.4.1.3 External Request Selecter Unit (ERS)

Each ERS selects one of four inputs as the one input signal of the respective input channel. **Figure 8-36** shows the structure of this block.

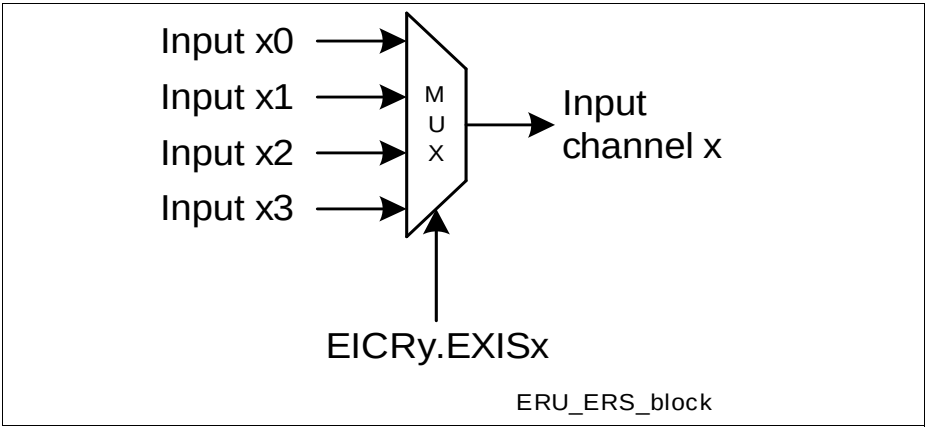

Figure 8-36 External Request Select Unit Overview

The ERS unit for channel x is controlled via bit field EICRy.EXISx.

8.4.1.4 Event Trigger Logic (ETL)

For each Input Channel x, an event trigger logic ETLx derives a trigger event and a status from the input channel x delivered by the associated ERSx unit. Each ETLx is based on an edge detection block, where the detection of a rising or a falling edge can be individually enabled. Both edges lead to a trigger event if both enable bits are set (e.g. to handle a toggling input).
Each pair of the four ETL units has an associated EICRy register, that controls all options of an ETL (the register also holds control bits for the associated ERS unit pair, e.g. EICR0 to control ESR0 and ESR1 plus and ETL0 and ETL1).

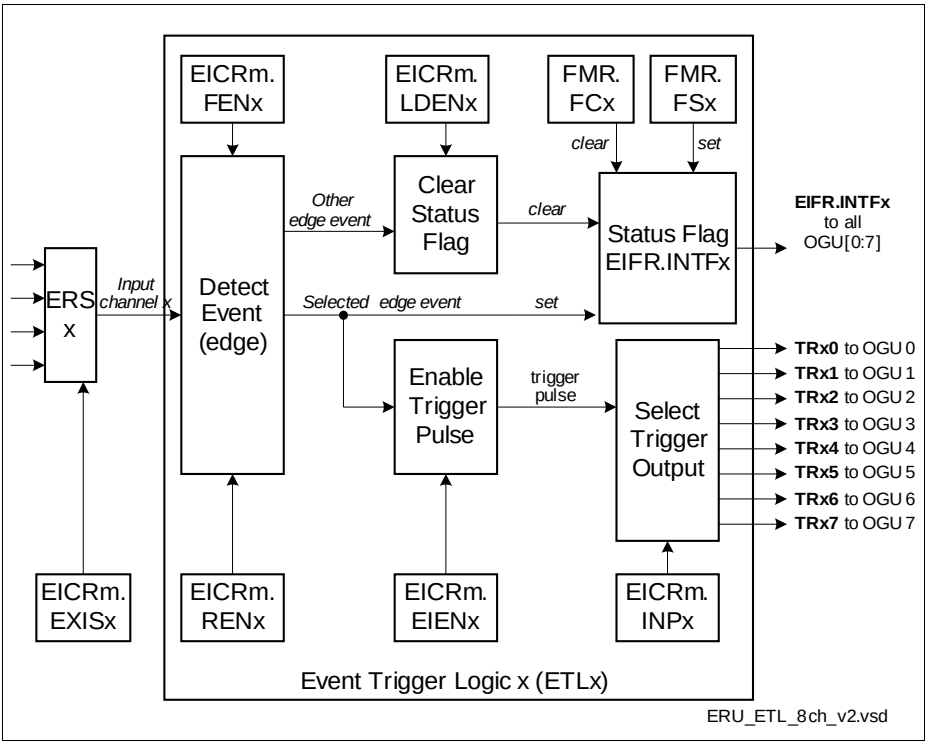

Figure 8-37 Event Trigger Logic Overview

When the selected event (edge) is detected, the status flag EIFR.INTFx becomes set. The status flag is cleared automatically if the “opposite” event is detected, if so enabled via bit EICRy.LDENx = 1. For example, if only the falling edge detection is enabled to set the status flag, it is cleared when the rising edge is detected. In this mode, it can be used for pattern detection where the actual status of the input is important (enabling both edge detections is not useful in this mode).
The output of the status flag is connected to all following Output Gating Units (OGUz) in parallel (see **Figure 8-38**) to provide **pattern detection capability of all OGUz** units based on different or the same status flags.

In addition to the modification of the status flag, a trigger pulse output TRxz of ETLx can be enabled (by bit EICRy.EIENx) and selected to **trigger actions in one of the OGUz** units. The target OGUz for the trigger is selected by bit field EICRy.INPx.
The trigger becomes active when the selected edge event is detected, independently from the status flag EIFR.INTFx.

8.4.1.5 Connecting Matrix

The connecting matrix distributes the trigger signals (TRxy) and status signals (EIFR.INPFx) from the different ETLx units between the OGUy units. **Figure 8-38** provides a complete overview of the connections between the ETLx and the OGUz units.

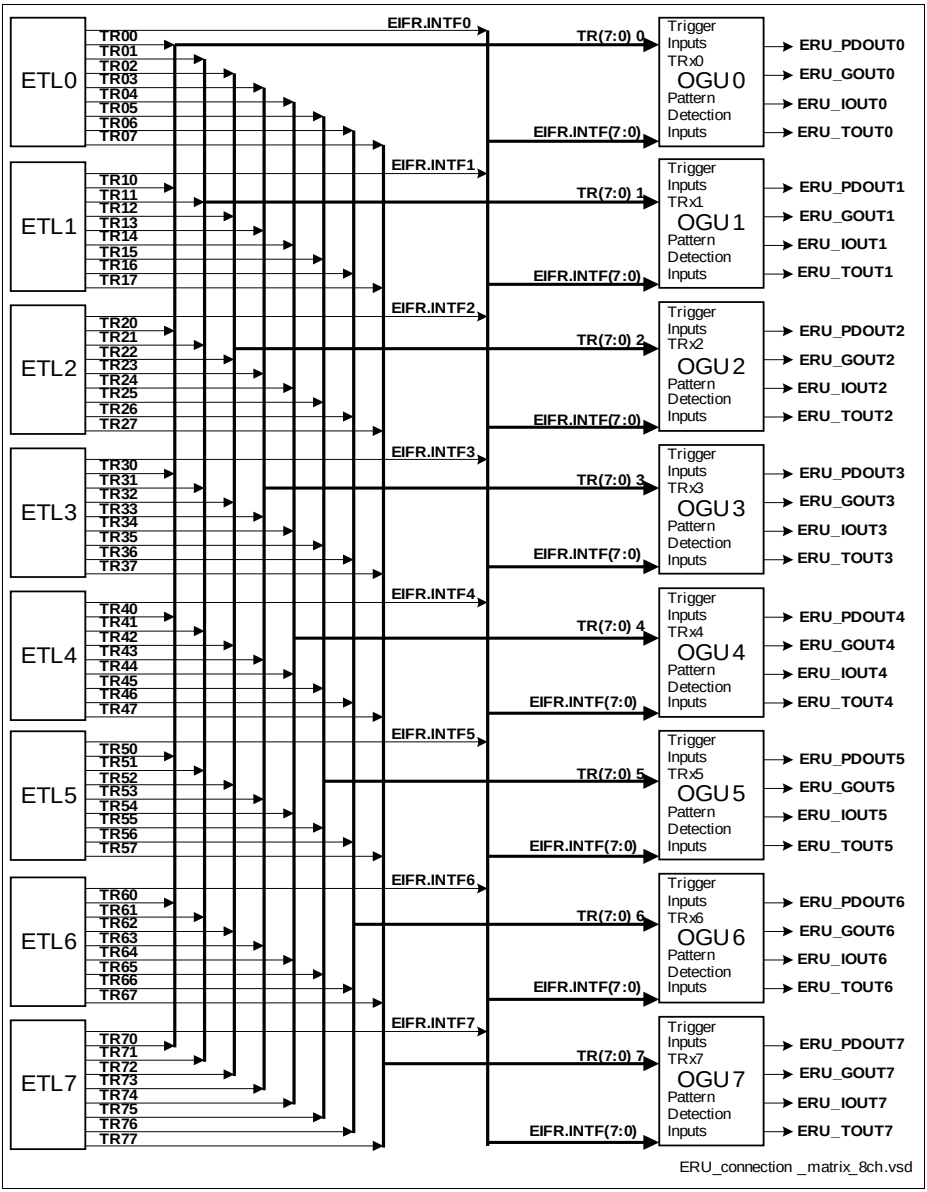

Figure 8-38 Connecting Matrix between ETLx and OGUy

8.4.1.6 Output Gating Unit (OGU)

Each OGUy unit combines the available trigger events and status flags from the Input Channels and distributes the results to the system. **Figure 8-39** illustrates the logic blocks within an OGUy unit. All functions of an OGUy unit are controlled by the associated IGCRm registers, one for each pair of output channels e.g. IGCR1 for OGU2 and OGU3. The function of an OGUy unit can be split into two parts:

- **Trigger combination**:
  All trigger signals TRxy from the Input Channels that are enabled and directed to OGUy and a pattern change event (if enabled) are logically OR-combined.
- **Pattern detection**:
  The status flags EIFR.INTFx of the Input Channels can be enabled to take part in the pattern detection. A pattern match is detected while all enabled status flags are set.

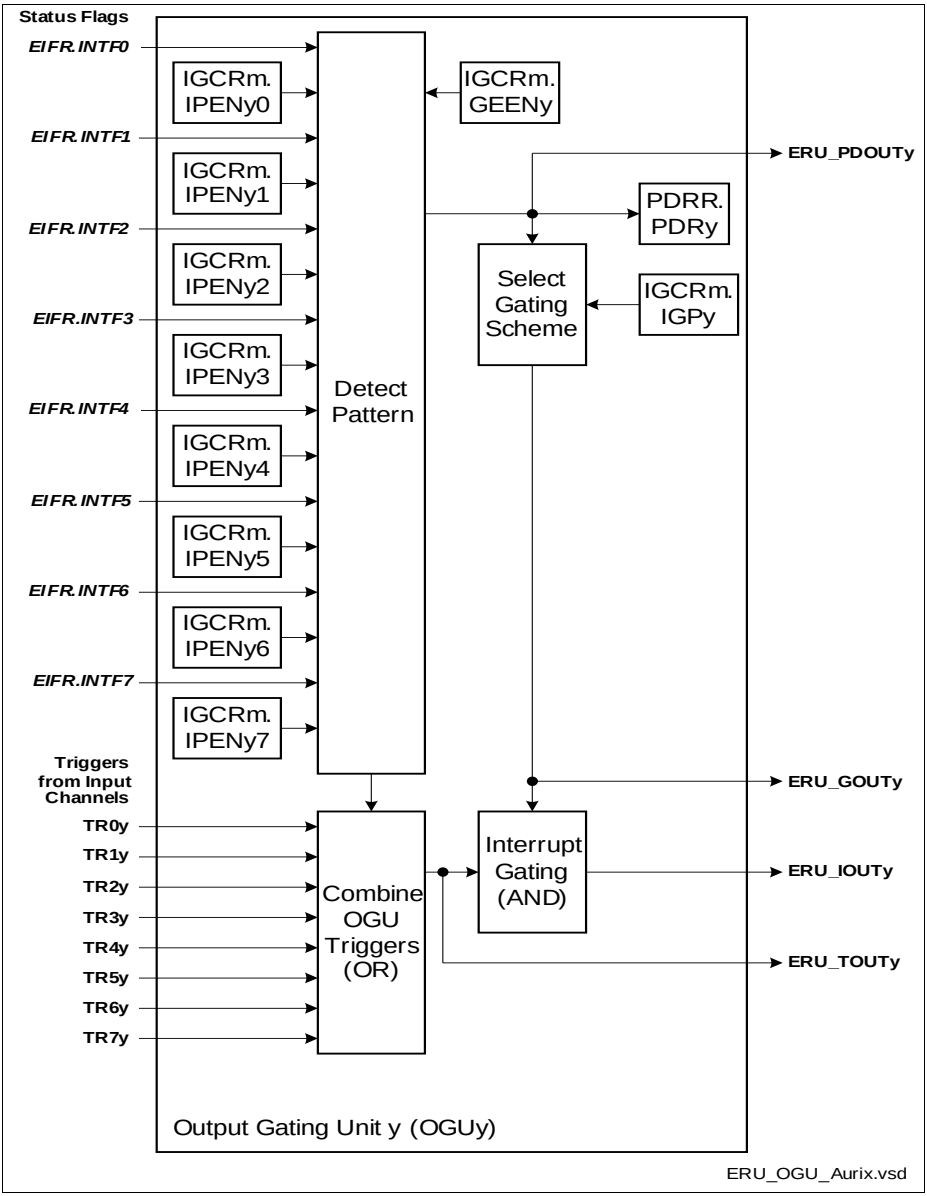

Figure 8-39 Output Gating Unit for Output Channel y

Each OGUy units generates 4 output signals that are distributed to the system.

- **ERU_PDOUTy** to directly output the pattern match information for gating purposes in other modules (pattern match = 1).
- **ERU_GOUTy** to output the pattern match or pattern miss information (inverted pattern match), or a permanent 0 or 1 under software control for gating purposes in other modules.
- **ERU_TOUTy** as combination of a peripheral trigger, a pattern detection result change event, or the ETLx trigger outputs TRxy to trigger actions in other modules.
- **ERU_IOUTy** as gated trigger output (ERU_GOUTy logical AND-combined with ERU_TOUTy) to trigger interrupts (e.g. the interrupt generation can be gated to allow interrupt activation during a certain time window).

Trigger Combination

The trigger combination logically OR-combines different trigger inputs to form a common trigger ERU_TOUTy. Possible trigger inputs are:

- In each ETLx unit of the **Input Channels**, the trigger output TRxy can be enabled and the trigger event can be directed to one of the OGUy units.
- In the case that at least one **pattern detection** input is enabled (IGCRm.IPENxy) and a change of the pattern detection result from pattern match to pattern miss (or vice-versa) is detected, a trigger event is generated to indicate a pattern detection result event (if enabled by IGCRm.GEENy).

The trigger combination offers the possibility to program different trigger criteria for several input signals (independently for each Input Channel) or peripheral signals, and to combine their effects to a single output, e.g. to generate an interrupt or to start an ADC conversion. This combination capability allows the generation of an interrupt per OGU that can be triggered by several inputs (multitude of request sources -> one reaction).

Pattern Detection

The pattern detection logic allows the combination of the status flags of all ETLx units. Each status flag can be individually included or excluded from the pattern detection for each OGUy, via control bits IGCRm.IPENxy. The pattern detection block outputs the following pattern detection results:

- **Pattern match** (PDRR.PDRy = 1 and ERU_PDOUTy = 1):
  A pattern match is indicated while all status flags that are included in the pattern detection are 1.
- **Pattern miss** (PDRR.PDRy = 0 and ERU_PDOUTy = 0):
  A pattern miss is indicated while at least one of the status flags that are included in the pattern detection is 0.

In addition, the pattern detection can deliver a trigger event if the pattern detection result changes from match to miss or vice-versa (if enabled by IGCRm.GEENy = 1). The

pattern result change event is logically OR-combined with the other enabled trigger events to support interrupt generation or to trigger other module functions (e.g. in an ADC). The event is indicated when the pattern detection result changes and PDRR.PDRy becomes updated.

The interrupt generation in the OGUy is based on the trigger ERU_TOUTy that can be gated (masked) with the pattern detection result ERU_PDOUTy. This allows an automatic and reproducible generation of interrupts during a certain time window, where the request event is elaborated by the trigger combination block and the time window information (gating) is given by the pattern detection. For example, interrupts can be issued on a regular time base while a combination of input signals occurs (pattern detection based on ETLx status bits).

Only four interrupt/service requests are generated by the ERU. The mapping of interrupt requests to OGUy blocks is shown in the ERU connection diagram.

A programmable gating scheme introduces flexibility to adapt to application requirements and allows the generation of interrupt requests ERU_IOUTy under different conditions:

- **Pattern match** (IGCRm.IGPy = 10_B):
  An interrupt request is issued when a trigger event occurs while the pattern detection shows a pattern match.
- **Pattern miss** (IGCRm.IGPy = 11_B):
  An interrupt request is issued when the trigger event occurs while the pattern detection shows a pattern miss.
- **Independent** of pattern detection (IGCRm.IGPy = 01_B):
  In this mode, each occurring trigger event leads to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy with interrupt requests on trigger events).
- **No interrupts** (IGCRm.IGPy = 00_B, default setting)
  In this mode, an occurring trigger event does not lead to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy without interrupt requests on trigger events).

8.4.1.7 ERU Output Pin Connections

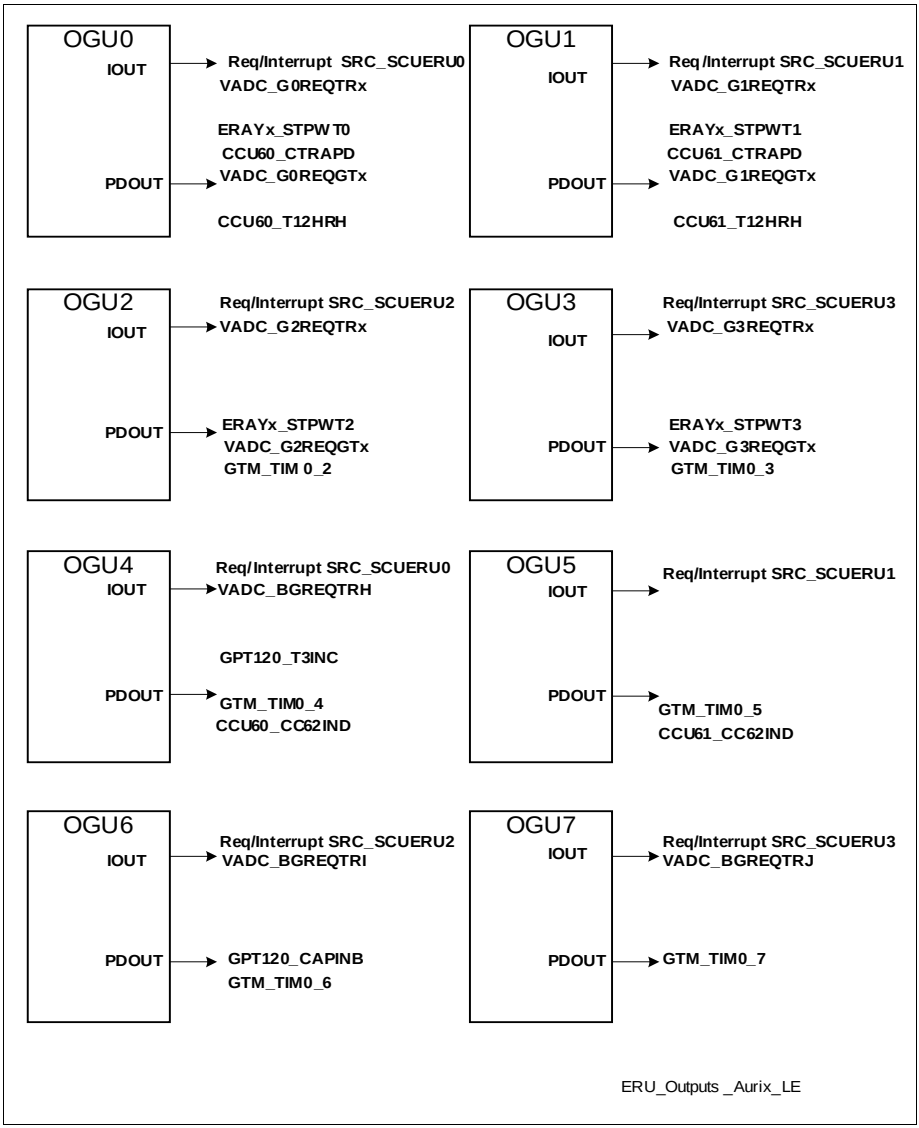

Figure 8-40 External Request Unit Output Connections for TC22x/TC23x

8.4.1.8 External Request Unit Registers

The External Input Channel Registers EICRi (i=0 to 3) for the 4 external input channels contain bits to configure the external request selection ERS and the event trigger logic ETL.

Field	Bits	Type	Description
EXIS0	[6:4]	rw	**External Input Selection 0** This bit field determines which input line is selected for Input Channel (2i). 000_B Input (2i) 0 is selected 001_B Input (2i) 1 is selected 010_B Input (2i) 2 is selected 011_B Input (2i) 3 is selected 100_B Reserved 101_B Reserved 110_B Reserved 111_B Reserved

Field	Bits	Type	Description
FEN0	8	rw	**Falling Edge Enable 0** This bit determines if the falling edge of Input Channel (2i) is used to set bit INTF(2i). 0_B The falling edge is not used 1_B The detection of a falling edge of Input Channel 0 generates a trigger event. INTF(2i) becomes set.
REN0	9	rw	**Rising Edge Enable 0** This bit determines if the rising edge of Input Channel (2*i) is used to set bit INTF(2i). 0_B The rising edge is not used 1_B The detection of a rising edge of Input Channel (2*i) generates a trigger event. INTF(2*i) becomes set
LDEN0	10	rw	**Level Detection Enable 0** This bit determines if bit INTF(2i) is cleared automatically if an edge of the input Input Channel (2i) is detected, which has not been selected (rising edge with REN0 = 0 or falling edge with FEN0 = 0). 0_B Bit INTF(2i) will not be cleared 1_B Bit INTF(2i) will be cleared
EIEN0	11	rw	**External Input Enable 0** This bit enables the generation of a trigger event for request channel (2i) (e.g. for interrupt generation) when a selected edge is detected. 0_B The trigger event is disabled 1_B The trigger event is enabled

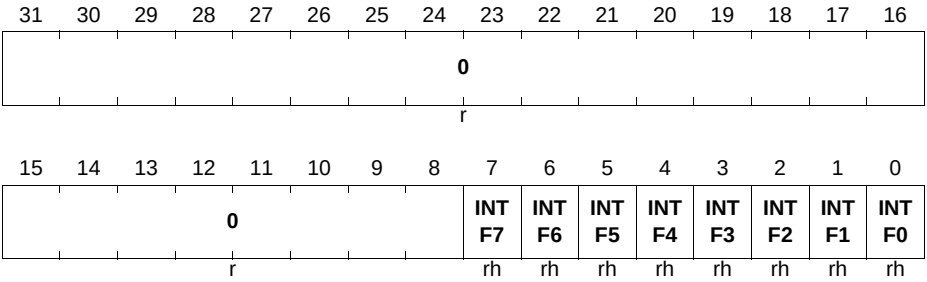
Field	Bits	Type	Description
INP0	[14:12]	rw	**Input Node Pointer** This bit field determines the destination (output channel) for trigger event (2i) (if enabled by EIEN(2i)). 000_B An event from input ETL 2i triggers output OGU0 (signal TR(2i) 0) 001_B An event from input ETL 2i triggers output OGU1 (signal TR(2i) 1) 010_B An event from input ETL 2i triggers output OGU2 (signal TR(2i) 2) 011_B An event from input ETL 2i triggers output OGU3 (signal TR(2i) 3) 100_B An event from input ETL 2i triggers output OGU4 (signal TR(2i) 0) 101_B An event from input ETL 2i triggers output OGU5 (signal TR(2i) 0) 110_B An event from input ETL 2i triggers output OGU6 (signal TR(2i) 0) 111_B An event from input ETL 2i triggers output OGU7 (signal TR(2i) 0)
EXIS1	[22:20]	rw	**External Input Selection 1** This bit field determines which input line is selected for Input Channel (2i+1). 000_B Input (2i+1) 0 is selected 001_B Input (2i+1) 1 is selected 010_B Input (2i+1) 2 is selected 011_B Input (2i+1) 3 is selected 100_B Reserved 101_B Reserved 110_B Reserved 111_B Reserved
FEN1	24	rw	**Falling Edge Enable 1** This bit determines if the falling edge of Input Channel (2i+1) is used to set bit INTF(2i+1). 0_B The falling edge is not used 1_B The detection of a falling edge of Input Channel 1 generates a trigger event. INTF(2i+1) becomes set

Field	Bits	Type	Description
REN1	25	rw	**Rising Edge Enable 1** This bit determines if the rising edge of Input Channel (2i+1) is used to set bit INTF(2i+1). 0_B The rising edge is not used 1_B The detection of a rising edge of Input Channel 1 generates a trigger event . INTF(2i+1) becomes set
LDEN1	26	rw	**Level Detection Enable 1** This bit determines if bit INTF(2i+1) is cleared automatically if an edge of the input Input Channel (2i+1) is detected, which has not been selected (rising edge with REN1 = 0 or falling edge with FEN1 = 0). 0_B Bit INTF(2i+1) will not be cleared 1_B Bit INTF1(2i+1) will be cleared
EIEN1	27	rw	**External Input Enable 1** This bit enables the generation of a trigger event for request channel (2i+1) (e.g. for interrupt generation) when a selected edge is detected. 0_B The trigger event is disabled 1_B The trigger event is enabled
INP1	[30:28]	rw	**Input Node Pointer** This bit field determines the destination (output channel) for trigger event (2i+1) (if enabled by EIEN(2i+1)). 000_B An event from input ETL 2i+1 triggers output OGU0 (signal TR(2i+1) 0) 001_B An event from input ETL 2i+1 triggers output OGU1 (signal TR(2i+1) 1) 010_B An event from input ETL 2i+1 triggers output OGU2 (signal TR(2i+1) 2) 011_B An event from input ETL 2i+1 triggers output OGU3 (signal TR(2i+1) 3) 100_B An event from input ETL 2i+1 triggers output OGU4 (signal TR(2i+1) 0) 101_B An event from input ETL 2i+1 triggers output OGU5 (signal TR(2i+1) 0) 110_B An event from input ETL 2i+1 triggers output OGU6 (signal TR(2i+1) 0) 111_B An event from input ETL 2i+1 triggers output OGU7 (signal TR(2i+1) 0)

Field	Bits	Type	Description
0	[3:0], 7, [19:15], 23, 31	r	**Reserved** Read as 0; should be written with 0.

The External Input Flag Register EIFR contains all status flags for the external input channels. The bits in this register can be cleared by software by setting FMR.FCx, and set by setting FMR.FSx.

EIFR
External Input Flag Register **(220_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
INTFx (x = 0-7)	x	rh	**External Event Flag of Channel x** This bit monitors the status flag of the event trigger condition for the input channel x. This bit is automatically cleared when the selected condition (see RENx, FENx) is no longer met (if LDENx = 1) or remains set until it is cleared by software (if LDENx = 0).
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

FMR
Flag Modification Register **(224_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								w	w	w	w	w	w	w	w

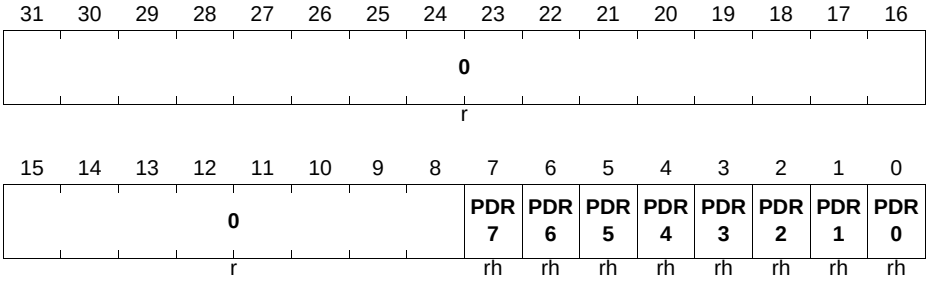
Field	Bits	Type	Description
FSx (x = 0-7)	x	w	**Set Flag INTFx for Channel x** Setting this bit will set the corresponding bit INTFx in register EIFR. Reading this bit always delivers a 0. If both FSx and FCx are set in the same access then the bit x in register EIFR is not modified. 0_B The bit x in register EIFR is not modified 1_B The bit x in register EIFR is set
FCx (x = 0-7)	16 + x	w	**Clear Flag INTFx for Channel x** Setting this bit will clear the corresponding bit INTFx in register EIFR. Reading this bit always delivers a 0. If both FSx and FCx are set in the same access then the bit x in register EIFR is not modified. 0_B The bit x in register EIFR is not modified 1_B The bit x in register EIFR is cleared
0	[15:8], [31:24]	r	**Reserved** Read as 0; should be written with 0.

The Pattern Detection Result Register monitors the combinatorial output status of the pattern detection units.

PDRR
Pattern Detection Result Register (228_H) Reset Value: 0000 00FF$_H$



Field	Bits	Type	Description
PDRy (y = 0-7)	y	rh	**Pattern Detection Result of Channel y** This bit monitors the output status of the pattern detection for the output channel y.
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

The Interrupt Gating Control Registers IGCRj (j=0 to 3) contain bits to enable the pattern detection and to control the gating for the output channels.

IGCR0
Flag Gating Register 0 **($22C_H$)** **Reset Value: 0000 0000$_H$**
IGCR1
Flag Gating Register 1 **(230_H)** **Reset Value: 0000 0000$_H$**
IGCR2
Flag Gating Register 2 **(234_H)** **Reset Value: 0000 0000$_H$**
IGCR3
Flag Gating Register 3 **(238_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw		rw	r					rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
IPEN0x (x = 0-7)	x	rw	**Flag Pattern Enable for Channel 0** Bit IPEN0x determines if the flag INTFx of channel x takes part in the pattern detection for the gating of the requests for the output signals GOUT(2*j) and IOUT(2*j). 0_B The bit INTFx does not take part in the pattern detection 1_B The bit INTFx is taken into consideration for the pattern detection
GEEN0	13	rw	**Generate Event Enable 0** Bit GEEN0 enables the generation of a trigger event for output channel (2*j) when the result of the pattern detection changes. When using this feature, a trigger (e.g. for an interrupt) is generated during the first clock cycle when a pattern is detected or when it is no longer detected. 0_B The trigger generation at a change of the pattern detection result is disabled 1_B The trigger generation at a change of the pattern detection result is enabled

Field	Bits	Type	Description
IGP0	[15:14]	rw	**Interrupt Gating Pattern 0** In each register IGCRj, bit field IGP0 determines how the pattern detection influences the output lines GOUT(2j) and IOUT(2j). 00_B IOUT(2j) is inactive.The pattern is not considered. 01_B IOUT(2j) is activated in response to a trigger event. The pattern is not considered. 10_B The detected pattern is considered. IOUT(2j) is activated if a trigger event occurs while the pattern is present. 11_B The detected pattern is considered. IOUT(2j) is activated if a trigger event occurs while the pattern is not present.
IPEN1x (x = 0-7)	16+x	rw	**Interrupt Pattern Enable for Channel 1** Bit IPEN(2j+1)x determines if the flag INTFx of channel (2j+1) takes part in the pattern detection for the gating of the requests for the output signals GOUT(2j+1) and IOUT(2j+1). 0_B The bit INTFx does not take part in the pattern detection 1_B The bit INTFx is taken into consideration for the pattern detection
GEEN1	29	rw	**Generate Event Enable 1** Bit GEEN1 enables the generation of a trigger event for output channel (2j+1) when the result of the pattern detection changes. When using this feature, a trigger (e.g. for an interrupt) is generated during the first clock cycle when a pattern is detected, or when it is no longer detected. 0_B The trigger generation at a change of the pattern detection result is disabled 1_B The trigger generation at a change of the pattern detection result is enabled

Field	Bits	Type	Description
IGP1	[31:30]	rw	**Interrupt Gating Pattern 1** In each register IGCRj, bit field IGP1 determines how the pattern detection influences the output lines GOUT(2j+1) and IOUT(2j+1). 00_B IOUT(2j+1) is inactive.The pattern is not considered. 01_B IOUT(2j+1) is activated in response to a trigger event. The pattern is not considered. 10_B The detected pattern is considered. IOUT(2j+1) is activated if a trigger event occurs while the pattern is present. 11_B The detected pattern is considered. IOUT(2j+1) is activated if a trigger event occurs while the pattern is not present.
0	[12:8], [28:24]	r	**Reserved** Read as 0; should be written with 0.

8.4.2 Lockstep CPU Configuration

This section contains the registers which are used to configure and enable CPU Lockstep Mode. These registers are only writeable by start-up firmware and are configured from the BMI . See the Firmware and Lockstep Control Logic chapters for further details.

8.4.2.1 Logic Monitor Control Registers

LCL CPU0 Control

Provides control for CPU0 lockstep compare logic block.

LCLCON0
LCL CPU0 Control Register **(134_H)** **Reset Value: 8001 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LSEN							0								LS
rw							r								rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															
r															

Field	Bits	Type	Description
0	[15:0]	r	**Reserved** will be read as 0_B, should be written as 0_B
LS	16	rh	**Lockstep Mode Status** This bit indicates whether CPU0 is currently running in lockstep monitor mode 0_B Not in lockstep mode 1_B Running in lockstep mode
0	[30:17]	r	**Reserved** will be read as 0_B, should be written as 0_B
LSEN	31	rw	**Lockstep Enable** This bit may only be written by SSW during boot. Enable lockstep CPU monitoring for the associated processor core, CPU0. After cold reset, lockstep is enabled by default. The LSEN bit may be cleared during the boot to disable lockstep mode. SMU lockstep fault reporting should be disabled when lockstep is disabled. 0_B Lockstep is disabled 1_B Lockstep enabled (Default after Cold Power-On Reset)

LCL CPU1 Control

Provides control for CPU1 lockstep compare logic block.

LCLCON1
LCL CPU1 Control Register (138$_H$) Reset Value: 8000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LSEN							0								LS
rw							r								rh

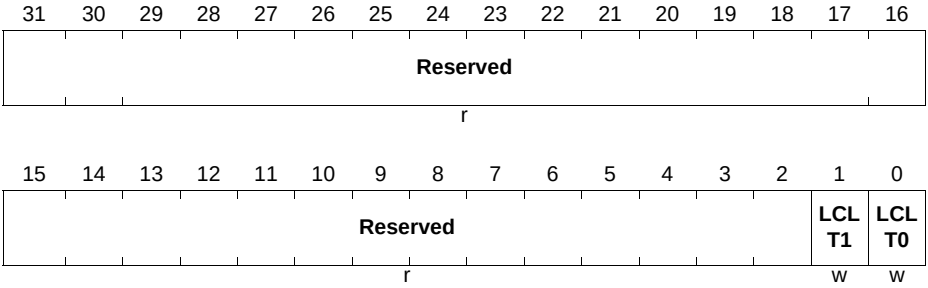
0															
r															

Field	Bits	Type	Description
0	[15:0]	r	**Reserved** will be read as 0_B, should be written as 0_B
LS	16	r	**Reserved in this product** will be read as 0_B, should be written as 0_B
0	[30:17]	r	**Reserved** will be read as 0_B, should be written as 0_B
LSEN	31	rw	**Reserved in this product** will be read as 1_B, should be written as 1_B

LCL Test Register

Provides the capability for software to inject a fault condition into the comparators of each lockstep compare logic block. The implementation should generate a single cycle fault each time the bit is written with ‘1’.

LCLTEST
LCL Test Register **($13C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	[31:2]	r	**Reserved**
LCLT0	0	rwh	**LCL0 Lockstep Test** Fault injection for LCL0. Reads as zero. 0_B No action 1_B Inject single fault in LCL0
LCLT1	1	r	**Reserved in this product**

Critical Register Monitoring

Safety critical SCU registers are protected by the Safety Endinit signal against accidental software writes. In addition to this, a continuous monitoring mechanism is provided to check the content of these safety critical registers have not been affected by random single bit flip-flop failures. This mechanism is controlled by the SMU.

The System Control registers with write access mode “SE” listed in **Table 8-29** are covered by this mechanism. This includes:

- CCU registers OSCCON, PLLCONx, PLLERAYCONx, CCUCONx, FDR, EXTCON
- RCU registers RSTCON, ARSTDIS, SWRSTCON, RSTCONx, ESRCFGx, ESROCFG, PDISC
- EVR registers EVRRSTCON, EVRSDCOEFF*, EVRSDCTRL*, EVRTRIM, EVR13CON
- PMC registers PMSWCRx, PMCSRx , PMSWSTATCLR
- Emergency Stop register EMSR
- Registers controlling safety monitors WDTSCONx1, WDTCPU*CON1, LBISTCTRLx, EVRUVMON, EVROVMON
- MTU registers MEMTEST, MEMMAP, MEMSTAT, ECCS and RAR

Any single bit flipflop failures will be reported via an SMU alarm.

8.4.3 Die Temperature Measurement

The Die Temperature Sensor (DTS) generates a measurement result that indicates directly the current temperature. The result of the measurement is displayed via bit field DTSSTAT.RESULT. In order to start one measurement bit DTSCON.START needs to be set.

The DTS has to be enabled before it can be used via bit DTSCON.PWD. When the DTS is powered after the start-up time of the DTS (defined in the Data Sheet) a temperature measurement can be started.

Note: If bit field DTSSTAT.RESULT is read before the first measurement was finished it will return 0x000.

When a measurement is started the result is available after the measurement time passed. If the DTS is ready to start a measurement can be checked via bit DTSSTAT.RDY. If a started measurement is finished or still in progress is indicated via the status bit DTSSTAT.BUSY. The measurement time is also defined in the Data Sheet.

In order to adjust production variations bit field DTSCON.CAL is available. DTSCON.CAL is automatically programmed with a predefined value.

Note: The first measurement after the DTS was powered delivers a result without calibration adjustment and should be ignored therefore.

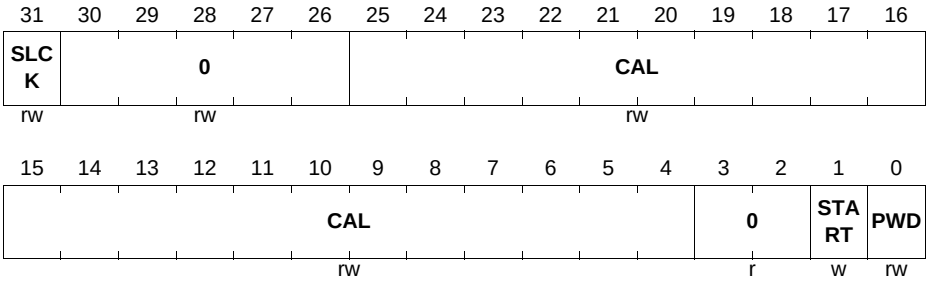
The formula to calculate the die temperature is defined in the Data Sheet.

Note: The maximum resolution is only achieved for a measurement that is part of multiple continuous measurements (recommended to ignore are two here).

An interrupt service request (SRC_SCUDTS) is generated when DTS busy indication changes from 1 to 0.

8.4.3.1 Die Temperature Sensor Register

DTSCON
Die Temperature Sensor Control Register($0E4_H$) **Reset Value: $0000\ 0001_H$**



Field	Bits	Type	Description
PWD	0	rw	**Sensor Power Down** This bit defines the DTS power state. 0_B The DTS is powered 1_B The DTS is not powered
START	1	w	**Sensor Measurement Start** This bit starts a measurement of the DTS. 0_B No DTS measurement is started 1_B A DTS measurement is started If set this bit is automatically cleared. This bit always reads as zero.
CAL	[25:4]	rw	**Calibration Value** This bit field interfaces the calibration values to the DTS.

Field	Bits	Type	Description
SLCK	31	rw	**Security Lock** 0_B No lock active 1_B Lock is active If this bit is set, no bits in this register (except START) are writeable. Attempted writes when LCK is set will cause an SMU SPB error alarm trigger. This bit can not by cleared by software. This bit can only be set by an access from the HSM master (TAG = 001101_B). A set operation performed by any other master is ingnored and the bit is not modified.
0	[3:2], [30:24]	r	**Reserved** Read as 0; should be written with 0.

DTSSTAT

Die Temperature Sensor Status Register($0E0_H$) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BUSY	RDY	0				RESULT									
rh	rh	r				rh									

Field	Bits	Type	Description
RESULT	[9:0]	rh	**Result of the DTS Measurement** This bit field shows the result of the DTS measurement. The value given is directly related to the die temperature. Only the bit [9:2] have to be evaluated.
RDY	14	rh	**Sensor Ready Status** This bit indicate the DTS is ready or not. 0_B The DTS is not ready 1_B The DTS is ready

Field	Bits	Type	Description
BUSY	15	rh	**Sensor Busy Status** This bit indicate the DTS is currently busy or not. If the sensor is busy currently a measurement is running and the result should not be used. 0_B The DTS is not busy 1_B The DTS is busy *Note: This bit is updated 2 cycles after bit DTSCON.START is set.*
0	[13:10], [31:16]	r	**Reserved** Read as 0; should be written with 0.

DTSLIM

Die Temperature Sensor Limit Register(240_H) **Reset Value: $03FF\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UOF	**SLCK**	**0**				**UPPER**									
rwh	rw	r				rw									

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LLU	**0**					**LOWER**									
rwh	r					rw									

Field	Bits	Type	Description
LOWER	[9:0]	rw	**Lower Limit** This bit field defines the lower limit of the DTS temerature check. The DTS measurement result is compared against this value and if the measurement result is smaller than LOWER bit LLU is set.

Field	Bits	Type	Description
LLU	15	rwh	**Lower Limit Underflow** 0_B No temperature underflow was detected 1_B A temperature underflow was detected When this bit is set an HSM temperature underflow trigger is generated. When this bit is set an temperature SMU DTS alarm trigger is generated. This bit is cleared by writting a zero. Writting a one has no effect. This bit is updated when either a DTS measurement is finished or if bit field LOWER is changed.
UPPER	[25:16]	rw	**Upper Limit** This bit field defines the upper limit of the DTS temperature check. The DTS measurement result is compared against this value and if the measurement result is greater than UPPER bit UOF is set
SLCK	30	rw	**Security Lock** 0_B No lock active 1_B Lock is active If this bit is set both bit fields LOWER and UPPER can not longer be written. Write requests when LCK is set will cause a SMU SPB error alarm trigger. This bit can not by cleared by software. This bit can only be set by an access from the HSM master (TAG = 001101_B). A set operation performed by any other master is ingnored and the bit is keep as cleared.
UOF	31	rh	**Upper Limit Overflow** 0_B No temperature overflow was detected 1_B A temperature overflow was detected When this bit is set an HSM temperature overflow trigger is generated. When this bit is set an SMU DTS alarm trigger is generated. This bit is cleared by writting a zero. Writting a one has no effect. This bit is updated when either a DTS measurement is finished or if bit field UPPER is changed.

Field	Bits	Type	Description
0	[14:10], [29:26]	r	**Reserved** Read as 0; should be written with 0.

8.4.4 Watchdog Timers

This section describes the TC21x/TC22x/TC23x Watchdog Timers (WDTs). Topics include an overview of the WDT functions and descriptions of the registers, the password-protection scheme, accessing registers, modes, and initialization.

The TC21x/TC22x/TC23x contains the following Watchdog Timers:

- Safety Watchdog
- CPU0 Watchdog

8.4.4.1 Watchdog Timers Overview

The WDTs provide a highly reliable and secure way to detect and recover from software or hardware failure. The WDTs help to abort an accidental malfunction of a CPU or TC21x/TC22x/TC23x system within a user-specified time period.

In addition to this standard “Watchdog” function, each of the WDTs incorporates an End-of-Initialization (ENDINIT) feature which can protect critical registers from accidental writes.

Servicing the Watchdogs and modifying the ENDINIT bits are critical functions that must not be allowed in case of a system malfunction. To protect these functions a sophisticated scheme is implemented that requires a password and guard bits during accesses to the WDT control registers. Any write access that does not deliver the correct password or the correct value for the guard bits is regarded as a malfunction of the system, and results in a watchdog alarm. In addition, even after a valid access has been performed and an ENDINIT bit has been cleared to provide access to the critical registers, the Watchdog imposes a time limit for this access window. If the ENDINIT bit has not been properly set again before this limit expires, the system is assumed to have malfunctioned, and a Watchdog alarm is reported to the Safety Management Unit (SMU). These stringent requirements, although not guaranteed, nonetheless provide a high degree of assurance of the robustness of system operation.

Configuration options are available which enable a Watchdog service to additionally check code execution sequence and intermediate code execution time. If these checks are enabled then any incorrect sequence or out-of-limit execution time will also result in an SMU alarm request.

Expiry of any of the TC21x/TC22x/TC23x WDTs leads to an SMU alarm request. It is possible to program the SMU to provide an interrupt or NMI to provide some time for recovery or status recording before further action is taken (eg reset of the device or stopping of the CPU via idle request).

Safety Watchdog

The Safety Watchdog Timer provides an overall system level watchdog which is independent from the CPU watchdogs and also provides temporal protection against unintended writes to critical system registers which could have impact on safety-critical

systems. When the Safety WDT is enabled, it can cause an SMU alarm request if it is not serviced within a user-programmable time period. A CPU must service the Safety WDT within this time interval to prevent this. The response to a Safety WDT timeout is configurable within the SMU. Hence, periodic servicing of the Safety WDT confirms that the system is functioning as expected.

Typically the SCU write protection (ACCEN) will be configured so that only restricted “Safety” CPU(s) can configure system-critical functionality. This includes the ability to service the Safety Watchdog. In addition, Safety Watchdog disable/enable/configuration function requires a Safety ENDINIT password.

The registers marked “SE” in **Table 8-29** and other module Register Tables are considered to be static properties of a safety-critical system and are all write-protected by the Safety ENDINIT feature so that they cannot be changed without unlocking the Safety Watchdog.

CPU Watchdogs

The individual CPU Watchdog Timers provide the ability to monitor separate CPU execution threads without the need for software to co-ordinate the shared use of a common watchdog. Each CPUx watchdog timer also incorporates a local CPUx_Endinit feature which provides temporal protection against unintended writes to critical local CPU registers and also some system registers which require protection but are not already covered by the Safety ENDINIT.

When a CPU WDT is enabled it can cause an SMU alarm request if it is not correctly serviced within a user-programmable time period. The CPU must service its CPU WDT within this time interval to prevent this. The response to each CPUx watchdog timeout is configurable within the SMU. Hence, periodic servicing of a CPU WDT confirms that the corresponding CPU is executing a software sequence as expected.

After a reset, CPU0 runs and CPU0 watchdog timer starts automatically. Other CPUs are initially in a HALT state and therefore their corresponding Watchdog Timers are disabled. The other CPU Watchdogs are not configured to generate a time-out reset by default, but this can be enabled (See SMU section). A CPU Watchdog may only be configured, enabled or disabled by its corresponding CPU.

8.4.4.2 Features of the Watchdog Timers

The main features of the WDTs are summarized here.

- 16-bit Watchdog counter
- Selectable input frequency: f_{SPB}/64, f_{SPB}/256 or f_{SPB}/16384
- 16-bit user-definable reload value for normal Watchdog operation, fixed reload value for Time-Out Mode
- Incorporation of the corresponding ENDINIT bit and monitoring of its modifications
- Sophisticated Password Access mechanism with user-definable password fields
- Access Error Detection: Invalid password (during first access) or invalid guard bits (during second access) trigger an alarm request to the SMU
- Temporal and logical monitoring capabilities:
  - Optional Code Sequence checking. An incorrect code sequence signature identification will trigger an alarm request to the SMU
  - Optional Code Execution Time checking. Code execution times out of expected limits will trigger an alarm request to the SMU.
- Overflow Error Detection: An overflow of the WDT counter triggers an alarm request to the SMU
- Watchdog function can be disabled; access protection and ENDINIT bit monitor function remain enabled
- Configurable mechanism to prevent Watchdog reloads after an unserviced safety warning alarm to ensure that unserviced warnings lead to an SMU hardware response
- External “Alive heartbeat” indication to show that WDT is running and SMU is not in alarm mode

8.4.4.3 The Endinit Functions

There are a number of registers in the TC21x/TC22x/TC23x that are usually programmed only once during the initialization sequence of the system or application. Modification of such registers during normal application run can have a severe impact on the overall operation of modules or the entire system.

While the Supervisor Mode and the Access Protection scheme provide a certain level of protection against unintentional modifications, they may not be sufficient to protect against all unintended accesses to system-critical registers.

The TC21x/TC22x/TC23x provides one more level of protection for such registers via the various Endinit features. This is a highly secure write-protection scheme that makes unintentional modifications of registers protected by this feature nearly impossible.

The Endinit feature consists of an ENDINIT bit incorporated in each WDT control register. Registers protected via an Endinit determine whether or not writes are enabled. Writes are only enabled if the corresponding ENDINIT = 0 AND Supervisor Mode is active. Write attempts if this condition is not true will be discarded and the register

contents will not be modified in this case. The BCU controls the further operation following a discarded write access.

To get the highest level of security, writes to the ENDINIT bits are protected by a highly secure access protection scheme implemented in the WDTs. This is a complex procedure, that makes it nearly impossible for ENDINIT bits to be modified unintentionally. In addition, each WDT monitors ENDINIT bit modifications by starting a time-out sequence each time software opens access to the critical registers through clearing the corresponding ENDINIT bit. If the time-out period ends before the corresponding ENDINIT bit is set again, a malfunction of the software is assumed and a Watchdog fault response is generated.

The access-protection scheme and the Endinit time-out operation of the WDTs is described in the following sections. In the register overview tables for each module (including the SCU itself) the registers which are protected via each Endinit type are identified in the column describing write accesses as follows:

- “CE0”- writeable only when CPU0 ENDINIT bit is zero
- “E” - writeable when any (one or more) CPUx ENDINIT bit is zero
- “SE” - writeable only when Safety ENDINIT bit is zero
- None of the above - accessible at any time

Note: The clearing of an ENDINIT bit takes some time. Accesses to Endinit-protected registers after the clearing of an ENDINT bit must only be done when the ENDINIT bit is really cleared. As a solution the ENDINIT bit should be read back once before Endinit-protected registers are accessed the first time after bit ENDINIT has been cleared.

Password Access to WDTxCON0

A correct password must be written to register WDTxCON0 (x=S,CPU0) in order to unlock it for modifications. Software must either know the correct password in advance or compute it at runtime. The passwords for each of the Watchdogs (x=S,CPU0) can be different in order to provide independent watchdog functionality program flows to have independent watchdog functions.

The Safety Watchdog password register WDTSCON0 is protected by the generic SCU protection scheme which allows only configured master(s) to have write access (See **ACCEN0**).

CPU-specific Watchdog password registers WDTCPUyCON0 are individually protected such that they may only be written by the corresponding CPUy

A watchdog may be used within a safety application to provide a recovery time period during which software might attempt to recover from a safety alarm warning. To ensure that a CPU fault could not allow a fault to be ignored an option is provided to prevent watchdog unlocking if the Safety Management Unit (SMU) is not in the RUN state. This option may be enabled by bit WDTxCON0.UR.

If the password is valid and the SMU state meets the requirements of the WDTxCON0.US bit then WDTxCON0 will be unlocked as soon as the Password Access is completed. The unlocked condition will be indicated by WDTxCON0.LCK = 0. To ensure the correct servicing sequence, a password access is only permitted when the WDTxCON0.LCK bit was set prior to the access.

If an improper password value is written to WDTxCON0 during the Password Access, a Watchdog Access Error condition exists. Bit WDTxSR.AE is set and an alarm request is sent to the Safety Management Unit (SMU).

The 14-bit user-definable password, WDTxCON0.PW, provides additional options for adjusting the password requirements to the application’s needs. It can be used, for instance, to detect unexpected software loops, or to monitor the execution sequence of routines.

Table 8-25 summarizes the requirements for the password. Various options exist, which are described in more detail below

Table 8-25 Password Access Bit Pattern Requirements

Bit Position	Required Value
[1:0]	Fixed; must be written to 01_B
[15:2]	If PAS=0: WDTxCON0.PW[7:2] must be written with inverted current value read from WDTxCON0.PW[7:2] WDTxCON0.PW[15:8] must be written with non-inverted current value read from WDTxCON0.PW[15:8] If PAS=1: Must be written with Expected Next Sequence Password
[31:16]	If TCS=0: Must be written with current value of user-definable reload value, WDTxCON0.REL If TCS=1: Must be written with inverted estimate of the WDT count value, WDTxSR.TIM. This value must be within +/- WDTxSR.TCT of the actual value

Static Password

In the static password mode (WDTxSR.PAS=0) the password can only be changed by a valid Modify Access. The Password Access has been designed such that it is not possible simply to read the register and re-write it. Some of the password read bits must be inverted (toggled) before being re-written. This prevents a simple malfunction from accidentally unlocking the WDT through a simple read/write sequence.

Automatic Password Sequencing

If automatic password sequencing is enabled (WDTxSR.PAS=1) then the password changes automatically after each password check (i.e. Password Access or Check Access). The Expected Next Password follows a pseudo-random sequence based upon a 14-bit Fibonacci LFSR (Linear Feedback Shift Register) with characteristic polynomial x14+x13+x12+x2+1. An initial password (or subsequent manual password updates) can also be provided by Modify Accesses.

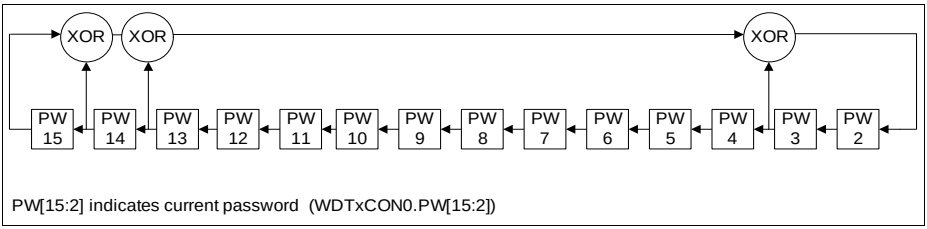


Figure 8-41 Password Sequencing LFSR

Time-Independent Password

If time checking is not enabled (WDTxSR.TCS=0) then the REL field of the WDTxCON0 register must be simply re-written with the existing reload value during the Password Access.

Time Check Password

If time checking is enabled (WDTxSR.TCS=1) the the REL field of the WDTxCON0 register must be written with an inverted (bitflipped) estimate of the current WDT count value. The acceptable margin of error of this estimate (in WDT clock periods) is specified by the value of WDTxSR.TCT. If the written estimate is outside the range WDTxSR.TIM +/- WDTxSR.TCT, then an SMU alarm condition is indicated. This mechanism can provide a check of the elapsed program execution time since the last WDT restart. Note that a Time Check comparison is still required for a Password or Check Access while the WDT is operating in Time-Out mode (e.g. After accessing ENDINIT-protected registers).

Check Access to WDTxCON0

A Check Access is identical to a Password Access except that the lock bit is not cleared and a subsequent Modify Access is therefore not allowed. A Check Access does not trigger an SMU Alarm Request provided that the write data requirements are satisfied. A Check Access may only be performed when the LCK bit is set.

This type of access is used for intermediate checkpoints between WDT services. This may be used (e.g. in conjunction with the timestamp count checking feature or sequence passwords) for task sequence or execution time monitoring.

Table 8-26 Check Access Bit Pattern Requirements

Bit Position	Required Value
[1:0]	Fixed; must be written to 11_B
[15:2]	If PAS=0: WDTxCON0.PW[7:2] must be written with inverted current value read fromWDTxCON0.PW[7:2] WDTxCON0.PW[15:8] must be written with non-inverted current value read from WDTxCON0.PW[15:8] If PAS=1: Must be written with Expected Next Sequence Password
[31:16]	If TCS=0: Must be written with current value of user-definable reload value, WDTxCON0.REL If TCS=1: Must be written with inverted estimate of the WDT counter WDTxSR.TIM. This value must be within +/- WDTxSR.TCT of the actual value

If an improper value is written to WDTxCON0 during the Check Access, a Watchdog Access Error condition exists. Bit WDTxSR.AE is set and an alarm request is sent to the Safety Management Unit (SMU).

Modify Access to WDTxCON0

If a WDTxCON0 is successfully unlocked by a Password Access, the following write access to WDTxCON0 can modify it. However, this access must also meet certain requirements in order to be accepted and regarded as valid. **Table 8-27** lists the required bit patterns. If the access does not follow these rules, a Watchdog Access Error condition is detected, bit WDTxSR.AE is set, and an alarm request is sent to the Safety Management Unit (SMU).

Table 8-27 Modify Access Bit Pattern Requirements

Bit Position	Value
0	User-definable; desired value for bit WDTxCON0.ENDINIT.
1	Fixed; must be written with 1_B.
[15:2]	User-definable; desired value of user-definable password field, WDTxCON0.PW.
[31:16]	User-definable; desired value of user-definable reload value, WDTxCON0.REL.

After the Modify Access has completed, WDTxCON0.LCK is set again, automatically re-locking WDTxCON0. Before the register can be modified again, a valid Password Access must be executed again.

External WDT “Alive Heartbeat” Indication

The current state of the SAFECON.HBT bit may optionally be routed to external pin(s). This register may only be written during a Safety WDT service (between a Modify Access with Safety ENDINIT=0 and the subsequent Modify Access with Safety ENDINIT=1). Periodic toggling of this bit by software can therefore be used to indicate to an external monitor that the CPU is operational and the Safety Watchdog Timer is still running. If the Unlock Restriction (UR bit) is also enabled then any other SMU safety alarm condition will prevent a WDT refresh and hence stop the heartbeat automatically.

Access to Endinit-Protected Registers

If write access to Endinit-protected registers is required during run time, write access can be re-enabled for a limited time period. To re-enable access, WDTxCON0 must first be unlocked with a valid Password Access. In the subsequent valid Modify Access, ENDINIT can be cleared. Access to Endinit-protected registers is now open again. However, when WDTxCON0 is unlocked, the WDT is automatically switched to Time-Out Mode. The access window is therefore time-limited. Time-Out Mode is only terminated after ENDINIT has been set again, requiring another Valid Password and Valid Modify Access to WDTxCON0.

If the WDT is not used in an application and is therefore disabled (WDTxSR.DS = 1), the above described case is the only occasion when WDTxCON0 must be accessed again after the system is initialized. If there are no further changes to critical system registers needed, no further accesses to WDTxCON0, WDTxCON1, or WDTxSR are necessary. However, it is recommended that the WDT be used in an application for safety reasons.

For debugging support the Cerberus module can override all the ENDINIT controls of all WDTs to ease the debug flow. If bit CBS_OSTATE.ENIDIS is set all ENDINIT protection is disabled independent of the current status configured by the WDTs. If CBS_OSTATE.ENIDIS is cleared the complete control is within the WDTs.

8.4.4.4 Timer Operation

The timers for Safety Watchdog and CPU0 are automatically active after an Application Reset . Each 16-bit counter implementing the timer functionality is either triggered with f_{SPB} / 64, f_{SPB} / 256 or f_{SPB} / 16384. The three possible counting rates are controlled via bit WDTxCON1.IRx.

Determining WDT Periods

All WDTs use the SPB clock f_{SPB}. A clock divider in front of each WDT provides three WDT counter frequencies, f_{SPB} / 64, f_{SPB} / 256 and f_{SPB} / 16384.

The general formula to calculate a Watchdog timeout period is:

(8.26)

$$\text{period} = \frac{(2^{16} - \text{startvalue}) \cdot \text{divider}}{f_{SPB}}$$

The parameter startvalue represents the fixed value $FFFC_H$ for the calculation of the Time-Out Period, and the user-programmable reload value WDTxCON0.REL for the calculation of the Normal Period.

The parameter divider represents the user-programmable source clock division selected by WDTxCON0.IRx, which can be 64, 256 or 16384.

Timer Modes

Each Watchdog Timer can operate in one of three different operating modes:

- Time-Out Mode
- Normal Mode
- Disable Mode

The following overview describes these modes and how the WDT changes from one mode to the other.

Time-Out Mode

The Time-Out Mode is entered after an Application Reset or when a valid Password Access to register WDTxCON0 is performed. The Time-Out Mode is indicated by bit WDTxSR.TO = 1. The timer is set to $FFFC_H$ and starts counting upwards. Time-Out Mode can only be exited properly by setting ENDINIT = 1 with a correct access sequence. If an improper access to the WDT is performed, or if the timer overflows before ENDINIT is set, and an alarm request is sent to the Safety Management Unit (SMU).

A proper exit from Time-Out Mode can either be to the Normal or the Disable Mode, depending on the state of the disable request bit WDTxCON1.DR.

Normal Mode

In Normal Mode (DR = 0), the WDT operates in a standard Watchdog fashion. The timer is set to WDTxCON0.REL, and begins counting up. It has to be serviced before the counter overflows. Servicing is performed through a proper access sequence to the control register WDTxCON0. This enters the Time-Out Mode.

If the WDT is not serviced before the timer overflows, a system malfunction is assumed. Normal Mode is terminated and an alarm request is sent to the Safety Management Unit (SMU)

Disabled Mode

Disabled Mode is provided for applications which truly do not require the WDT function. It can be requested from Time-Out Mode when the disable request bit WDTxCON1.DR is set. The Disabled Mode is entered when was requested AND bit WDTxCON0.ENDINIT is set. The timer is stopped in this mode. However, disabling the WDT only stops it from performing the standard Watchdog function, eliminating the need for timely service of the WDT. It does not disable Time-Out mode. If an access to register WDTxCON0 is performed in Disabled Mode, Time-Out Mode is entered if the access was valid, and an alarm request is sent to the Safety Management Unit (SMU) if the access was invalid. Thus, the ENDINIT monitor function as well as (a part of) the system malfunction detection will still be active.

WDT Alarm Request

SMU alarm requests are generated for three cases:

- Invalid write data during access to register WDTxCON0
- Not executing a password access before a timer overflow occurs in the Time-Out Mode
- Not serving the WDT before a timer overflow occurs in the Normal Mode

The resulting alarm response(eg NMI, Reset etc) is programmable within the Safety Management Unit (SMU).

Note: The WDT itself is reset by any Application Reset .

Servicing the Watchdog Timer

If the WDT is used in an application and is enabled (WDTxSR.DS = 0), it must be regularly serviced to prevent it from overflowing.

Service is performed in two steps, a valid Password Access followed by a valid Modify Access. The valid Password Access to WDTxCON0 automatically switches the WDT to Time-Out Mode. Thus, the Modify Access must be performed before the time-out expires or an alarm request will be sent to the Safety Management Unit (SMU).

During the next Modify Access, the strict requirement is that WDTxCON0.ENDINIT is written with 1.

Note: ENDINIT must be written with 1 to perform a proper service, even if it is already set to 1.

Changes to the reload value WDTxCON0.REL, or the user-definable password WDTxCON0.PW, are not required.

When a WDT service is properly executed, Time-Out Mode is terminated, and the WDT switches back to its former mode of operation, and the WDT service is complete.

Check Accesses are optional and may be performed at any time when the WDT is locked.

WDT Operation During Power-Saving Modes

If one or more of the CPU are in Idle Mode, they cannot service a WDT because no software is running. Excluding the case where the system is running normally, a strategy for managing WDTs is needed while a CPU is in Idle Mode. There are two ways to manage a WDT in these cases. Firstly, the Watchdog can be disabled before idling the CPU. The disadvantage of this is that the system will no longer be monitored during the idle period.

A better approach to this problem relies upon the wake-up feature of the WDTs. Whenever CPUx is put in Idle or Sleep Mode and the WDT is not disabled, the CPUx is woken at regular intervals. When WDTx changes its count value (WDTxSR.TIM) from $7FFF_H$ to 8000_H, CPUx is woken and continues execution at the instruction following the instruction that was executed before entering the Idle or Sleep Mode.

Note: Before switching into a non-running power-management mode, software should perform a Watchdog service sequence. At the Modify Access, the Watchdog reload value, WDTxCON0.REL, should be programmed such that the wake-up occurs after a period which best meets application requirements. The maximum period between two CPU wake-ups is one-half of the maximum WDT period.

Suspend Mode Support

During a debug session the Watchdog functionality might lead to unintended alarms.

By default the WDTs are disabled when OCDS is enabled. However, it is possible to enable the WDTs also when debug is enabled. Please refer to the manual of your debugger tool for details.

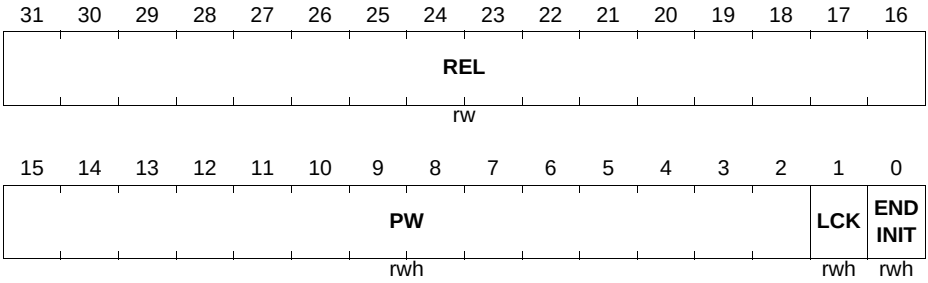
8.4.4.5 Watchdog Timer Registers

Watchdog Timer Control Register 0

This register is written with check data in Check Accesses and Password Accesses. It also stores the timer reload value, password update and the corresponding End-of-Initialization (ENDINIT) control bit during a Modify Access.

There is a WDTxCON0 register for each Watchdog x.

WDTSCON0
Safety WDT Control Register 0 ($0F0_H$) Reset Value: $FFFC\ 000E_H$
WDTCPU0CON0
CPU0 WDT Control Register 0 (100_H) Reset Value: $FFFC\ 000E_H$



Field	Bits	Type	Description
ENDINIT	0	rwh	**End-of-Initialization Control Bit** 0_B Access to Endinit-protected registers is permitted. 1_B Access to Endinit-protected registers is not permitted. This bit must be written with a ‘1’ during a Password Access or Check Access (although this write is only used for the password-protection mechanism and is not stored). This bit must be written with the required ENDINIT update value during a Modify Access.

Field	Bits	Type	Description
LCK	1	rwh	**Lock Bit to Control Access to WDTxCON0** 0_B Register WDTxCON0 is unlocked 1_B Register WDTxCON0 is locked (default after ApplicationReset) The current value of LCK is controlled by hardware. It is cleared after a valid Password Access to WDTxCON0 when WDTxSR.US is 0 (or when WDTxSR.US is 1 and the SMU is in RUN mode), and it is automatically set again after a valid Modify Access to WDTxCON0. During a write to WDTxCON0, the value written to this bit is only used for the password-protection mechanism and is not stored. This bit must be cleared during a Password Access to WDTxCON0, and set during a Modify Access to WDTxCON0. A Check Access does not clear LCK.
PW	[15:2]	rwh	**User-Definable Password Field for Access to WDTxCON0** This bit field is written with an initial password value during a Modify Access. A read from this bitfield returns this initial password, but bits [7:2] are inverted (toggled) to ensure that a simple read/write is not sufficient to service the WDT. If corresponding WDTxSR.PAS = 0 then this bit field must be written with its current contents during a Password Access or Check Access. If corresponding WDTxSR.PAS = 1 then this bit field must be written with the next password in the LFSR sequence during a Password Access or Check Access The default password after Application Reset is 00000000111100_B

Field	Bits	Type	Description
REL	[31:16]	rw	**Reload Value for the WDT (also Time Check Value)** The reload value can be changed during a Modify Access to WDTxCON0 (Default after ApplicationReset is $FFFC_H$).If the Watchdog Timer is enabled and in Normal Timer Mode, it will start counting from this value after a correct Watchdog service. A read from this bitfield always returns the current reload value. During a Password Access or a Check Access this bitfield may be used for additional checks. Writes during such checks have no effect upon the reload value. If corresponding WDTxSR.TCS=0 then this bit field must be written with its current contents during a Password Access or Check Access. If corresponding WDTxSR.TCS=1 then this bit field must be written with an inverted estimate of the current WDTxSR.TIM value during a Password Access or Check Access.

The following register is implemented but is not functional in this product.

WDTCPU1CON0

Watchdog Timer Control Register 1

The register WDTxCON1 for each Watchdog manages operation of the WDT. It includes the disable request, password configuration and frequency selection bits. Each WDTxCON1 register is protected by the corresponding ENDINIT which it controls.

WDTSCON1 has an additional bit CLRIRF which can be used to clear the internal reset status used to detect double SMU (eg WDT) resets.

WDTSCON1
Safety WDT Control Register 1 ($0F4_H$) Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw							rw	rw	rw	rw	r	rw	rw	r	rwh

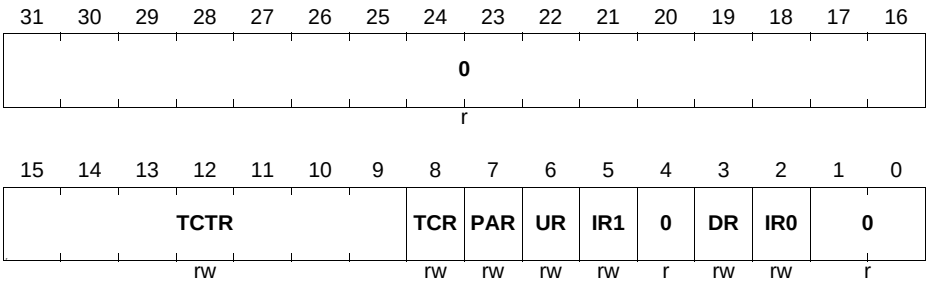
Field	Bits	Type	Description
CLRIRF	0	rwh	**Clear Internal Reset Flag** This bit is used to request a clear of the internal flag which indicates whether a previous SMU reset has already been requested 0_B No action 1_B Request to clear the internal previous-SMU-reset flag This bit can only be modified if WDTSCON0.ENDINIT is cleared. The internal flag is cleared when ENDINIT is set again. As long as ENDINIT is cleared, the internal flag is unchanged and continues to determine the response to a further SMU reset request. When ENDINIT is set again with a valid Modify Access, the internal flag is cleared together with this bit.

Field	Bits	Type	Description
IR1, IR0	5,2	rw	**Input Frequency Request Control** 00_B Request to set input frequency to f_{SPB}/16384. 01_B Request to set input frequency to f_{SPB}/256. 10_B Request to set input frequency to f_{SPB}/64. 11_B Reserved. Do not use. Bit IR0 and IR1 should be programmed together to determine the WDT timer frequency. These bits can only be modified if the corresponding WDTSCON0.ENDINIT is cleared. WDTSSR.ISx are updated by these bit only when ENDINIT is set again. As long as ENDINIT is cleared, WDTSSR.ISx controls the current input frequency of the Watchdog Timer. When ENDINIT is set again, WDTSSR.ISx is updated with the values of IRx.
DR	3	rw	**Disable Request Control Bit** 0_B Request to enable the WDT 1_B Request to disable the WDT This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTSSR.DS is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTSSR.DS controls the current enable/disable status of the WDT. When the ENDINIT is set again with a Valid Modify Access, WDTSSR.DS is updated with the state of DR.
UR	6	rw	**Unlock Restriction Request Control Bit** 0_B Request to disable SMU restriction of WDT unlock 1_B Request to enable SMU restriction of WDT unlock This bit can only be modified if the corresponding WDTSCON0.ENDINIT is cleared. WDTxSR.US is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTSSR.US controls whether unlocking is possible at all times or only when the SMU is in the RUN state. When the ENDINIT is set again with a Valid Modify Access, WDTSSR.US is updated with the state of UR.

Field	Bits	Type	Description
PAR	7	rw	**Password Auto-sequence Request Bit** 0_B Request no automatic change of password after each Modify Access or Check Access 1_B Request automatic sequence of password after each Modify Access or Check Access This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.PAS is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.PAS controls password sequencing. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.PAS is updated with the state of PAR.
TCR	8	rw	**Counter Check Request Bit** 0_B Request to check only that REL field is written with existing REL value during Modify Access or Check Access 1_B Request to check that REL field is written with correct TIM Count (within tolerance of WDTxSR.TCT) during Modify Access or Check Access This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.TCS is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.TCS controls whether counter check is enabled. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.TCS is updated with the state of TCR
TCTR	[15:9]	rw	**Timer Check Tolerance Request** This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.TCT is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.TCT controls the tolerance of timer checks. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.TCT is updated with the state of TCTR
0	1,4, [31:16]	r	**Reserved** Read as 0; should be written with 0.

The register WDTxCON1 for each CPU Watchdog manages operation of the WDT. It includes the disable request, password configuration and frequency selection bits. Each WDTxCON1 register is protected by the corresponding ENDINIT which it controls.

WDTCPU0CON1
CPU0 WDT Control Register 1 (104_H) Reset Value: 0000 0000_H



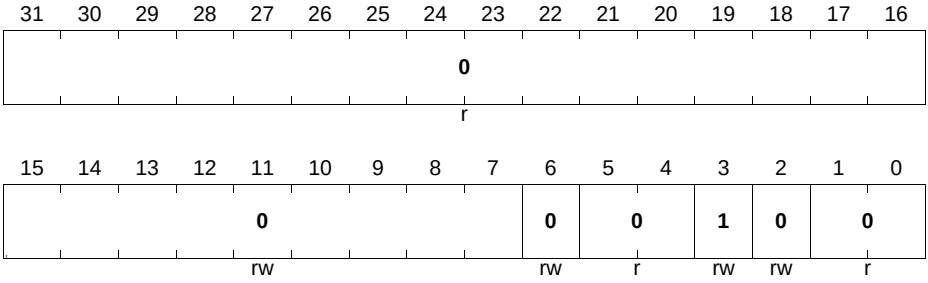
Field	Bits	Type	Description
IR1, IR0	5,2	rw	**Input Frequency Request Control** 00_B Request to set input frequency to f_{SPB}/16384. 01_B Request to set input frequency to f_{SPB}/256. 10_B Request to set input frequency to f_{SPB}/64. 11_B Reserved. Do not use. Bit IR0 and IR1 should be programmed together to determine the WDT timer frequency. These bits can only be modified if the corresponding WDTSCON0.ENDINIT is cleared. WDTSSR.ISx are updated by these bit only when ENDINIT is set again. As long as ENDINIT is cleared, WDTSSR.ISx controls the current input frequency of the Watchdog Timer. When ENDINIT is set again, WDTSSR.ISx is updated with the values of IRx.

Field	Bits	Type	Description
DR	3	rw	**Disable Request Control Bit** 0_B Request to enable the WDT 1_B Request to disable the WDT This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.DS is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.DS controls the current enable/disable status of the WDT. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.DS is updated with the state of DR.
UR	6	rw	**Unlock Restriction Request Control Bit** 0_B Request to disable SMU restriction of WDT unlock 1_B Request to enable SMU restriction of WDT unlock This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.US is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.US controls whether unlocking is possible at all times or only when the SMU is in the RUN state. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.US is updated with the state of UR.
PAR	7	rw	**Password Auto-sequence Request Bit** 0_B Request no automatic change of password after each Modify Access or Check Access 1_B Request automatic sequence of password after each Modify Access or Check Access This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.PAS is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.PAS controls password sequencing. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.PAS is updated with the state of PAR.

Field	Bits	Type	Description
TCR	8	rw	**Counter Check Request Bit** 0_B Request to check only that REL field is written with existing REL value during Modify Access or Check Access 1_B Request to check that REL field is written with correct TIM Count (within tolerance of WDTxSR.TCT) during Modify Access or Check Access This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.TCS is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.TCS controls whether counter check is enabled. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.TCS is updated with the state of TCR
TCTR	[15:9]	rw	**Timer Check Tolerance Request** This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.TCT is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.TCT controls the tolerance of timer checks. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.TCT is updated with the state of TCTR
0	0,1,4, [31:16]	r	**Reserved** Read as 0; should be written with 0.

The following registers are implemented for reuse but are not functional in the TC21x/TC22x/TC23x.

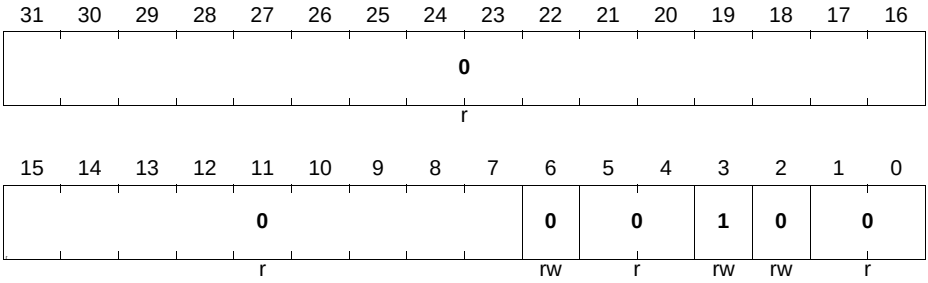
WDTCPU1CON1
Reserved Register **(110_H)** **Reset Value: 0000 0008$_H$**



Field	Bits	Type	Description
0	[31:16],5,4,1,0	r	**Reserved** Not functional in this device.
0	[15:6],2	rw	**Reserved** Not functional in this device.
1	3	rw	**Reserved** Not functional in this device.

The following registers are implemented for reuse but are not functional in the TC21x/TC22x/TC23x.

WDTCPU2CON1
Reserved Register **($11C_H$)** **Reset Value: 0000 0008$_H$**

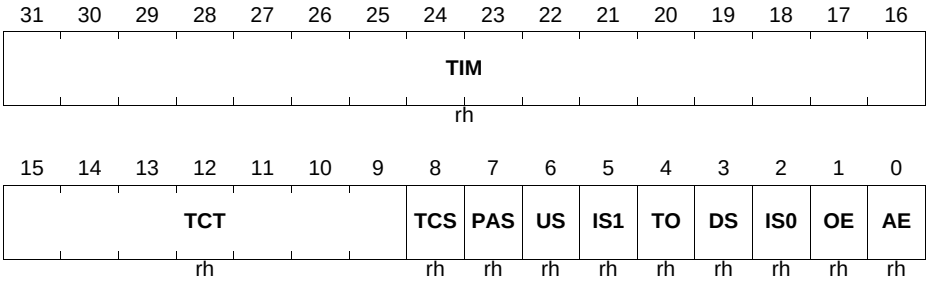


Field	Bits	Type	Description
0	[31:7], 5,4,1,0	r	**Reserved** Not functional in this device.
0	6,2	rw	**Reserved** Not functional in this device.
1	3	rw	**Reserved** Not functional in this device.

Watchdog Timer Status Register

The WDTxSR registers show the current state of each WDT. Status include bits indicating Time-Out, enable/disable status, input clock status, and access error status.

WDTSSR
Safety WDT Status Register **($0F8_H$)** **Reset Value: $FFFC\ 0010_H$**
WDTCPU0SR
CPU0 WDT Status Register **(108_H)** **Reset Value: $FFFC\ 0010_H$**



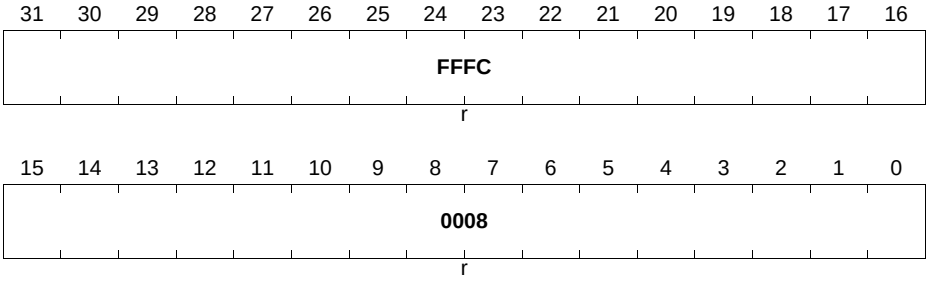
Field	Bits	Type	Description
AE	0	rh	**Watchdog Access Error Status Flag** 0_B No Watchdog access error 1_B A Watchdog access error has occurred This bit is set when an illegal Password Access or Modify Access to register WDTxCON0 was attempted. This bit is only cleared when WDTxCON0.ENDINIT is set during a valid Modify Access

Field	Bits	Type	Description
OE	1	rh	**Watchdog Overflow Error Status Flag** 0_B No Watchdog overflow error 1_B A Watchdog overflow error has occurred This bit is set when the WDT overflows from $FFFF_H$ to 0000_H. This bit is only cleared when WDTxCON0.ENDINIT is set to 1 during a valid Modify Access.
IS1, IS0	5,2	rh	**Watchdog Input Clock Status** 00_B WDT counter frequency is f_{SPB}/16384. 01_B WDT counter frequency is f_{SPB}/256. 10_B WDT counter frequency is f_{SPB}/64. 11_B Reserved. Do not use. Bit IS0 and IS1 should be programmed together. These bits are updated with the state of bits WDTxCON1.IRx after WDTxCON0.ENDINIT is written with 1 during a valid Modify Access to register WDTxCON0.
DS	3	rh	**Watchdog Enable/Disable Status Flag** 0_B WDT is enabled (default after ApplicationReset) 1_B WDT is disabled This bit is updated with the state of bit WDTxCON1.DR (after WDTxCON0.ENDINIT is set during a Valid Modify Access to register WDTxCON0) and it is cleared when Time-Out mode is entered.
TO	4	rh	**Watchdog Time-Out Mode Flag** 0_B The Watchdog is not operating in Time-Out Mode 1_B The Watchdog is operating in Time-Out Mode (default after ApplicationReset) This bit is set when Time-Out Mode is entered. It is automatically cleared when Time-Out Mode is left.

Field	Bits	Type	Description
US	6	rh	**SMU Unlock Restriction Status Flag** 0_B WDT unlock permitted at any time 1_B WDT unlock only permitted when the SMU is in the RUN state. WDTxCON0.LCK will not be unlocked by a valid Password Access if this bit is '1' and the SMU is not in the RUN state
PAS	7	rh	**Password Auto-sequence Status Flag** 0_B No change of password after each Modify Access or Check Access 1_B Automatically sequence the password after each Modify Access or Check Access This bit is updated with the state of bit WDTxCON1.PAR after WDTxCON0.ENDINIT is written with 1 during a valid Modify Access to register WDTxCON0.
TCS	8	rh	**Timer Check Status Flag** 0_B Check only that REL field is written with existing REL value during Modify Access or Check Access 1_B Check that REL field is written with inverted estimated TIM value (within +/- TCT value) during Password Access or Check Access This bit is updated with the state of bit WDTxCON1.TCR after WDTxCON0.ENDINIT is written with 1 during a Valid Modify Access to register WDTxCON0.
TCT	[15:9]	rh	**Timer Check Tolerance** This field determines the tolerance of the timer check during Password or Check Access (See TCS).This bit is updated with the state of bit WDTxCON1.TCTR after WDTxCON0.ENDINIT is written with 1 during a Valid Modify Access to register WDTxCON0.
TIM	[31:16]	rh	**Timer Value** Reflects the current content of the WDT.

The following registers are implemented for reuse but are not functional in the TC21x/TC22x/TC23x.

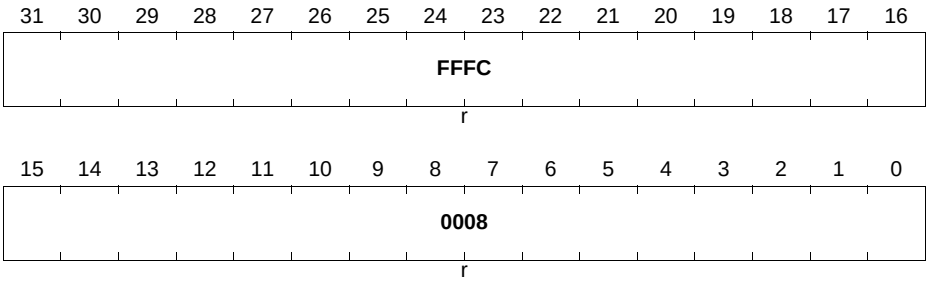
WDTCPU1SR
CPU1 WDT Status Register **(114_H)** **Reset Value: FFFC 0008$_H$**



Field	Bits	Type	Description
FFFC	[31:16]	r	**Reserved** Not functional in this device
0008	[15:0]	r	**Reserved** Not functional in this device

The following registers are implemented for reuse but are not functional in the TC21x/TC22x/TC23x.

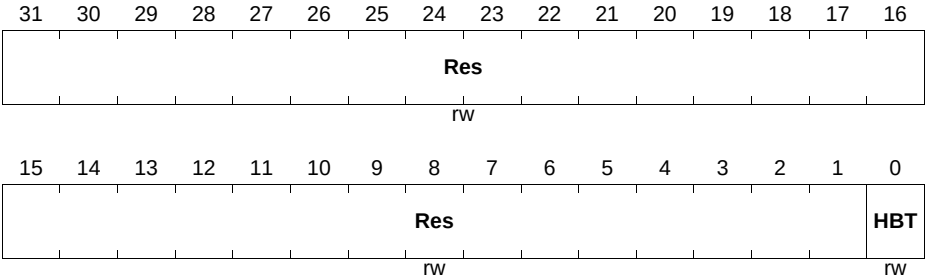
WDTCPU2SR
CPU2 WDT Status Register **(120_H)** **Reset Value: FFFC 0008$_H$**



Field	Bits	Type	Description
FFFC	[31:16]	r	**Reserved** Not functional in this device
0008	[15:0]	r	**Reserved** Not functional in this device

Safety Heartbeat Register

SAFECON
Safety Heartbeat Register **(150_H)** **Reset Value: XXXX XXXX$_H$**



Field	Bits	Type	Description
HBT	0	rw	**Heartbeat** This bit can be used by software to provide a “heartbeat” indication to an external safety monitoring device. It directly controls the output on the heartbeat ports. WDTxLCK P20.9, P20.8, P20.7 and/or P20.6 (Subject to port configuration). 0_B Port drives low (reset value) 1_B Port drives high Writes are only possible when Safety ENDINIT=0
Res	[31:1]	rw	**Reserved** Content must not be changed. Write back only the original read value.

8.4.5 Emergency Stop Output Control

The emergency stop feature of the TC21x/TC22x/TC23x provides a fast reaction to an emergency event without the intervention of software. In response to the emergency event, selected output ports can be immediately placed into a defined state (for more information see the port chapter).

An emergency stop may be triggered by either of the following emergency events:

- A transition on the port which is configured as the Emergency Stop input
- An SMU alarm event or SMU command which is enabled and configured to generate a port emergency stop (PES). See SMU Chapter for details.

Figure 8-42 shows a diagram of the emergency stop input logic. This logic is controlled by the SCU Emergency Stop Register EMSR.

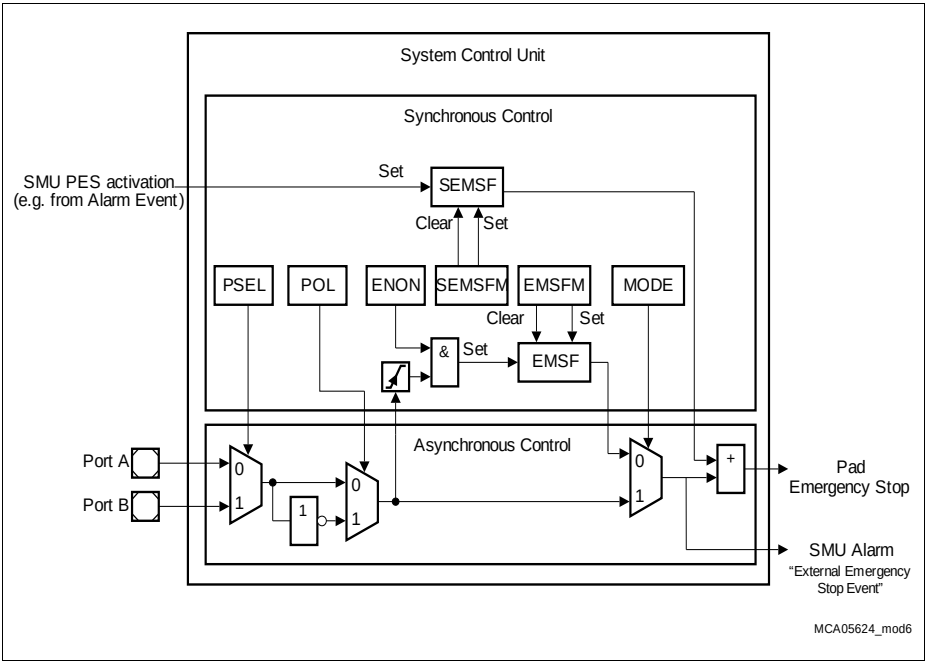


Figure 8-42 Emergency Stop Control

8.4.5.1 Port Triggered Emergency Stop

This can be configured to trigger on either transition edge of either one of two ports.

The two input port options for TC21x/TC22x/TC23x are (A) P 33.8 and (B) P21.2.

The emergency stop control logic for the ports can basically operate in two modes:

- Synchronous Mode (default after reset):
  Emergency case is activated by hardware and released by software.
- Asynchronous Mode:
  Emergency case is activated and released by hardware.

In Synchronous Mode (selected by EMSR.MODE = 0), the port signal is sampled for a inactive-to-active level transition, and an emergency stop flag EMSR.EMSF is set if the transition is detected. The setting of EMSR.EMSF activates the emergency stop. A port triggered emergency state can only be terminated by clearing EMSR.EMSF via software (Write EMSR.EMSFM with 10_B). The synchronous control logic is clocked by the system bus clock f_{SPB}. This results in a small delay between the port signal and emergency stop signal generation.

In Asynchronous Mode (selected by EMSR.MODE = 1), the occurrence of an active level at the port input immediately activates the emergency stop signal. Of course, a valid-to-invalid transition of the port input (emergency case is released) also immediately deactivates the emergency stop signal.

The EMSR.POL bit determines the active level of the input signal from the port. The EMSR.MODE bit selects Synchronous or Asynchronous Mode for emergency stop signal generation and the EMSR.PSEL bit selects which of the two ports is used as the emergency stop trigger.

8.4.5.2 SMU Event Triggered Emergency Stop

The Safety Alarm(s) which can trigger an Emergency Stop are configured and enabled within the Safety Management Unit (SMU). All SMU triggered Emergency Stop cases are in Synchronous Mode, regardless of the state of EMSR.MODE. The safety emergency stop flag EMSR.SEMSF is set when a configured and enabled SMU Safety Alarm occurs. The setting of EMSR.SEMSF activates the emergency stop. An SMU triggered emergency state can only be terminated by clearing the EMSR.SEMSF via software (Write EMSR.SEMSFM with 10_B). The synchronous control logic is clocked by the system bus clock f_{SPB}.

8.4.5.3 Emergency Stop Register

The Emergency Stop Register EMSR contains control and status bits/flags of the emergency stop input logic.

EMSR
Emergency Stop Register **(0FC$_H$)** **Reset Value: 0000 0001$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				SEMSFM		EMSFM		0						SEMSF	EMSF
r				w		w		r						rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												PSEL	ENON	MODE	POL
r												wr	rw	rw	rw

Field	Bits	Type	Description
POL	0	rw	**Input Polarity** This bit determines the polarity of the configured Emergency Stop input. 0_B Input is active high 1_B Input is active low
MODE	1	rw	**Mode Selection** This bit determines the operating mode of the emergency stop signal. 0_B Synchronous Mode selected; emergency stop is derived from the state of flag EMSF 1_B Asynchronous Mode selected; emergency stop is directly derived from the state of the input signal
ENON	2	rw	**Enable ON** This bit enables the setting of flag EMSF by an inactive-to-active level transition of input signal. 0_B Setting of EMSF is disabled 1_B Setting of EMSF is enabled

Field	Bits	Type	Description
PSEL	3	rw	**PORT Select** This bit selects which one of the two Emergency Stop port options is monitored. 0_B Port A is used as Emergency Stop input 1_B Port B is used as Emergency Stop input
0	[15:4]	r	**Reserved** Read as 0; should be written with 0.
EMSF	16	rh	**Emergency Stop Flag** This bit indicates that a synchronous mode port-triggered emergency stop condition has occurred. 0_B An emergency stop has not occurred 1_B An emergency stop has occurred and emergency stop state becomes active (if MODE = 0)
SEMSF	17	rh	**SMU Emergency Stop Flag** This bit indicates that an SMU Safety Alarm triggered emergency stop condition has occurred. 0_B An emergency stop has not occurred 1_B An emergency stop has occurred and emergency stop state becomes active
0	[23:18]	r	**Reserved** Read as 0; should be written with 0.
EMSFM	[25:24]	w	**Emergency Stop Flag Modification** This bit field sets or clears flag EMSF via software. 00_B EMSF remains unchanged 01_B EMSF becomes set 10_B EMSF becomes cleared 11_B EMSF remains unchanged EMSFM is always read as 00_B.
SEMSFM	[27:26]	w	**SMU Emergency Stop Flag Modification** This bit field sets or clears flag SEMSF via software. 00_B SEMSF remains unchanged 01_B SEMSF becomes set 10_B SEMSF becomes cleared 11_B SEMSF remains unchanged SEMSFM is always read as 00_B.
0	[31:28]	r	**Reserved** Read as 0; should be written with 0.

8.4.6 LBIST Support

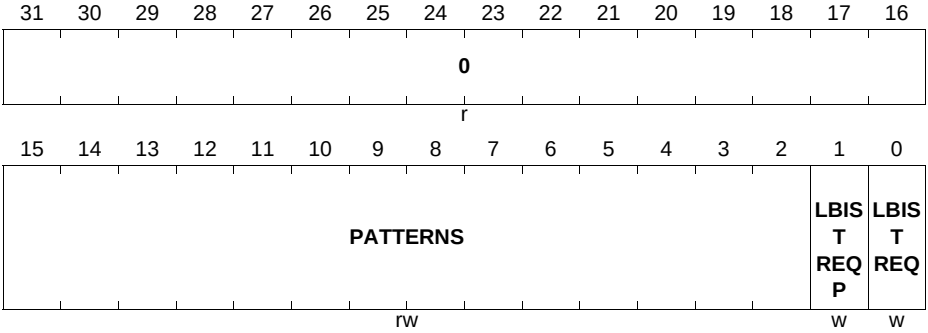
For TC21x/TC22x/TC23x an automatic executed scan-test mechanism is implemented, allowing the structural verification of the silicon in an application system. This process is controlled and monitored by the LBIST registers.

8.4.6.1 LBIST Control Register

The LBISTCTRL Control Register provides the link between software and the LBIST-controller.

LBISTCTRL0 - Logic BIST Control 0 Register

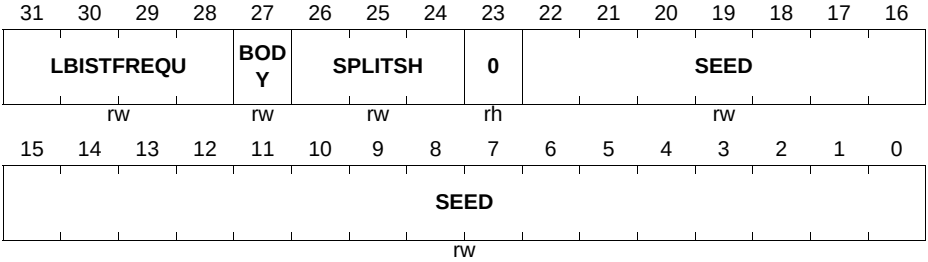
LBISTCTRL0
Logic BIST Control 0 Register **(164_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
LBISTREQ	0	w	**LBIST Request** If written high this bit requests the execution of an automatic scan-test procedure. Whether the request is successful or not depends on whether the LBIST procedure has already been executed since the last power-on-reset. If read this bit always returns a '0'. *Note: LBIST execution time depends on the number of scan-loads as defined in the PATTERNS field.*
LBISTREQP	1	w	**LBIST Request Protection Bit** Protect LBISTREQ against unintended changes. 0_B LBISTREQ is not changed. 1_B LBISTREQ is updated by this write access.
PATTERNS	[15:2]	rw	**LBIST Pattern Number** This field defines the number of scan-patterns (i.e. scan-loads), which will be executed during the LBIST-procedure. The two LSBs of scan pattern number are always assumed as '1' so LBIST patterns number can only be controlled with an accuracy of 4.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

LBISTCTRL1 - Logic BIST Control 1 Register

LBISTCTRL1
Logic BIST Control 1 Register **(168_H)** **Reset Value: 0000 0000$_H$**

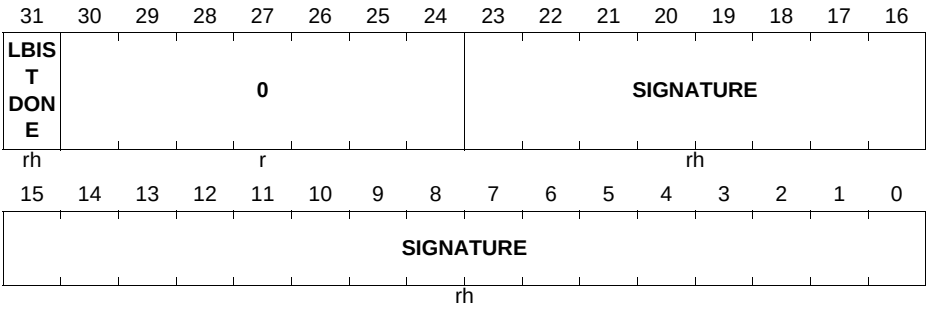


Field	Bits	Type	Description
SEED	[22:0]	rw	**LBIST Seed** This field determines which pattern is applied during LBIST execution.
0	23	r	**Reserved** Read as 0; should be written with 0.
SPLITSH	[26:24]	rw	**LBIST Split-Shift Selection** The value of this bit will allow to run LBIST with partitioned scan-shift operation in order to reduce the power consumption. $0xx_B$, Concurrent scan-shift is selected. $1x0_B$, Partitioned scan-shift is selected (four scan partitions). $1x1_B$, Partitioned scan-shift is selected (two scan partitions).
BODY	27	rw	**Body Application Indicator** The value of this bit will determine the static reset behavior of all GPIOs during LBIST execution. If set to low GPIOs will show a weak pull-up behavior, if set to high GPIOs are constrained to tri-state. A high value must be written to this bit in case LBIST shall be executed for body applications.

Field	Bits	Type	Description
LBISTFREQU	[31:28]	rw	**LBIST Frequency Selection** Through this register-field a pre-scaler factor between 1..16 is selectable for LBIST operation clock (derived from EVR-oscillator). This will allow to determine the LBIST scan-shift frequency. Value of these bits will be mirrored inside of LBIST-controller and become effective if a new LBIST-procedure has been successfully initiated via LBISTCTRL0.LBISTREQ.

LBISTCTRL2 - Logic BIST Control 1 Register

LBISTCTRL2
Logic BIST Control 2 Register **($16C_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SIGNATURE	[23:0]	rh	**LBIST Signature** This field reflects the MISR signature from the last LBIST execution. It is mirrored from LBIST-controller and is only valid if LBISTCTRL0.LBISTDONE = 1.
0	[30:24]	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
LBISTDONE	31	rh	**LBIST Execution Indicator** This bit indicates if since the last power-on-reset an automatic scan-test procedure has been executed: 0_B No LBIST was executed since last power-on-reset. 1_B LBIST was executed since last power-on-reset.

8.4.7 Global Overlay Controls

The following registers control the Global Overlay functionality.

8.4.7.1 Global Overlay Control

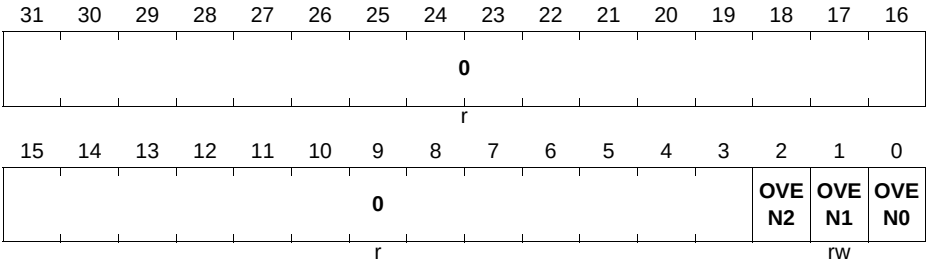
Two registers globally control the overlay operation for all CPUs:

- Overlay Enable Register OVCENABLE disables or enables data access overlay individually for each CPU.
- Overlay Control Register OVCCON can be used to perform the following actions on a selected set of CPUs:
  – concurrently enable / disable selected overlay blocks,
  – concurrently disable overlay blocks,
  – invalidate data cache.

All overlay control registers are reset to their default values with the Application Reset . A special debug reset is not considered.

The external overlay feature is not available in product variants offering ADAS functionality.

OVCENABLE
Overlay Enable Register **(1E0H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
OVEN0	0	rw	**Overlay Enable 0** 0_B OVC is disabled on CPU0. All Overlay redirections are disabled regardless of the state of OVC0_RABRy.OVEN. 1_B OVC is enabled on CPU0.
OVEN1	1	rw	**Reserved in this Product**
OVEN2	2	rw	**Reserved in this Product**
0	[31:3]	r	**Reserved** Read/write 0.

OVCCON
Overlay Control Register **(1E4H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0						POVCONF	OVCONF	0					DCINVAL	OVSTP	OVSTRT
r						w	rw	r					w	w	w

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0													CSEL2	CSEL1	CSEL0
r													w	w	w

Field	Bits	Type	Description
CSEL0	0	w	**CPU Select 0** 0_B CPU0 not affected, 1_B Action selected by OVSTRT, OVSTP, DCINVAL bits, set by the same register write access, is applied to CPU0. Return 0 if read.
CSEL1	1	r	**Reserved in this Product** Return 0 if read.
CSEL2	2	r	**Reserved in this Product** Return 0 if read.
0	[15:3]	r	**Reserved** Read/write 0.
OVSTRT	16	w	**Overlay Start** 0_B No action 1_B For each CPU selected with CSEL, all the blocks selected with OVCx_OSEL will be activated. In the selected CPUs all the blocks deselected with OVCx_OSEL will be deactivated. CPUs which are not selected are not affected. No action is taken if OVSTP is also set. Return 0 if read.

Field	Bits	Type	Description
OVSTP	17	w	**Overlay Stop** 0_B No action 1_B For CPUs selected with CSEL, all the overlay blocks are deactivated. OVCx_RABRy.OVEN bits are cleared. CPUs which are not selected are not affected No action is taken if OVSTRT is also set. Return 0 if read.
DCINVAL	18	w	**Data Cache Invalidate** No function in devices without data cache in CPU. 0_B No action 1_B Data Cache Lines in DMI are invalidated[1)] Data Cache is affected only in the CPUs selected with CSEL. Return 0 if read.
0	[23:19]	r	**Reserved** Read/write 0.
OVCONF	24	rw	**Overlay Configured** Overlay configured status bit 0_B Overlay is not configured or it has been already started 1_B Overlay block control registers are configured and ready for overlay start This bit may be used as handshake bit between a debug device (via JTAG interface and Cerberus) and CPU(s).
POVCONF	25	w	**Write Protection for OVCONF** 0_B OVCONF remains unchanged. 1_B OVCONF can be changed with write access to register OVCCON This bit enables OVCONF write during OVCCON write. Return 0 if read.
0	[31:26]	r	**Reserved** Read/write 0.

1) Dirty (modified) cache lines are not effected by this operation. If data cache contains modified data, it is not invalidated, and has to be written-back and invalidated by the user. Therefore, it is highly recommended to either: access overlaid data in read-only mode, or use only non-cached access.

.

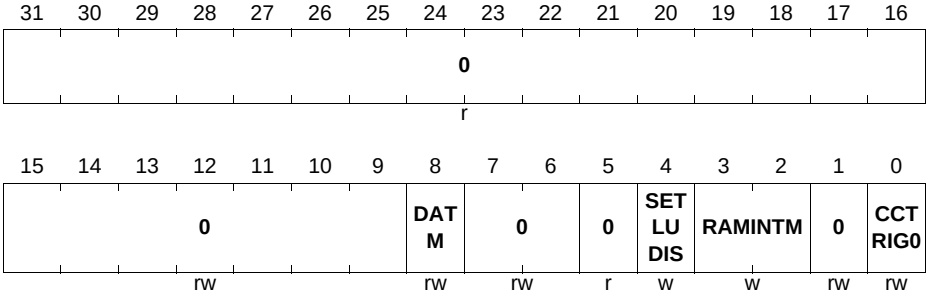
8.4.8 Miscellaneous System Control

This section collects different registers that serve various system purposes.

8.4.8.1 System Control Register

This register controls various functionality used by the SCU but that are located outside of the module. Additionally some functions for other modules are included.

SYSCON
System Control Register **($07C_H$)** **Reset Value: 0000 0000$_H$**



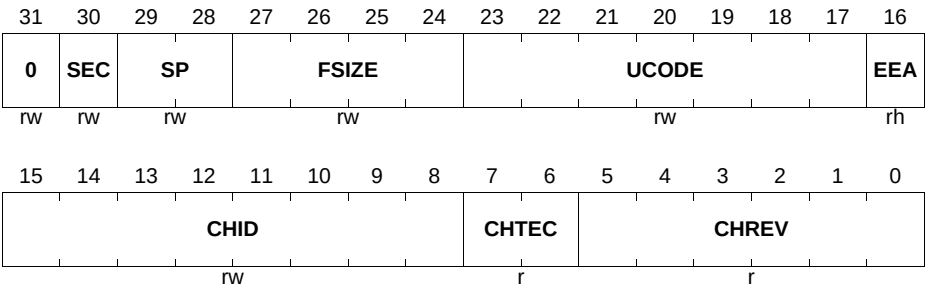
Field	Bits	Type	Description
CCTRIG0	0	rw	**Capture Compare Trigger 0** This bit is used to trigger the Synchronous Start feature of the CCU6.
RAMINTM	[3:2]	w	**RAM Integrity Modify** 00_B No effect 01_B Set STSTAT.RAMINT (No effect in test mode) 11_B No effect 10_B Clear STSTAT.RAMINT
SETLUDIS	4	w	**Set Latch Update Disable** Setting this bit sets bit STSTAT.LUDIS. Clearing this bit has no effect. This bit reads always as zero.
DATM	8	rw	**Disable Application Test Mode (ATM)** 0_B ATM not disabled 1_B ATM disabled

Field	Bits	Type	Description
0	[15:9],7, 6,1	rw	**Reserved** Write only the read value
0	5	r	**Reserved** Read as 0
0	[31:16]	r	**Reserved** Read as 0

8.4.8.2 Identification Registers

The CHIPID register allows the user to determine the product, package option, FSI microcode version and chip revision (silicon step).

CHIPID
Chip Identification Register **(140_H)** **Reset Value: XXXX XXXX$_H$**

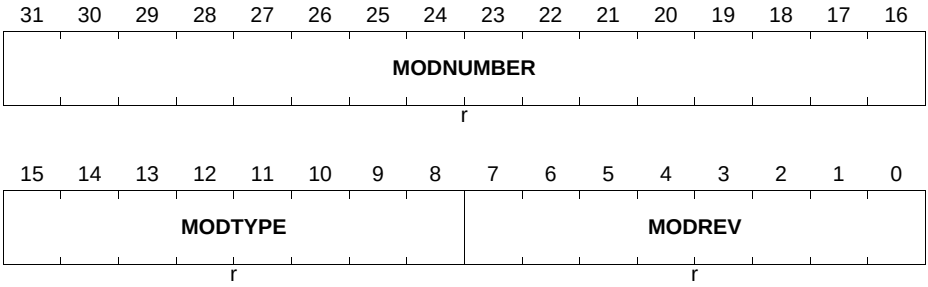


Field	Bits	Type	Description
CHREV	[5:0]	r	**Chip Revision Number** This bit field indicates the revision number of the TC21x/TC22x/TC23x device. The value of this bit field is defined in the TC21x/TC22x/TC23x Data Sheet. Bits [3:0] are used to indicate the steps. These updates can be done with any metal-fix or FW ROM change. Bits [5:4] define the major silicon design steps (A, B, C, D). These bits can be changed only with a major redesign. Note that this specification refers to the latest available productive design step. Earlier silicon functionality may vary. Consult the appropriate delta documentation for details. $00XXXX_B$ A-step silicon $01XXXX_B$ B-step silicon $10XXXX_B$ C-step silicon $11XXXX_B$ D-step silicon

Field	Bits	Type	Description
CHTEC	[7:6]	r	**Chip Family** These bits indicate the product family and are changed only with a redesign. 00_B Reserved 01_B AURIX Gen1 Family 10_B Reserved 11_B Reserved
CHID	[15:8]	rw	**Chip Identification Number** This bit field defines the product by a unique number. This number may be used by SW to identify the system architecture (e.g. number of available CPUs). See Product Datasheet Addendum for more details.
EEA	16	rh	**Emulation Extension Available** Indicates if the emulation extension is available or not. 0_B EEC is not available 1_B EEC is available
UCODE	[23:17]	rw	**µCode Version** This bit field displays the Version X.Y of the flash µCode.
FSIZE	[27:24]	rw	**Program Flash Size** This bit field indicates available program flash size for this device. Detailed information is shown in the Data Sheet. 0000_B256 KByte Program Flash (TC2xxx-4Fx) 0001_B0.5 MByte Program Flash (TC2xxx-8Fx) 0010_B1.0 MByte Program Flash (TC2xxx-16Fx) 0011_B1.5 MByte Program Flash (TC2xxx-24Fx) 0100_B2.0 MByte Program Flash (TC2xxx-32Fx) 0101_B2.5 MByte Program Flash (TC2xxx-40Fx) 0110_B3.0 MByte Program Flash (TC2xxx-48Fx) 0111_B4.0 MByte Program Flash (TC2xxx-64Fx) 1000_B5.0 MByte Program Flash (TC2xxx-80Fx) 1001_B6.0 MByte Program Flash (TC2xxx-96Fx) 1010_B7.0 MByte Program Flash (TC2xxx-112Fx) 1011_B8.0 MByte Program Flash (TC2xxx-128Fx) 1100_BReserved, do not use this combination 1101_BReserved, do not use this combination 1110_BReserved, do not use this combination 1111_BReserved, do not use this combination

Field	Bits	Type	Description
SP	[29:28]	rw	**Speed** This bit field indicates the maximum allowed frequency for the application CPU(s) 00_B Default speed grade 01_B Speed grade two 10_B Speed grade three 11_B Speed grade four
SEC	30	rw	**Security Device** This bit field indicates whether the product has a Hardware Security Module (HSM) 0_B No Hardware Security Module 1_B Hardware Security Module is available
0	31	rw	**Reserved** Must not be written.

ID
Identification Register **(008_H)** **Reset Value: $00C4\ C081_H$**

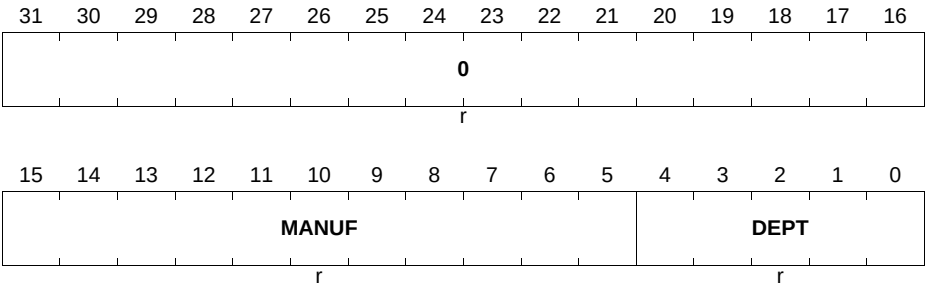


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field indicates the revision number of the AURIX SCU module (81_H).
MODTYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines a 32-bit module

Field	Bits	Type	Description
MODNUMBER	[31:16]	r	**Module Number** This bit field defines the module identification number. The idenfication number for the AURIX SCU is $00C4_H$

MANID

Manufacturer Identification Register (144_H) **Reset Value: $0000\ 1820_H$**



Field	Bits	Type	Description
DEPT	[4:0]	r	**Department Identification Number** = 00_H: indicates the ATV Microcontroller department within Infineon Technologies.
MANUF	[15:5]	r	**Manufacturer Identification Number** This is a JEDEC normalized manufacturer code. MANUF = $C1_H$ stands for Infineon Technologies.
0	[31:16]	r	**Reserved** Read as 0.

8.4.8.3 SCU Access Restriction Registers

The Access Enable Register 0 restricts write access to all SCU registers so that they may only be written by specified bus masters (eg CPUs). See the Bus chapter for the mapping of TAG ID to specific system masters and CPUs).

ACCEN0
Access Enable Register 0 **($3FC_H$)** **Reset Value: $FFFF\ FFFF_H$**

8.4.9 SCU Register Address

Table 8-28 Registers Address Spaces - SCU Kernel Registers

Module	Base Address	End Address	Note
SCU	$F003\ 6000_H$	$F003\ 63FF_H$	-

8.4.10 SCU Kernel Registers

This section describes the kernel registers of the SCU module. Most of SCU kernel register names described in this section will be referenced in other parts of the TC21x/TC22x/TC23x User's Manual by the module name prefix "SCU_".

SCU Kernel Register Overview

Table 8-29 Register Overview of SCU (Offset from Main Register Base)

Short Name	Long Name	Offset Addr. [1]	Access Mode		Reset	Description See

ACCEN0	Access Enable Register 0	$3FC_H$	U, SV	SV, SE	Application Reset	Page 8-277

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

2) Some registers marked (CPUx) are writeable only from the specified CPU. For these registers the setting of the ACCEN bits have no effect. For all other registers the ACCEN bits control access. Attempted writes by other masters or CPUs will not be successful, but no bus error will result.

9 Memory Test Unit (MTU)

All of the internal memories within the TC21x/TC22x/TC23x have a unified interface for the control of ECC (Error Correction), BIST (Built-in-Self-Test) and redundancy features. This interface can also be used to fill the memories with a predefined data value for initialization. The Memory Test Unit (MTU) controls and monitors these memory test, initialization and data integrity checking functions.

The MTU comprises two sections:

- MTU configuration registers.
- Memory Controller related registers.

The configuration registers are used to enable and disable memory test functionality. For some memories, a special sequence must be followed in order to execute memory tests without compromising data security. This sequence is ensured by simple state machines which automatically prevent test access to the memories at times when data content may be sensitive.

The Memory Controller registers are replicated for each memory bank in the device. These registers control the individual MBIST, redundancy and ECC settings for that specific memory block.

9.1 Memory Content Initialization

In security applications it is important that the MTU does not permit reading or modification of restricted memory content via the MBIST modules. In other applications (e.g. safety) it is important that modification of memory content is possible via MBIST (e.g. for ECC error injection or runtime self-test).

The TC21x/TC22x/TC23x can be configured for either of these application options via FLASH0.PROCOND.

Note that if RAMs embedded inside IP modules are not configured for initialization at boot then software initialization may be required before the IP module can be used. (E.g. GTM, ERAY modules)

9.1.1 Non-Security Applications

If FLASH0.PROCOND.RAMIN=11 then no automatic initialization of RAM content is performed on a reset and no automatic initialization of RAM content is performed when MBIST modules are enabled or disabled with MTU_MEMTEST.MEMxEN registers.

This permits the use of the MBIST controller by an application (E.g. for error injection, data modification or runtime memory testing) without unwanted corruption of memory content.

9.1.2 Security Applications

If FLASH0_PROCOND.RAMIN = 00, 01 or 10 then automatic memory content initialization is enabled. PROCOND.RAMIN configures whether the initialization is triggered by cold resets, warm resets or both. In these modes, an automatic initialization of security-sensitive memories is also triggered whenever the corresponding MTU_MEMTEST.MEMxEN is changed (i.e. The MBIST controller is enabled or disabled).

The following MBIST Controller enables are considered to be security-sensitive in this product:

- FSI0
- CPU0PTEN
- CPU0PSEN (Initializes only the cache part of the memory)
- CPU0DS2EN (Initializes only the cache part of the memory)

For security reasons, no MTU registers associated with HSM or FSI modules are accessible to the user after start-up.

9.2 Safety Notifications

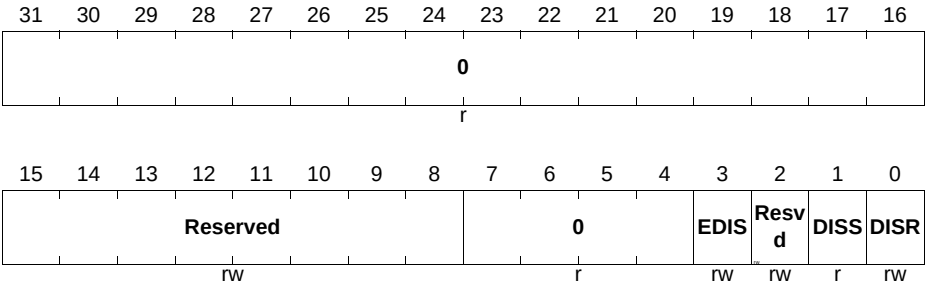
SRAM ECC errors from all system SRAMs may be reported to the Safety Management Unit (SMU). The SMU may be programmed to initiate appropriate action.

9.3 Memory Test Unit (MTU) Kernel Registers

These are the MTU control registers

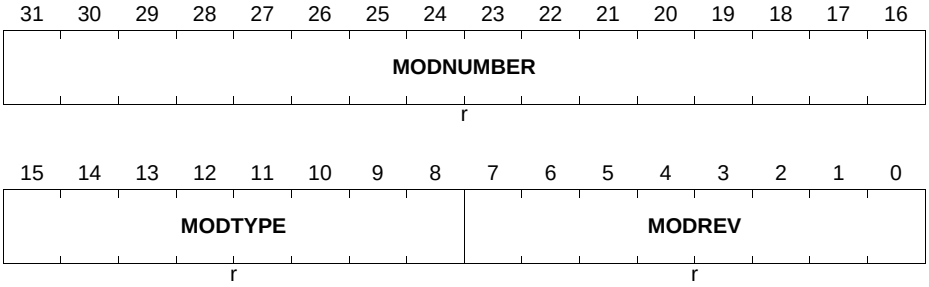
9.3.1 Descriptions

MTU_CLC
Identification Register **(F006 0000$_H$)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested 1_B Module disable is requested
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module 0_B Module is enabled 1_B Module is disabled If the RMC field is implemented and if it is 0, DISS is set automatically.
Resvd	2	rw	**Resvd** Read as 0. Must be written with 0_H
EDIS	3	rw	**Sleep Mode Enable Control** Used for module Sleep Mode control. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode on a request. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered on a request.
Reserved	[15:8]	rw	**Reserved** Read as 0. Must be written with 0_H
0	[31:16], [7:4]	r	**0** Read as 0.

MTU_ID
Identification Register (F006 0008$_H$) Reset Value: 00B2 C0XX$_H$



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field indicates the revision number of the MTU module .
MODTYPE	[15:8]	r	**Module Type** This bit field is C0$_H$. It defines a 32-bit module
MODNUMBER	[31:16]	r	**Module Number** This bit field defines the module identification number. The idenfication number for the AURIX MTU is 00B2$_H$

The memory test register MEMTEST holds CPU configurable select bits for the various MBIST controllers.

MTU_MEMTEST0
Memory MBISTEnable Register 0 (F006 0010$_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1) The absolute register address is calculated as follows:
Memory Module Register Base Address + Offset Address (shown in this column)

9.4 Memory Controllers

9.4.1 Control and Status Interfaces

9.4.1.1 Direct CPU Interface

There is a dedicated interface to the registers of each MBIST/ECC controller.

Register Mapping

Registers have an MTU system address and can be accessed through normal 16 bit SPB bus accesses. In the MTU the registers appear as if they were 16 bits wide.

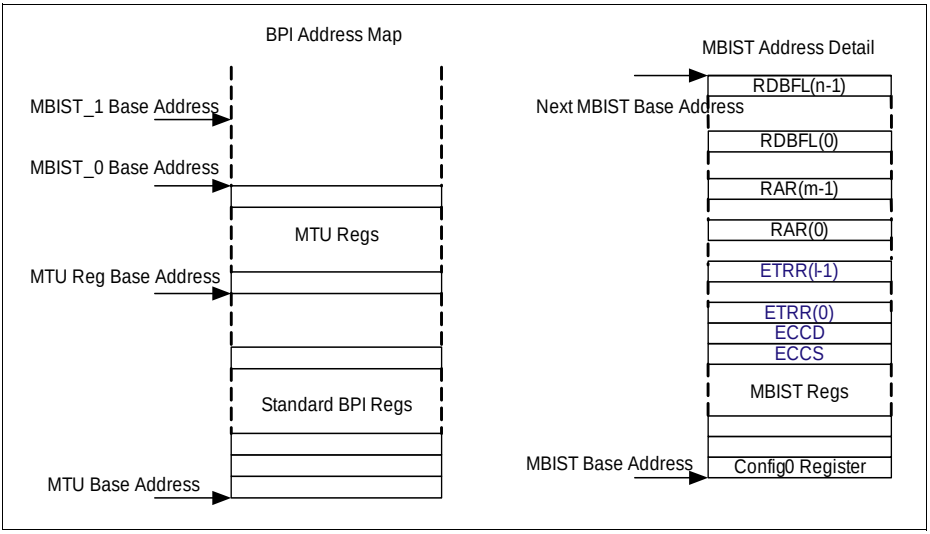

Figure 9-1 MBIST/ECC Register Mapping Scheme

9.4.2 Registers

9.4.2.1 MBIST/ECC Registers

Some register field sizes or content depend upon the physical sizes of the memories. The default settings enable fill/test of the entire physical RAM and the register descriptions show the maximum bitfield sizes.

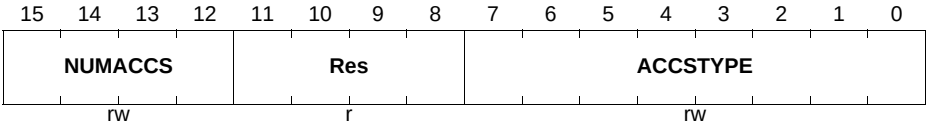
Configuration Registers

The bits in these registers can be used to control and program any march and hammer sequences. All bits concerning these test are concentrated here. All bits do not change during a test run. MCONTROL.START will start the tests defined here. MSTATUS.DONE is reset at the beginning of a test and set after completion. If no legal

operation was defined in CONFIG1.AG_MOD nothing will be done but the handshake of MCONTROL.START and MSTATUS.DONE is carried out.

The reset values of the CONFIG0/1 and MCONTROL registers will perform a {⇑(w0,r0)} operation (direction up, write 0 to all cells and check for 0) which initializes the whole memory with 0 and checks the contents if MCONTROL.START is set. This is the start sequence of many tests.

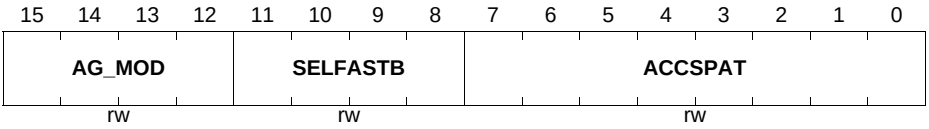
CONFIG0
Configuration Register 0 **(00_H)** **Reset Value: 2002_H**



Field	Bits	Type	Description
NUMACCS	15:12	rw	**Number of accesses per address** This field specifies the total number of accesses which are being performed to each single address in the current marching element. Range is from 0 to 15. With the sizes of ACCSPAT and ACCSTYPE given only 0 to 8 make sense. NUMACCS=0 will not access a memory.
Res	11:8	r	**Reserved** Reads return 0
ACCSTYPE	7:0	rw	**Access type** This field specifies the type of access which is being performed to each single address in the current marching element. ACCSTYPE[n] specifies n-th access of the marching element. 0_B , write access 1_B , read access

Configuration Register 1

CONFIG1
Configuration Register 1 **(02_H)** **Reset Value: 0000_H**



Field	Bits	Type	Description
AG_MOD	15:12	rw	**Address Generator Mode** These bits enable the special hardware for performing the more complex addressing schemes. In case RANGE.RAEN (range enable) is set to 0 (single access) linear address mode has to be selected and NUMACCS set to 1. 0000_B, run the test with linear address generation 0001_B, run the right half select test 0010_B, run the test with GALPAT9 algorithm 0011_B, run the left half select test 0100_B, run the test with the GALPAT5 algorithm 0101_B, run the non-destructive inversion test 1000_B, run the write mask test 1010_B, run the test with 2^i address generation **others**, Nothing is done but the handshake of START and DONE is carried out.

Field	Bits	Type	Description
SELFASTB	11:8	rw	**Select Fast Bit** This field defines during a 2^i test the address bit position that has the Hamming distance of 1, i. e. changes fastest. Bit 0 of either column or row address is swapped with the indicated bit of either column or row according to MCONTROL.RCADR. MCONTROL.RCADR=0 -> column MCONTROL.RCADR=1 -> row 0000_B, normal addressing sequence, bit 0 in its normal position. **others**, bit 0 swapped with the indicated position.
ACCSPAT	7:0	rw	**Access pattern** This field specifies directly the bit pattern which is being used for an access to each single address in the current marching element. ACCSPAT[n] specifies the n-th access of the marching element. These patterns are toggled according to BITTOG and ROWTOG.

MBIST Control Register

The bits in this register control the behavior of the MBIST, start and define tests to be performed. Any test will be performed and started when the startbit is set. The end will be signalled by MSTATUS.DONE . .

Required data (e.g. march elements, select fast bit) are taken from CONFIG0 and CONFIG1.

None of the tests are interruptable.

“Fast Row”, “Fast Column” (formerly called Fast Y and Fast X resp.) are defined as follows: “Fast Row” moves along the word-lines first and then in bit-line direction, “Fast Column” along the bit-lines first.

Note: Writes to this register are only permitted when no test is under way.

MCONTROL
MBIST Control Register **(04_H)** **Reset Value: 4008_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res	**Res4**			**Res**		**FAIL DMP**	**GP_ BASE**	**BITT OG**	**ROW TOG**	**RCA DR**	**DINI T**	**DIR**	**EST F**	**RES UME**	**STA RT**
r	rw			r		rw	rw	rw	rw	rw	rw	rw	rw	rwh	rw

Field	Bits	Type	Description
Res	15	r	**Reserved** Reads return 0
Res4	14:10	r	**Reserved** Read returns 0x4 Must always be written with 0x4

Field	Bits	Type	Description
FAILDMP	9	rw	**Fail bitmap dump** This field enables a dump of the failing address and a fail bit map after a fault has been detected. The memory test is suspended afterwards and resumed by RESUME. MSTATUS.FDA shows that a fail dump is available. This functionality can be used only if bit LDRED = 1. In case a fail dump is available, RDBFL will contain the fail bit map and ETRR the failing address. ECCS/ECCD.AENE shouldn't be set at the same time as MCONTROL.FAILDUMP is set because wrong address errors are notified when a fail dump is available. 0_B Do not dump 1_B Dump each fault
GP_BASE	8	rw	**Galpat Base** This bit defines the value which is written into the base cell during the galpat mode.BITTOG and ROWTOG modify the actual value written. 0_B Write a zero into the base cell prior to reading the background pattern from the adjacent cells 1_B Write a one into the base cell prior to reading the background pattern from the adjacent cells
BITTOG	7	rw	**Bit toggling** This field specifies whether to toggle the used bit pattern (non inverted/inverted) with each physical memory column. This is required when writing a checkerboard pattern or a column stripe pattern. 0_B Do not toggle 1_B Do toggle with each column
ROWTOG	6	rw	**Row toggling** This field specifies whether to toggle the used bit pattern (non inverted/inverted) with each physical memory row. This is required when writing a checkerboard pattern or a row stripe pattern. Setting both BITTOG=1 and ROWTOG=1 would not make sense. The user must ensure that only one of these is set. 0_B Do not toggle 1_B Do toggle with each row

Field	Bits	Type	Description
RCADR	5	rw	**Fast Row / Fast Column Addressing Scheme Select** This bit selects between fast row and fast column addressing. It is compatible with the MBP 4.2 X/Y definitions. 0_B Fast row 1_B Fast column
DINIT	4	rw	**Data Initialization Enable** This bit enables a write of the RDBFL data to all locations defined by the range register. RDBFL can contain data that will produce an ECC error. Execution is started with MCONTROL.START. For this predefined action any information contained in CONFIG0/1 registers and the bits BITTOG, ROWTOG and DIR are ignored. 0_B Disabled 1_B Enabled
DIR	3	rw	**Direction Select** This field specifies the direction of a memory test operation. 0_B Address direction is highest to lowest. 1_B Address direction is lowest to highest.
ESTF	2	rw	**Enable Sticky Fail Bit** This bit enables the sticky fail bit MSTATUS.SFAIL. If set any fails will be collected in MSTATUS.SFAIL. Resetting this bit to 0 will also reset MSTATUS.SFAIL. 0_B Do not collect fail events 1_B Collect fail events
RESUME	1	rwh	**Resume failed test** This bit allows a test with fail that got suspended to be resumed after the dump of the fail bit map. A restart is possible only if MSTATUS.FDA was reset by hardware. It will be reset by hardware once the test is resumed. 0_B Do not resume 1_B Resume suspended MBIST run

Field	Bits	Type	Description
START	0	rw	**START** If this bit is written to ’1’ by software the memory test will start. If it is reset by software, and the test has finished, MSTATUS.DONE will be set to 1. If MCONTROL.FAILDMP is set, a fail will stop the current execution. RESUME will continue a suspended test. 1_B Start memory test 0_B No test started, finished or waiting for test end

Fail Dump

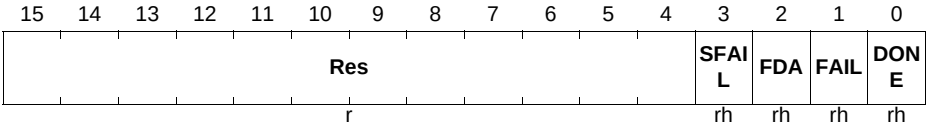
Bit FAILDMP enables a dump of the failing address and a fail bit map after a fault has been detected. The memory test is suspended afterwards and resumed by RESUME. MSTATUS.FDA shows that a fail dump is available.

This bit has to be polled by the tester hardware as there is no signal that shows a stopped test.

MBIST Status Register

The bits in the status register show the status of the currently running and last test respectively.

MSTATUS
Status Register **(06_H)** **Reset Value: 0001_H**



Field	Bits	Type	Description
Res	15:4	r	**Reserved** Reads return 0
SFAIL	3	rh	**Sticky Fail Bit** This bit is set to 1 together with FAIL provided MCONTROL.ESTF is set. In contrast to FAIL it will not be reset when a new test is started. Therefore it will collect fail information over more than one MBIST run. It will be reset when MCONTROL.ESTF is reset or the 0_B , No fail collected. 1_B , A fail occured during one of the test runs since MCONTROL.ESTF was set to 1.

Field	Bits	Type	Description
FDA	2	rh	**Fail Dump Available** This bit shows that a fail has occurred if MCONTROL.FAILDMP is set. The test is suspended and fail dump information is available. The fail bit map is in RDBFL and the associated address is in ETRR(0). As long as no fail has occurred RDBFL contains the last read information and ETRR has no valid data . This bit will be set by hardware. It will be reset when MSTATUS was read with MSTATUS.FDA = 1 and the dump information was read from ETRR and RDBFL. Only the last read from the last word of RDBFL is checked by the hardware and taken as an indication for a complete read. A suspended test will be resumed by MCONTROL.RESUME if FDA was reset. This forms some sort of handshake to insure that a suspended test can only be resumed (by a broadcasted) MCONTROL.RESUME if the last fail information was actually collected. 0_B , No fail dump data available. A suspended MBIST run can be resumed. 1_B , Fail dump data is available and waiting for read.
FAIL	1	rh	**FAIL** This bit will be reset when a test is being started. It will be set to ‘1’ by hardware under the following conditions: FAIL:=’1’ if the memory has at least one fault
DONE	0	rh	**DONE** Reset value is 1. This bit is reset at the start of a test and set when a test is completed and MCONTROL.START was reset by software. It is not set when a test is interrupted for fail dump.

Range Register

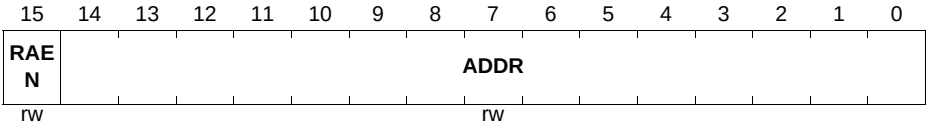
The Range Register can be used to run a test only on a dedicated part of the RAM. This can be helpful to shorten the time which is needed to find a defect cell in a FAR where there's already some information available about a failing memory cell because it's not necessary to run the test using the full address range of the RAM under test.

The range can be set in 64 word increments.

The range register can also be used to write to one specific logical address or read from it. In this case the range is disabled and the remaining part of the register is used as the logical address field.

RANGE
Range Register, single address mode (08_H)

Reset Value: $xxxx_H$



Field	Bits	Type	Description
RAEN	15	rw	**Range Enable** 0 disabled, single address mode. In this case a single word can be addressed for read or write. Config registers have to be set as follows CONFIG.NUMACCS:= "0001" (single access) CONFIG.AG_MOD := "0000" (linear) MCONTROL.DIR :=1 (up) For read just the value in this location will be delivered. No check against expected values is made; i.e. MSTATUS.FAIL will not be set.
ADDR	14:0	rw	**Address** This field specifies the logical address (before descrambling) of a single memory location. Reads and writes to this location are possible.

Setting Address Ranges

If the RAEN field is set to '1' then range mode is enabled. In this case, the ADDR field of the RANGE register is interpreted as two separate fields:

ADDR[14:7] is interpreted as the Upper Range Limit.

This field specifies the upper logical block address limit in 64 word increments.

Upper end of the address range is UPLIMIT & 111111B

ADDR[6:0] is interpreted as the Lower Range Limit

This field specifies the upper logical block address limit in 64 word increments.

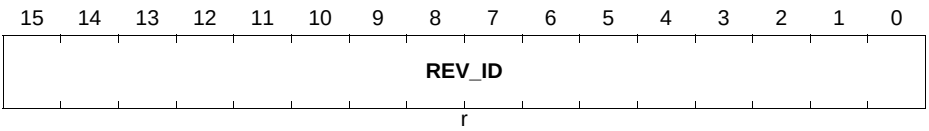
Lower end of the address range is LOLIMIT & 000000B

Note that the default reset value of the ADDR field will be set to the maximum range of the physical memory. The default behaviour is therefore that an initialization or test will operate over the whole memory.

Revision ID Register

The revision ID register contains a hard coded read only constant which describes the current status of the MBIST/ECC IP.

REVID
Revision ID Register **($0C_H$)** **Reset Value: 0510_H**



Field	Bits	Type	Description
REV_ID	15:0	r	**Revision Identifier** This field defines the currently implemented release, version and functionality of the used MBIST/ECC controller to track the MBIST/ECC version for easier handling at the tester.

ECC Safety Register

This register controls the various error detection and notification modes.

Writes to this register are only permitted when safe_endinit= 0 and no test is under way.

The hardware features that implement fault tolerance mechanisms for the SRAMs (e.g. single bit correction) shall be enabled per default after any reset. This is ensured by the reset value of the ECC safety register where ECCS.ECE = 1 after a reset.

ECCS
ECC Safety Register **($0E_H$)** **Reset Value: $00XF_H$**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res				TC_WAY_SEL		ECCMAP		SFLE		BFLE	TRE	ECE	AENE	UENE	CENE
r				rw		rw		rw		rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
Res	15:12	r	**Reserved** Reads return 0
TC_WAY_SEL	11:10	rw	**TriCore Cache Way Select** TriCore Cache only. These two bits select a cache way to run the non-destructive inversion test on. The bits represent the way number.
ECCMAP	9:8	rw	**ECC Bit Mapping Mode** ECCMAP sets three different test modes to allow access to data or ECC bits separately and independently. 00_B Normal operation 01_B Test mode. Only data bits mapped. All ECC functionality disabled. 10_B Test mode. ECC check bits mapped to lower data bit positions. Other bits read as zero. All ECC functionality disabled. Data bits are not affected by write operations. 11_B not allowed.

Field	Bits	Type	Description
SFLE	7:6	rw	**Signature Bit Flip Enables** If any SFLE bit is set no error tracking will take place. 00_B Normal operation 01_B Test mode only. Flips bitline address check signature bits. 10_B Test mode only. Flips wordline address check signature bits. 11_B Test mode only. Combination makes no sense.
BFLE	5	rw	**Bit Flip Enable** 0_B Normal operation 1_B Test mode only. Flips data and check bits according to RDBFL.
TRE	4	rw	**Tracking Enable** All errors will be tracked, if the associated notification enable bit is set. For TriCore Memory MC Modules [1] this bit is set by default 0_B Do not track address of detected error 1_B Track address of detected error
ECE	3	rw	**Error Correction Enable** This bit shadows ECCD.ECE. Either bit can be written and both bits will read the last written value. 0_B Do not correct correctable errors 1_B Correct correctable errors
AENE	2	rw	**Address Error Notification Enable** This bit shadows ECCD.AENE. Either bit can be written and both bits will read the last written value. 0_B Do not report address errors 1_B Report detected address errors
UENE	1	rw	**Uncorrectable Error Notification Enable** This bit shadows ECCD.UENE. Either bit can be written and both bits will read the last written value. 0_B Do not report uncorrectable data errors 1_B Report detected uncorrectable errors to SMU

Field	Bits	Type	Description
CENE	0	rw	**Correctable Error Notification Enable** This bit shadows ECCD.CENE. Either bit can be written and both bits will read the last written value. 0_B Do not report correctable data errors 1_B Report detected correctable errors to SMU

1) A special reset value of ‘1’ is implemented for TRE bit of MCs of all TriCore Memories. TriCore Memories means all DTAG, PTAG, PSPR, DSPR and DSPR2 Memory Controllers (if present in product)

ECC Detection Register

The ECC detection register contains information on the errors detected and the tracking register clear.

Bits EOV, AERR, UERR and CERR are signals as well. While the bits are cleared by software write, the signals have a handshake associated to cater for different clock domains.

ECCD
Memory ECC Detection Register (10_H) Reset Value: 7800_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EOV	**ECE**	**AENE**	**UENE**	**CENE**	**Res**	**VAL**					**TRC**	**AERR**	**UERR**	**CERR**	**SERR**
rh	rw	rw	rw	rw	rwh	rh					w	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
EOV	15	rh	**Error Overflow** 0_B all errors detected since last clear were tracked. 1_B more errors were detected since last clear than error tracking registers are available. Also, this bit is set if more than one memory block was in error at the same time. See ETRR.MBI for details. Enabled by ECCS.TRE and reset by ECCD.TRC
ECE	14	rw	**Error Correction Enable** Note that this bit is only writeable when Safety Endinit = 0. Other writes will not change this bit. 0_B Do not correct correctable errors 1_B Correct correctable errors

Field	Bits	Type	Description
AENE	13	rw	**Address Error Notification Enable** This bit enables ECCD.AERR and the hardware flag to SMU. Note that this bit is only writeable when Safety Endinit = 0. Other writes will not change this bit. AENE shouldn't be set at the same time as MCONTROL.FAILDUMP is set because wrong address errors are notified when a fail dump is available. 0_B Do not report address errors 1_B Report detected address errors
UENE	12	rw	**Uncorrectable Error Notification Enable** This bit enables ECCD.UERR and the hardware flag to SMU. Note that this bit is only writeable when Safety Endinit = 0. Other writes will not change this bit. 0_B Do not report uncorrectable data errors 1_B Report detected uncorrectable errors to SMU
CENE	11	rw	**Correctable Error Notification Enable** This bit enables ECCD.CERR and the hardware flag to SMU. Note that this bit is only writeable when Safety Endinit = 0. Other writes will not change this bit. 0_B Do not report correctable data errors 1_B Report detected correctable errors to SMU
VAL	9:5	rh	**Valid Bits** Every tracking register has a valid bit associated. Reset by ECCD.TRC. Up to five error tracking registers are available and five valid bits. Unused valid bits always read 0.
TRC	4	w	**Tracking Clear** Writing this bit with '1' clears the EOV, VAL bits plus the tracking registers. This bit will always read 0. 0_B No effect 1_B Clear bits

Field	Bits	Type	Description
AERR	3	rwh	**Address Error Detected** Write of '0' clears the sticky status. Write of '1' has no effect. A write does not clear the hardware flag.[1)] Read as: 0_B No address error detected 1_B Address error detected (AERR)
UERR	2	rwh	**Uncorrectable Error Detected** Write of '0' clears the sticky status. Write of '1' has no effect. A write does not clear the associated hardware flag. Read as: 0_B No uncorrectable error detected 1_B Uncorrectable error detected (UERR)
CERR	1	rwh	**Correctable Error Detected** Write of '0' clears the sticky status. Write of '1' has no effect. A write does not clear the associated hardware flag. Read as: 0_B No correctable error detected 1_B Correctable error detected (CERR)
SERR	0	rwh	**Error Detected** Write of '0' clears the sticky status. Write of '1' has no effect. Read as: 0_B No error detected 1_B Error detected: any error detected :CERR, UERR or AERR

1) Note: A write to AERR, UERR and CERR does not clear the hardware flags.

Error Tracking Register(s)

This/these register(s) contain(s) the address of error(s) detected. Up to five registers are implemented per MBIST according to VHDL generic nb_etrr_buf_g (theoretically there is address space for 8 registers). Default value of the generic is 1. ETRR(0) contains the last error detected. If more than one register is implemented, successive errors will push previous errors up. Correctable, uncorrectable and address errors are stored here in the same manner. Only new errors will be taken into consideration. I. e. errors at stored addresses will be ignored, no matter whether the cause is the same or different from the stored address.

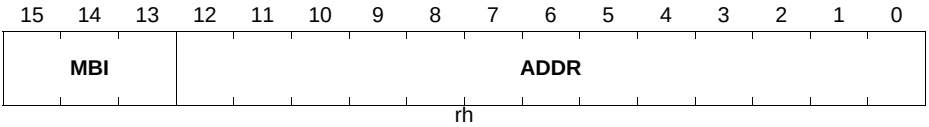
The address tracked is physical i.e. the address is directly equivalent to the SRAM address input signals a_i.

The associated valid bit(s) is/are contained in the register ECCD.VAL. ECCD.TRC clears the associated valid bits and all contents of ETRR will also be cleared.

It/they contain(s) the faulty address(es) of both the correctable, uncorrectable case and address errors.

Once all registers are used up ECCD.EOV is set .

ETRRx (x=0-4)
Error Tracking Register x **(12_H+x*02_H)** **Reset Value: 0000_H**



Field	Bits	Type	Description
MBI	15:13	rh	**Memory Block Index of Error(i)** If f more than one memory is implemented in parallel, these three bits contain the index of the memory block in error to identify the memory in error and the tracked address belongs to this memory. Otherwise these bits always are set to 0. Only one error can be tracked at one time. If more than one error occurs at the same time ECCD.EOV will be set, no matter how many ETRR registers are still available and the lowest memory index is stored.
ADDR	12:0	rh	**Address of Error(i)** Address of the error detected since last clear operation.

Read Data and Bit Flip Register

This register is used for several purposes whenever a register with the size of the memory width is needed.

Normally this register contains the data which are directly read back from the RAM (without any data scrambling) during the last read access.

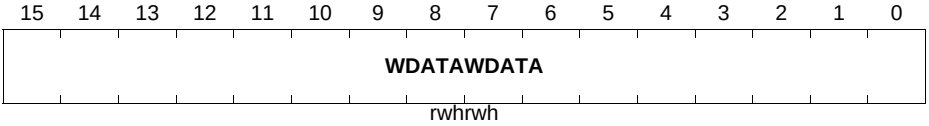
During logic test (LBIST) it contains the bit flip information. If ECCS.BFLE is set, this information is used to flip bits written to the SRAM.

After a failed test it contains the failed bit map if MCONTROL.FAILDMP is set. The address part is contained in the error tracking register.

When MCONTROL.DINIT is set, this information is written to all locations within range.

Writes to this register are not permitted while a test is underway.

RDBFLy (y=0-39)
Read Data and Bit Flip Register y ($A0_H$+ y*02_H) **Reset Value: 0000_H**



Field	Bits	Type	Description
WDATA	15:0	rwh	**Word Data** This field contains the data of the last memory read operation. The width of WDATA does always match the memory data width. m = nb_mems_g * (n + k)

9.4.3 Safety Features

Several Safety features are implemented in conjunction with ECC and Safety SRAMs.

There are three signals to provide an alarm to the SMU:

correctable error detected

uncorrectabe error detected

address error detected. Address errors are detected by the Safety SRAM feature. This discovers all wordline failures including broken wordlines and decoder malfunctions.

The codes used for ECC are of the SECDED (single error correction double error detection) type..

All codes are able to detect all zeroes and all ones, despite the fact that all physical faults resulting in this condition are covered by the Safety SRAM feature.

Whenever a new error is detected, not only a signal is set as an alarm, also an associated bit is set in ECCD. Three bits available are ECCD.CERR, ECCD.UERR and ECCD.AERR. They are cleared by writing a 0 to their location.

Bit ECE switches error correction on and off.

All errors are being tracked in error tracking registers (1 to 4). Correctable and uncorrectable errors are treated the same way except for the alarms and notificaton bits.

If an error is tracked then the associated register contains a valid value and a valid bit is set ECCD.VAL

The valid bits can be cleared by writing to ECCD.TRC

A valid bit is associated with each error entry. Bit ECCD.EOV is set when the error tracking register has recorded the maximum number of errors already and another error gets detected before the error tracking register is read by software and the event cleared by ECCD.TRC. All errors are treated the same way.

.

Uncorrectable errors are treated the same way as correctable errors and stored in the same registers.

Also, valid bits are used the same way.

ECCS.ECCMAP allows to select separately either the data bits of the stored information or the ECC check bits or data bits with ECC bits operational. In normal mode (ECCS.ECCMAP = 00) only access to data with correctly enabled ECC is possible and the ECC bits as such are neither visible nor accessible.

This mode (ECCS.ECCMAP ≠ “00”) cannot be left without prior changing safe_endinit.

Bit will switch on special test modes to inject errors into the ECC encoder to ECC decoder path. This way the redundancy of this path can be broken and the logic tested. Also, the ECC can be tested by firmware by writing illegal codes into the ECC data fields. Then any bit combination can be written to the ECC bits.

There is a Safety SRAM feature implemented to detect errors that involve more errors that can be detected by ECC. Also, there are signature bit flip enables provided to test the logic of address error detection.

The Safety SRAM feature will also detect the failure mode where a valid SRAM access request present at the SRAM input is not processed by the SRAM, as long as the attempted access does not have the same address as the last functioning valid access to the SRAM

The Safety SRAM feature detects addressing faults for both read and write accesses. Atomic read-modify-write sequences are also considered.

When such an error occurs or when a bit flip enable is set, an address error is flagged, provided ECCS.AENE is set.

Normally SRAM, MBIST and ECC are delivered as block. If the ECC decoder and/or decoder are embedded in a pipeline, then the blocks can be separated.

9.4.4 Operation Modes

9.4.4.1 Starting a Memory Test Sequence (example)

It's not possible any longer to start simple standard tests such as Checkerboard, Row Stripe, March C+ and March U without writing special values to the CONFIG registers. These tests now also require to write dedicated values into the CONFIG registers as described in the following example:

1. Enter memory test mode
2. Initialize registers
   Write the desired march sequence into the CONFIG registers
   CONFIG1.ACCSPAT is the pattern to be executed, CONFIG0.ACCSTYPE the read/write sequence and CONFIG0.NUMACCS the number of bits in CONFIG1.ACCSPAT and CONFIG0.ACCSTYPE to used
   AG_MOD contains the address mode to be used
   RANGE := <memory range to be tested>
3. Start memory test by writing a 1 to register bit MCONTROL.START
4. Reset MCONTROL.START
5. Wait for the end of the test
   - poll MSTATUS.DONE
   - or poll primary output DONE
6. Check the result of the test
   - verify MSTATUS.FAIL
   - or verify primary output FAIL

Complex algorithm may require several march starts to get a full test.

9.4.4.2 Getting Detailed Memory Test Results

The FAIL and DONE bits provide a general pass/fail information.

If MCONTROL.FAILDMP = '1', the test stops after a failed test and the fail information is immediately available for dump. MSTATUS.FDA (fail dump available) is set and signal faildumpreq asserted in this case. RDBFL contains the fail bit map and ETRR the failed address. Reading MSTATUS with MSTATUS.FDA = '1' and RDBFL(n-1) will reset MSTATUS.FDA and faildumpreq. A consequent setting of MCONTROL.RESUME will restart the interrupted test sequence.

The RANGE register can be used to run consecutive tests on constantly shifted memory ranges so that in the end the complete memory has been analyzed.

9.4.4.3 Dumping Fail Bitmap

Any dump information has to be polled from registers RDBFL and ETRR(0).

9.4.4.4 Filling a Memory with Defined Contents

The MBIST/ECC can be used to fill a memory range or a complete memory with a defined pattern very fast, i.e. one write access per cycle with the full memory data width. There are three methods implemented, one using bit MCONTROL.DINIT, one using input mtu_auto_data_init and another one using input mtu_partial_erase_i.

MCONTROL.DINIT will write a range with any pattern in RDBFL no matter whether this is a valid ECC code or not. This is useful if memories have additional ECC or parity bits and must be initialized before they can be used. The necessary steps are:

1. Enter memory test mode
2. Initialize registers
   RDBFL := <desired pattern>
   RANGE := <memory range to be filled>
3. Start fill operation by setting MCONTROL.DINIT and MCONTROL.START of the MCONTROL register
4. Wait for MSTATUS.DONE to be reset and clear MCONTROL.START.
5. Wait for the end of fill operation by polling MSTATUS.DONE bit
6. Leave memory test mode.

Also, two hardware signals named mtu_auto_data_init_i and mtu_partial_erase_i are available to fill the whole memory with the data on d_i or erase parts of the memory. ECC codes are automatically correct. Range is ignored if mtu_auto_data_init_i is applied, in case mtu_partial_erase_i is used nb_partial_erase_size_g blocks of 1kB starting from the top of the memory are erased. Memory testmode does not need to be switched on but a clock must be available.

Both signals will have priority over MCONTROL.START and are not interruptable.

9.4.4.5 Reading a Single Memory Location

The MBIST/ECC can also be used to read the contents of a single word. The RDBFL register holds the contents of a complete memory word and thus it is possible to read all memory bits, including ECC or parity bits. The necessary steps are:

1. Enter memory test mode
2. Initialize registers
   RANGE := RAEN = 0 (range disabled = single address) & address to be read
   CONFIG0 := 1001_H (NUMACCS = 1_H, ACCSTYPE = 01_H (read))
   CONFIG1 := 0000_H (linear mode, non inverted pattern)
3. MCONTROL := 4009_H (FAILDMP = 0, direction up, start): Start read operation
4. MCONTROL := 4008_H (clear START)
5. Wait for MSTATUS.DONE to be reset
6. Read RDBFL register
7. Leave memory test mode

9.4.4.6 Writing to a Single Memory Location

The MBIST/ECC can also be used to write the contents of RDBFL register to a single memory location. RDBFL holds the contents of a complete memory word and thus it is possible to write to all memory bits, including ECC or parity bits. The necessary steps are:

1. Enter memory test mode
2. Initialize registers
   RDBFL := write data
   RANGE := RAEN= 0 (range disabled = single address) & address to be written to
   CONFIG0 := 1000_H (NUMACCS = 1_H, ACCSTYPE = 00_H (write))
   CONFIG1 := 0000_H (linear mode, non inverted pattern)
3. MCONTROL := 4009_H (FAILDMP = 0, direction up, start): Start write operation
4. MCONTROL := 4008_H (clear START)
5. Wait for MSTATUS.DONE to be reset
6. Leave memory test mode

9.4.5 Memory Controller Register Addresses

There is one set of Memory Controller Registers for each logical memory module in the TC21x/TC22x/TC23x.

The sets of registers are located at offsets from the following base addresses.

Table 9-2 Registers Address Space - Memory Controller Registers

Module	Base Address	End Address	Note
MC0	$F006\ 1000_H$	$F006\ 10FF_H$	-

9.4.6 Memory Controller Register Overview

This section describes registers in each memory controller module. Register names described in this section will be referenced in other parts of the TC21x/TC22x/TC23x User's Manual by the prefix "MCx_" where x is the index or name of the specific memory controller. The registers are replicated for each memory controller.

MTU Memory Control Kernel Register Overview

Table 9-3 Register Overview of each MTU Memory Control register block

Short Name	Long Name	Offset Addr.[1)]	Access Mode		Reset	Description See
			Read	Write		
CONFIG0	Memory Config Register 0	00_H	U, SV, 16	U, SV, 16		Page 9-18

–	Reserved	$F0_H$-FF_H	BE	BE	–	–

1) The absolute register address is calculated as follows:
Memory Module Register Base Address + Offset Address (shown in this column)

9.5 ECC Implementation

9.5.1 ECC

9.5.1.1 ECC Codes

Most ECC codes except for the cache tag memories are of the SECDED (single error correction and double error detection) type. These are specially designed Hsiao codes optimized for triple error detection. They will detect all correctable errors and allow correction, detect all double errors and detect a relatively high percentage of triple errors. The cache tag memories will get DED codes (double error detection).

All codes will detect “all zeros” and “all ones”. However, with the safety SRAM concept of address error detection this feature is not required anymore as all physical faults that might produce an “all ones” or “all zeros” error are covered there.

SECDED Codes

14 bits total length, 8 bits data, 6 check bits

Matrix: [1, 2, 4, 8, 16, 32, 7, 11, 19, 35, 13, 22, 44, 52]

Check part of the matrix as bits:

00010011

00100101

01001010

10001111

11110100

11111000

No double columns, can be used as SEC code.

Type: Hsia-Code (all columns have odd weight)

Table 9-4 Code Characteristics 8/6

Number of codes with weight 3	0
Number of codes with weight 4	34
Can be used as SECDED code	
Undetectable double errors (correction on)	0
Undetectable triple errors (correction on)	136
Percentage of undetectable triple errors (correction on)	37.362637
Row weights	[6, 6, 6, 4, 4, 4]
Number of ones in the matrix	30

22 bits total length, 16 bits data, 6 check bits

Matrix: [1, 2, 4, 8, 16, 32, 7, 11, 19, 35, 13, 21, 37, 25, 41, 14, 22, 38, 26, 50, 44, 52]

Check part of the matrix as bits:

0001001010010111

0010010100101101

0100100111001010

1000111001110011

1111000001111100

1111111110000000

No double columns, can be used as SEC code.

Type: Hsia-Code (all columns have odd weight)

Table 9-5 Code Characteristics 16/6

Number of codes with weight 3	0
Number of codes with weight 4	252
Undetectable double errors (correction on)	0
Undetectable triple errors (correction on)	1008
Percentage of undetectable triple errors (correction on)	64.454544
Row weights	[10, 10, 10, 8, 8, 8]
Number of ones in the matrix	54

28 bits total length, 21 bits data, 7 check bits

Matrix: [1, 2, 4, 8, 16, 32, 64, 76, 13, 35, 52, 69, 88, 28, 49, 38, 19, 73, 84, 11, 56, 50, 22, 97, 14, 67, 98, 104]

Check part of the matrix as bits:

11111111111110000000000000000000

No double columns, can be used as SEC code.

Type: Hsia-Code (all columns have odd weight)

Table 9-9 Code Characteristics 32/7

Number of codes with weight 3	0
Number of codes with weight 4	1363
Can be used as SECDED code	
Undetectable double errors (correction on)	0
Undetectable triple errors (correction on)	5452
Percentage of undetectable triple errors (correction on)	59.656418
Row weights	[14, 14, 15, 15, 15, 15, 15]
Number of ones in the matrix	103

40 bits total length, 32 bits data, 8 check bits

Matrix: [1, 2, 4, 8, 16, 32, 64, 128, 161, 98, 35, 194, 14, 11, 38, 41, 69, 134, 25, 52, 176, 138, 196, 88, 19, 145, 67, 74, 97, 26, 164, 73, 162, 152, 148, 13, 44, 21, 84, 76]

Check part of the matrix as bits:

1001000001001110010000101110000 0
0101000010000011001110010000001 1
1110001100011000000010101000100 0
0000000000111001110001000110011 0
0000110100100101000101010101100 1
0000101011010010000000100011111 1
0111111001000100101101001000000 0
1010010110100000111010010001010 0

No double columns, can be used as SEC code.

Type: Hsia-Code (all columns have odd weight)

Table 9-10 Code Characteristics 32/8

Number of codes with weight 3	0
Number of codes with weight 4	766
Undetectable double errors (correction on)	0
Undetectable triple errors (correction on)	3064
Percentage of undetectable triple errors (correction on)	31.012146
Row weights	[14, 14, 14, 14, 12, 12, 12, 12]
Number of ones in the matrix	104

42 bits total length, 35 bits data, 7 check bits

Matrix: [1, 2, 4, 8, 16, 32, 64, 7, 11, 19, 35, 67, 13, 21, 37, 69, 25, 41, 73, 49, 81, 97, 14, 22, 38, 70, 26, 42, 74, 50, 82, 98, 28, 44, 76, 52, 84, 100, 56, 88, 104, 112]

Check part of the matrix as bits:

0000100010010110001001010110010110111

0001000100101010010010101010110011

0010001001001100100100110100110110 1

0100010001110001000111000111000111 0

1000011110000001111000000111111000 0

1111100000000001111111110000000000

1111111111111110000000000000000000

No double columns, can be used as SEC code.

Type: Hsia-Code (all columns have odd weight)

Table 9-11 Code Characteristics 35/7

Number of codes with weight 3	0
Number of codes with weight 4	1855
Can be used as SECDED code	
Undetectable double errors (correction on)	0
Undetectable triple errors (correction on)	7420
Percentage of undetectable triple errors (correction on)	64.63415

Table 9-11 Code Characteristics 35/7

Row weights	[16, 16, 16, 16, 16, 16, 16]
Number of ones in the matrix	112

44 bits total length, 36 bits data, 8 check bits

Matrix: [1, 2, 4, 8, 16, 32, 64, 128, 21, 28, 74, 26, 7, 70, 140, 112, 138, 11, 196, 161, 22, 41, 193, 152, 100, 35, 56, 137, 200, 37, 131, 168, 50, 73, 82, 176, 81, 14, 52, 164, 84, 224, 42, 97]

Check part of the matrix as bits:

0000001010110011000110110001000101000

0010010100100010100010000110100011101

0000000100010100111001011001001101111

No double colums, can be used as SEC code.

Type: No Hsiao code (at least one row has even weight

Table 9-14 Code Characteristics 128/9

Number of codes with weight 3	0
Number of codes with weight 4	45921
Undetectable double errors (correction on)	0
Undetectable triple errors (correction on)	183684
Percentage of undetectable triple errors (correction on)	43.81566
Row weights	[62, 50, 62, 62, 64, 64, 62, 62, 62]
Number of ones in the matrix	550

DED Codes

2-Bit-error detection, but no correction possible!

25 bits total length, 20 bits data, 5 check bits

Matrix: [1, 2, 4, 8, 16, 3, 5, 9, 17, 6, 10, 18, 12, 20, 24, 7, 11, 19, 13, 21, 14, 26, 28, 15, 31]

Check part of the matrix as bits:

0001001011001010110 1

0010010101010111 11

0100100110100111 0111

1000111000111001 1011

1111000000111110 0011

No double colums, can be used as SEC code.

Type: No Hsiao code (at least one row has even weight)

Table 9-15 Code Characteristics 20/5

Number of codes with weight 3	80
Number of codes with weight 4	435
Can be used as DED code only	
Percentage of undetectable triple errors	3.4782608
Row weights	[12, 12, 12, 12, 10]
Number of ones in the matrix	58

26 bits total length, 21 bits data, 5 check bits

Matrix: [1, 2, 4, 8, 16, 3, 5, 9, 17, 6, 10, 18, 12, 20, 24, 7, 11, 19, 13, 21, 25, 14, 22, 26, 28, 31]

Check part of the matrix as bits:

0001001011001011011 11

0010010101010110111 1

0100100110100110110 11

1000111000111000111 01

1111000000111111000 01

No double colums, can be used as SEC code.

Type: No Hsiao code (at least one row has even weight

Table 9-16 Code Characteristics 21/5

Number of codes with weight 3	90
Number of codes with weight 4	515
Can be used as DED code only	
Percentage of undetectable triple errors	3.4615386
Row weights	[12, 12, 12, 12, 12]
Number of ones in the matrix	60

27 bits total length, 22 bits data, 5 check bits

Matrix: [1, 2, 4, 8, 16, 3, 5, 9, 17, 6, 10, 18, 12, 20, 24, 7, 11, 19, 13, 21, 25, 14, 22, 26, 15, 23, 27]

Check part of the matrix as bits:

0001001011001011011011

0010010101010101101101

0100100110100110110110

1000111000111000111111

1111000000111111000111

No double colums, can be used as SEC code.

Type: No Hsiao code (at least one row has even weight)

Table 9-17 Code Characteristics 22/5

Number of codes with weight 3	101
Number of codes with weight 4	606
Can be used as DED code only	
Percentage of undetectable triple errors	3.4529915
Row weights	[14, 14, 12, 12, 12]
Number of ones in the matrix	64

30 bits total length, 24 bits data, 6 check bits

Matrix: [1, 2, 4, 8, 16, 32, 3, 5, 9, 17, 33, 6, 10, 18, 34, 12, 20, 36, 24, 40, 7, 11, 19, 35, 13, 49, 22, 42, 52, 56]

Check part of the matrix as bits:

000010001001010001010111

000100010010100010011011

001000100100110100100101

010001000111001000101010

100001111000001111001100

111110000000001111110000

No double colums, can be used as SEC code.

Type: No Hsiao code (at least one row has even weight)

Table 9-18 Code Characteristics 24/6

Number of codes with weight 3	75
Number of codes with weight 4	458
Can be used as DED code only	
Percentage of undetectable triple errors	1.8472906
Row weights	[12, 12, 10, 10, 10, 10]
Number of ones in the matrix	64

71 bits total length, 64 bits data, 7 check bits

Matrix: [1, 2, 4, 8, 16, 32, 64, 3, 5, 9, 17, 33, 65, 6, 10, 18, 34, 66, 12, 20, 36, 68, 24, 40, 72, 48, 80, 96, 7, 11, 19, 35, 67, 13, 21, 37, 69, 25, 41, 73, 49, 81, 97, 14, 22, 38, 70, 26, 42, 74, 50, 82, 98, 28, 44, 76, 52, 84, 100, 56, 88, 104, 112, 15, 23, 43, 51, 101, 89, 102, 90]

Check part of the matrix as bits:

00000100001000100101100001000100101100010010110010110111000011111

No double colums, can be used as SEC code.

Type: No Hsiao code (at least one row has even weight)

Table 9-20 Code Characteristics 64/7

Number of codes with weight 3	1812
Number of codes with weight 4	55286
Can be used as DED code only	
Percentage of undetectable triple errors	0.44190812
Row weights	[52, 50, 52, 52, 50, 50, 50, 52]
Number of ones in the matrix	408

9.5.2 Address Error Detection

Address error detection has to capture several memory faults that cause multiple or all bits of a word to fail. Such faults could be address decoder stuck-at-faults, broken word-lines, bridged word-lines etc. Because of this origin an ECC detection would not cover these cases because the words read back from memory would have perfectly matched check bits despite corrupted word selects.

In this version of MBIST/ECC the SRAMs will detect any of the faulty cases.

.

9.6 Implementation Section

All Memory Controller register regions which are not allocated in the table below are not implemented. Attempted accesses to regions which are not implemented will return a bus error.

9.6.1 Memory Control Register Implementation

9.6.1.1 MEMTEST Implementation

The memory test register MEMTEST contains enable bits for the various Memory Controllers.

Memory control registers described in this chapter are accessible only when the Memory Controller is enabled (MTU_MEMTEST.MEMxEN = 1).The only exceptions to this are registers ECCDand ETRR (for each memory) which are available at all times to permit easy runtime access to ECC features.

Note:

2. *When a Memory Controller is enabled, functional access to the memory is temporarily unavailable. When a memory is being tested it is essential to prevent an attempted functional access to that memory (e.g. While testing a CPU's local memories, the CPU should be in an idle state, or executing from other memory). Attempted functional accesses to memories when MEMxEN=1 may result in unexpected behaviour.*

3. *Correct execution of a Memory Controller operation (e.g. MBIST or initialization sequence) requires that both the MTU and the module containing the memory-under-test are both operational for the duration of the sequence. A module reset of the MTU or the module containing the memory-under-test, during execution of such an MBIST sequence may result in unexpected behaviour.*

9.6.1.2 MEMMAP Implementation

The Memory Mapping Enable register MEMMAP has configurable control bits to select memory-mapped test mode for each CPU memory.

Cache and Scratchpad memories are physically implemented as a single RAM, but this register function assumes two separate logical RAM partitions. In this register additional bits CPUxDCMAP and CPUxPCMAP are defined. These control the Cache partitions of the RAMs for Data Side and Program side respectively. Since cache content and tags of a cache must be simultaneously switched from memory mapped to cache functional mode, the control bits are mirrored and only one bit is writeable for each cache. The bits corresponding to the tag memories of the same cache will always take the same value as that written to the main Cache Memory control bit. This linkage is product specific.

9.6.1.3 MEMSTAT Implementation

The Memory Status registers MEMSTATx have an implemented bit for each security-relevant RAM.

Cache and Scratchpad memories are physically implemented as a single RAM with a single MBIST, so bits CPUxDSAIUand CPUxPSAIU give the status of the partial initialization of the cache partitions for Data Side and Program side respectively. Since cache content and tags of a cache may take different lengths of time to erase, both are implemented as separate status bits.

10 Safety Management Unit (SMU)

10.1 Introduction

The SMU is a central and modular component of the safety architecture providing a generic interface to manage the behavior of the microcontroller under the presence of faults. The SMU centralizes all the alarm signals related to the different hardware and software-based safety mechanisms. Each alarm can be individually configured to trigger internal actions and/or notify externally the presence of faults via a fault signaling protocol. The default fault signaling protocol is a bi-stable Error Pin. The severity of each alarm shall be configured according to the needs of the safety application(s): per default every alarm is disabled with the exception of the watchdog timeout alarms. For debug and diagnosis purposes the alarm events are logged, the logged information is resilient to any system or application reset. The SMU also implements some housekeeping functions related to the management and test of dedicated safety mechanisms. A special test mode is available to test the SMU itself enabling to detect latent faults as required by the ISO 26262 safety standard. In addition to the generic register access protection, the SMU implements an independent configuration locking mechanism.

The SMU in combination with the embedded safety mechanisms enable to detect and report more than 99% of the critical failure modes of the microcontroller within the fault tolerance time interval. The timing characteristics of the fault tolerance time interval can be configured in the SMU.

Figure 10-1 “SMU Interfaces” on Page 10-2 gives an overview of the SMU interfaces.

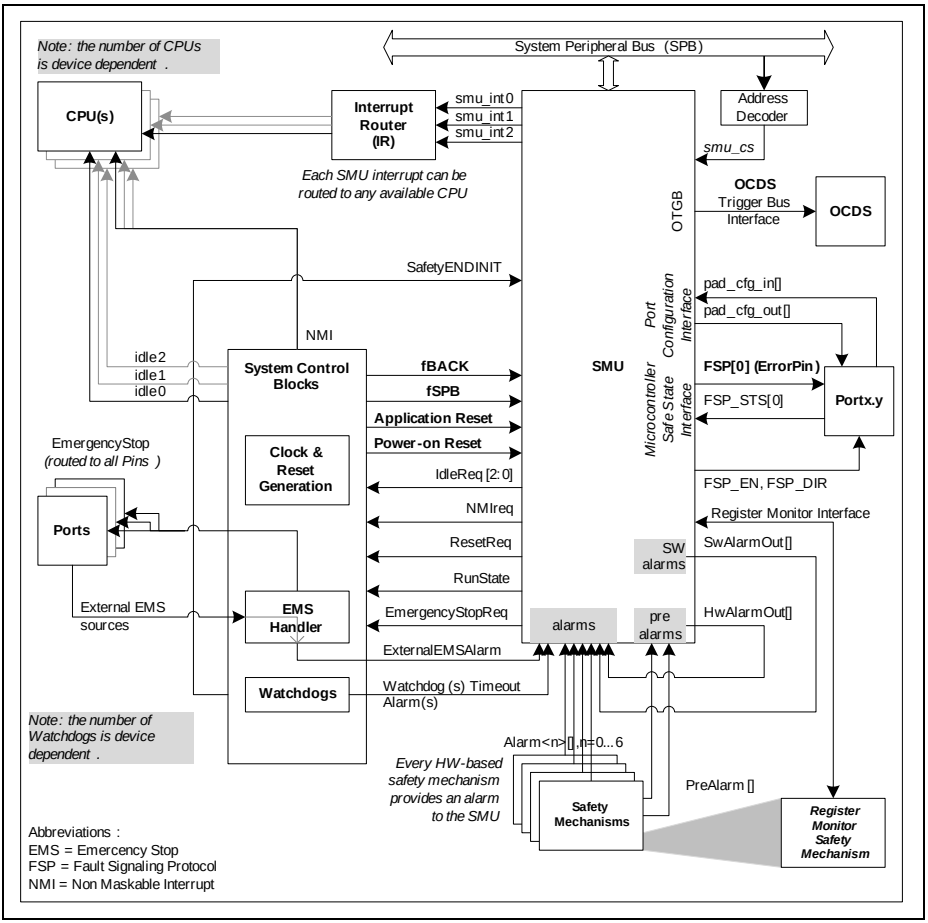

Figure 10-1 SMU Interfaces

10.2 Features

The SMU implements the following features:

- Collects every alarm (error notification) information from every safety mechanism:
  - CPU Lockstep
  - SRAM single bit error correction
  - SRAM uncorrectable error
  - SRAM Monitor: Address Buffer overflow
  - SRAM addressing fault
  - Program FLASH single bit error correction
  - Program FLASH double bit error correction
  - Program FLASH arbitrary multiple-bit uncorrectable error
  - Program FLASH Monitor: address buffer full
  - Program FLASH addressing fault
  - Processor interconnect (SRI) safety mechanisms
  - Safety Flip-Flop
  - Clock monitors
  - System PLL & Flexray-PLL loss of lock
  - Input/Output Monitoring Module
  - Interrupt Router and Interrupt Control Units hardware monitor
  - Voltage Monitor for internal voltage regulators
  - Error reporting from Shared Resource Interconnect and System Peripheral Bus
  - Die Temperature Sensor
- Alarm flags are stored in a debug register that is only reset by the Power-on reset, to enable fault diagnosis and possible recovery.
- An alarm emulation facility is provided to enable software-based diagnostics to post an alarm condition with the same properties as the hardware alarms.
- Implements the access protection and SafetyEndinit modes to protect configuration registers.
- Implements a Fault Signaling Protocol (FSP) reporting internal faults to the external environment. The FSP can be configured using the following modes:
  - Bi-stable single pin output (push-pull active low configuration using FSP[0]), also called ErrorPin.
  - Single-bit timed protocol using FSP[0]
- The FSP value driven by the microcontroller can be observed via an internal status flag
  - Additionally a monitor is available to check the timing and state properties of the FSP protocol when a fault is reported.
- After power-on reset the FSP is disabled, software needs to connect the FSP to the assigned port. The port is configured as GPIO.
- Each individual alarm can be configured to activate the fault signaling protocol and/or one of the following internal actions:

  - generate an Interrupt request to any of the CPUs, concurrent interrupts to several CPUs can be configured
  - generate a NMI request to the System Control Unit
  - generate a reset request to the System Control Unit leading to a system or application reset
  - activate the pad emergency stop signal controlling the safe state of output pads
  - generate a CPU idle request
- After reset every alarm (except watchdog timeout) is disabled.
- A lock mechanism is available to protect the SMU configuration in addition to the standard access protection
- Implements internal watchdog(s) timeout pre-warning function.
- Implements an internal watchdog called recovery timer to monitor the execution of critical software error handlers. The watchdog is started automatically by hardware according to configurable alarm events.

10.3 Functional Overview

The SMU collects all the error flags (called alarms in this document) from all the hardware monitors (safety mechanisms) defined by the safety concept. The section **“Alarm Mapping” on Page 10-14** specifies the alarm interface and classifies them into alarm groups. The alarm groups do not define any hierarchy but only a logical mapping used to map input alarm signals to internal configuration registers. The section **“Alarm Handling” on Page 10-41** describes the configuration options that can be specified. The configuration options specify the behavior of the SMU when an alarm event is detected. The alarm event can trigger an internal action and/or the activation of the Error Pin that indicates the presence of a dangerous fault to the external environment. The section **“SMU Control Interface” on Page 10-48** specifies how the SMU can be controlled by software and the dependencies with the hardware operation. The section **“Fault Signaling Protocol (FSP)” on Page 10-52** describes the properties of the external fault signaling protocol defining the timing and logical properties of the Error Pin(s).

The SMU implements the technical safety requirements

10.4 Functional Description

10.4.1 Reset Types

The SMU requires multiple reset types for its operation. The reset types are fully specified in the System Control Units. The reset types that are required by the SMU are:

- Power-on Reset.
- Debug Reset.
- Application Reset.

Additionally the SMU supports the **module reset** feature. The module reset acts as an application reset, it is fully controlled by software using the **SMU_KRST0**, **SMU_KRST1**, **SMU_KRSTCLR** registers. The module reset only affects the SMU kernel and not the System Peripheral Bus (SPB) bus interface logic.

Table 10-1 “Effect of Reset Types to SMU functionality” on Page 10-6 specifies the scope of each reset type to the SMU functions (a function includes the control and configuration registers and the related logic).

Table 10-1 Effect of Reset Types to SMU functionality

SMU Function	Module Reset	Application Reset	Debug Reset	System Reset	Power-on Reset
SMU FSP Function **Chapter 10.4.8**	Not Affected	Not Affected	Not Affected	Not Affected	Reset
SMU SSM Function **Chapter 10.4.7**	Not Affected	Not Affected	Not Affected	Not Affected	Reset

10.4.2 Interfaces Overview

This section describes the main interface signals between the SMU and the other modules.

10.4.2.1 Interfaces to SCU

Internal actions resulting from an alarm event that interface to the System Control Unit. The interface signals are:

- Emergency Stop Request
- Reset Request
- Idle Request
- NMI Request

10.4.2.2 Interfaces to the Interrupt Router

Internal actions resulting from an alarm event that interface to the Interrupt Router. The interface signals are:

- SMU Interrupt Request 0
- SMU Interrupt Request 1
- SMU Interrupt Request 2

The mapping of SMU Interrupt Requests to the Interrupt Router (IR) interrupt nodes can be found in the IR chapter.

The **SMU_AGC**.IGCS<i>, i={0,1,2} register fields provide the software interface to control how the SMU triggers interrupt requests to the interrupt router.

Each **SMU_AGC**.IGCS<i> is a 3-bits bit-field: **SMU_AGC**.IGCS<i>[2:0] that defines a direct relationship to the 3 SMU interrupt requests:

- **SMU_AGC**.IGCS<i>[0] shall be set to ‘1’ to trigger SMU Interrupt Request 0
- **SMU_AGC**.IGCS<i>[1] shall be set to ‘1’ to trigger SMU Interrupt Request 1
- **SMU_AGC**.IGCS<i>[2] shall be set to ‘1’ to trigger SMU Interrupt Request 2

The usage of the three **SMU_AGC**.IGCS<i> bit-fields is defined in **“Alarm Configuration” on Page 10-41**; where each **SMU_AGC**.IGCS<i> can be selected as an internal action.

10.4.2.3 Interface to the Ports (Error Pin)

The generic port structure is presented in presented in **Figure 10-2 “Generic Port Structure” on Page 10-9**.

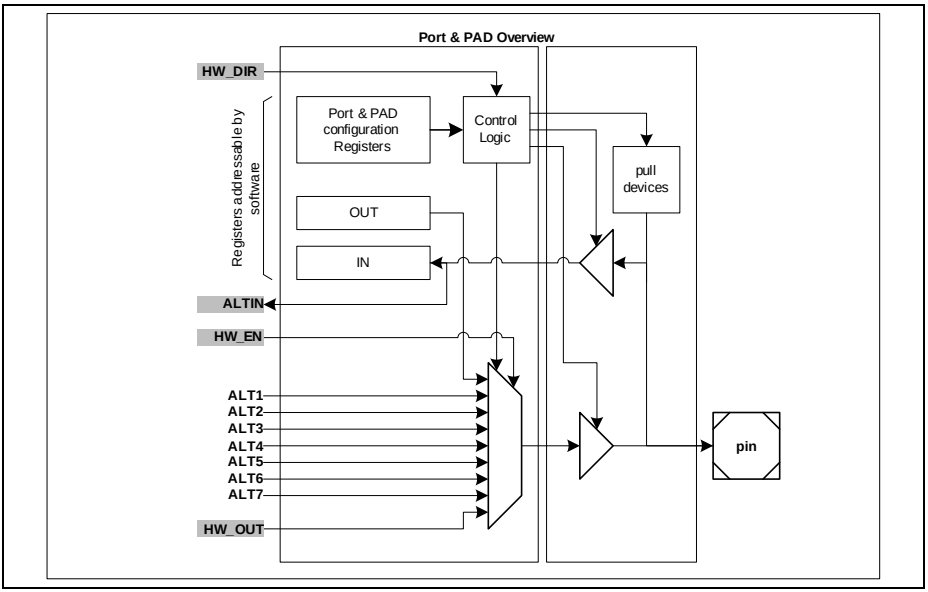

Figure 10-2 Generic Port Structure

The port can be connected to peripheral functions via the ALTx inputs. This is the default state of the port after power-on reset. The SMU connects to the port using the HW_DIR, ALTIN, HW_EN, HW_OUT signals. When the HW_EN port input is driven active by the SMU, SMU gets full control over the port data path, bypassing any other software configuration related to the usage of the ALTx inputs.

Figure 10-3 "SMU Data Path Interfaces with the Ports" on Page 10-10 fully specifies the data path connectivity of the SMU with the Ports. The mapping to the port for the product can be found in the port specification chapter of the TC21x/TC22x/TC23x microcontroller.

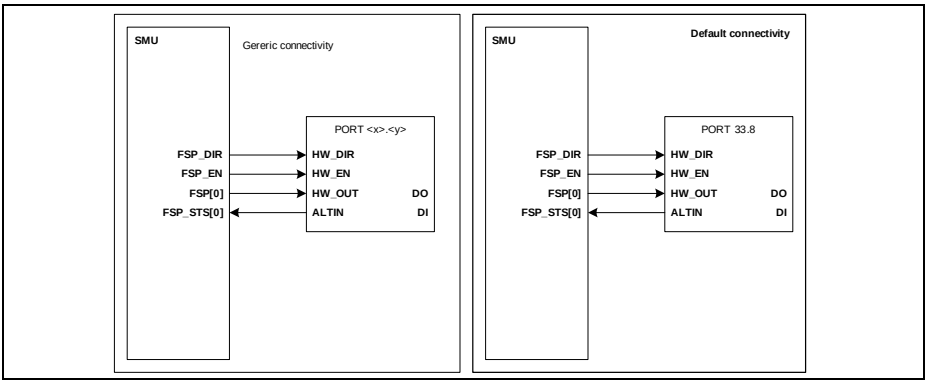

Figure 10-3 SMU Data Path Interfaces with the Ports

Figure 10-4 “SMU/PAD Control Interface to the PADs” on Page 10-10 provides a more detailed overview of the PORT structure and highlights the signals that play a role in the SMU connectivity.

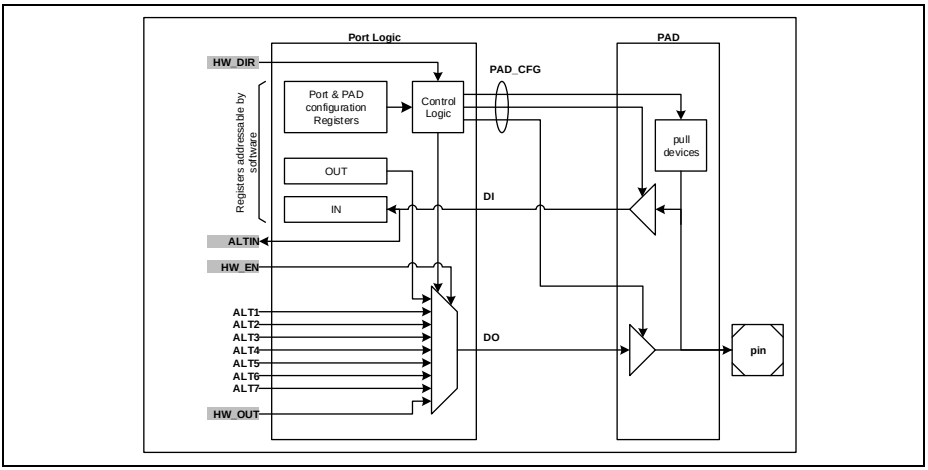

Figure 10-4 SMU/PAD Control Interface to the PADs

While FSP[0] is controlled by hardware, the FSP_DIR and FSP_EN are controlled by software as follows:

- FSP_DIR output is directly driven by the **SMU_PCTL** register HWDIR field
- FSP_EN output is directly driven by the **SMU_PCTL** register HWEN field

SMU_PCTL provides a field PCS that enables software to change the PAD control. With **SMU_PCTL** HWDIR, HWEN and PCS fields, software can control the PAD ownership transition from GPIO to full SMU hardware control following the guidelines provided by the **SMU_PCTL** register description.

To satisfy safety requirements it shall be ensured that the PAD operation is not affected by an application or system reset: the application can configure a system reset and the SMU Error Pin fault state activation upon detection of a critical alarm. This is achieved by safeguarding all the PAD configuration signals (see PAD_CFG signals **Figure 10-4**) into a special register. The contents of this register are exposed to software using the **SMU_PCTL**.PCFG field. They are only available for debug purposes.

The contents of the **SMU_PCTL** register are locked by the **SMU_KEYS** register and are only reset by a power-on reset, therefore the PAD configuration remains stable even in the presence of an application or system reset. Furthermore the **SMU_PCTL** register is implemented using dedicated Safety Flip-Flops safety mechanism that detects in run-time any bit change caused by a random hardware fault.

Refer to **“SMU Integration Guidelines” on Page 10-13** for the SMU and PORT configuration steps that are required to use the Error Pin.

10.4.2.4 Interface to the Safety Flip-Flop Safety Mechanism

The SMU provides a register interface that enables to test the Safety Flip-Flop safety mechanism. The register interface is realized by the **SMU_RMCTL**, **SMU_RMEF**, **SMU_RMSTS** registers.

10.4.3 SMU Integration Guidelines

This chapters extends the **"Interfaces Overview" on Page 10-8** section by providing additional information for the usage of the Error Pin (**"Fault Signaling Protocol (FSP)" on Page 10-52**) in combination with other input/output (GPIO) functions of the microcontroller.

Note: The PAD properties (push-pull, open-drain, drive strength,...) are configured in the registers of the PORT to which the SMU connects to. These registers are described in the PORT chapter of the microcontroller.

- During power-on-reset, the Error Pin is in high impedance: the pull devices are disabled under hardware control.
- After power-on-reset the default mode of the PORT to which the Error Pin is connected is GPIO. In that mode the pull devices can be used.
- Before changing the ownership of the PAD to SMU, software shall configure the PORT registers including the following:
  - Software shall disable the pull devices if GPIO is not used
  - Software shall program the GPIO registers of the error pin to strong driver output constant low
- To enable SMU to control the Error Pin PAD, software shall activate the PAD configuration safeguarding process (see **"Interface to the Ports (Error Pin)" on Page 10-8**).
  - The safeguarding process requires a software action that consists on writing a 1 into the **SMU_PCTL**.PCS field. **Only with the first transition from 0 to 1 leads to the safeguarding process. A new PORT configuration followed by a new transition from 0 to 1 of the SMU_PCTL.PCS has no effect to the hardware.**

10.4.4 Alarm Mapping

This section defines the mapping between the alarm signals at the input of the SMU and the alarm configuration registers. For that purpose alarm groups are defined. There is a one to one relationship between an alarm group index ALM<n>[index] signal and the alarm configuration and status registers (AG<n>[index]). A group is made of up to 32 input alarms; for convenience some entries may be reserved.

10.4.4.1 Pre-alarm Definition

There are situations where it is not necessary to implement configuration and status registers for every alarm; a typical case is a module with multiple SRAM instances. For that purpose a so-called PreAlarm[] bus is available to which the alarms that can be combined together are connected to. The result of the combination is sent to a HwAlarmOut[] output so that HwAlarmOut[] = Combine(PreAlarm[n], PreAlarm[m],...). The tables in **“Pre-alarm Signals” on Page 10-14** fully specify the arguments for the Combine() functions. The Combine() function implements a logical OR between all arguments.

Note: The unspecified (or unused) PreAlarm[] bits shall be tied to the logic level ‘0’ at the SMU input.

Note: The unspecified (or unused) HwAlarmOut[] bits shall be driven to the logic level ‘0’ by the SMU.

10.4.4.2 Pre-alarm Signals

In the next tables the PreAlarm[] bits are specified in the form index=MODULE.(type of error message), where MODULE.(type of error message) enables to identify the module instance and the nature of the error message. The error message is specified in a functional way and does not refer to a real signal name in the design. The modules connecting to the SMU shall use the same functional name to enable a cross-reference through the overall specification.

HwAlarmOut[47]= PreAlarm[186=PMU.PFLASH0.(ECC double bit correction notification)] or PreAlarm[187=PMU.PFLASH1.(ECC double bit correction notification)]
HwAlarmOut[48]= PreAlarm[194=PMU.PFLASH0.(ECC non correctable multiple bit error)] or PreAlarm[195=PMU.PFLASH1.(ECC non correctable multiple bit error)]
HwAlarmOut[49]= PreAlarm[202=PMU.PFLASH0.(Addressing error)] or PreAlarm[203=PMU.PFLASH1.(Addressing error)]
HwAlarmOut[50]= PreAlarm[210=PMU.PFLASH0.(Address buffer full)] or PreAlarm[211=PMU.PFLASH1.(Address buffer full)]

Table 10-14 HwAlarmOut[51]: Access Enable Alarms

Function
HwAlarmOut[51]= PreAlarm[218=IR.(Access Enable Error)][1] or PreAlarm[219=SCU.DTS.(Access Enable Error)]
PreAlarm[229:220] bits are reserved for extensions of the Access Enable Alarms

1) This alarm is related to the event where a master not configured in the module ACCEN register tries to access a register protected by the ACCEN scheme. Depending on the module all or only a subset of the module registers are protected by the ACCEN. Most of the modules only generate a bus error condition and no dedicated ACCEN alarm when the aforementioned event happens.

10.4.4.3 Non-compliant Alarms

This section describes the alarms that are not compliant with the SMU alarm protocol and for which a special processing is required. They are first connected to a pre-alarm to be processed by the SMU in order to deliver a SMU compatible input alarm signal.

Table 10-15 HwAlarmOut[63] specification: SCR Alarm

Function
HwAlarmOut[63]= PreAlarm[255=SCR(Standby Controller Alarm)]
PreAlarm[255] is a signal clocked by the fBACK clock, it shall be synchronized to the fSPB clock. HwAlarmOut[63] shall be connected to ALM3[24].

Note: The Standby Controller is not available in all devices. When not available PreAlarm[255] shall be connected to '0' and ALM3[24] shall be reserved.

10.4.4.4 Internal SMU Alarms

The SMU has also the capability to generate its own alarm signals. They are specified in **Table 10-16 “Internal Alarms” on Page 10-23**.

Table 10-16 Internal Alarms

HwAlarmOut	Function
HwAlarmOut[60]	Recovery Timer 0 Timeout
HwAlarmOut[61]	Recovery Timer 1 Timeout
HwAlarmOut[62]	FSP Fault State Activation
HwAlarmOut[63]	Reserved

10.4.4.5 Alarm Signals

The following tables fully specify the mapping between the alarms provided by the safety mechanisms implemented by the microcontroller and the alarm groups. Cells in **bold** refer to alarms coming from multiple instances of the same safety mechanism that are logically combined to a single alarm definition at the SMU level.

In the following tables the column “Safety Mechanism & Error Indication” indicates to which safety mechanism the alarm is related to. If multiple safety mechanisms are indicated, the alarm corresponds to the detection of an error by one of the listed safety mechanisms.

For some safety mechanisms different terms are used in the microcontroller documents; the following list provides a guideline between the term used in the alarm tables and the other definitions. In bold the definition used in the alarm tables.

- **Register Access Protection** or alternatively called Safety Register Protection
  - Purpose: Monitors the master identifier of a given bus-master during a write access to a configuration register. The master identifier is a hard-coded information that is provided during any bus access. If the master identifier is not enabled by the Register Access Protection configuration registers (ACCEN0) the write is aborted. Most of the modules do not provide a dedicated alarm for this event and instead will generate a bus error. Therefore the Register Access Protection is only documented where a dedicated alarm is available.
  - Note: for peripherals that implement memory-mapped SRAMs, the write accesses to the memories are monitored as well.
- **Bus-level Memory Protection Unit** (MPU) or alternatively called Safety Memory Protection
  - Purpose: Monitors the master identifier and the address of a given bus-master during a write access to a local SRAM. The master identifier is a hard-coded information that is provided during any bus access. If the master identifier is enabled by the Bus-level MPU configuration registers and the address is within the valid address range the write is accepted, otherwise the write is aborted and a Bus-level MPU alarm is issued.
  - The SRAMs monitored are the {PSPR, DSPR} SRAMs of each CPU and the LMU SRAMs when available in the product.

Table 10-17 TC21x/TC22x/TC23x **Alarm Mapping related to Alarm 0 group**

Alarm Index	Module	Safety Mechanism & Alarm Indication
ALM0[0]	CPU0	Safety Mechanism: Lockstep CPU Alarm: Lockstep Comparator Error
ALM0[1]	CPU0	Safety Mechanism: Bus-level Memory Protection Unit Alarm: Bus-level MPU violation. Safety Mechanism: Register Access Protection Alarm: Access Protection violation.

10.4.5 Alarm Handling

This section specifies the hardware and software alarm processes.

10.4.5.1 Alarm protocol

Each safety mechanism shall interface with the SMU using a pre-defined protocol. The protocol enables to cross clock domains in a reliable manner. The operation of the protocol has no influence to the software layers.

10.4.5.2 Alarm Configuration

Upon reception of an alarm event the SMU decodes the actions to be performed. The action can be classified into an internal behavior and an external behavior. Both the internal and external behavior can be configured for every alarm.

The external behavior is related to the Fault Signaling Protocol (see **“Fault Signaling Protocol (FSP)” on Page 10-52**). The external behavior is configured via the following registers:

- **SMU_AG0FSP**
- **SMU_AG1FSP**
- **SMU_AG2FSP**
- **SMU_AG3FSP**
- **SMU_AG4FSP**
- **SMU_AG5FSP**
- **SMU_AG6FSP**

Alarm Action Configuration Registers

The internal behavior of the SMU under the presence of an alarm is controlled via the following registers:

- **SMU_AG0CFx (x=0-2)**
- **SMU_AG1CFx (x=0-2)**
- **SMU_AG2CFx (x=0-0)**, **SMU_AG2CFx (x=1-1)**, **SMU_AG2CFx (x=2-2)**
- **SMU_AG3CFx (x=0-0)**, **SMU_AG3CFx (x=1-1)**, **SMU_AG3CFx (x=2-2)**
- **SMU_AG4CFx (x=0-2)**
- **SMU_AG5CFx (x=0-2)**
- **SMU_AG6CFx (x=0-2)**

Alarm Action Configuration Codes

The internal behavior is specified by a 3-bit code as follows:

- Code = SMU_AG<n>CF2. SMU_AG<n>CF1. SMU_AG<n>CF0, n=0...6

Table 10-24 SMU Alarm Configuration

Code	Name	Behavior
0x0	SMU_NA	No Action. Reset value. Alarm disabled.
0x1	SMU_RSVD	Reserved. No Action. Alarm disabled.
0x2	SMU_IGCS0	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 0 from the **SMU_AGC** register.
0x3	SMU_IGCS1	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 1 from the **SMU_AGC** register.
0x4	SMU_IGCS2	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 2 from the **SMU_AGC** register.
0x5	SMU_NMI	Sends an NMI request to the SCU
0x6	SMU_RESET	Sends a reset request to the SCU. The SCU shall be configured to generate an application or system reset.
0x7	SMU_IDLE	Triggers a CPU idle request using Idle Configuration Set from the **SMU_AGC** register

Unless otherwise specified the reset state of the alarms is “No Action”. Refer to reset values of registers listed in **“Alarm Action Configuration Registers” on Page 10-41** and special cases described in **“Watchdog Alarms” on Page 10-46**.

10.4.5.3 Alarm operation

Whenever an input alarm event is detected and the SMU state machine is in the RUN or FAULT state, the SMU checks for the corresponding actions to be done for the internal action and for the FSP in a concurrent way. If an input alarm event is detected and no action is specified for the alarm, the corresponding bit shall be set to 1 as well but no action takes place.

The processing of the incoming alarm events is performed as follows:

- The alarm groups are scanned in a linear order starting with alarm group 0. The switching from one alarm group to the next one, takes several clock cycles.
- During the switch operation to a new alarm group (AGy) a snapshot of the pending alarms for AGy is made by hardware.
- If there are no pending alarms for the active alarm group AGy nothing happens during the processing time slot related to this alarm group.
- If there are pending alarms they are processed in a fixed order 0 up to 31.
  - If new alarms arrived for the active alarm group, they are only processed in the next time slot for the alarm group.
  - The processing of an alarm within an alarm group may take several fSPB cycles.
  - If the status flag related to a pending alarm event is already set to 1 the alarm event is ignored and the next available pending alarm within the active group is searched.
  - Whenever a pending alarm event is processed, the corresponding status bit is set to 1 by hardware in the AG<x> register. If an internal SMU action is configured the action counter (ACNT) in the **SMU_AFCNT** register is incremented.

10.4.5.4 Alarm Status Registers

Table 10-25 “Handling of Alarm Status” on Page 10-44 specifies the possible software actions on the AG<x> alarm group status registers depending on the SMU State machine state.

Table 10-25 Handling of Alarm Status

SMU State Machine	SW Action	Effect on AG<x>
START	SMU_ASCE(0) command Write **Data** at AG<x> Address	If (**Data[i]** == 1) AG<x>[i] = 0 else AG<x>[i] unchanged
START	Write **Data** at AG<x> Address	If (**Data[i]** == 1) AG<x>[i] = 1 else AG<x>[i] unchanged
RUN	SMU_ASCE(0) command Write **Data** at AG<x> Address	If (**Data[i]** == 1) AG<x>[i] = 0 else AG<x>[i] unchanged
RUN	Write **Data** at AG<x> Address	No Effect
FAULT	SMU_ASCE(0) command Write **Data** at AG<x> Address	If (**Data[i]** == 1) AG<x>[i] = 0 else AG<x>[i] unchanged
FAULT	Write **Data** at AG<x> Address	No Effect

In the START state software has the possibility to “emulate” the occurrence of input alarm events by writing at an AG<x> address. The resulting set of an AG<x> bit per software can take several hundreds of clock cycles depending on the hardware decoding state and the number of active alarms. Software shall read back the AG<x> register to ensure the completion of the operation if necessary.

10.4.5.5 Alarm Debug Registers

The Alarm debug registers enable the application to improve the diagnosis of the root cause that lead to a malfunction. In that context they may help to implement recovery strategies, if allowed by the application. The **SMU_ADx (x=0-6)** debug registers shall make a snapshot of the **SMU_AGx (x=0-6)** when:

- the action to be executed by the SMU is a reset when the SMU is in the RUN or in the FAULT state
- a SMU state machine (SSM) transition to the FAULT state takes place, either controlled by the SMU hardware or a software command

The **SMU_ADx (x=0-6)** shall only cleared by a power-on reset.

10.4.5.6 Port Emergency Stop

The port emergency stop feature enables forcing a pad into General Purpose Input Mode. The port emergency stop request to the SCU can be activated by any of the following situations:

- a SMU_ActivatePES() software command
- an alarm event with SMU_AG<x>FSP enabled and **SMU_FSP**.PES enabled
- an alarm event with an internal action configured in SMU_AG<x>CFx registers and SMU_AGC.PES enabled for that action.

10.4.5.7 Recovery Timer

A recovery timer (RT) is available to enable the monitoring of the duration or internal error handlers activated by an alarm NMI or Interrupt action. In the current SMU implementation two independent instances (RT0 and RT1) are available. The recovery timer duration (identical for all instances) is configured in the register **SMU_RTC**. It is possible to enable or disable each instance, however RT0 is enabled by default as it is required for the operation of the CPU watchdogs (see also **“Watchdog Alarms” on Page 10-46**). In addition to **SMU_RTC** an additional configuration register (SMU_RTC<n>) is available per instance to configure the alarm mapping.

The alarm mapping consists of a pair of parameters {GID<n>[2:0], ALID<n>[4:0]}, where GID<n>[2:0] is a group identifier and ALID<n>[4:0] is the alarm identifier belonging to the group. Four {GID[], ALID[]} pairs can be configured per recovery timer instance. It is possible to configure multiple time the same group identifier. If less than four alarms need to be mapped to a recovery timer, the same {GID[], ALID[]} shall be configured multiple times.

Note: The use of the recovery timer only makes sense if the internal action is an interrupt or NMI. However no hardware check is done, it is up to software to configure the SMU in the appropriate way.

If a recovery timer is enabled and for any of the {GID[], ALID[]} pairs and an alarm event occurs and if an internal action is configured resulting to an internal action (the alarm status shall be cleared) the recovery timer is automatically started by hardware. Such situation is called a recovery timer event. An alarm without internal action shall not start a recovery timer.

Once an recovery timer event is occurs, the recovery timer starts and counts until software stops it with the SMU_RTStop(). If the timer expires an internal SMU alarm (Recovery Timer Timeout) is issued. During the time the recovery timer is running any other action that requests the recovery timer is ignored. If such event happens, the bit RTME (Recovery Timer Missed Event) is set to ‘1’ by hardware in the **SMU_STS** register. The bit RTME can only be cleared by software. The bit RTS (Recovery Timer Status) is set to ‘1’ by hardware in the **SMU_STS** register during the time the recovery

timer is running: from the timer activation until a SMU_RTStop() is received or the timer expires. The bit RTS is cleared by hardware upon reception of SMU_RTStop() or the timer expires.

If a SMU_RTStop() command is received when the recovery timer is not active, the command returns an error response.

10.4.5.8 Watchdog Alarms

The watchdogs (WDT) timeout alarms require a special processing in order to ensure a correct microcontroller behavior if the watchdogs are not serviced by software or firmware. It shall be ensured that the microcontroller is reset after a pre-warning phase, where software can still perform some critical actions.

- Every Timeout Alarm shall activate an NMI
- Recovery Timer 0 shall be configured to service WDT timeout alarms
- Recovery Timer 0 timeout alarm shall be configured to issue a reset request and activate the Fault Signalling Protocol.

The aforementioned properties are implemented as reset values for the watchdog(s) timeout alarm(s) and for the recovery timer 0.

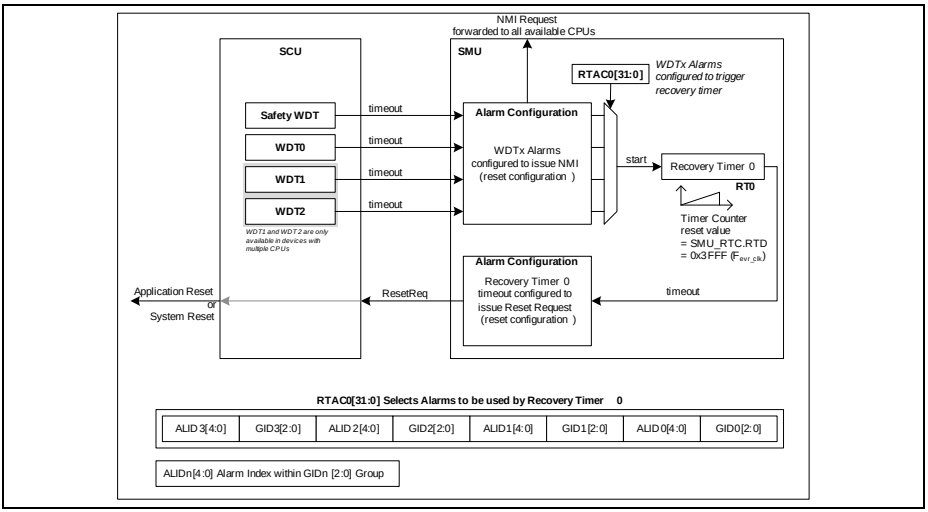

Figure 10-5 Watchdog timeout alarm configuration

The watchdog timeout detection is required from the very first instruction executed by a CPU: the SMU shall process any watchdog timeout alarm during the START state.

Note: If the same behavior is expected for all WDT alarms, it is recommended to use the global WDT timeout alarm that implements a logical OR among all WDT timeout

*alarms, thus freeing some {GID[], ALID[]} configuration pairs in **SMU_RTAC0** for other purposes.*

10.4.6 SMU Control Interface

The core functionality of the SMU is introduced through its control interface. The control interface defines how the SMU can be controlled by software, as summarized in **Table 10-26 "SMU Commands" on Page 10-48**. The control interface is directly linked to the SMU state machine (SSM) operation described in **"SMU state machine" on Page 10-50** and to the Fault Signaling Protocol (FSP) described in **"Fault Signaling Protocol (FSP)" on Page 10-52**.

The control interface is implemented by the **SMU_CMD** register using the CMD and ARG fields. The command completion status is available via the **SMU_STS** register.

Table 10-26 SMU Commands

Command	Description	Code
SMU_Start(ARG)	Forces the SSM to go to the RUN state from the START state. Argument ARG shall be set to 0.	0x0
SMU_ActivateFSP(ARG)	Activates the Fault Signaling Protocol. This action is possible in any state of the SSM. Argument ARG shall be set to 0.	0x1
SMU_ReleaseFSP(ARG)	Turns the FSP into the fault free state. In the START state, SMU_ActivateFSP() and SMU_ReleaseFSP() can be called as many times as necessary to perform self tests of every alarm source. Argument ARG shall be set to 0.	0x2
SMU_ActivatePES(ARG)	Triggers the activation of the Port Emergency Stop (PES). The PES is also directly controlled by the SMU when entering the FAULT state. Argument ARG shall be set to 0.	0x3
SMU_RTSop()	Stop the recovery Timer. Argument ARG shall be set to the recovery timer instance available in the product.	0x4

Table 10-26 SMU Commands (cont'd)

Command	Description	Code
SMU_ASCE(ARG)	Alarm Status Clear Enable Command. Software shall execute this command prior to clear a AG<n> alarm status bit. This command sets the ASCE bit in the **SMU_STS** register. Argument ARG shall be set to 0.	0x5
SMU_Alarm(ARG)	Triggers a software based alarm. ARG specifies the alarm index according to the mapping defined in **"Alarm Mapping" on Page 10-14**. A software alarm has the same properties as an hardware alarm.	0x6

Note: If the argument does not comply with the specification of the command the command is ignored and returns an error code.

The next table specifies the legal conditions that shall be followed for the execution of the commands. The conditions depend on the SMU state machine (SSM) states (see **"SMU state machine" on Page 10-50**). Any situation not specified leads to an error code.

Table 10-27 SMU commands and valid conditions

Command	SSM state	Other conditions
SMU_Start(ARG)	START	ARG == 0
SMU_ActivateFSP(ARG)	Any	ARG == 0
SMU_ReleaseFSP(ARG)	START	ARG == 0
SMU_ReleaseFSP(ARG)	FAULT	ARG == 0 & **SMU_AGC**.EFRST == 1[1)]
SMU_ActivatePES(ARG)	Any	ARG == 0
SMU_RTStop(ARG)	Any	ARG >= 0 and ARG <= Number of Recovery Timer Instances and Recovery Timer Enabled
SMU_ASCE(ARG)	Any	ARG == 0
SMU_Alarm(ARG)	RUN, FAULT[2)]	ARG >= 0

1) See also **"Fault Signaling Protocol (FSP)" on Page 10-52**.

2) In the START state of the SMU input alarms are not processed, therefore software triggered alarms will have no effect.

10.4.7 SMU state machine

Figure 10-6 "SMU state machine (SSM): transition conditions and actions" on Page 10-50 and **Figure 10-6 "SMU state machine (SSM): transition conditions and actions" on Page 10-50** fully specifies the behavior of the SMU state machine (SSM).

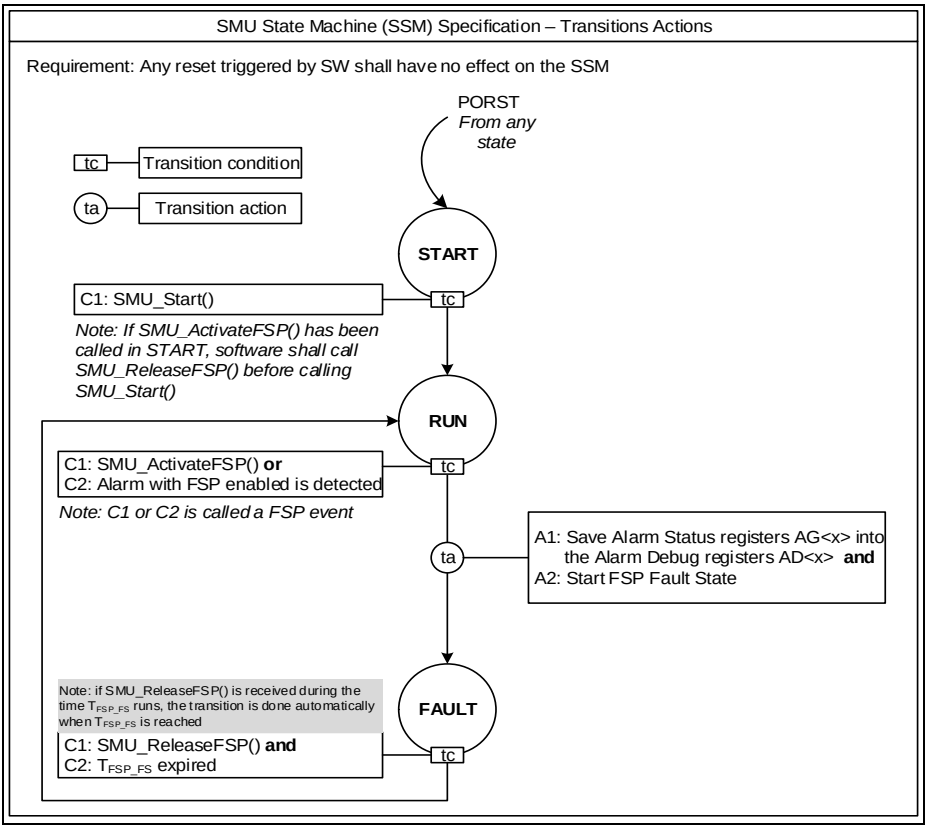

Figure 10-6 SMU state machine (SSM): transition conditions and actions

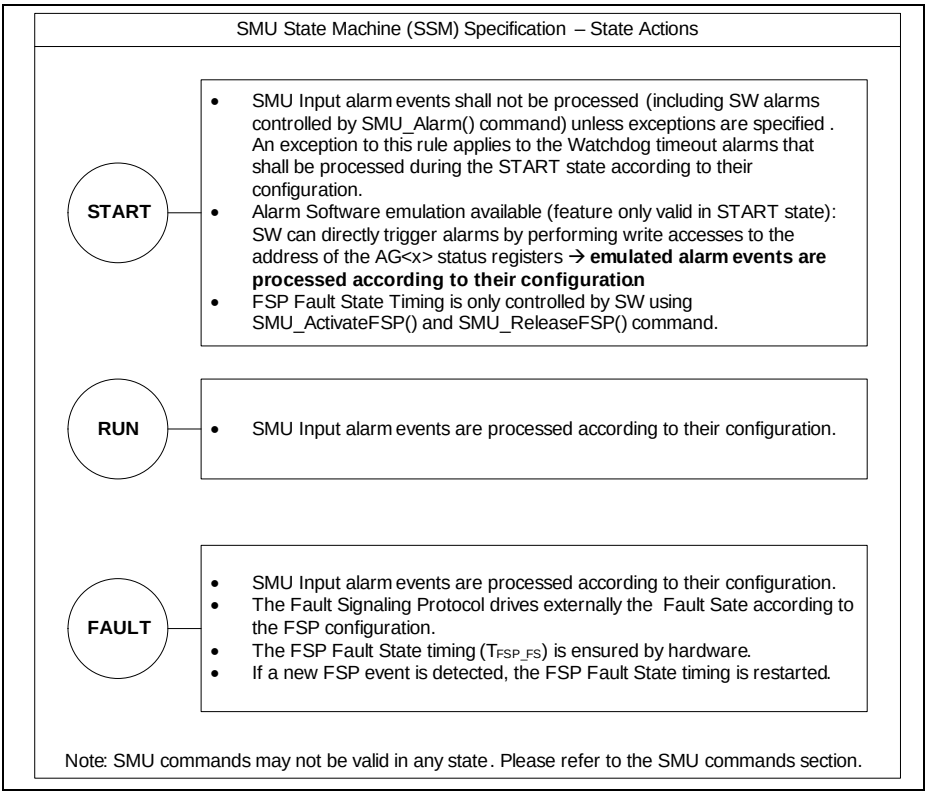

Figure 10-7 SMU state machine: state actions

Fault Counter

The SMU implements a Fault Counter (**SMU_AFCNT**) that counts the number of transitions from the RUN state to the FAULT state. The Fault Counter register is only reset by a power-on-reset.

10.4.8 Fault Signaling Protocol (FSP)

The Fault Signaling Protocol enables the microcontroller to report a critical situation to an external safety controller device in order to control the safe state of the safety system.

10.4.8.1 Introduction

The fault signaling protocol is configured via the **SMU_FSP** command register. The FSP has three states:

- The power-on reset state. After power-on reset the SMU is disconnected from the ports (see **"SMU Integration Guidelines" on Page 10-13**). After power-on reset the SMU FSP output shall be the Fault State.
- The Fault-free State. Whenever the fault-free state is controlled by a timing, the timing will be called T_{FSP_FFS} and is controlled by the **SMU_FSP** register.
- The Fault State. The timing of the fault state is controlled by the **SMU_FSP** register. The minimum active fault state time is called $T_{FSP\_FS.}$

The Fault-free and fault state behavior can be configured with the following protocols:

- Bi-stable protocol (default)
- Time-switching protocol

The FSP can be controlled by:

- Software using the SMU_ActivateFSP() and SMU_ReleaseFSP() commands using the **SMU_CMD** register
- Hardware based on the **SMU_AG0FSP**, **SMU_AG1FSP**, **SMU_AG2FSP**, **SMU_AG3FSP**, **SMU_AG4FSP**, **SMU_AG5FSP**, **SMU_AG6FSP** configuration registers.
- The logic state of the FSP PAD can be observed by reading the FSP field of the **SMU_STS** register.

Figure 10-8 "Reference clocks for FSP timings" on Page 10-53 specifies the intermediate clocks to generate the T_{FSP_FFS} and T_{FSP_FS} timings.

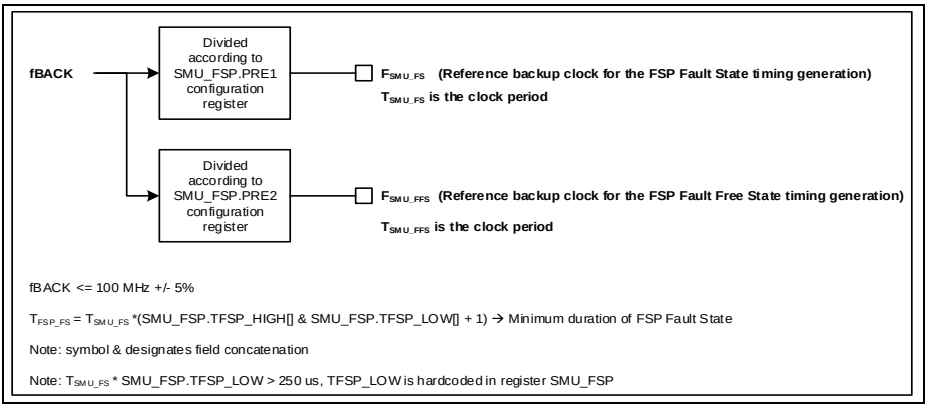

Figure 10-8 Reference clocks for FSP timings

10.4.8.2 Bi-stable fault signaling protocol

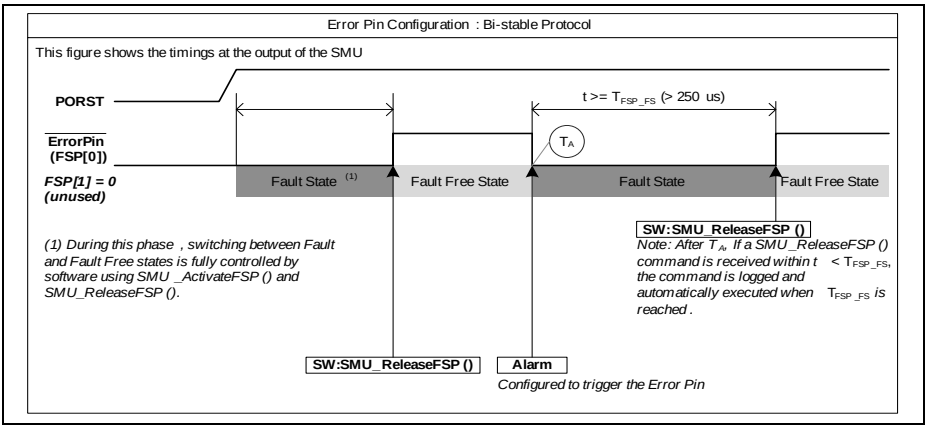

Figure 10-9 Bi-stable fault signaling protocol

Operation

FSP[0] is switched to a static logic level 0 or logic level 1 under software or hardware control.

- During power-on-reset FSP[0] = 0 (fault state)
- After power-on reset FSP[0] stays in the fault state
- FSP[0] must be set to the fault free state per software (SMU_ReleaseFSP()).
- Upon detection of an alarm event configured to activate the FSP, FSP[0] goes to the fault state and remains in this state until a SMU_ReleaseFSP() command is received and T_{FSP_FS} is satisfied or a Power-on Reset takes place.

10.4.8.3 Time switching protocol

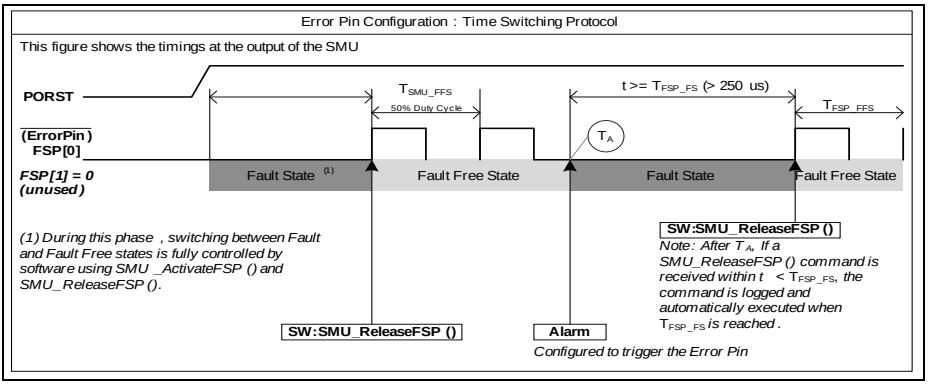

Figure 10-10 Time switching protocol

Operation

FSP[0] is toggled between logic level 0 and logic level 1 with a defined frequency. This frequency modulation protocol is violated when the SMU enters the FAULT state.

- During power-on-reset FSP[0] = 0 (fault state).
- After power-on-reset FSP[0] stays in the fault state.
- FSP[0] must be set to the fault free state per software (SMU_ReleaseFSP()).
- In the fault free state, FSP[0] oscillates between logic level 0 and logic level 1 with the frequency configured via the **SMU_FSP** register (see **Figure 10-10**).
- Upon detection of an alarm event configured to activate the FSP, FSP[0] goes immediately to the fault state and remains in this state until a SMU_ReleaseFSP() command is received and T_{FSP_FS} is satisfied or a Power-on Reset takes place.

10.4.8.4 FSP Fault State

When an alarm configured to activate the FSP, the SMU automatically switches to the FAULT state. During this time it is also possible for the safety-related software to try to analyze the root cause (when the microcontroller is still operational) and decide about the severity of the error. As the FSP is active for at least T_{FSP_FS} (see **SMU_FSP** register), it is ensured that the safe state of the system is entered through external mechanisms independent from the microcontroller (besides FSP itself).

While in the Fault State, if a new alarm event configured to activate the FSP is received and the T_{FSP_FS} has not yet been reached, the T_{FSP_FS} timing shall be restarted.

During the time TFSP_FS FSP is in the Fault State, software may have concluded that the fault is uncritical and decides to issue a SMU_ReleaseFSP() command, notifying the SMU it can return to the RUN state (the run-time of the software error handler is not directly correlated with the TFSP_FS duration and in practice shall be much shorter). This feature shall be used with caution: a microcontroller reset is highly recommended to restart the operation of the safety function when a fault reported by the SMU is assessed to be uncritical. Therefore this feature is per default disabled and shall be configured with the EFRST (Enable Fault to Run State Transition) field in the **SMU_AGC** register.

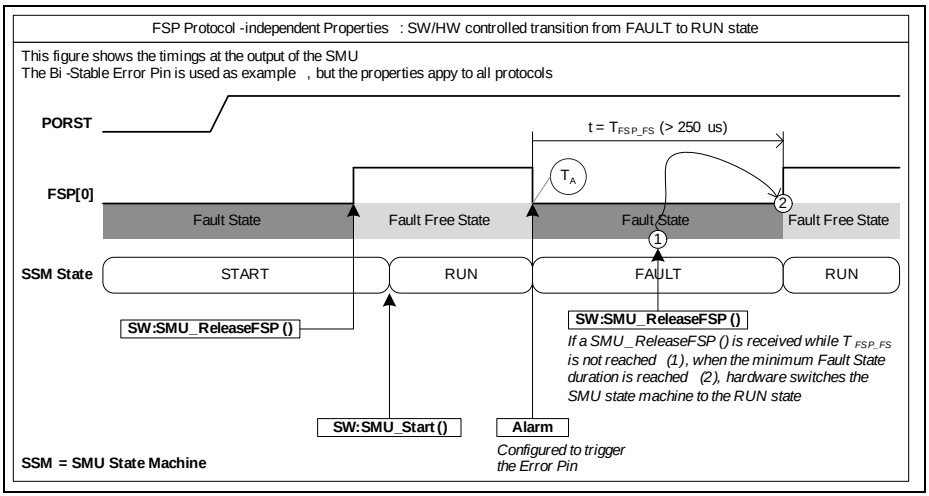

Figure 10-11 FSP: Fault State to Fault Free State Transition

10.4.8.5 FSP and SMU START State

Figure 10-12 "Software Control of FSP during SMU START State" on Page 10-57 shows a typical use case where the FSP transitions between the Fault State and Fault Free State are controlled by software using the SMU_ReleaseFSP() and SMU_ActivateFSP() commands.

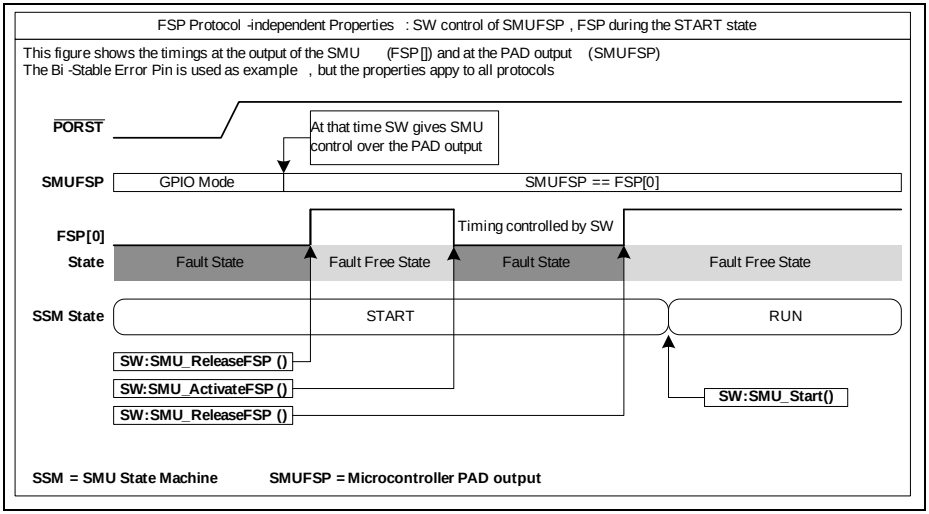

Figure 10-12 Software Control of FSP during SMU START State

Conditions of Use

- Software shall ensure that the FSP is in the Fault Free State before entering the RUN state with the SMU_Start() command.

10.4.9 OCDS Trigger Bus (OTGB) Interface

The SMU concentrates all failure indicator signals (alarms) of the device. By using them as MCDS trace information (failure type) and trace control (stop trace recording), the analysis of a failure's root cause is supported. This is even the case, when the alarm handling within the system includes a PORST, since the content of the trace memory will be still valid after the PORST.

The alarms handled in the SMU are very rare and sporadic. So it's acceptable that they are visible on the Trigger Bus with a small delay and not all in parallel with a cycle accurate timing resolution. The SMU Trigger Set is shown in **Table 10-28**. It is output on OTGB0 or OTGB1 controlled by the **SMU_OCS** register.

Table 10-28 TS16_SMU Trigger Set SMU

Bits	Name	Description
0	AA	Any ALM bit active
1		Reserved
[3:2]	ABI	ALM Byte Index, selecting the byte within the ALM group
[6:4]	AGI	ALM Group Index
7		Reserved
[15:8]	ALM	Selected byte of the ALM group

If no alarm is active, TS16_SMU will be all zero. If alarms are only active within one ALM Byte, TS16_SMU will show statically this byte. If alarms are active in two or more ALM Bytes, TS16_SMU will change between these bytes.

Note that due to the implementation, that all the ALM Bytes are being scanned one per clock cycle, the TS16_SMU ALM Byte information on OTGB0/1 can be delayed by up to 27 clock cycles for the second alarm. TS16_SMU.AA will however become active (and inactive) immediately. The implementation will make sure, that the ALM Byte with the first causing alarm will be traced with MCDS before a reset as safety action clears this information.

10.4.10 Register Properties

10.4.10.1 Register Write Protection

The SMU registers are write protected against illegal master accesses by the master protection mechanism implemented in the System Peripheral Bus interface logic. The registers controlling the master access protection are described in the section **"System Registers description" on Page 10-68**. In addition the SMU registers can only be written if the SafeEinit is enabled. Read accesses have no restriction as there is no side effect specified when reading registers. The SafeEinit has the same properties as the system Einit but it is generated by the safety watchdog. In order to access a SMU register the software must first activate the safety watchdog via a signature protected sequence. The safety watchdog is configured to enable only safety-related software to activate the SafeEinit.

Configuration Lock

In addition to the aforementioned standard features, additional mechanisms are implemented to control and protect the SMU configuration. In order to configure and lock the SMU configuration the following steps shall be followed:

- The SMU configuration is only possible if the CFGLCK field of the **SMU_KEYS** register is set to 0xBC.
- If the PERLCK field of the **SMU_KEYS** register is set to 0xFF no further SMU configuration is possible, including the **SMU_KEYS** register itself. No SMU configuration is possible anymore until the PERLCK field of the **SMU_KEYS** register is reset to 0x00 by a an application reset.

The SMU configuration registers controlled by the **SMU_KEYS** register properties are:

- **SMU_FSP**
- **SMU_AGC**
- **SMU_RTC**
- **SMU_RTAC0**
- **SMU_RTAC1**
- **SMU_AG0CFx (x=0-2)**
- **SMU_AG1CFx (x=0-2)**
- **SMU_AG2CFx (x=0-0)**
- **SMU_AG3CFx (x=0-0)**
- **SMU_AG4CFx (x=0-2)**
- **SMU_AG5CFx (x=0-2)**
- **SMU_AG6CFx (x=0-2)**
- **SMU_AG0FSP**
- **SMU_AG1FSP**

- **SMU_AG2FSP**
- **SMU_AG3FSP**
- **SMU_AG4FSP**
- **SMU_AG5FSP**
- **SMU_AG6FSP**
- **SMU_PCTL**
- **SMU_RMCTL**

The **SMU_CMD** register is not locked as it is used for run-time hardware/software interaction, it is not a configuration register.

The **SMU_AGx (x=0-6)** registers are not locked as it is possible during run-time to clear the alarm flags by software.

The **SMU_OCS**, **SMU_KRSTCLR**, **SMU_KRST1**, **SMU_KRST0**, **SMU_ACCEN1**, **SMU_ACCEN0** do not belong to the SMU kernel but to the standard bus interface module, therefore they are not controlled by the **SMU_KEYS** register.

The read only registers are not protected by the lock mechanism.

10.4.10.2 Safety Flip-Flops

Safety Flip-Flops are special Flip-Flops that implement an hardware mechanism capable to detect single event effects that may lead to single event upsets (bit flip). The SMU configuration registers that shall be implemented with safety flip-flops are:

- **SMU_FSP**
- **SMU_AGC**
- **SMU_RTC**
- **SMU_KEYS**
- **SMU_PCTL**
- **SMU_RTAC0**
- **SMU_RTAC1**
- **SMU_AG0CFx (x=0-2)**
- **SMU_AG1CFx (x=0-2)**
- **SMU_AG2CFx (x=0-0)**
- **SMU_AG3CFx (x=0-0)**
- **SMU_AG4CFx (x=0-2)**
- **SMU_AG5CFx (x=0-2)**
- **SMU_AG6CFx (x=0-2)**
- **SMU_AG0FSP**
- **SMU_AG1FSP**
- **SMU_AG2FSP**
- **SMU_AG3FSP**
- **SMU_AG4FSP**
- **SMU_AG5FSP**
- **SMU_AG6FSP**

Additionally the following SMU functions shall also be implemented with safety flip-flops:

- SMU state machine registers
- Registers implementing the FSP function

10.5 SMU Module Registers

Figure 10-13 shows the SMU module register map.

Table 10-29 shows the SMU Address Space

Table 10-30 lists all registers implemented in the SMU.

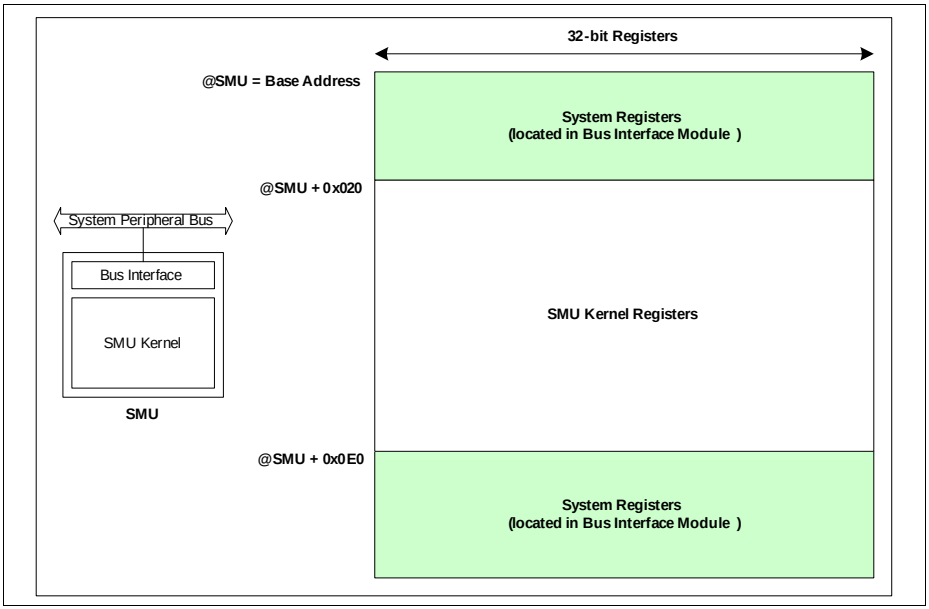

Figure 10-13 SMU Register Map

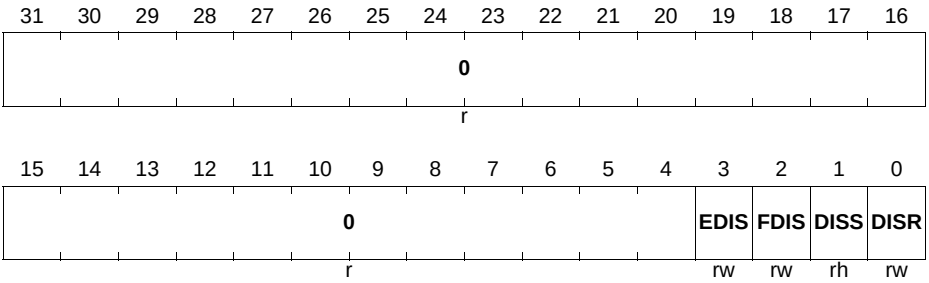
10.5.1 System Registers description

SMU Clock Control Register (CLC)

The Clock Control Register allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The SMU shall be enabled per default

SMU_CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0000_H**



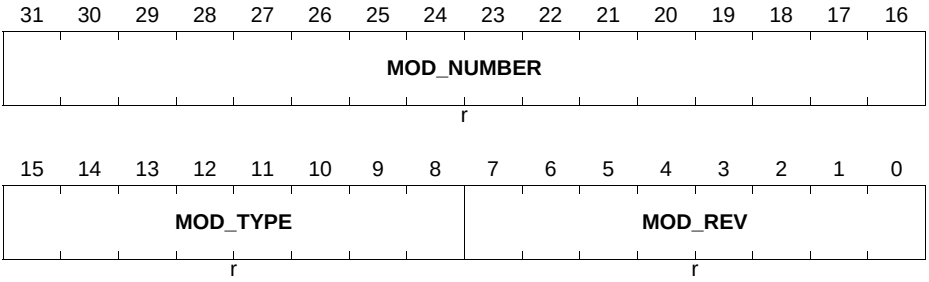
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested 1_B Module disable is requested
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module is enabled 1_B Module is disabled
FDIS	2	rw	**Force Disable** The feature controlled by this field is not used. Read as 0; should be written with 0.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode. Sleep Mode is not supported safety applications. During the process of entering and resuming from sleep mode the intended processing of alarm events is not guaranteed.

Field	Bits	Type	Description
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.

Note: The other features controlled by the CLC register are not supported by the SMU.

SMU Module Identification Register

SMU_ID
Module Identification Register **(08_H)** **Reset Value: $0089\ C001_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to $C0_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the SMU module is 0089_H.

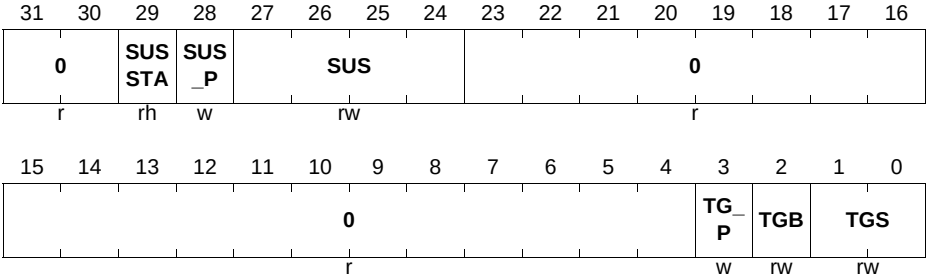
SMU OCDS Control Register. This register is implemented in the BPI.

The OCDS Control and Status (OCS) register is reset by Debug Reset.

The OCS register includes the module related control bits for the OCDS Trigger Bus (OTGB).

The register can only be written and the OCS control register bits are only effective while the OCDS is enabled (OCDS enable = ´1´). While OCDS is not enabled, OCS reset values/modes are effective.

SMU_OCS
OCDS Control and Status **($7E8_H$)** **Reset Value: $0000\ 0000_H$**

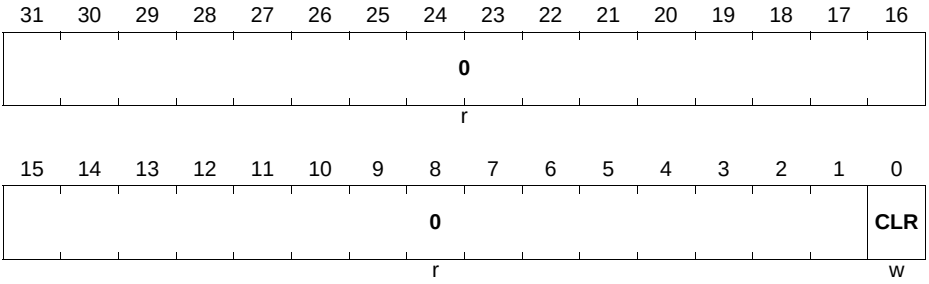


Field	Bits	Type	Description
TGS	[1:0]	rw	**Trigger Set for OTGB0/1** 0_H No Trigger Set output 1_H TS16_SMU **others**, reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	[27:24]	rw	**OCDS Suspend Control** No effect. SMU will not suspend. Read as 0; must be written with 0.
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.

Field	Bits	Type	Description
SUSSTA	29	rh	**Suspend State** Read as 0; must be written with 0.
0	[23:4], [31:30]	r	**Reserved** Read as 0; must be written with 0.

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (<>_KRST0.RSTSTAT).

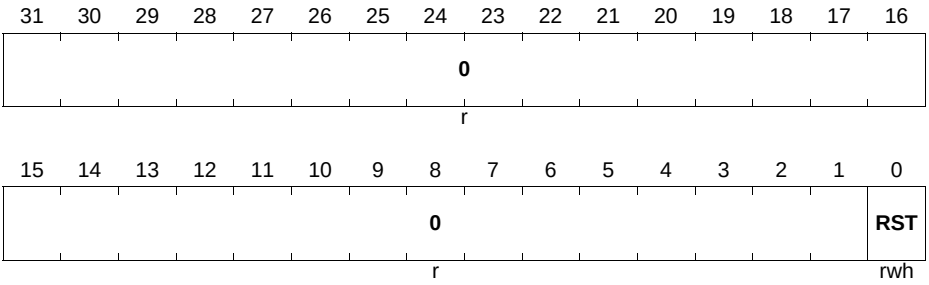
SMU_KRSTCLR
SMU Reset Status Clear Register (7EC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (<>_KRSTx1.RST and <>_KRSTx0.RST) related to the module kernel that should be reset (kernel 0 or kernel 1). The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

SMU_KRST1
SMU Reset Register 1 **($7F0_H$)** **Reset Value: 0000 0000_H**

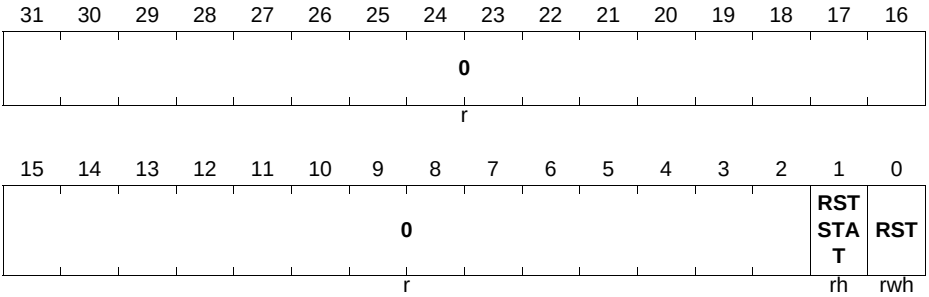


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). In order support modules with two kernel the BPI_FPI provides two set of kernel reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the related KRSTCLRx.CLR register bit.

SMU_KRST0
SMU Reset Register 0 **(7F4$_H$)** **Reset Value: 0000 0000$_H$**

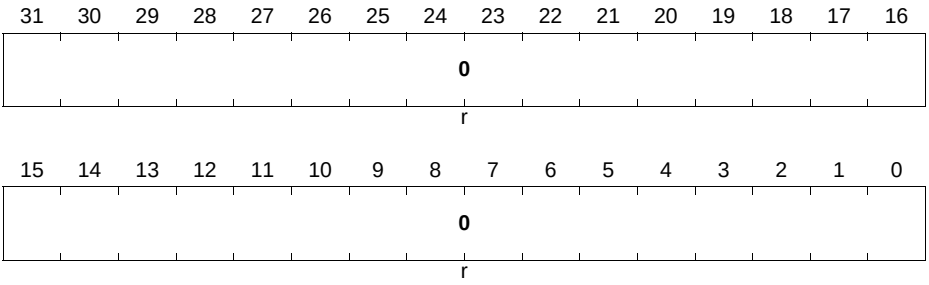


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.

Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

SMU_ACCEN1
SMU Access Enable Register 1 ($7F8_H$) Reset Value: 0000 0000_H



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

SMU_ACCEN0
SMU Access Enable Register 0 ($7FC_H$) Reset Value: FFFF FFFF$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

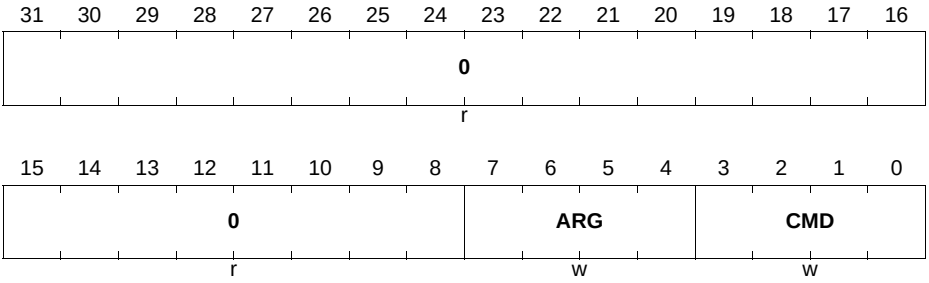
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Note: The mapping with the on-chip master-capable modules is described in the bus chapters of the TC21x/TC22x/TC23x microcontroller.

10.5.2 SMU Configuration Registers

SMU Command Register.

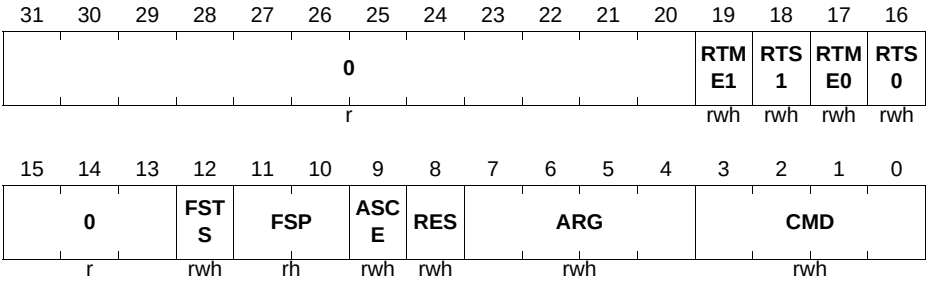
SMU_CMD
Command Register **(20_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CMD	[3:0]	w	**Implements the SMU Command Interface.** See **Table 10-26 “SMU Commands” on Page 10-48** for the command encoding. Read as 0.
ARG	[7:4]	w	**Implements the SMU Command Interface.** Argument to be used with the command. See **Table 10-26 “SMU Commands” on Page 10-48** for the argument encoding. Read as 0.
0	[31:8]	r	**Reserved** Read as 0; should be written with 0

SMU Status Register.

SMU_STS
Status Register **(24_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CMD	[3:0]	rwh	**Last command received** Same encoding as CMD field of **SMU_CMD** register
ARG	[7:4]	rwh	**Last command argument received** Same encoding as ARG field of **SMU_CMD** register
RES	8	rwh	**Result of last received command** 0_B Command was successful 1_B Command failed
ASCE	9	rwh	**Alarm Status Clear Enable** This bit controls if a status flag set in an AG<x> register upon detection of an alarm event can be cleared by software or not. When ASCE is enabled software shall write a 1 to the bit position in AG<x> to clear the bit (W1C). When a W1C action takes place the ASCE bit is automatically cleared to 0 by hardware and software shall set the ASCE bit again by using the SMU_ASCE() command. 0_B Alarm status bits AG<x> can not be cleared 1_B Alarm status bits AG<x> can be cleared.

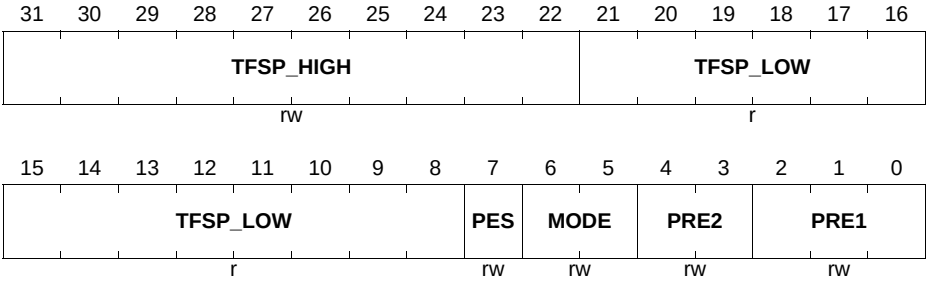
Field	Bits	Type	Description
FSP	[11:10]	rh	**Fault Signaling Protocol status** FSP[0] = FSP_STS[0] input signal FSP[1] = FSP_STS[1] input signal This field is updated by hardware every clock cycle, therefore a software clear on write is not meaningful for this field.
FSTS	12	rwh	**Fault State Timing Status** This bit indicates if the minimum timing duration of the FSP fault state has been reached or not. The bit is cleared by hardware when the fault state is entered. 0_B Minimum timing duration not reached 1_B Minimum timing duration reached
RTS0	16	rwh	**Recovery Timer 0 Status** See **"Recovery Timer" on Page 10-45** for the usage of this field. 0_B Recovery Timer not running 1_B Recovery Timer running
RTME0	17	rwh	**Recovery Timer 0 Missed Event** See **"Recovery Timer" on Page 10-45** for the usage of this field. 0_B Recovery Timer event not detected 1_B Recovery Timer event detected
RTS1	18	rwh	**Recovery Timer 1 Status** See **"Recovery Timer" on Page 10-45** for the usage of this field. 0_B Recovery Timer not running 1_B Recovery Timer running
RTME1	19	rwh	**Recovery Timer 1 Missed Event** See **"Recovery Timer" on Page 10-45** for the usage of this field. 0_B Recovery Timer event not detected 1_B Recovery Timer event detected
0	[31:20], [15:13]	r	**Reserved** Read as 0; should be written with 0.

Note: A write to this register (regardless of the data written) clears all the fields with the wrh type. If on the same cycle a software write event and hardware event is detected the hardware action wins.

SMU Fault Signalling Timing Configuration.

This register controls the timing of the fault signaling protocol.

SMU_FSP
Fault Signaling Protocol **(28_H)** **Reset Value: 003F FF00$_H$**



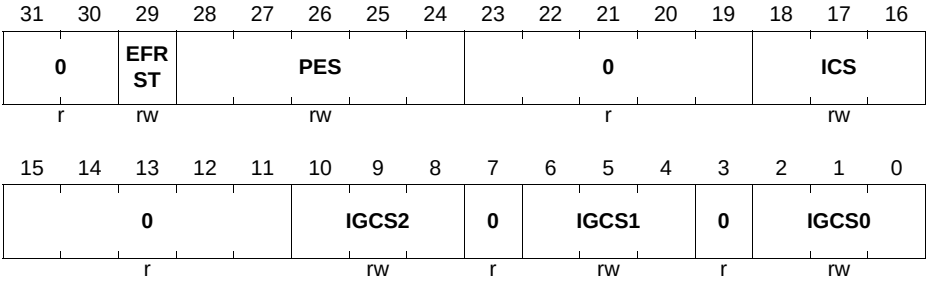
Field	Bits	Type	Description
PRE1	[2:0]	rw	**Prescaler1** Dividing factor to apply to the reference clock fBACK. **It is assumed that the maximal value for fBACK is 100 Mhz with a precision of 5%**. The divided clock is used as reference to generate the timing of the fault signaling protocol fault state. The frequency of the divided clock (called F_{SMU_FS}) is defined as follows: 0_H reference clock frequency divided by 2 1_H reference clock frequency divided by 4 2_H reference clock frequency divided by 8 3_H reference clock frequency divided by 16 4_H reference clock frequency divided by 32 5_H reference clock frequency divided by 64 6_H reference clock frequency divided by 128 7_H reference clock frequency divided by 256

Field	Bits	Type	Description
PRE2	[4:3]	rw	**Prescaler2** Dividing factor to apply to the reference clock fBACK in order to generate the timing of the fault free state for the time switching modes of the fault signaling protocol. The frequency of the divided clock (called F_{SMU_FFS}) is defined as follows: 0_H reference clock frequency divided by 512 1_H reference clock frequency divided by 1024 2_H reference clock frequency divided by 2048 3_H reference clock frequency divided by 4096
MODE	[6:5]	rw	**Fault Signaling Protocol configuration** 0_H Bi-stable protocol 1_H Reserved 2_H Time switching protocol 3_H Reserved
PES	7	rw	**Port Emergency Stop (PES)** When this bit is set a Port Emergency Stop is automatically requested when an alarm event configured to start the Fault Signalling Protocol is detected. 0_B Port Emergency Stop disabled 1_B Port Emergency Stop enabled
TFSP_LOW	[21:8]	r	**Specification of the FSP fault state duration** T_{FSP_FS}= TFSP_HIGH & TPSP_LOW. Note: symbol & designates a concatenation TFSP_LOW shall be specified as a number of FSMU_FS ticks. TFSP_LOW is defined so that the minimum duration is greater than 250 us. It can not be changed by software. Refer to **Figure 10-8 “Reference clocks for FSP timings” on Page 10-53**
TFSP_HIGH	[31:22]	rw	**Specification the FSP fault state duration** T_{FSP_FS}= TFSP_HIGH & TPSP_LOW. Note: symbol & designates a concatenation TFSP_HIGH shall be specified as a number of FSMU_FS ticks. TFSP_HIGH and PRE1 shall enable to configure a fault state duration of 500 ms.

SMU Alarm Global Configuration.

This register controls some properties related to the behavior of the SMU to alarm.

SMU_AGC
Alarm Global Configuration **($2C_H$)** **Reset Value: 0000 0000$_H$**



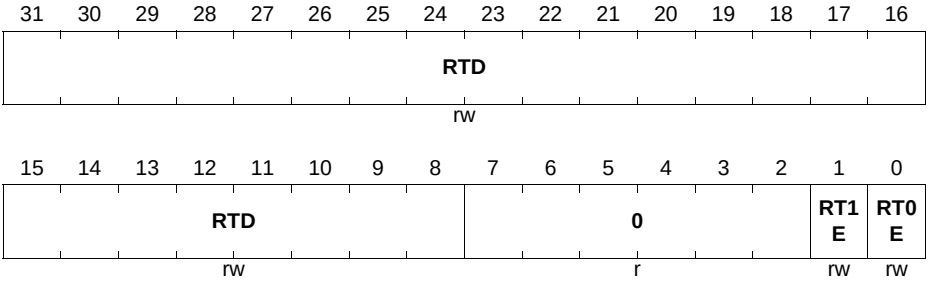
Field	Bits	Type	Description
IGCS0	[2:0]	rw	**Interrupt Generation Configuration Set 0** Defines the output value of the interrupt request vector when the alarm configuration flag selects the interrupt configuration set 0. Enables to issue an interrupt request to several CPUs: see **“Interfaces to the Interrupt Router” on Page 10-8**.
IGCS1	[6:4]	rw	**Interrupt Generation Configuration Set 1** Defines the output value of the interrupt request vector when the alarm configuration flag selects the interrupt configuration set 1. Enables to issue an interrupt request to several CPUs: see **“Interfaces to the Interrupt Router” on Page 10-8**.
IGCS2	[10:8]	rw	**Interrupt Generation Configuration Set 2** Defines the output value of the interrupt request vector when the alarm configuration flag selects the interrupt configuration set 2. Enables to issue an interrupt request to several CPUs: see **“Interfaces to the Interrupt Router” on Page 10-8**.

Field	Bits	Type	Description
ICS	[18:16]	rw	**Idle Configuration Set** Defines the output value of the idle request vector when the alarm configuration flag selects the Idle Configuration Set. Enables to issue an idle request to several CPUs if required. More complex idle scenarios can be handled by using software interrupts.
PES	[28:24]	rw	**Port Emergency Stop** This field enables control of the Port Emergency Stop (PES) feature independently for each internal action. When an action is triggered and if the corresponding bit (as defined below) is set, the hardware triggers automatically a port emergency stop request. Each bit of PES is allocated to an action as follows: 1_H SMU_IGCS0 activates PES 2_H SMU_IGCS1 activates PES 4_H SMU_iGCS2 activates PES 8_H SMU_NMI activates PES 10_H SMU_IDLE activates PES
EFRST	29	rw	**Enable FAULT to RUN State Transition** See **“FSP Fault State” on Page 10-56** chapter for the usage of this field.
0	[31:30], [23:19], [15:11], 7, 3	r	**Reserved** Read as 0; should be written with 0

SMU Recovery Timer Duration Configuration.

This register controls the timing duration of the recovery timer.

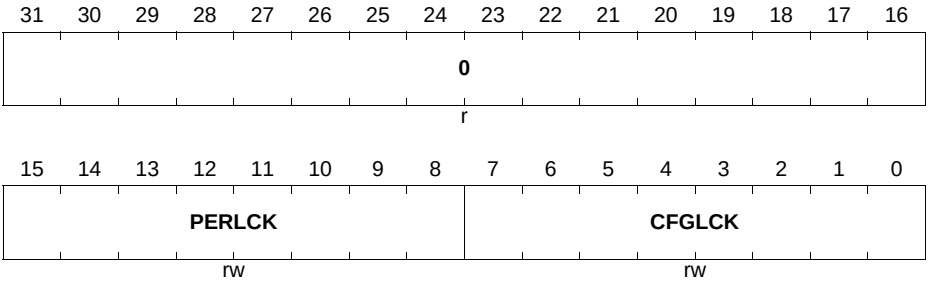
SMU_RTC
Recovery Timer Configuration (30_H) Reset Value: 003F FF01$_H$



Field	Bits	Type	Description
RTD	[31:8]	rw	**Recovery Timer Duration** This field specifies the maximum duration of the recovery timer. When the timer counter reaches the programmed value, the internal alarm rt_timeout is issued. The timer is stopped by a SMU_RTStop() command before the recovery timer. RTD shall be specified as a number of the **F_{SMU_FS} clock** ticks.
RT1E	1	rw	**RT1 Enable Bit** 0_B Recovery Timer 1 is disabled 1_B Recovery Timer 1 is enabled
RT0E	0	rw	**RT0 Enable Bit** 0_B Recovery Timer 0 is disabled 1_B Recovery Timer 0 is enabled
0	[7:2]	r	**Reserved** Read as 0; should be written with 0

SMU Keys Register.

SMU_KEYS
Key Register **(34_H)** **Reset Value: $0000\ 0000_H$**

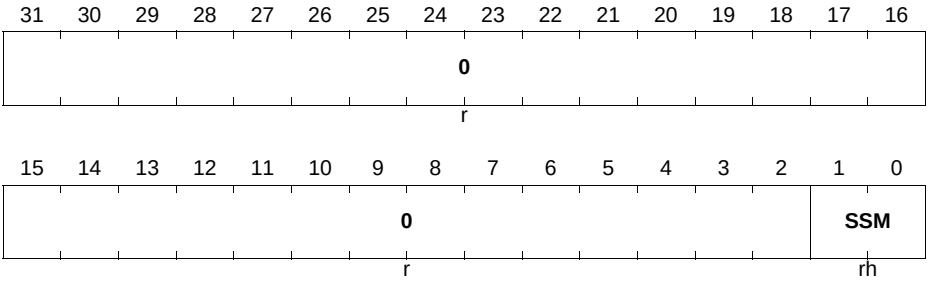


Field	Bits	Type	Description
CFGLCK	[7:0]	rw	**Configuration Lock** The SMU configuration is only possible if this field is set to 0xBC. Refer to **"Register Properties" on Page 10-59** for the list of registers controlled by this field.
PERLCK	[15:8]	rw	**Permanent Lock** If this field is set to 0xFF, no further configuration of the SMU is possible. Refer to **"Register Properties" on Page 10-59** for the list of registers controlled by this field.
0	[31:16]	r	**Reserved** Read as 0; shall be written with 0

SMU Debug Register.

This register enables to observe some internal states of the SMU hardware. Definition will be completed based on design information.

SMU_DBG
Debug Register **(38_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SSM	[1:0]	rh	**Running state of the SMU State Machine** 0_H START state 1_H RUN state 2_H FAULT state 3_H unspecified state
0	[31:2]	r	**Reserved** Read as 0; should be written with 0

SMU register controlling the connectivity with the Ports.

SMU_PCTL
Port Control **($3C_H$)** **Reset Value: XXXX[1] 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PCFG															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								PCS	0					HWEN	HWDIR
r								rw	r					rw	rw

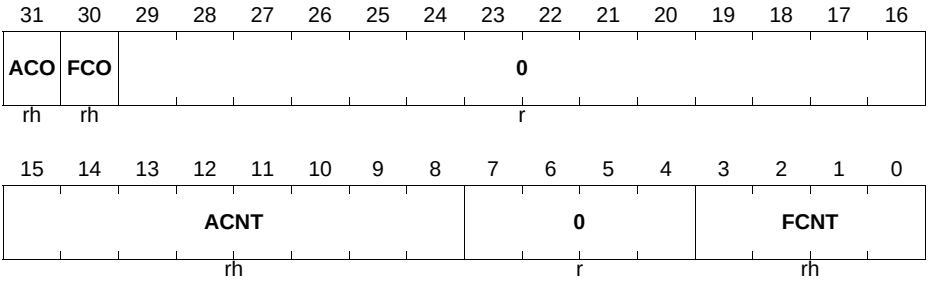
1) The PCFG reset value depends on several conditions. The PFCG value is only relevant after user software configuration.

Field	Bits	Type	Description
HWDIR	0	rw	**Port Direction.** This bit directly controls the value of the FSP_DIR SMU output signal. Also refer to the General Purpose I/O Ports chapter for the HW_DIR signal specification. 0_B sets the PAD to input state 1_B sets the PAD to output state
HWEN	1	rw	**Port Enable.** This bit directly controls the value of the FSP_EN SMU output signal. When set to 1 the port output is directly driven by SMU FSP signal (Error Pin). Also refer to the General Purpose I/O Ports chapter for the HW_EN signal specification.

Field	Bits	Type	Description
PCS	7	rw	**PAD Configuration Select** This bit controls the latching of the SMU FSP (Error Pin) PAD configuration signals to ensure that upon an application reset or system reset the SMU FSP (Error Pin) PAD configuration is not affected. This field is only reset by power-on reset. 0_B The PAD configuration is controlled by the PORT registers. 1_B The PAD configuration is controlled by the SMU. • **Only with the first transition from 0 to 1 of this field the SMU FSP is operational. Any further configuration change in this bit field has no effect to the hardware**. • **The fields HWDIR, HWEN and PCS shall be configured with a single software write command. Configuring each bit-field separately may lead to configuration inconsistencies. Refer to "Interface to the Ports (Error Pin)" on Page 10-8 for the overview of the SMU FSP (Error Pin) connectivity.**
PCFG	[31:16]	rh	**PAD Configuration** This field contains the FSP PAD configuration input signals. The PAD configuration related to FSP[0] is provided by PCFG[7:0] The upper-bits PCFG[15:8] are not used.
0	[15:8], [6:2]	r	**Reserved** Read as 0; should be written with 0

SMU Alarm and Fault Counter Register.

SMU_AFCNT
Alarm and Fault Counter **(40_H)** **Reset Value: $0000\ 0000_H$**

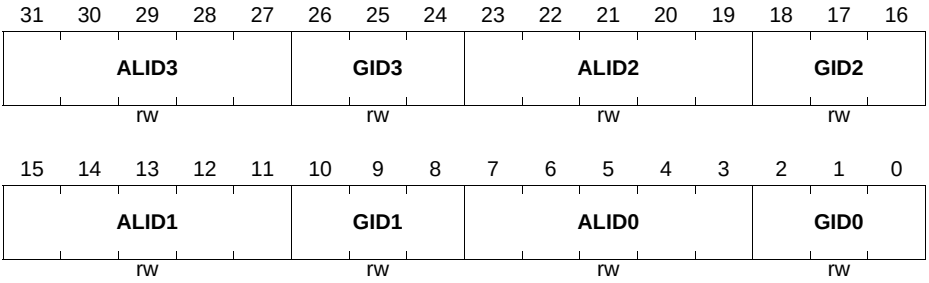


Field	Bits	Type	Description
FCNT	[3:0]	rh	**Fault Counter.** This field is incremented by hardware when the SMU state machine goes from the RUN state to the FAULT state (see **Figure 10.4.7 “SMU state machine” on Page 10-50**). The counter value holds if the maximum value is reached.
ACNT	[15:8]	rh	**Alarm Counter.** This field is incremented by hardware when the SMU processes an **internal** action related to an alarm event (see **Figure 10.4.5.3 “Alarm operation” on Page 10-43**). The counter value holds if the maximum value is reached.
FCO	30	rh	**Fault Counter Overflow.** This bit is set by hardware if the FCNT counter reached the maximum value and an increment condition is present.
ACO	31	rh	**Alarm Counter Overflow.** This bit is set by hardware if the ACNT counter reached the maximum value and an increment condition is present.
0	[29:16], [7:4]	r	**Reserved** Read as 0; should be written with 0.

SMU Recovery Timer 0 Alarm Configuration.

SMU_RTAC0

Recovery Timer Alarm Configuration (60_H) **Reset Value: A39B 938B$_H$**



Field	Bits	Type	Description
GID0	[2:0]	rw	**Group Index 0.** This field enables to specify if an alarm from this alarm group can use the recovery timer 0. The functionality of this field is described in **"Recovery Timer" on Page 10-45**.
ALID0	[7:3]	rw	**Alarm Identifier 0.** This field specifies the Alarm Index related to the Group Index specified in GID0.
GID1	[10:8]	rw	**Group Index 1.** This field enables to specify if an alarm from this alarm group can use the recovery timer 0. The functionality of this field is described in **"Recovery Timer" on Page 10-45**.
ALID1	[15:11]	rw	**Alarm Identifier 1.** This field specifies the Alarm Index related to the Group Index specified in GID1.
GID2	[18:16]	rw	**Group Index 2.** This field enables to specify if an alarm from this alarm group can use the recovery timer 0. The functionality of this field is described in **"Recovery Timer" on Page 10-45**.

Field	Bits	Type	Description
ALID2	[23:19]	rw	**Alarm Identifier 2.** This field specifies the Alarm Index related to the Group Index specified in GID2.
GID3	[26:24]	rw	**Group Index 3.** This field enables to specify if an alarm from this alarm group can use the recovery timer 0. The functionality of this field is described in **“Recovery Timer” on Page 10-45**.
ALID3	[31:27]	rw	**Alarm Identifier 3.** This field specifies the Alarm Index related to the Group Index specified in GID3.

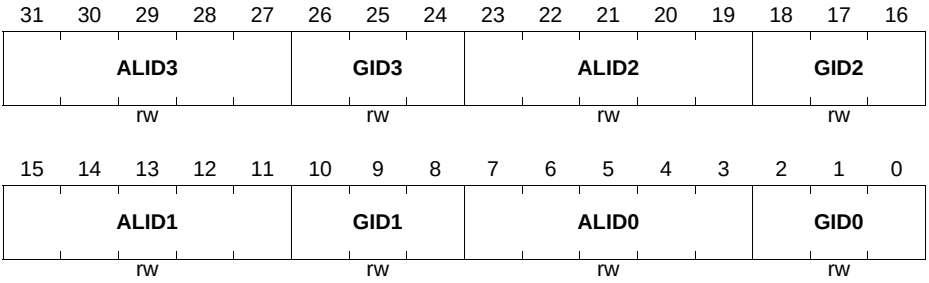
Note: It is possible to configure multiple times the same group identifier in GID0/1/2/3 fields. The reset value maps the watchdog timeout alarms to the recovery timer 0. The number of available watchdogs is product dependent.

Note: The reset values corresponds to Alarms 17,18,19,20 from Alarm Group 3

SMU Recovery Timer 1 Alarm Configuration.

SMU_RTAC1

Recovery Timer Alarm Configuration (64_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
GID0	[2:0]	rw	**Group Index 0.** This field enables to specify if an alarm from this alarm group can use the recovery timer 1. The functionality of this field is described in **"Recovery Timer" on Page 10-45**.
ALID0	[7:3]	rw	**Alarm Identifier 0.** This field specifies the Alarm Index related to the Group Index specified in GID0.
GID1	[10:8]	rw	**Group Index 1.** This field enables to specify if an alarm from this alarm group can use the recovery timer 1. The functionality of this field is described in **"Recovery Timer" on Page 10-45**.
ALID1	[15:11]	rw	**Alarm Identifier 1.** This field specifies the Alarm Index related to the Group Index specified in GID1.
GID2	[18:16]	rw	**Group Index 2.** This field enables to specify if an alarm from this alarm group can use the recovery timer 1. The functionality of this field is described in **"Recovery Timer" on Page 10-45**.

Field	Bits	Type	Description
ALID2	[23:19]	rw	**Alarm Identifier 2.** This field specifies the Alarm Index related to the Group Index specified in GID2.
GID3	[26:24]	rw	**Group Index 3.** This field enables to specify if an alarm from this alarm group can use the recovery timer 1. The functionality of this field is described in **“Recovery Timer” on Page 10-45**.
ALID3	[31:27]	rw	**Alarm Identifier 3.** This field specifies the Alarm Index related to the Group Index specified in GID3.

Note: It is possible to configure multiple times the same group identifier in GID0/1/2/3 fields.

10.5.3 SMU Alarm Configuration Registers

SMU Alarm Configuration Registers related to Alarm Group 0.

SMU_AG0CFx (x=0-2)
Alarm Configuration Register (100_H + x*04_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
STSn (n = 0-31)	n	rwh	**Ready flag related to the different instances of the Safety Flip-Flop safety mechanism.** This bit indicates whether the Safety Flip-Flop test is finished or not (when SMU_RMCTL.TE=1). This bit can only be cleared by software, a set by software has no effect. The mapping of STSn flags to Modules is: STS0: SMU STS1: SCU STS2: MTU STS3...31 not used 0_B Self-test has not completed 1_B Self-test has completed

11 Program Memory Unit (PMU)

The Program Memory Unit (PMU) controls the Flash memory and the BootROM and connects them to the SRI crossbar.

The devices of the AURIX family have at least one PMU. This is named “PMU0”. Depending on the amount of Flash memory more PMUs are added which are named “PMU1”, and so on. All PMUs are independent from each other.

TC21x/TC22x/TC23x has 1 PMU(s). Throughout this document a generic PMU is specified. The **Chapter 11.2** lists the configuration parameters of each PMU and their values in the TC21x/TC22x/TC23x. When PMU functionality depends on a parameter this is indicated in the text.

This chapter has the following structure:

- Generic feature list and block diagram (**Chapter 11.1**).
- PMU configuration of the TC21x/TC22x/TC23x (**Chapter 11.2**).
- Functionality of the BootROM (**Chapter 11.3**).
- Functionality of the tuning protection (**Chapter 11.4**).
- Functionality of the Flash memory (**Chapter 11.5**).
- Signaling to the Safety Management Unit “SMU” (**Chapter 11.6**).
- Register Set (**Chapter 11.7**).
- Application Hints (**Chapter 11.8**).

11.1 Generic Feature List

In general a PMU has the following features:

- Only in PMU0: BootROM.
- Program Flash “PFlash” with one or more banks “PFx”.
- Data Flash “DFlash” with one or more banks “DFx” containing:
  - Sectors for EEPROM emulation (only in PMU0).
  - UCB sectors for protection data.
- One Flash Standard Interface “FSI” that controls all Flash operations.
- Access control for safety and security for all assigned memories.
- Only in PMU0: Tuning protection (commonly called “Secure Watchdog”).
- Configuration and control registers.
- SRI interface(s) to all included resources. Separate SRI interfaces for DFlash and for each bank of PFlash.

Figure 11-1 shows an abstracted block diagram of PMU, FSI, Flash and BootROM.

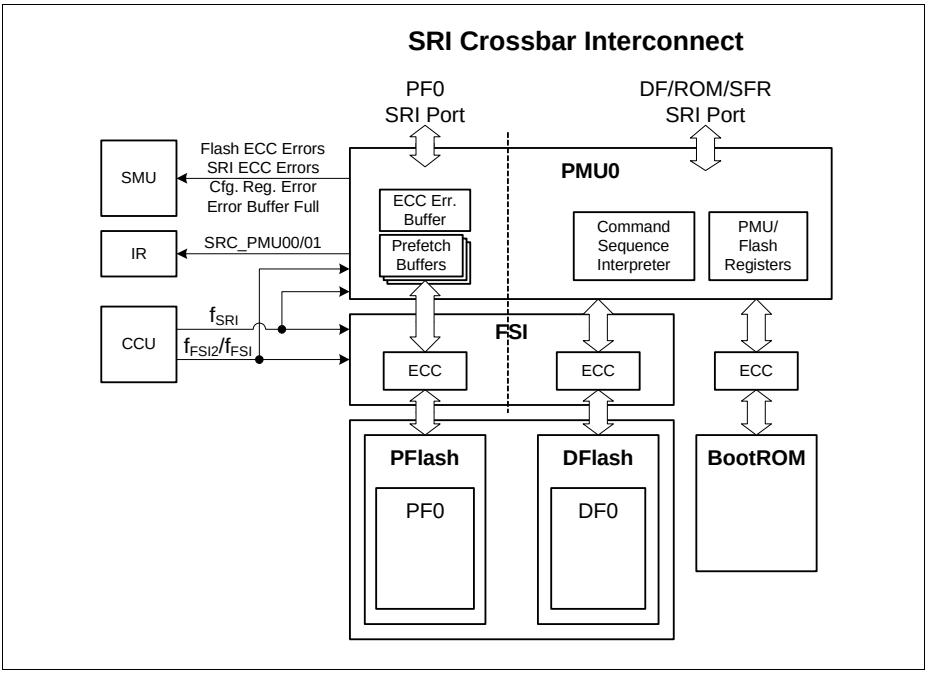

Figure 11-1 PMU/FSI/Flash Basic Block Diagram

11.2 PMU Configuration of TC21x/TC22x/TC23x

This chapter describes the superset of a range of devices with the following configuration:

- Number of PMUs: 1

Configuration of PMU0:

- PF0: 2 MByte.
- DF0 consisting of:
  - DF_EEPROM: 128 KByte (16 logical sectors “EEPROM0 … EEPROM15”).
  - DF_UCB: Flash area for protection data (16 logical sectors “UCB0 … UCB15” with 1 KByte each).

Address Map

The following table(s) contains the address map.

Table 11-1 Address Map of PMU0

Start Address	Size	Range	Start Address Symbol
$8000\ 0000_H$	2 MByte	PF0	AC_PF0
$8FFF\ 8000_H$	32 KByte	BootROM	AC_BROM0
$A000\ 0000_H$	2 MByte	PF0	AN_PF0
$AF00\ 0000_H$	128 KByte	DF0 (DF_EEPROM)[1)]	AN_DFlash_B0
$AF10\ 0000_H$	16 KByte	DF0 (DF_UCB)	
$AF11\ 0000_H$	64 KByte	Not implemented (Reserved for DF1)	AN_DFlash_B1
$AFFF\ 8000_H$	32 KByte	BootROM	AN_BROM0
$F800\ 0500_H$	256 Byte	PMU Registers	
$F800\ 1000_H$	5 KByte	Flash Registers	
$FF11\ 0000_H$	64 KByte	Not implemented (Reserved for DF1, HSM private access)	AN_DFlash_B1F

1) In derivates with reduced amount of DF0 (see data sheet) the available range is contiguous and starts also AN_DFlash_B0.

Derived Devices

This specification describes a superset of a range of devices. The concrete number and size of implemented Flash ranges is given in the respective Data Sheet.

In devices with PFlash banks of reduced size the sectors (see **Chapter 11.5.2.1**) with higher sector number are unavailable. The complete PFlash range is contiguous in all devices starting on AC_PF0/AN_PF0.

The “unavailable” PFlash sectors cannot exist or can be blocked during device manufacturing (the PMU handles these sectors then as not existing) or they stay accessible. In the latter case these sectors are delivered in the erased state. Full reliability is not ensured. These sectors shall not be read, programmed or erased. The write and OTP protection can be activated for these sectors to prevent later modification.

In devices with DFlash of reduced size the sectors EEPROMx (see **Chapter 11.5.2.2**) with higher sector number x are unavailable (the whole DF_EEPROM range stays contiguous).

The “unavailable” DFlash sectors cannot exist or can be blocked during device manufacturing (the PMU handles these sectors then as not existing) or they stay accessible. In the latter case these sectors are delivered in the erased state.

The available DFlash sectors must be used round-robin to prevent accumulation of disturbs in unevenly cycled sectors (see **Chapter 11.5.2.2**).

11.2.1 Features of the BootROM

The BootROM contains the firmware:

- Startup software “SSW”: this software is executed at every reset.
- Test firmware: factory test routines for Infineon purposes.

Additionally the BootROM and is control logic implement the Tuning protection feature (“Secure Watchdog”).

11.2.2 Features of the Program and Data Flash

Depending on the PMU configuration the following Flash features are implemented. Timing and reliability figures are just indicative. Binding data can be found in the “Data Sheet”.

11.2.2.1 Program Flash Features:

Summary of Program Flash features:

- Consists of 1 bank(s). All banks are concurrently readable.
- Separate SRI ports, ECC decoders and pre-fetch logic for each bank.
- Commonly used for instructions and constant data.
- High throughput burst read based on a 256-bit Flash access (see parameter table t_{PF}).
- Application optimized sector structure with logical sectors ranging from 16 KBytes to 256 KBytes.
- Write protection separately configurable per logical sector (one-time programmable and 256-bit password protected).
- Password based read protection combined with write protection.
- Sectors (one 16 KB and two 64 KB) configurable as HSM code sectors by setting HSM_exclusive flag.
- Separate read, write and OTP protection for the HSM code sectors.
- Erase counter counts each sector erase (saturating).
- Fast programming of 32 byte pages (see Data Sheet t_{PRP}).
- High throughput burst programming of 256 byte units (see Data Sheet t_{PRPB}).
- Erase time per logical sector: see Data Sheet t_{ERP}.
- For development purposes sectors may incur more program/erase cycles than for productive purposes. Additionally further restrictions apply as an increased failure rate and lower retention.
- High throughput erase by multi-sector erase commands: see Data Sheet t_{MERP}.
- Erase and program performed by a Flash specific control logic independent of the CPU.

- Fast suspend erase to read and suspend burst programming to read command.
- Erase verify command.
- End of erase and program operations reported by interrupt.
- Configurable stall or bus error generation when reading busy PFlash banks.
- Dynamic correction of single-bit and double-bit errors and detection of triple-bit errors (“DEC-TED”).
- “Safe read path” ensuring detection of transient and permanent errors including addressing faults.
- ASIL-D optimized ECC for detection of >99% of faults in the white-noise model.
- Error reporting to the SMU, additionally local status flags and bus error generation.
- Margin reads for quality assurance.
- Delivery in the erased state.
- Configurable wait-state configuration.
- Endurance and retention figures are documented in the Data Sheet.
- Pad supply voltage used for program and erase. Separate programming modes for 5V and 3.3V supplied devices.

11.2.2.2 Data Flash Features

Summary of Data Flash features:

- Contains 16 EEPROMx sectors commonly used for EEPROM emulation (data storage at application run-time).
- UCBx sectors used for protection installation and the erase-cycle counter.
- Read-only UCB configured by Infineon with unique chip identifier and trimming data.
- Password based read protection combined with write protection.
- Flash read access based on 64-bit reads (see Data Sheet t_{DF}).
- Read path separated from PFlash (DFlash reads don’t influence PFlash read accesses).
- Burst read is not supported.
- Requested read (data reading performed in background, read data supplied in registers).
- Fast programming of 8 byte pages (see Data Sheet t_{PRD}).
- High throughput burst programming of 32 byte units (see Data Sheet t_{PRDB}).
- Erase time per sector: see Data Sheet t_{ERD}.
- High throughput erase by multi-sector erase commands: see Data Sheet t_{MERD}.
- Erase and program performed by a Flash specific control logic independent of the CPU.
- Fast suspend erase to read command.
- End of erase and program operations reported by interrupt.
- Dynamic correction of single-bit, double-bit and triple-bit errors and detection of quad-bit errors (“TEC-QED”).
- Error reporting to the SMU, additionally local status flags and bus error generation.
- Margin reads for quality assurance.

- Delivery in the erased state.
- Configurable wait-state configuration.
- The high endurance (see Data Sheet N_E) is granted under the condition of a robust EEPROM emulation algorithm (see corresponding section in the PMU chapter of the User's Manual).
- Endurance and retention figures are documented in the Data Sheet.
- Pad supply voltage used for program and erase.

11.3 BootROM

The content of the BROM is described in a separate chapter.

The BROM is readable and executable for user software but its functions shall only be executed when especially advised by Infineon.

All write accesses to the BootROM are refused with a bus error.

Its content is protected with ECC having SEC-DED capability and address error detection.

In the SRI address range it is mapped to the following start addresses:

- AC_BROM0 (cached address range).
- AN_BROM0 (non-cached address range).

11.4 Tuning Protection

The special tuning protection support represents a security function provided additionally to Flash read/write/OTP protection.

For details on the tuning protection please contact your Infineon representative.

11.5 Flash

This chapter introduces the Flash memory of the TC21x/TC22x/TC23x. It is split into the following sections:

- Definition of terms (**Chapter 11.5.1**): what means “program”, “erase”, “sector”, “pages”, …
- Structure of a Flash module (**Chapter 11.5.2**): separation into “banks”, “sectors”, “word-lines”, “pages”, …
- Reading Flash (**Chapter 11.5.3**).
- Command sequences for Flash (**Chapter 11.5.4**): programming, erasing, handling protection.
- Flash protection (**Chapter 11.5.5**): read and write protection.
- Data integrity and safety (**Chapter 11.5.6**): ECC and margin checks.
- Interrupt and traps (**Chapter 11.5.7**).
- Reset and startup (**Chapter 11.5.8**).
- Power reduction by sleep and idle (**Chapter 11.5.9**).

11.5.1 Definition of Terms

The description of Flash memories uses a specific terminology for operations and the hierarchical structure.

Flash Operation Terms

- **Erasing**: The erased state of a Flash cell is logical ‘0’. Forcing a cell to this state is called “erasing”. Depending on the Flash area always complete physical sectors, logical sectors or word-lines are erased. All Flash cells in this area incur one “cycle” that counts for the “endurance”.
- **Programming**: The programmed state of a cell is logical ‘1’. Changing an erased Flash cell to this state is called “programming”. The 1-bits of a page are programmed concurrently.
- **Retention**: This is the time during which the data of a flash cell can be read reliably. The retention time is a statistical figure that depends on the operating conditions of the device (e.g. temperature profile) and is affected by operations on other Flash cells in the same word-line and physical sector. With an increasing number of program/erase cycles (see endurance) the retention is lowered.
- **Endurance**: As described above the data retention is reduced with an increasing number of program/erase cycles. The maximum number of program/erase cycles of each Flash cell is called “endurance”. As said for the retention it is a statistical figure that depends on operating conditions and the use of the flash cells and not to forget on the required quality level. The endurance is documented in the data sheet separately for PFlash logical sectors, UCBs and EEPROM sectors.

Flash Structure Terms

- **Flash Module**: A PMU contains one “Flash module” with its own operation control logic.
- **Bank**: A “Flash module” contains separate “banks”. In the PFlash there are one or more PFx banks and in the DFlash two DFx banks. “Banks” support concurrent operations with some limitations due to common logic.
- **Sub-Sector**: A Flash “bank” consists of sub-sectors. There are “physical sub-sectors” which are isolated from each other and “logical sub-sectors”. A PFlash bank is built from 512 KByte physical sub-sectors. A DFlash bank is separated into logical sub-sectors.
- **Logical Sector**: The sub-sectors are further separated into “logical sectors” which are groups of word-lines. They can be erased with a single operation.
- **Sector**: The plain term “sector” means “logical sector”.
- **User Configuration Block “UCB”**: A “UCB” is a specific logical sector. It is part of a DF_UCB sub-sector of bank DF0. It contains the protection settings and other data configured by the user.
- **Configuration Sector**: The “configuration sector” is a logical sector of the PFlash. It is not directly accessible to the user.
- **Page**: In the PFlash a page is an aligned group of 32 bytes and in DFlash of 8 bytes. It is the smallest unit that can be programmed (ECC width).
- Program **Burst**: A “burst” is the maximum amount of data that can be programmed with one command. The programming throughput is higher than for programming single pages. A burst in PFlash consists of 8 pages (256 bytes) and in DFlash 4 pages (32 bytes).
- **Word-Line**: In the PFlash and DFlash a word-line is an aligned group of 512 bytes.

11.5.2 Flash Structure

The PMU0 of TC21x/TC22x/TC23x contains the following Flash banks. The offset address of each sector is relative to the base address of its bank which is given in **Table 11-1**. In devices of the same family the Flash banks keep the same base address.

11.5.2.1 PFlash

All banks PFx of the PFlash of all PMUs are based on the same sectorization (see **Table 11-2**). PFx banks with reduced capacity are built by cutting off sectors at the end. A 2 MByte bank implements logical sectors S0 to S26, a 1.5 MByte bank logical sectors S0 to S24 and a 1 MByte bank logical sectors S0 to S22. The implemented bank sizes are described in the Data Sheet.

Table 11-2 Sector Structure of PFx of PMU0

Logical Sector	Phys. Sub-Sector	Size	Offset Address[1)]
S0	PS0 (512 KB)	16 KB	$00'0000_H$
S1		16 KB	$00'4000_H$
S2		16 KB	$00'8000_H$
S3		16 KB	$00'C000_H$
S4		16 KB	$01'0000_H$
S5		16 KB	$01'4000_H$
S6		16 KB	$01'8000_H$
S7		16 KB	$01'C000_H$
S8		32 KB	$02'0000_H$
S9		32 KB	$02'8000_H$
S10		32 KB	$03'0000_H$
S11		32 KB	$03'8000_H$
S12		32 KB	$04'0000_H$
S13		32 KB	$04'8000_H$
S14		32 KB	$05'0000_H$
S15		32 KB	$05'8000_H$
S16		64 KB	$06'0000_H$
S17		64 KB	$07'0000_H$
S18	PS1 (512 KB)	64 KB	$08'0000_H$
S19		64 KB	$09'0000_H$
S20		128 KB	$0A'0000_H$
S21		128 KB	$0C'0000_H$
S22		128 KB	$0E'0000_H$
S23	PS2 (512 KB)	256 KB	$10'0000_H$
S24		256 KB	$14'0000_H$
S25	PS3 (512 KB)	256 KB	$18'0000_H$
S26		256 KB	$1C'0000_H$

1) Offset with respect to AC_PFx and AN_PFx (see **Table 11-1**).

The sectors S0, S3, S7 and S8 of PF0 in PMU0 contain the BMI headers.

The sectors S6, S16 and S17 of PF0 in PMU0 are used as HSM code sectors in devices with HSM. Their access control (read, program, erase) is different from other PFlash sectors.

The sector S5 of PF0 in PMU0 has a specific purpose with an enabled Tuning Protection.

11.5.2.2 DFlash of PMU0

Bank DF0 of the DFlash of PMU0 (see **Table 11-3**).

Attention: In the DF_EEPROM all sectors must be used round-robin in order to prevent the accumulation of erase disturbs in static sectors[1]. In derivates with reduced amount of DFlash all sectors in this reduced DFlash range must be used round-robin.

Attention: In DF_EEPROM the overall number of erase commands over lifetime is limited by the parameter N_{ERD0}[2], in DF_HSM by N_{ERD1}[3].

Attention: In DF_EEPROM and DF_HSM at most 384 KByte shall be erased with one erase command.

Table 11-3 Sector Structure of DFlash Bank 0

Logical Sector	Log. Sub-Sector	Size	Offset Address[1]
EEPROM0	DF_EEPROM	8 KByte	$00'0000_H$
EEPROM1		8 KByte	$00'2000_H$
EEPROM2		8 KByte	$00'4000_H$
EEPROM3		8 KByte	$00'6000_H$
…		…	…
EEPROM15		8 KByte	$01'E000_H$

1) The parameter N_{DFD} (see Electrical Parameters or Data Sheet) documents the erase disturb limit. It is chosen higher than needed for pure round-robin usage to cover also error cases (e.g. repetition of erase commands on the same range due to power failures during operation).

2) This parameter is chosen to not reduce the endurance when always with one erase command at least 1/6th of the available DF_EEPROM is erased.

3) This parameter is chosen to not reduce the endurance when always with one erase command at least 1/4th of the available DF_HSM is erased

Table 11-3 Sector Structure of DFlash Bank 0 (cont'd)

Logical Sector	Log. Sub-Sector	Size	Offset Address[1)]
UCB0 = UCB_PFlash	DF_UCB	1 KByte	$10'0000_H$
UCB1 = UCB_DFlash		1 KByte	$10'0400_H$
UCB2 = UCB_HSMCOTP		1 KByte	$10'0800_H$
UCB3 = UCB_OTP		1 KByte	$10'0C00_H$
UCB4 = UCB_IFX		1 KByte	$10'1000_H$
UCB5 = UCB_DBG		1 KByte	$10'1400_H$
UCB6 = UCB_HSM		1 KByte	$10'1800_H$
UCB7 = UCB_HSMCFG		1 KByte	$10'1C00_H$
UCB8		1 KByte	$10'2000_H$
UCB9		1 KByte	$10'2400_H$
UCB10		1 KByte	$10'2800_H$
UCB11		1 KByte	$10'2C00_H$
UCB12		1 KByte	$10'3000_H$
UCB13		1 KByte	$10'3400_H$
UCB14		1 KByte	$10'3800_H$
UCB15		1 KByte	$10'3C00_H$

1) Offset with respect to AN_DFlash_B0 (see **Table 11-1**).

11.5.3 Flash Read Access

Flash banks that are active and in read mode can be directly (memory mapped) read as ROM.

The wait cycles for the Flash access must be configured as described in (**Chapter 11.5.3.3**).

The PFlash allows SRI bursts BTR4 and BTR2 and single transfers.

The Tricore uses BTR4 for code fetches from the cached address range in order to fill one cache line. Code fetches from the non-cached area are also performed with BTR4. Data reads from the cached range are performed with BTR4. Data reads from the non-cached address range are performed with single transfers.

The DFlash allows only single transfers. Therefore they are only accessible in the non-cached address range and Tricore can't fetch instructions from them.

Read accesses from Flash can be blocked by the read protection (see **Chapter 11.5.5**).

Read accesses from busy Flash banks are not possible (see **Chapter 11.5.4.1**).

ECC errors can be detected and corrected (see **Chapter 11.5.6**).

The DFlash sectors EEPROMx can be also read with requested reads (see **Chapter 11.5.3.4**).

11.5.3.1 Read Ports

For optimum performance the PFlash is read via dedicated SRI slave ports. Each PFp bank is assigned to one SRI port determined by its address (see **Table 11-4**). The DFlash, the BootROM and the registers share a separate SRI slave port.

Table 11-4 Memory Range to SRI Port Assignment

SRI Port	Address Range	Memory Ranges
p = 0 mapped to SCI 7	8000 0000$_H$ – 801F FFFF$_H$	PF0 (cached)
p = 0 mapped to SCI 7	A000 0000$_H$ – A01F FFFF$_H$	PF0 (non-cached)
mapped to SCI 6	8FFF 8000$_H$ – 8FFF FFFF$_H$ AF00 0000$_H$ – AF01 FFFF$_H$ AF10 0000$_H$ – AF10 3FFF$_H$ AF11 0000$_H$ – AF11 FFFF$_H$ AFFF 8000$_H$ – AFFF FFFF$_H$ F800 0500$_H$ – F800 05FF$_H$ F800 1000$_H$ – F800 23FF$_H$ FF11 0000$_H$ – FF11 FFFF$_H$	BootROM DF0 (DF_EEPROM) DF0 (DF_UCB) reserved for DF1 BootROM PMU Registers Flash Registers reserved for HSM private Flash command interface and DF1.

Each SRI port can be independently read. Each has its own path to its Flash range and its own ECC decoding logic.

As additional performance increasing measure each of the PFp ports has its own prefetching logic and a set of 3 read buffers.

Every read buffer is assigned by configuration (see **Chapter 11.7.2.7**) to one bus master. Additionally all read data passes through a pipeline stage in the FSI called “global read buffer”. The read buffers can be filled with a single PFlash read which delivers 256 data bits.

Upon finishing a pre-fetch and with no request from the bus the PMU reads the sequentially following 256 bits into the global read buffer. Buffer hits in this read buffer are also supported and don’t cause a Flash read. When this read buffer is also filled the PMU sends already the address for the following 256 bits to the Flash and keep this address stable (this feature can be disabled with FCON.IDLE). A hit with this address is also detected and will reduce the Flash access time.

All read buffers are invalidated upon executing a command sequence that changed PFlash content. The read buffers are not invalidated by changes to the configuration registers (e.g. changing wait-states or changing the ECC correction).

11.5.3.2 DFlash, BootROM Read Port

The other resources (DFlash, BootROM, registers, etc) share a separate SRI slave port independent of the PFlash read ports.

Read accesses to the DFlash are always serviced by reading the Flash. Buffer hits are not supported.

11.5.3.3 Configuring Flash Wait Cycles

The Flash read path including the ECC decoders and read buffer accesses use the following clocks:

- PFx read ports: clocked with f_{FSI2}.
- DFlash, BootROM, register read port: clocked with f_{FSI}.

The wait cycles in register FCON are counted with this reference clock. The minimum number of wait cycles can be calculated based on the delays given in the Data Sheet or Electrical Specification as described in **Table 11-5**.

Note: Please note that in case of using the FM-PLL the maximum frequency of these clocks has to enter the calculation.

Attention: After System Reset and Power-On Reset the wait cycles are configured for the clock configuration used during startup, i.e. f_{FSI} and f_{FSI2} running with maximum 100 MHz. Before changing to higher clock frequencies this default configuration must be changed.

The clock f_{FSI2} can be configured to be identical to f_{SRI} or f_{FSI}. Selecting the higher clock frequency increases the read performance.

Table 11-5 Wait Cycle Calculation

	Register Field	Minimum Value[1)]
PFlash read access delay	FCON.WSPFLASH	$Ceil(t_{PF} * f_{FSI2}) - 1$
PFlash ECC decode delay	FCON.WSECPF	$Ceil(t_{PFECC} * f_{FSI2}) - 1$
DFlash read access delay	FCON.WSDFLASH	$Ceil(t_{DF} * f_{FSI}) - 1$
DFlash ECC decode delay	FCON.WSECDF	$Ceil(t_{DFECC} * f_{FSI}) - 1$

1) The Ceil(r) function rounds a real number up, i.e. the result is the smallest integer not less than the real argument. The mathematical function name is “Ceiling(r)”.

Examples

Example configuration for t_{PF} = 30 ns, t_{PFECC} = 10 ns, t_{DF} = 100 ns, t_{DFECC} = 20 ns with f_{FSI2} = 200 MHz and f_{FSI} = 100 MHz:

- FCON.WSPFLASH = 5
- FCON.WSECPF = 1
- FCON.WSDFLASH = 9
- FCON.WSECDF = 1

11.5.3.4 Requested DFlash Read

The direct memory mapped DFlash read stalls the requesting master for the duration of the read access. Applications that favor latency over throughput can use the “requested read” feature. This supports interrupt driven background reads from the DFlash.

In devices with DF_HSM a separate set of registers exist to perform requested reads on the HSMx sectors (**Chapter 11.7.2.11**).

The start address is written into RRAD.ADD. RRCT.CNT contains the number of 8 byte aligned transfers that will be performed.

The reading of each 8 byte block is started by setting RRCT.STRT. When the PMU starts the read process is clears RRCT.STRT and sets RRCT.BUSY.

When the data is available in RRD0-1 the flag RRCT.BUSY is cleared and RRCT.DONE is set. If RRCT.EOBM is set the requested read interrupt (SRC_PMU1) is triggered. The address in RRAD.ADD is incremented to the next address and the counter RRCT.CNT is decremented by 1.

The reading of the next 8 byte block has to be triggered again by setting RRCT.STRT. This clears RRCT.DONE.

The requested read can be aborted by setting RRCT.STP. This clears RRCT.STRT, RRCT.BUSY and RRCT.DONE. The requested read interrupt is not triggered.

An error is reported by RRCT.ERR when the read access addresses an illegal address (outside of the assigned DFlash ranges, insufficient access rights) or when started with CNT=0. This sets also RRCT.DONE.

The occurrence of an uncorrectable ECC error sets RRCT.ERR. The ECC error flags in the FSR are not influenced by requested reads.

Direct reads to the DFlash are not blocked by ongoing requested reads. They are executed with higher priority than requested reads.

11.5.4 Flash Operations

The Flash memory knows operations for reading, changing data (program/erase) and handling protection settings. This section and the following describe only the features as such. How to use them is described in the application notes (**Chapter 11.8**).

11.5.4.1 Modes of Operation

A Flash module can be in one of the following states:

- Active (normal) mode.
- Sleep mode (see **Chapter 11.5.8**).

In sleep mode write and read accesses to all Flash ranges of this PMU are refused with a bus error.

When the Flash module is in normal mode a Flash bank can be in one of these modes:

- Read mode.
- Command mode.

In read mode a Flash bank can be read and command sequences are interpreted. In read mode a Flash bank can additionally enter page mode which enables it to receive data for programming.

In command mode an operation is performed. During its execution the Flash bank reports BUSY in FSR. In this mode read accesses to this Flash bank are refused with a bus error or the ready is suppressed until BUSY clears. This can be configured (see **FCON**.STALL). At the end of an operation the Flash bank returns to read mode and BUSY is cleared. Only operations with a significant duration (shown in the command documentation) set BUSY.

Note: Using FCON.STALL = "STALL" is not recommended because the stalled CPU is inoperable and also the PMU SRI port is blocked as long the ready is suppressed. This feature should be only used under controlled conditions by a Flash loader.

*Note: Using FCON.STALL = "STALL" together with Flash sleep (**Chapter 11.5.9**) is prohibited as it might lead to device hang-up.*

In command mode further command sequences in this flash module are not allowed. They are refused with a bus error.

Flash modules of different PMUs are completely independent.

Register read and write accesses are not affected by these modes.

11.5.4.2 Command Sequences

All Flash operations except memory mapped reads are performed with command sequences. Every write access to the DF0 memory range is interpreted as command cycle belonging to a command sequence.

Write accesses to the PFlash memory range are refused with bus error.

Command sequences consist of 1 to 9 command cycles. The command interpreter checks that a command cycle is correct in the current state of command interpretation. Else a SQER is reported.

When the command sequence is accepted the last command cycle finishes read mode and the Flash bank transitions into command mode.

Command sequences can be blocked by the register access protection (see **Chapter 11.5.5.2**).

Generally when the command interpreter detects an error it reports a sequence error by setting FSR.SQER. Then the command interpreter is reset and a page mode is left. The next command cycle must be the 1st cycle of a command sequence. The only exception is “Enter Page Mode” when a Flash is already in page mode (see below).

11.5.4.3 HSM Command Interface

In devices with DF_HSM there is a separate command interface (interpreting writes to the DF1 memory range) to perform operations on this Flash bank. In devices without DF_HSM this command interface doesn’t accept any commands.

11.5.4.4 Command Sequence Definitions

The command sequence descriptions use the following nomenclature (symbolic assembly language):

ST addr, data: Symbolic representation of a command cycle moving “data” to “addr”.

The parameter “addr” is defined as followed:

- **$CCCC_H$**: The “addr” must point into the DFlash. The last 16 address bits must match $CCCC_H$.

The parameter “data” can be one of the following:

- **PA**: Absolute start address of the Flash page. Must be aligned to burst size for “Write Burst” or to the page size for “Write Page”.
- **SA**: Absolute start address of a Flash sector. Allowed are the PFlash sectors Sx and the DFlash sectors EEPROMx, UCBx.
- **WD**: 64-bit or 32-bit write data to be loaded into the page assembly buffer.
- **xxYY**: 8-bit write data as part of a command cycle. Only the byte “YY” is used for command interpretation. The higher order bytes “xx” are ignored.
  - **xx5y**: Specific case for “YY”. The “y” can be “0_H” for selecting the PFlash or “D_H” to select the DFlash.
  - **xxnn**: Specific case for “YY”. The “nn” quantifies the number of logical sectors that are erased or verified. This number underlies certain restrictions (see **Erase Logical Sector Range** on **Page 11-20**).
- **UC**: Identification of the UCBx for which the password checking shall be performed: $xx00_H$ for UCB0 = UCB_PFlash, $xx01_H$ for UCB1 = UCB_DFlash, $xx05_H$ for UCB5 = UCB_DBG.
- **PWx**: 32-bit word of a 256-bit password.

When using for command cycles 64-bit transfers the “data” is expected in the correct 32-bit word as indicated by the address “addr”.

Command Sequence Overview Table

The **Table 11-6** summarizes all commands sequences. The following sections describe each command sequence in detail.

Table 11-6 Command Sequences for Flash Control

Command Sequence		1. Cycle	2./6. Cycle	3./7. Cycle	4./8. Cycle	5./9. Cycle	6. Cycle
Reset to Read	Address Data	.5554 ..xx**F0**					
Enter Page Mode	Address Data	.5554 ..xx**5y**					
Load Page	Address Data	.55F0 1) **WD**					
Write Page	Address Data	.AA50 **PA**	.AA58 ..xx**00**	.AAA8 ..xx**A0**	.AAA8 ..xx**AA**		
Write Page Once	Address Data	.AA50 **PA**	.AA58 ..xx**00**	.AAA8 ..xx**A0**	.AAA8 ..xx**9A**		
Write Burst	Address Data	.AA50 **PA**	.AA58 ..xx**00**	.AAA8 ..xx**A0**	.AAA8 ..xx**7A**		
Erase Logical Sector Range	Address Data	.AA50 **SA**	.AA58 ..xx**nn**	.AAA8 ..xx**80**	.AAA8 ..xx**50**		
Verify Erased Logical Sector Range	Address Data	.AA50 **SA**	.AA58 ..xx**nn**	.AAA8 ..xx**80**	.AAA8 ..xx**5F**		
Resume Prog/Erase	Address Data	.AA50 **PA/SA**	.AA58 ..xx**nn**	.AAA8 ..xx**70**	.AAA8 ..xx**CC**		
Disable Protection	Address Data	.553C **UC**	.553C **PW0/4**	.553C **PW1/5**	.553C **PW2/6**	.553C **PW3/7**	
Resume Protection	Address Data	.5554 ..xx**F5**					
Clear Status	Address Data	.5554 ..xx**FA**					

1) Address depends on data width of WD (see description of Load Page below).

Reset to Read

Calling:

- ST 5554_H, $xxF0_H$

Function:

This function resets the addressed command interpreter to its initial state (i.e. the next command cycle must be the 1st cycle of a sequence). A page mode is aborted.

This command is the only that is accepted without SQER when the command interpreter has already received command cycles of a different sequence but is still not in command mode. Thus “Reset to Read” can cancel every command sequence before its last command cycle has been received.

The error flags of **FSR** (OPER, SQER, PROER, PFSBER, PFDBER, PFMBER, DFSBER, DFDBER, DFTBER, DFMBER, ORIER, PVER, EVER) are cleared. The flags can be also cleared in the status registers without command sequence.

Enter Page Mode

Calling:

- ST 5554_H, $xx5y_H$

Function:

The PFlash or the DFlash assembly buffer enter page mode selected by the parameter “y”.

The write pointer of the page assembly buffer is set to 0, its previous content is maintained.

The page mode is signaled by the flags PFPAGE/DFPAGE in the FSR separately for PFlash and DFlash.

If a new “Enter Page Mode” command sequence is received while any Flash is already in page mode SQER is set, the existing page mode is aborted, and the new “Enter Page Mode” sequence is correctly executed (i.e. in this case the command interpreter is not reset).

Load Page

Calling:

- ST $55F0_H$/$55F4_H$, WD

Function:

Loads the data “WD” into the page assembly buffer and increments the write pointer to the next position.

All WD transfers for one page must have the same width (either all 32-bit or all 64-bit). Else the transfer is refused with SQER.

When using 64-bit transfers then all have to address the offset address $55F0_H$.

When using 32-bit transfers then the lower order word has to be written first to offset $55F0_H$ and then the higher order word to offset $55F4_H$. This alternating pattern is repeated for all WD.

If “Load Page” is called more often than allowed by the available buffer space of 256 bytes the overflow data is discarded, the page mode is not left. This overflow is reported by the following Write Page/Burst command with SQER.

Write Page

Calling:

- ST $AA50_H$, PA
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xxA0_H$
- ST $AAA8_H$, $xxAA_H$

Function:

This function starts the programming process for one page with the data transferred previously by “Load Page” commands. Upon entering command mode the page mode is finished (indicated by clearing the corresponding PAGE flag) and the BUSY flag of the bank is set.

A page shall be programmed only once after erasing.

This command is refused with SQER when the addressed Flash is not in page mode.

SQER is also issued when PA addresses an unavailable Flash range or when PA does not point to a legal page start address.

If after “Enter Page Mode” too few data, no data or too much data was transferred to the assembly buffer with “Load Page” then “Write Page” programs the page but sets SQER. Missing data is programmed with the previous content of the assembly buffer.

When the page “PA” is located in a sector with active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

When the programming process incurs an error the flag PVER is set.

Write Page Once

Calling:

- ST $AA50_H$, PA
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xxA0_H$
- ST $AAA8_H$, $xx9A_H$

Function:

This function starts the programming process for one page as the normal “Write Page” does. But before programming it checks if the page is erased. If the page is not erased (allowing correctable errors) the command fails with PVER and EVER.

When the programming itself incurs an error the flag PVER is set.

On sectors with “write-once” protection only this write command can be applied.

This command is only supported for PFlash. When applied to DFlash the command fails with SQER.

Write Burst

Calling:

- ST $AA50_H$, PA
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xxA0_H$
- ST $AAA8_H$, $xx7A_H$

Function:

This function starts the programming process for an aligned group of pages. The programming process is more efficient than for a single page, achieving a significantly higher throughput (see data sheet).

In the PFlash 8 pages (256 bytes) are programmed and in DFlash 4 (32 bytes). The pages are programmed one after the other with increasing addresses.

Please note that with disabled ECC generation with ECCW.PECENCDIS or DECENCDIS this command sequence must not be used. It causes unpredictable results.

For further details see “Write Page”.

Erase Logical Sector Range

Calling:

- ST $AA50_H$, SA
- ST $AA58_H$, $xxnn_H$
- ST $AAA8_H$, $xx80_H$
- ST $AAA8_H$, $xx50_H$

Function:

This command erases “nn” sectors starting at the sector addressed by “SA”. Upon entering command mode the BUSY flag of the corresponding bank is set. When erasing PFlash sectors additionally D0BUSY is set (because the erase counters are programmed in DF0).

SQER is returned when SA does not point to the base address of a correct sector (as specified at the beginning of this section) or to an unavailable sector.

When SA or any of the following nn-1 sectors has an active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

The command fails with SQER if the range of logical sectors is not contained in one physical sector.

The error flag EVER is set to indicate an error during the erase process. The flags EVER and PVER are set when the erase counter programming incurs an error.

Note: The duration of an erase command applied to DFlash can be much shorter than documented as maximum duration (t_{ERD}, t_{MERD}).

Verify Erased Logical Sector Range

Calling:

- ST $AA50_H$, SA
- ST $AA58_H$, $xxnn_H$
- ST $AAA8_H$, $xx80_H$
- ST $AAA8_H$, $xx5F_H$

Function:

This command verifies if “nn” sectors starting at the sector addressed by “SA” are correctly erased, i.e. contain 0 data and ECC bits. Upon entering command mode the BUSY flag of the corresponding bank is set.

When the PFlash Safety ECC is enabled (see **Chapter 11.5.6.2**) the PFlash cannot be checked for “0” content by direct reads.

The error flag EVER is set to identify a found verification error.

SQER is returned when SA does not point to the base address of a correct sector (as specified at the beginning of this section) or to an unavailable sector.

The command fails with SQER if the range of logical sectors is not contained in one physical sector.

Especially security concerned customers can limit this function by configuring PROCONHSMCOTP.BLKFLAN to ‘1’:

- If PROCONHSMCOTP.BLKFLAN is 0 then “Verify Erase Logical Sector Range” is enabled for every address.
- If PROCONHSMCOTP.BLKFLAN is 1 then “Verify Erase Logical Sector Range” is blocked as follows:
  - If one of the PROCONCOTP.HSMsX = 1: blocked on the corresponding HSM code sector “s”.
  - If FPRO.PROINP = 1 and FPRO.PRODISP = 0: blocked on UCB_PFlash.
  - If FPRO.PROIND = 1 and FPRO.PRODISD = 0: blocked on UCB_DFlash.
  - If FPRO.PROINDBG = 1 and FPRO.PRODISDBG = 0: blocked on UCB_DBG.

If this function is blocked the command fails by setting PROER.

Resume Prog/Erase

Calling:

- ST $AA50_H$, PA/SA
- ST $AA58_H$, $xxnn_H$
- ST $AAA8_H$, $xx70_H$
- ST $AAA8_H$, $xxCC_H$

Function:

A suspended programming or erasing process is restarted as described in **Chapter 11.5.4.5**.

Disable Protection

Calling:

- ST $553C_H$, UC
- ST.W $553C_H$, PW0
- ST.W $553C_H$, PW1
- ST.W $553C_H$, PW2
- ST.W $553C_H$, PW3
- ST.W $553C_H$, PW4
- ST.W $553C_H$, PW5
- ST.W $553C_H$, PW6
- ST.W $553C_H$, PW7

Function:

The password protection of the selected UCB (if this UCB offers this feature) is temporarily disabled by setting FPRO.PRODISx (with “x” indicating the UCB) when all the passwords PW0–PW7 match their configured values in the corresponding UCB.

The command fails by setting PROER when any of the supplied PWs does not match. In this case until the next application reset all further calls of “Disable Protection” fail with PROER independent of the supplied password.

Resume Protection

Calling:

- ST 5554_H, $xxF5_H$

Function:

This command clears all FPRO.PRODISx effectively enabling again the Flash protection as it was configured.

Clear Status

Calling:

- ST 5554_H, xxFA_H

Function:

The flags FSR.PROG and FSR.ERASE and the error flags of **FSR** (OPER, SQER, PROER, PFSBER, PFDBER, PFMBER, DFSBER, DFDBER, DFTBER, DFMBER, ORIER, PVER, EVER) are cleared. These flags can be also cleared in the status registers without command sequence.

11.5.4.5 Operation Suspend and Resume

The operations “Erase Logical Sector Range”, “Verify Erased Logical Sector Range” and “Write Page”[1] and “Write Burst”[2] can be suspended.

An operation is suspended by writing ‘1’ to **MARD**.SPND. The Flash operation stops when it reaches an interruptible state. After that the flag **FSR**.SPND is set and busy is cleared.

There can be at most one operation in the suspended state. Erroneous suspend and resume requests are detected and prevented by the PMU.

The target range of a suspend program or erase operation is in an undefined state. Reading this range delivers unpredictable results.

The suspended operation can be resumed with the command sequence “Resume Prog/Erase”. The flag **FSR**.SPND is cleared and the busy flag is set again.

The arguments “PA” or “SA” and “nn” of the resume command must be identical to the original argument of the suspended command[3]. Using a different argument is detected by the PMU and lets the resume fail with FSR.SQER and FSR.SPND stays set.

When the operation had already finished when receiving the suspend request the request is ignored. The flag **FSR**.SPND is not set. Also **MARD**.SPND is immediately cleared again.

If a resume is requested without any suspended operation SQER is set.

Attention: Please ensure that between start or resume of an erase process and the suspend request normally at least ~1 ms erase time can pass. Shorter erase durations are allowed but the erase process will not advance.

In the suspended programming state:

1) The “Write Page” operation is suspended between end of the programming and start of the verification. Therefore the programming process itself is not suspended.

2) The “Write Burst” operation in PFlash is suspended during the programming process. In DFlash it is only suspended after end of the programming before starting the verification.

3) For resuming a “Write Burst” the argument “nn” of “Resume Prog/Erase” has to be “00”.

- Reading Flash is allowed.
- New programming and erase commands are rejected with SQER.

In the suspended erase state:

- Reading Flash is allowed.
- New erase commands are rejected with SQER.
- Programming commands can be performed on any bank.
- However programming in the target range of the suspended erase fails with SQER.
- Suspending a programming command is not possible and fails by setting **MARD**.SPNDERR.

In the suspended “Verify Erased Logical Sector Range” state:

- Reading Flash is allowed.
- New erase commands are rejected with SQER.
- Programming commands can be performed on any bank.
- Suspending a programming command is not possible and fails by setting **MARD**.SPNDERR.

11.5.4.6 Programming Voltage Selection

In devices which support 5 V supply via V_{EXT} this control bit allows to select the external supply as source of the programming voltage.

Attention: In this 3.3 V device this function is not supported and FCON.PR5V must be set to “P3V”.

11.5.5 Protection

Protection has several aspects: security, safety, preventing maloperation.

The safety protection ensures that reading from PFlash can’t be disturbed by software crashes or accesses by “unsafe” masters. Further on it ensures integrity of the read data. This is achieved by the following features:

- Safety ENDINIT protection of configuration registers.
- Master specific protection of PFlash relevant control and configuration registers.
- Protection of these registers against single-event effects “SEEs”.
- Master specific access control for command sequences.
- Integrity of read data is ensured by ECC (see **Chapter 11.5.6**).

The security protection prevents unauthorized Flash read and write from internal masters or from external:

- Flash read protection: protected Flash sections can only be read when booting from internal Flash.
- Flash write protection: protected Flash sections can only be changed after authentication.

- Flash OTP (One-Time Programmable) protection: these Flash sections can't be changed anymore.
- HSM specific protection: it ensures that the HSM can protect its private data from access by other software. Additionally selected data can only be read during HSM boot phase.
- HSM debug protection: when the HSM allows internal debugging, accesses by the debug master ("Cerberus") have the same privileges as the HSM itself.
- Device debug protection (see **Chapter 11.5.5.6**): depending on the boot mode and the configuration of debug protection and the Flash read protection and further controlled by HSM the debug access to the device is enabled.

The following features protect the Flash against maloperation including software crashes (even of "safe" masters):

- ENDINIT and SV mode protection of configuration registers.
- Command sequences that can change Flash content need more command cycles. SQER stops command interpretation.

Security features supplement safety because Flash data protected by the write protection is also safe against software crashes.

The following table gives an overview of all protection features and for which resources they are effective.

Table 11-7 Protection Layers

	PFlash	DFlash	Registers
Master Specific Access Control	–	–	Restricts Write Accesses
ENDINIT, SV, "Safety ENDINIT"	Restricts Commands (only SE)	–	Restrict Write Accesses
Flash Write Protection	Restricts Commands	Restricts Commands	–
Flash Read Protection	Restricts Read	Restricts Read	–

Any access to these resources has to pass all checks before the operation is performed.

Note: This means that an activation of a protection after start of the operation doesn't affect the operation anymore. Especially the "Safety ENDINIT" can become active as soon as a Flash command (e.g. program or erase) has started.

11.5.5.1 Master Specific Access Control

The master specific access control is configured and controlled by the registers ACCEN0 and ACCEN1 (see **Chapter 11.7.2.1**).

The registers ACCEN determine which master is allowed to perform writes to the protected resources. In the PMU the following resources are protected by this mechanism:

- Write access to all PMU and Flash registers with following exceptions (see also “Registers Overview” tables **Table 11-16** and **Table 11-18**):
  - Write access to ACCEN is controlled by the Safety ENDINIT.
  - Write accesses to the HSM private registers: HSMFSR, HSMMARD.

Write accesses that are blocked by this mechanism create a bus error as response.

11.5.5.2 Register Access Control

The master unspecific register access control features “Safety ENDINIT”, “ENDINIT”, “Supervisor Mode” are described in the SCU chapter.

In the PMU the following resources are protected by Safety ENDINIT:

- When the Safety ENDINIT is active program and erase commands on the PFlash are rejected with PROER.
- Write access to ACCEN.

11.5.5.3 Effective Flash Read Protection

The Flash read protection depends on the master and the Flash address range.

The following Flash ranges have separate read protections:

- PFlash (with specific handling of the HSM code sectors in PF0).
- And in the DFlash:
  - EEPROMs.
  - UCBs.

PFlash Read Protection

A read access to PFlash (with the exception of sectors S6, S16 and S17 in PF0 of PMU0) fails with bus error under the following conditions:

- Tricore CPU0 PMI (code fetch): FPRO.DCFP.
- Tricore CPU0 DMI (data read): FPRO.DDFP.
- All other masters: FPRO.DDFPX.

The read access to the HSM code sectors S6, S16 and S17 depends on the setting of PROCONHSMCOTP.HSMsX which defines the “HSM_exclusive” attribute of these sectors.

If PROCONHSMCOTP.HSMsX is set for such a sector:

- HSM: full read access.
- All masters except HSM: a read fails with a bus error.
- Cerberus: with enabled HSM debug same access rights as HSM itself, with disabled HSM debug access rights as all other masters.

If PROCONHSMCOTP.HSMsX is cleared for such a sector: the same rules as for the other PFlash0 sectors based on PROCONP0 as described above are valid.

DFlash Read Protection

A read access to the DFlash sectors EEPROMx fails with a bus error under the following conditions:

- All masters: FPRO.DDFD.

The read access to the UCBs is described in **Chapter 11.5.5.5**.

Activating Read Protection

The bits FPRO.DCFP, FPRO.DDFP, FPRO.DDFPX and FPRO.DDFD are initialized by the startup software depending on the configured protection and the startup mode. They can also be directly modified by the user software under conditions noted in the description of **FPRO**.

11.5.5.4 Effective Flash Write Protection

A range of Flash can be write protected by several means that are all configured in the UCBs.

PFlash Write Protection

Programming or erasing of a group of PFlash sectors (with the exception of sectors S6, S16 and S17 in PF0 of PMU0) fails with PROER if any of the following conditions is true:

- PROCONP0.RPRO and not FPRO.PRODISP (global write protection).
- PROCONPx.SxL and not FPRO.PRODISP (sector specific write protection).
- PROCONOTPx.SxROM (sector specific OTP protection).
- PROCONWOPx.SxWOP (sector specific write-once protection).
  - A set PROCONWOPx.SxWOP prohibits “Write Page”, “Write Burst” and erase commands. These fail with PROER.
  - Only “Write Page Once” is accepted by the PMU. The FSI checks if the addressed Flash range is erased. If this is not the case the FSI reports a PVER and doesn’t start programming.

Programming and erasing of the HSM reserved code sectors S6, S16 and S17 in PF0 of PMU0 depends on the setting of PROCONHSMCOTP.HSMsX which defines the “HSM_exclusive” attribute of these sectors and which master performs the access.

Programming or erase of such sectors fails if any of the following conditions is true:

- Not PROCONHSMCOTP.HSMsX and PROCONP0.RPRO and not FPRO.PRODISP (“global” write protection).
- Not PROCONHSMCOTP.HSMsX and PROCONP0.SxL and not FPRO.PRODISP (sector specific write protection).
- PROCONHSMCOTP.SxROM (HSM code sector specific OTP protection).
- For all masters except HSM: PROCONHSMCOTP.HSMsX.

For Cerberus the following rules apply: with enabled HSM debug same access rights as HSM itself, with disabled HSM debug access rights as all other masters.

DFlash Write Protection

Programming and erasing of the DFlash sectors EEPROMx fails with PROER when any of the following conditions is true:

- PROCOND.RPRO and not FPRO.PRODISD.
- PROCOND.L and not FPRO.PRODISD.

Program and erase conditions for the UCBs are described in **Chapter 11.5.5.5**.

11.5.5.5 Configuring Protection in the UCB

As indicated above the effective protection is determined by the content of the PROCONx registers. These are loaded during startup after each reset from the UCBs. Each UCB comprises 1 KByte of DFlash organized in 128 UC pages of 8 bytes.

An UCB is erased with the command “Erase Logical Sector Range”. It can be programmed with “Write Page” and “Write Burst”. Each UCB has its own access control.

When programming or erasing fail because of this access control PROER is set. When reading fails a bus error is returned.

The following UCBs are defined:

UCB_PFlash

Password protection of the PFlash.

Table 11-8 UCB_PFlash Content

Offset[1)]	Content	Description
00_H	PROCONP0	Read protection for complete PFlash. Write protection for logical sectors of PF0.
04_H		Reserved for PROCONP1.
08_H		Reserved for PROCONP2.

Table 11-8 UCB_PFlash Content (cont'd)

Offset[1)]	Content	Description
$0C_H$		Reserved for PROCONP3.
10_H	PROCONP0	Copy.
14_H		Reserved for copy of PROCONP1.
18_H		Reserved for copy of PROCONP2.
$1C_H$		Reserved for copy of PROCONP3.
20_H	PW0 – PW7	256-bit password, from least significant word to most significant word (8 words).
40_H	PW0 – PW7	Copy of 256-bit password.
70_H	Confirmation	4 bytes.
78_H	Confirmation	Copy.

1) The offsets are given in number of bytes.

See **PROCONPp (p=0-0)** on **Page 11-68**.

The confirmed state of this UCB is indicated by FPRO.PROINP.

In the errored state of this UCB also FPRO.PROINP is set. Disabling the protection is not possible in this state.

This UCB is write and read protected if:

- FPRO.PROINP and not FPRO.PRODISP.

UCB_DFlash

Password protection of the DFlash.

This UCB is also used for configuring the PFlash ECC algorithm between the "Safety" and the "Legacy" version, configuring the memory initialization and contains an oscillator configuration.

Table 11-9 UCB_DFlash Content

Offset[1)]	Content	Description
00_H	PROCOND	Read and write protection for the DFlash sectors EEPROMs, oscillator configuration, and enable of RAM initialization.
10_H	PROCOND	Copy.
20_H	PW0 – PW7	256-bit password, from least significant word to most significant word (8 words).

Table 11-9 UCB_DFlash Content (cont'd)

Offset[1)]	Content	Description
40_H	PW0 – PW7	Copy of 256-bit password.
70_H	Confirmation	4 bytes.
78_H	Confirmation	Copy.

1) The offsets are given in number of bytes.

See **PROCOND** on **Page 11-69**.

The confirmed state of this UCB is indicated by FPRO.PROIND.

In the errored state of this UCB also FPRO.PROIND is set. Disabling the protection is not possible in this state.

This UCB is write and read protected if:

- FPRO.PROIND and not FPRO.PRODISD.

UCB_OTP

This UCB configures the one-time programmable "OTP" and the write-page once "WOP" protection. It offers the possibility to add this type of protection to Flash sections incrementally.

Table 11-10 UCB_OTP Content

Offset[1)]	Content	Description
00_H	PROCONOTP0	OTP protection for the logical sectors of PF0, and enable of TP.
04_H		Reserved for PROCONOTP1.
08_H		Reserved for PROCONOTP2.
$0C_H$		Reserved for PROCONOTP3.
10_H	PROCONOTP0	Copy.
14_H		Reserved for copy of PROCONOTP1.
18_H		Reserved for copy of PROCONOTP2.
$1C_H$		Reserved for copy of PROCONOTP3.
20_H	PROCONWOP 0	WOP protection for the logical sectors of PF0.
24_H		Reserved for PROCONWOP1.
28_H		Reserved for PROCONWOP2.
$2C_H$		Reserved for PROCONWOP3.

Table 11-10 UCB_OTP Content (cont'd)

Offset[1)]	Content	Description
30_H	PROCONWOP 0	Copy.
34_H		Reserved for copy of PROCONWOP1.
38_H		Reserved for copy of PROCONWOP2.
$3C_H$		Reserved for copy of PROCONWOP3.
70_H	Confirmation	4 bytes.
78_H	Confirmation	Copy.
80_H		Start of next set.
…		

1) The offsets are given in number of bytes.

See **PROCONOTPp (p=0-0)** on **Page 11-71** and **PROCONWOPp (p=0-0)** on **Page 11-73**.

This configuration set can be stored 8 times. Each set has its own confirmation code. A protection set can be programmed when it is in the "unlocked" state, else it is write-protected.

The content of the PROCONOTP and PROCONWOP registers is initialized by the first configuration set at offset 0 (if this is "unlocked" or "confirmed"). All following confirmed sets are or-ed to this initial value.

An errored set activates all protection bits and activates write protection for this complete UCB.

Attention: This means that always each of the 8 confirmation codes and their copies shall be either in the "confirmed" or "unlocked" state (see UCB Confirmation on Page 11-36).

The confirmed state of the complete UCB is indicated by FPRO.PROINOTP. It is set when there is at least one protection set in the confirmed state.

If any set is in the errored state FPRO.PROINOTP is also set.

This UCB is protected from erasing if:

- FPRO.PROINOTP.

This UCB is readable.

UCB_HSMCFG

This UCB contains data supplied by Infineon during device production for the exclusive use of the HSM module.

UCB_IFX

This UCB contains data supplied by Infineon during device production.

Table 11-11 UCB_IFX Content

Offset[1]	Content	Description
00_H	UID	128-bit Unique ID.
10_H	Reserved	Reserved.
80_H		Up to 128 bytes used for DSADC trimming (see DSADC chapter in devices with DSADC).
100_H		Reserved for calibration data.
200_H		Reserved for test information data.
380_H		4 bytes “Test Pass Marker”.

1) The offsets are given in number of bytes.

This UCB is read-only. It is readable by every master.

The unique ID is a device unique 128-bit number. Its least significant byte has the value 64_D which identifies an Infineon device.

Note: In order to ensure proper traceability in case of FARs, the unique ID shall be stored by the customer in an adequate database.

The unique ID is supplemented with identification data in the SCU registers CHIPID (device identification and revision, speed grade, Flash size and µCode revision) and MANID (manufacturer identification). See SCU chapter.

These SCU registers are also sufficient to identify the needed Flash driver (replacement for the QRY record of the CFI standard).

The 4 bytes “Test Pass Marker” contains during test the value $FFFFFFFF_H$. When all tests have passed it signals this with the value 80658383_H. If customers receive a productive device with a different value in this address they can discard it.

UCB_DBG

This UCB configures the password protection for the debug interface.

Table 11-12 UCB_DBG Content

Offset[1]	Content	Description
00_H	PROCONDBG	Protection of the debug interface.
10_H	PROCONDBG	Copy.

Table 11-12 UCB_DBG Content (cont'd)

Offset[1)]	Content	Description
20_H	PW0 – PW7	256-bit password, from least significant word to most significant word (8 words).
40_H	PW0 – PW7	Copy of 256-bit password.
70_H	Confirmation	4 bytes.
78_H	Confirmation	Copy.

1) The offsets are given in number of bytes.

See **PROCONDBG** on **Page 11-74**.

The confirmed state of this UCB is indicated by FPRO.PROINDBG.

In the errored state of this UCB also FPRO.PROINDBG is set. Disabling the protection is not possible in this state.

This UCB is write and read protected if:

- (FPRO.PROINDBG and not FPRO.PRODISDBG) or (PROCONHSMCOTP.DESTDBG = "destructive" and (FDEST = 0 or "not executing Startup Software")) or PROCONDBG.EDM = "debug entered".

UCB_HSMCOTP

This UCB configures the OTP and HSM_exclusive protection for the dedicated HSM code sectors S6, S16 and S17 of PF0 of PMU0. It offers the possibility to add this type of protection to Flash sections incrementally.

Table 11-13 UCB_HSMCOTP Content

Offset[1)]	Content	Description
00_H	PROCONHSMCOTP	OTP and HSM_exclusive protection for HSM code sectors and configuration of the HSM boot.
10_H	PROCONHSMCOTP	Copy.
70_H	Confirmation	4 bytes.
78_H	Confirmation	Copy.
80_H		Start of next set.
…		

1) The offsets are given in number of bytes.

See **PROCONHSMCOTP** on **Page 11-76**.

This configuration set can be stored 2 times. Each set has its own confirmation code.

The content of the PROCONHSMCOTP register is initialized by the first configuration set at offset 0 (if this is “unlocked” or “confirmed”). All following confirmed sets are or-ed to this initial value.

The confirmed state of the complete UCB is indicated by FPRO.PROINHSMCOTP. It is set when there is at least one protection set in the confirmed state.

If any set is in the errored state FPRO.PROINHSMCOTP is also set. An errored set activates all protection bits.

Attention: This means that always each of the 2 confirmation codes and their copies shall be either in the “confirmed” or “unlocked” state (see UCB Confirmation on Page 11-36).

This UCB is protected from erasing when:

- FPRO.PROINHSMCOTP is set.

The set at offset 0 is protected from programming for all masters when it is in confirmed or errored state.

The set at offset 80_H is protected from programming for all masters except HSM when:

- FPRO.PROINHSMCOTP is set.

It is protected from programming by HSM when it is in the confirmed or errored state[1)].

This UCB is readable.

With enabled HSM debug Cerberus has the same access rights as HSM itself. With disabled HSM debug Cerberus is treated as any other master.

UCB_HSM

This UCB can be programmed and erased by all CPUs. However when its content is confirmed or errored only the HSM can modify this UCB.

Its content is only used in devices with activated HSM.

With enabled HSM debug Cerberus has the same access rights as HSM itself. With disabled HSM debug Cerberus is treated as any other master.

Table 11-14 UCB_HSM Content

Offset[1)]	Content	Description
00_H	PROCONHSM	HSM Configuration.
10_H	PROCONHSM	Copy.

1) Rationale: all masters can configure the protection in delivery state (both sets unlocked). When the first set is confirmed only HSM is allowed to program the second set. When this is also confirmed the complete UCB is OTP protected.

Table 11-14 UCB_HSM Content (cont'd)

Offset[1)]	Content	Description
70_H	Confirmation	4 bytes.
78_H	Confirmation	Copy.

1) The offsets are given in number of bytes.

See **PROCONHSM** on **Page 11-79**.

The confirmed state of this UCB is indicated by FPRO.PROINHSM.

In the errored state of this UCB also FPRO.PROINHSM is set.

This UCB is protected from programming and erasing by non-HSM masters if:

- FPRO.PROINHSM.

It can be read by every master.

Erase Counter UCB12 – UCB15

These UCBs are used to implement erase counters. From user point of view their content is read-only. They are readable by every master.

For every call of an "Erase Logical Sector Range" the FSI increases automatically the corresponding erase counters until the maximum counting range is reached.

Each UCB12 – UCB15 contains the erase counters for one bank of PFlash PF0 – PF3.

Each logical sector Sx of one PFlash bank has an assigned UCB range of 32 bytes starting at offset address x * 32_D.

The counting is performed by programming the least significant unprogrammed nibble with 1111_B. For reliability reasons a nibble is considered as "unprogrammed" when it contains at most one 1-bit.

Each counter saturates when the last nibble is programmed. Therefore each counter saturates after 64_D erases.

For evaluating the counters the DFlash ECC correction must be disabled with ECCRD.ECCORDIS because this "thermometer code" is not ECC correct.

Remaining UCB8 – UCB11

Currently not used.

These UCBs are read-only.

UCB Confirmation

As described above the UCBs (or sets of a UCB in case of UCB_OTP and UCB_HSMCOTP) can be in the states “confirmed”, “unlocked” and “errored”. This state is determined by the content of the confirmation code:

- 57B5 $327F_H$: the state is “confirmed”.
- 4321 1234_H: the state is “unlocked”. For over-programming this state (see below) the 4 bytes following the confirmation code need to be kept as 0.
- all other content including uncorrectable ECC errors: the state is “errored”.

An UCB is also in its errored state when at least one of its entries has an uncorrectable error in the original and its copy.

When during evaluation of the UCBs an errored state is detected the flag FSR.PROER is set. The derived values in the PROCONx registers are not set to the Flash content but as indicated in the register description the protection is fully activated. When during startup an errored UCB is detected by the SSW it recognizes this as failed Flash startup and consequently doesn’t boot the device.

As also the erased state is considered as “errored” the transition from “unlocked” to “confirmed” state can be done without erasing the UCB. For this the “unlocked” code in the pages with the confirmation code and the copied confirmation code can be over-programmed with 57B5 $327F_H$. It has to be ensured that the 4 bytes following the confirmation code (e.g. at offset 74_H, $7C_H$) are kept 0000 0000_H in the unlocked state and in the over-programmed data. Only then the result after over-programming is ECC clean.

Attention: In case of the multi-set UCBs “UCB_OTP” and “UCB_HSMCOTP” each of the n (8 or 2) confirmation codes and their copies have to be in the state “unlocked” or “confirmed” to prevent an errored state.

11.5.5.6 System Wide Effects of Flash Protection

An active Flash read protection needs to be respected in the complete system.

The startup software “SSW” checks if the HSM is available.

If yes the HSM module is booted. During its boot process it can lock the device debug interface.This interface can be locked either by HSM (see below **HSM Booting**) or by setting OSTATE.IF_LCK[1)].

Additionally the customer can configure in UCB_DBG that OCDS or the debug interface are disabled.

This results in the following lock conditions:

- OCDS disabled: PROCONDBG.OCDSDIS and not FPRO.PRODISDBG.
- Debug interface locked: OSTATE.IF_LCK[2)] or (HSM lock input) or (PROCONDBG.DBGIFLCK and not FPRO.PRODISDBG.

1) The register OSTATE is contained in the OCDS module. The distribution of OCDS documentation is restricted.

The SSW performs the following operations:

- The SSW leaves the debug interface locked (OSTATE.IF_LCK stays 1) if any Flash read protection is configured (PROCONP0.RPRO or PROCOND.RPRO are 1).
- If the selected boot mode executes from internal PFlash:
  – The SSW clears the FPRO bits DCFP, DDFP, DDFPX, DDFD.
- If the selected boot mode does not execute from internal PFlash:
  – The SSW sets the FPRO bits DCFP, DDFP, DDFPX, DDFD if their corresponding read protection is configured in PROCONP0.RPRO or PROCOND.RPRO.

HSM Booting

The SSW boots the HSM module (i.e. HSM executes its firmware) when the field PROCONHSMCOTP.HSMBOOTEN is set (i.e. the customer has installed HSM boot code in the HSM code sectors).

First the HSM firmware checks PROCONHSMCOTP.HSMDBGDIS. If this is cleared it enables HSM debug.

After that the HSM firmware checks PROCONHSM.DBGIFLCK. If this is cleared it releases its lock of the system debug interface.

After execution of the HSM firmware the HSM executes from the HSM code sectors (see HSM chapter). Depending on PROCONHSMCOTP.SSWWAIT the SSW waits for an acknowledge from the HSM before leaving the Firmware.

When the execution of the HSM firmware fails (e.g. due to missing HSM code) this is signaled to the SSW which stops executing. Consequently the device doesn't boot into user mode.

Destructive Debug Entry

As described before the debug interface can be opened by supplying the correct password of UCB_DBG to the PMU under the condition that HSM doesn't lock this interface.

A special destructive debug entry can be configured with **PROCONHSMCOTP**.DESTDBG. When this is configured as "destructive" only the SSW can accept the UCB_DBG password via debug interface (see BootROM chapter). Additionally the password is only accepted when the device pin "FDEST" is logic '1' and the field **PROCONDBG**.EDM is "debug not entered". When all these conditions match the field **PROCONDBG**.EDM is programmed by the SSW to "debug entered" before opening the debug interface. When EDM is "debug entered" automatically the clock system is manipulated to disallow communication via CAN or Flexray.

2) Only for illustration, this bit and its or-combination with the following signals is part of the OCDS not the PMU. The distribution of OCDS documentation is restricted.

11.5.6 Data Integrity and Safety

The data in Flash is stored with error correcting codes “ECC” in order to protect against data corruption. Also data transfer over the SRI bus is protected with ECC. The healthiness of Flash data can be checked with margin checks.

The following measures ensure for reading from PFlash a single point failure metric of >99% and a latent fault metric of >90%.

11.5.6.1 SRI ECC (Safe Fetch Path)

The data transfer over the SRI bus is protected by ECC. This is described in the Safety Concept. The address phase signals are accompanied with an ECC code with Hamming distance 4. The write and read data phase signals are accompanied with an ECC code (also calculated over the address) with Hamming distance 4.

11.5.6.2 Flash ECC

The data in Flash is stored with ECC codes. These are automatically generated when the data is programmed. When data is read these codes are evaluated. Depending on the Flash bank different algorithms with different error correction capabilities are used:

- Data in PFlash uses an ECC code with DEC-TED (Double Error Correction, Triple Error Detection) capabilities. Each block of 256 data bits is accompanied with a set of ECC bits.
  - The ECC algorithm in the PFlash can be switched between a “Safety ECC” which is default and a “Legacy ECC”.
  - The selection of this algorithm is done by the register field **FCON**.NSAFECC. This is set by the startup software depending on **PROCOND**.NSAFECC but can also be modified by software.
- Data in DFlash uses an ECC code with TEC-QED (Triple Error Correction, Quad Error Detection) capabilities. Each block of 64 data bits is accompanied with a set of ECC bits.

PFlash Safety ECC Details

The PFlash Safety ECC value is calculated over 256 data bits and the address bits 22:5 and the configuration area selection signal. This ECC has the following features:

- Correction of 1-bit and 2-bit errors.
- Detection of 3-bit errors.
- Detection of >99% of all error vectors in the white noise error model.
- Detection of >99% of all-0 and all-1 cases.
- Detection of addressing errors.

As side effect of the all-0 error detection an erased Flash range can't be read without ECC errors. Also over-programming of Flash ranges with all-1 would create entries with ECC errors.

The ECC is automatically generated when programming the PFlash when this is not disabled with ECCW.PECENCDIS.

The ECC is automatically evaluated when reading data. Errors are only reported for 256-bit data blocks for which at least one byte is read by a bus master. Errors found in internally pre-fetched data is stored and only reported when this data block is requested by a bus master.

The PMU does not know if the bus master uses the requested data or discards it (e.g. due to speculatively fetching code). Therefore this speculatively fetched data gets the same error response.

Error reporting and ECC disabling:

- Single-bit error:
  - Is noted in FSR.PFSBER.
  - Is reported to the SMU (which can trigger an interrupt).
  - Data and ECC value are corrected if this is not disabled with ECCRPp.ECCORDIS[1].
  - Depending on CBABCFGp.DIS and CBABCFGp.SEL the affected address is stored uniquely in the CBAB.
- Double-bit error:
  - Is noted in FSR.PFDBER.
  - Is reported to the SMU (which can trigger an interrupt).
  - Data and ECC value are corrected if this is not disabled with ECCRPp.ECCORDIS[1].
  - Depending on CBABCFGp.DIS and CBABCFGp.SEL the affected address is stored uniquely in the CBAB.
- Triple-bit error (i.e. uncorrectable bit error):
  - Is noted in FSR.PFMBER.
  - Is reported to the SMU (which can trigger an interrupt).
  - Causes a bus error if not disabled by MARP.TRAPDIS.
  - Depending on UBABCFG.DIS and UBABCFG.SEL the affected address is stored in the UBAB.
  - Can additionally report an address error.
- Address error:
  - Is noted in FSR.PFMBER.
  - Is reported to the SMU (which can trigger an interrupt).
  - Causes a bus error if not disabled by MARP.TRAPDIS.

1) Disabling the correction of errors with ECCORDIS is a test feature. During application run-time the correction must be enabled.

  - Depending on UBABCFG.DIS and UBABCFG.SEL the affected address is stored in the UBAB.
- All-0 and all-1 errors:
  - Are noted in FSR.PFMBER[1)].
  - Is reported to the SMU (which can trigger an interrupt).
  - Causes a bus error if not disabled by MARP.TRAPDIS.
  - Depending on UBABCFG.DIS and UBABCFG.SEL the affected address is stored in the UBAB.

PFlash Legacy ECC Details

The “Legacy” PFlash ECC is calculated only over 256 data bits, not over address bits or the configuration selection. Therefore addressing faults (correct data is read from an incorrect address) can not be detected by this algorithm.

This algorithm has the advantage that an erased PFlash range delivers ECC correct 0 data.

Consequently all-0 data and ECC is not reported as an error.

Note: Please note that this algorithm (in contrast to the Audo generation) does not have all-1 ECC bits for all-1 data, i.e. over-programming a page with all-1 will not create an ECC clean data block.

The error detection, reporting and correction capabilities for single-bit, double-bit and triple-bit errors is identical to the Safety ECC.

DFlash ECC Details

The DFlash ECC value is calculated over 64 data bits. This ECC has the following features:

- Correction of 1-bit, 2-bit and 3-bit errors.
- Detection of 4-bit errors.
- All-0 (data and ECC) is a correct code vector.
- All-1 (data and ECC) is a valid code vector.
- Address errors are not detected.

An erased data block has an ECC value 0000_H. Therefore an erased sector is free of ECC errors. A data block with all bits ‘1’ has an ECC value of $FFFF_H$. This is commonly used in EEPROM emulations to over-program data to mark it as “invalid”.

Error reporting and ECC disabling:

- Single-bit, double-bit, triple-bit errors:
  - Are noted in FSR.DFSBER, FSR.DFDBER, FSR.DFTBER respectively.

1) On some addresses additionally FSR.PFDBER is set.

  - Data and ECC value are corrected if this is not disabled with ECCRD.ECCORDIS[1)].
- Quad-bit error:
  - Is noted in FSR.DFMBER.
  - Causes a bus error if not disabled by MARD.TRAPDIS.

11.5.6.3 Margin Checks

The Flash memory offers a “margin check feature”: the limit which defines if a Flash cell is read as logic ‘0’ or logic ‘1’ can be shifted. This is controlled by the registers **MARP** and **MARD**.

After changing the read margin at least $t_{FL\_MarginDel}$ have to be waited before reading the affected Flash module.

11.5.6.4 PMU and Flash Register Supervision

Safety relevant registers of PMU and Flash are automatically protected against SEUs by the extensive ECC coverage of the complete PFlash read path.

Only the following configuration registers should be supervised by the safety software against accidental modification:

- FCON.STALL: However modification of this affects safety only in case of errors in the application software, when this is reading busy Flash banks.
- MARP.TRAPDIS: Not really safety relevant because all data read errors are anyhow notified to the SMU.

11.5.7 Interrupts and Traps

Generally the PMU reports fatal errors by issuing a bus error which is translated by the CPU into a trap (PMI sets PSE trap and DMI the DSE trap).

This is a list of conditions for reporting a bus error:

- Uncorrectable ECC error (if not disabled by MARP or MARD).
- Write access to read-only register.
- Write access to BootROM.
- Write access to an access controlled register or PFlash address range by a master without allowance by the register access protection (**Chapter 11.5.5.1**).
- Not allowed write access to protected register (e.g. SV or ENDINIT).
- Not allowed Flash read access with active read protection.
- Read and write access to all Flash memories when the Flash is in sleep mode.
- Read access to not available Flash memory.
- Read-modify-write access to the Flash memory.
- Read accesses to a busy Flash bank (if not disabled with **FCON**.STALL).

- Write access to DF0 address range when normal command interpreter is busy with a command.
- Read or write access to unoccupied register address.

Furthermore selected events can trigger interrupts. The service request nodes SRC_PMUp0/1 are documented in the IR[1].

The following events can trigger the SRC_PMUp0 service request node when enabled by **FCON**:

- End of busy: any transition of any of the FSR flags P0BUSY, P1BUSY, D0BUSY or D1BUSY from ‘1’ to ‘0’ triggers the interrupt (program and erase sequences, wake-up).
- Operational error: see OPER flag.
- Verify error: see PVER, EVER flags.
- Protection error: see PROER flag.
- Sequence error: see SQER flag.

The event that triggered the interrupt can be determined from the **FSR** register.

An interrupt event it also triggered when the event appears again and the corresponding status flag is still set.

The requested read feature (**Chapter 11.5.3.4**) signals availability of data with a separate read interrupt via SRC_PMUp1. This can be used to trigger a DMA controller.

The HSM command interface can trigger an application interrupt at the HSM module. The following events are notified when enabled by **HSMFCON**:

- End of busy: any transition from ‘1’ to ‘0’ of any of the **HSMFSR** busy flags.
- Operational error and verify error when any of the **HSMFSR** flags OPER, PVER, EVER gets set.
- Protection error when **HSMFSR**.PROER is set.
- Sequence error when **HSMFSR**.SQER is set.

11.5.8 Reset and Startup

The PMU is reset with the application reset with the exception of the following resources:

- Register bits: FSR.PROG, FSR.ERASE, FSR.OPER. These bits are reset with the power-on reset.
- The complete CBAB and UBAB (see **Chapter 11.7.2.13** and **Chapter 11.7.2.14**) including their status registers. These are also reset with the power-on reset.

The Flash module and the FSI are only reset with the system reset.

When during a Flash operation (program, erase) an application reset occurs the FSI is not reset but the operation is aborted to ensure that the Flash is readable during startup (see **Chapter 11.8.5**).

1) The parameter “p” in SRC_PMUp0/1 is “0” for PMU0 and “1” for PMU1.

During startup after the application reset the protection setting is installed from the UCBs. If a protection field has an uncorrectable error its copy is used. This is indicated by setting FSR.ORIER. If a copy has also an uncorrectable error the startup software does not enter the user code.

11.5.9 Power Reduction

The Flash module can enter sleep mode to reduce its power consumption. The sleep request can have two sources:

- Global sleep mode requested by the SCU (see “Power Management”). Only executed by the Flash when FCON.ESLDIS = 0.
- Writing ‘1’ to the bit FCON.SLEEP.

After receiving a sleep request the Flash starts the ramp down when the Flash becomes idle, i.e. none of the banks is in command mode and no reads are executed anymore. An ongoing read burst is finished completely. During ramp down to sleep mode all FSR.BUSYx are set.

The sleep mode is indicated in FSR.SLM. The FSR.BUSYx stay set.

The Flash module can be woken up by releasing the sleep request. It enters read mode again after t_{WU}. During the wake-up phase the FSR.BUSYx are set.

Note: It is not recommended to use the SCU controlled sleep mode with FCON.ESLDIS = 0. Because software had to ensure that upon wake-up the Flash is only read after it has returned to read mode. Earlier reads cause bus errors! Therefore the reset value of FCON.ESLDIS is 1.

Note: Requesting sleep mode does not disable automatically an enabled end-of-busy interrupt. When requesting sleep mode during an ongoing Flash operation with enabled end-of-busy interrupt, the operation finishes, the interrupt is issued and then the Flash enters sleep mode. However this end-of-busy interrupt will wake-up the CPU again.

An additional power reduction feature is enabled by setting FCON.IDLE. In this case the PFlash read path is switched off when no read access is pending and the read buffers are filled. System performance is slightly reduced because a flash line hit can not be exploited.

11.6 Signaling to the Safety Management Unit (SMU)

The Safety Management Unit “SMU” is described in its own chapter. This section describes the signaling from the PMU to the SMU.

The following error conditions are internally detected and reported to the SMU:

- PMU registers are automatically supervised by the extensive ECC coverage of the PFlash read path (see **Chapter 11.5.6.4**). No dedicate alarm is reported to the SMU.

- PFlash detected ECC errors. There are separate signals for corrected single-bit errors, corrected double-bit errors, address errors and uncorrected bit errors.
- CBAB became full.
- SRI ECC errors from address phase, data write phase, data read phase.

The ECC correction logic of each PFlash read path is continuously supervised by the “ECC Monitor”. A detected error is notified to the SMU.

The detection of this error can be checked by disabling the error correction with ECCRPp.ECCORDIS and reading ECC errored data from PFlash. As the correction is disabled the checker reports an error in the correction logic.

The ECC error detection logic of each PFlash read path is also independently continuously supervised by a redundant error detection unit and a comparator “EDC Comparator”. A detected error is notified to the SMU.

The detection of this error can be checked separately for each PFlash “p” error detection logic by setting bit ECCERRPp.EDCERRINJ. An error is injected in the checked detection path.

11.7 Register Set

The register set consists of some general PMU registers which are partly only implemented for PMU0 because they control its specific functionality (**Chapter 11.7.1**). The other registers control Flash functionality (**Chapter 11.7.2**). Register fields related to DFlash and its sub-sectors are implemented also when these Flash banks or their functionality is not available but they are without function.

The register access conditions use the following abbreviations:

- “U”: Access permitted in User Mode 0 or 1 (applicable to write and read).
- “SV”: Access permitted in Supervisor Mode (applicable to write and read).
- “E”: ENDINIT protected write. “E” means a write access is only allowed before ENDINIT or after disabling this protection with a password as described in the SCU chapter.
- “SE”: Safety ENDINIT protected write.
- “P”: The access is controlled by the master specific register access protection (**Chapter 11.5.5.1**).
- “H”: The access is only permitted for the HSM master or for Cerberus when HSM debug is enabled.
- “–” or “BE”: Access not permitted.

The PMU and Flash use the following combinations (see **Table 11-16** and **Table 11-18**):

- U, SV: access always allowed (i.e. in user mode or supervisor mode).
- P, U, SV: access always to masters allowed that are enabled by the register access protection (**Chapter 11.5.5.1**).
- P, SV: access only in supervisor mode for masters enabled by the register access protection.
- BE: access never allowed, causing a bus error.
- SV, E: access only in supervisor mode with disabled ENDINIT protection.
- P, SV, E: access only in supervisor mode with disabled ENDINIT protection for masters enabled by the register access protection.
- SV, SE: access only in supervisor mode with disabled Safety ENDINIT protection.

All accesses prevented due to these restrictions fail with a bus error.

Also accesses to unoccupied register addresses fail with a bus error.

Note: It is convention to use short register names (e.g. “FCON”) in the chapter that defines these registers. In all other chapters and in the development tools long register names are used that are a concatenation of the module instance (e.g. “PMU0” or “FLASH0”), an underscore and the short register name, i.e. “FLASH0_FCON”. This document uses for clarification also mostly the long names.

11.7.1 PMU Registers

Non-Flash related registers for the PMU. They have the prefix “PMUx_”.

Table 11-15 Registers Address Space

Module	Base Address	End Address	Note
PMU0	$F800\ 0500_H$	$F800\ 052B_H$	

Table 11-16 Registers Overview

Short Name	Description	Offset Addr.[1]	Access Mode		Reset	Page
			Read	Write		
ID	Module Identification	08_H	U, SV	BE	Application Reset	11-46

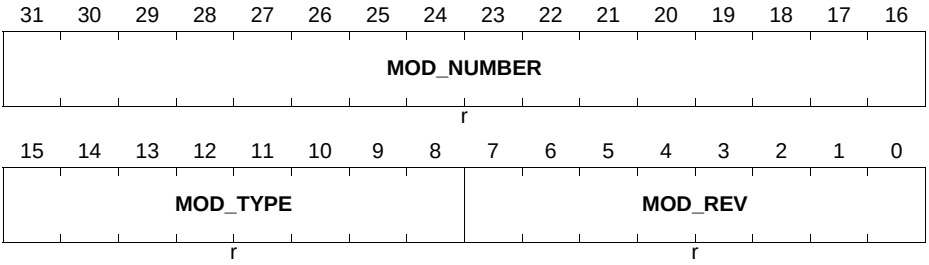
1) The absolute register address is calculated as follows:
Module Base Address (**Table 11-15**) + Offset Address (shown in this column)

11.7.1.1 PMU Identification

The PMU_ID register identifies the PMU and its version.

PMU0_ID

PMU0 Identification Register (F800 0508$_H$) Reset Value: 00D4 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first rev.).

Field	Bits	Type	Description
MOD_TYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines the module identification number for PMU0.

11.7.2 Flash Registers

The absolute address of a Flash register is calculated by the base address from **Table 11-17** plus the offset address of this register from **Table 11-18**.

Table 11-17 Registers Address Space

Module	Base Address	End Address	Note
FLASH0	F800 1000_H	F800 $23FF_H$	Flash registers of PMU0

1) The absolute register address is calculated as follows:
Module Base Address (**Table 11-17**) + Offset Address (shown in this column)

2) Some bits are not reset with the application reset but only with the power-on reset.

11.7.2.1 Master Specific Access Control

The master specific access control is described in **Chapter 11.5.5.1**.

Access Enable Register 0

The Access Enable Register 0 controls write access for transactions with the on-chip bus master TAG IDs 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID to master peripheral mapping). The PMU is prepared for a 6 bit TAG ID. The registers ACCEN0 and ACCEN1 provide one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, …, EN31 -> TAG ID 011111_B.

ACCEN0
Access Enable Register 0 ($13FC_H$) Reset Value: FFFF FFFF$_H$

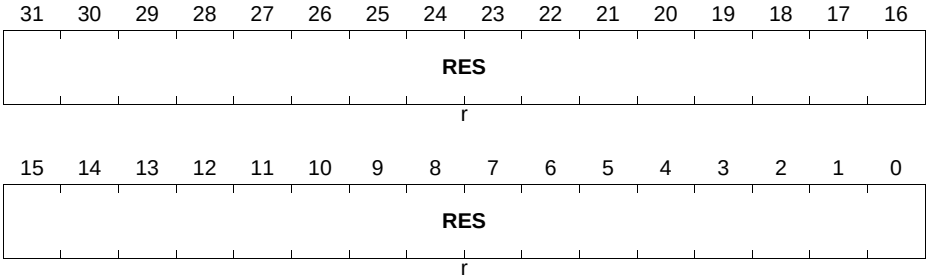
Field	Bits	Type	Description
ENx (x = 0-31)	x	rw	**Access Enable for Master TAG ID x** This bit enables write access to the protected resources (see **Chapter 11.5.5.1**) for transactions with the corresponding Master TAG ID 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID to master peripheral mapping). The PMU is prepared for a 6 bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

ACCEN1
Access Enable Register 1 **(13F8$_H$)** **Reset Value: 0000 0000$_H$**



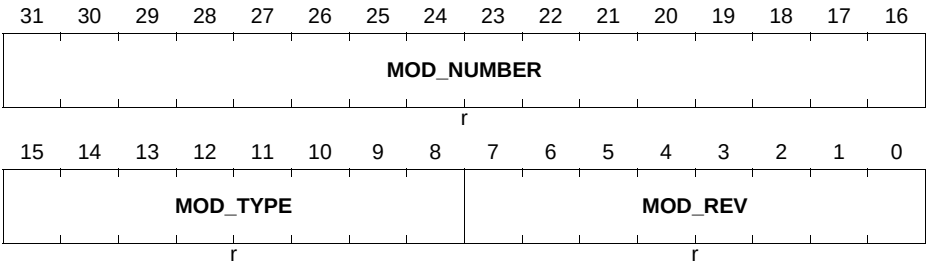
Field	Bits	Type	Description
RES	[31:0]	r	**Reserved** Read as 0; should be written with 0.

11.7.2.2 Flash Identification Register

The register identifies the Flash module which can have a different version from the PMU.

Flash Identification

ID
Flash Module Identification Register (1008$_H$) **Reset Value: 00DF (TC23x) / 00DE (TC22x) C0XX$_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. For the TC21x/TC22x/TC23x Flash0 this number is 00DF (TC23x) / 00DE (TC22x)$_H$.

11.7.2.3 Flash Status

The Flash Status Register FSR reflects the overall status of the Flash module after Reset and after reception of the different commands.

The error flags and the two status flags (PROG, ERASE) are affected by the “Clear Status” command. The error flags are also cleared with the “Reset to Read” command.

Some error flags are marked as writable. These flags can be cleared by writing a ‘1’ to this bit.

Flash Status Register

FSR
Flash Status Register **(1010_H)** **Reset Value: $0100\ 0000_H$[1)]**

rwh	rwh	rwh	rwh	rwh	rh	rh	rwh	rwh	rh	rh	rh	rh	rh	rh	rh

1) The startup process might report errors by setting some of the error flags.

Field	Bits	Type	Description
FABUSY	0	rh	**Flash Array Busy** [1)] Internal busy flag for testing purposes. Must be ignored by application software. This may only use PxBUSY and DxBUSY.
D0BUSY	1	rh	**Data Flash Bank 0 Busy**[1)] HW-controlled status flag. 0_B DFlash0 ready, not busy; DFlash0 in read mode. 1_B DFlash0 busy; DFlash0 not in read mode. Indication of busy state of DFlash bank 0 because of active execution of an operation; DFlash0 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the DFlash0 is not in read mode.
RES1	2	rh	**Reserved for Data Flash Bank 1 Busy**[1)]
P0BUSY	3	rh	**Program Flash PF0 Busy**[1)] HW-controlled status flag. 0_B PF0 ready, not busy; PF0 in read mode. 1_B PF0 busy; PF0 not in read mode. Indication of busy state of PF0 because of active execution of an operation; PF0 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state, the PF0 is not in read mode.
RES4	4	rh	**Reserved for Program Flash PF1 Busy**[1)]
RES5	5	rh	**Reserved for Program Flash PF2 Busy**[1)]
RES6	6	rh	**Reserved for Program Flash PF3 Busy**[1)]

Field	Bits	Type	Description
PROG	7	rwh	**Programming State** [2)3)] HW-controlled status flag. 0_B There is no program operation requested or in progress or just finished. 1_B Programming operation requested or in action or finished. Set with last cycle of Write Page/Burst command sequence, cleared with Clear Status command (if not busy) or with power-on reset. If one BUSY flag is coincidently set, PROG indicates the type of busy state. If OPER is coincidently set, PROG indicates the type of erroneous operation. Otherwise, PROG indicates, that operation is still requested or finished. Can be also cleared by writing '1' to it.
ERASE	8	rwh	**Erase State** [2)3)] HW-controlled status flag. 0_B There is no erase operation requested or in progress or just finished 1_B Erase/Verify operation requested or in action or finished. Set with last cycle of Erase/Verify command sequence, cleared with Clear Status command (if not busy) or with power-on reset. Indications are analogous to PROG flag. Can be also cleared by writing '1' to it.
PFPAGE	9	rh	**Program Flash in Page Mode**[1)4)] HW-controlled status flag. 0_B Program Flash not in page mode. 1_B Program Flash in page mode. Set with Enter Page Mode for PFlash, cleared with Write Page command *Note: Concurrent page and read modes are allowed*
DFPAGE	10	rh	**Data Flash in Page Mode**[1)4)] HW-controlled status flag. 0_B Data Flash not in page mode 1_B Data Flash in page mode Set with Enter Page Mode for DFlash, cleared with Write Page command. *Note: Concurrent page and read modes are allowed*

Field	Bits	Type	Description
OPER	11	rwh	**Flash Operation Error[2)3)4)]** 0_B No operation error. 1_B Flash array operation aborted, because of a Flash array failure, e.g. an ECC error in microcode. This bit is not cleared with application reset, but with power-on reset. Registered status bit; must be cleared per command or by writing ‘1’.
SQER	12	rwh	**Command Sequence Error[1)2)4)]** 0_B No sequence error 1_B Command state machine operation unsuccessful because of improper address or command sequence. A sequence error is not indicated if the Reset to Read command aborts a command sequence. Registered status bit; must be cleared per command or by writing ‘1’.
PROER	13	rwh	**Protection Error[1)2)4)]** 0_B No protection error 1_B Protection error. A Protection Error is reported e.g. because of a not allowed command, for example an Erase or Write Page command addressing a locked sector, or because of wrong password(s) in a protected command sequence such as “Disable Read Protection”. **A Protection Error is also reported if the safety protection (Chapter 11.5.5.2) prevented a program/erase operation in PFlash.** Registered status bit; must be cleared per command or by writing ‘1’.
PFSBER	14	rwh	**PFlash Single-Bit Error and Correction[1)2)4)]** 0_B No Single-Bit Error detected during read access to PFlash. 1_B Single-Bit Error detected. Registered status bit; must be cleared per command or by writing ‘1’.

Field	Bits	Type	Description
PFDBER	15	rwh	**PFlash Double-Bit Error[1)2)4)]** 0_B No Double-Bit Error detected during read access to PFlash. 1_B Double-Bit Error detected in PFlash. Registered status bit; must be cleared per command or by writing ‘1’.
PFMBER	16	rwh	**PFlash Uncorrectable Error[1)2)4)]** 0_B No uncorrectable error (3-bit error or more, address error, all-0/all-1) detected during read access to PFlash. 1_B Uncorrectable error (3-bit error or more, address error, all-0/all-1) detected in PFlash. Registered status bit; must be cleared per command or by writing ‘1’.
RES17	17	rwh	**Reserved[1)2)4)]** Registered status bit; must be cleared per command or by writing ‘1’.
DFSBER	18	rwh	**DFlash Single-Bit Error[1)2)4)]** 0_B No Single-Bit Error detected during read access to DFlash. 1_B Single-Bit Error detected. Registered status bit; must be cleared per command or by writing ‘1’.
DFDBER	19	rwh	**DFlash Double-Bit Error[1)2)4)]** 0_B No Double-Bit Error detected during read access to DFlash. 1_B Double-Bit Error detected. Registered status bit; must be cleared per command or by writing ‘1’.
DFTBER	20	rwh	**DFlash Triple-Bit Error[1)2)4)]** 0_B No Triple-Bit Error detected during read access to DFlash. 1_B Triple-Bit Error detected. Registered status bit; must be cleared per command or by writing ‘1’.

Field	Bits	Type	Description
DFMBER	21	rwh	**DFlash Uncorrectable Error[1)2)4)]** 0_B No uncorrectable error detected during read access to DFlash 1_B Uncorrectable error detected in DFlash. Registered status bit; must be cleared per command or by writing ‘1’.
SRIADDERR	22	rwh	**SRI Bus Address ECC Error[1)2)4)]** This flag is set when the PMU detects an ECC error in the address phase bus transaction on the SRI bus. 0_B No SRI address error detected. 1_B SRI address error detected. Registered status bit; must be cleared by writing ‘1’.
RES	24	rwh	**Reserved** Write zero. Read value unpredictable.
PVER	25	rwh	**Program Verify Error[1)2)4)]** A verify error was reported during a Flash program operation. 0_B The page is correctly programmed. All bits have full expected quality. 1_B A program verify error has been detected. Full quality of all bits cannot be guaranteed. Registered status bit; must be cleared per command or writing ‘1’.
EVER	26	rwh	**Erase Verify Error[1)2)4)]** A verify error was reported during a Flash erase operation. 0_B The sector is correctly erased. All erased bits have full expected quality. 1_B An erase verify error has been detected. Full quality erased bits cannot be guaranteed. Registered status bit; must be cleared per command or writing ‘1’.

Field	Bits	Type	Description
SPND	27	rwh	**Operation Suspended**[3)] Requested by MARD.SPND a program or erase operation is suspended. 0_B No Flash operation is suspended. 1_B Suspended Flash operation. Can be also cleared by writing '1' to it to clean up after a reset that killed a suspended operation context.
SLM	28	rh	**Flash Sleep Mode**[1)] HW-controlled status flag. Indication of Flash sleep mode taken because of global or individual sleep request; additionally indicates when the Flash is in shut down mode. 0_B Flash not in sleep mode 1_B Flash is in sleep or shut down mode
ORIER	30	rh	**Original Error**[1)2)4)] 0_B No original error detected during startup. 1_B Original data replaced by its copy.
0	31, 29, 23	r	**Reserved** Read zero, no write

1) Cleared with application reset
2) Cleared with command "Clear Status"
3) Cleared with power-on reset (PORST)
4) Cleared with command "Reset to Read"

Note: The xBUSY flags cannot be cleared with the "Clear Status" command or with the "Reset to Read" command. These flags are controlled by HW.

11.7.2.4 Flash Configuration Control

The Flash Configuration Register FCON reflects and controls the general Flash configuration functions.

FCON
Flash Configuration Register (1014_H) Reset value: 0091 XXXX$_H$[1)]

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EOBM	PR5V	0			PROERM	SQERM	VOPERM	RES23		RES21		STALL	NSAFEC	SLEEP	ESLDIS
rw	rw	r			rw	rw	rw	rh		rh		rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDLE	WSECDF			WSDFLASH						WSECPF		WSPFLASH			
rw	rw			rw						rw		rw			

1) The wait-cycles WSECDF, WSDFLASH, WSECPF and WSPFLASH are changed by the startup after system and power-on resets. **Attention: the configured value is only sufficient for the clock configuration used during startup.** The wait-cycles have to be configured after startup as described in **Chapter 11.5.3.3** before changing to higher clock frequencies.

Field	Bits	Type	Description
WSPFLASH	[3:0]	rw	**Wait States for read access to PFlash** This bitfield defines the number of wait states in number of FSI2 clock cycles, which are used for an initial read access to the Program Flash memory area (see **Chapter 11.5.3.3**). 0_D Read access takes 1 FSI2 clock cycle. 1_D Read access takes 2 FSI2 clock cycles. $...{}_D$ ...
WSECPF	[5:4]	rw	**Wait States for Error Correction of PFlash** This bitfield defines the number of wait-states for the ECC correction in FSI2 clock cycles (see **Chapter 11.5.3.3**). 0_D Error correction takes 1 FSI2 clock cycle. 1_D Error correction takes 2 FSI2 clock cycles. $...{}_D$ ...

Field	Bits	Type	Description
WSDFLASH	[11:6]	rw	**Wait States for read access to DFlash** This bitfield defines the number of wait states in number of FSI clock cycles, which are used for a read access to the Data Flash memory area (see **Chapter 11.5.3.3**). 0_D Read access takes 1 FSI clock cycle. 1_D Read access takes 2 FSI clock cycles. $...{}_D$ ...
WSECDF	[14:12]	rw	**Wait State for Error Correction of DFlash** This bitfield defines the number of wait-states for the ECC correction in FSI clock cycles (see **Chapter 11.5.3.3**). 0_D Error correction takes 1 FSI clock cycle. 1_D Error correction takes 2 FSI clock cycles. $...{}_D$ ...
IDLE	15	rw	**Dynamic Flash Idle** 0_B Normal/standard Flash read operation 1_B Dynamic idle of Program Flash enabled for power saving; static prefetching disabled *Note: In Data Flash, dynamic idle is always enabled (prefetching not supported).* Initial value after startup is 0_B.
ESLDIS	16	rw	**External Sleep Request Disable** 0_B External sleep request signal input is enabled 1_B Externally requested Flash sleep is disabled The ‘external’ signal input is connected with a global power-down/sleep request signal from SCU.
SLEEP	17	rw	**Flash SLEEP** 0_B Normal state or wake-up 1_B Flash sleep mode is requested, Wake-up from sleep is started with clearing of the SLEEP-bit.

Field	Bits	Type	Description
NSAFECC	18	rw	**Non-Safety PFlash ECC** This bit selects if the data in PFlash is written and read with the “Safety” ECC code (calculated over address bits), or the “Legacy” ECC code (see **Chapter 11.5.6**). 0_B Safety ECC is used. 1_B Legacy ECC is used. **Attention: this bit must not be changed while accessing Flash (reading, programming, erasing).** Initial value after startup depends on PROCOND.NSAFECC.
STALL	19	rw	**Stall SRI** This field selects if reading from busy Flash banks causes a bus error or wait-states until busy is cleared again. 1_B **Stall**, Reading busy Flash banks suppresses the SRI bus ready effectively causing wait-states until busy is cleared. 0_B **Error**, Reading busy Flash banks causes a bus error. *Note: This field must not be changed while any bank is busy. The results are unpredictable. Generally it’s strongly recommended to configure this field once and avoid changing it during operation.* *Note: Reading Flash in sleep mode causes always a bus error independent of this field (although it reports “busy”).*
RES21	[21:20]	rh	**Reserved** Write 0; Read value unpredictable.
RES23	[23:22]	rh	**Reserved** Write 0; Read value unpredictable.
VOPERM	24	rw	**Verify and Operation Error Interrupt Mask** 0_B Interrupt not enabled 1_B Flash interrupt because of Verify Error or Operation Error in Flash array (FSI) is enabled
SQERM	25	rw	**Command Sequence Error Interrupt Mask** 0_B Interrupt not enabled 1_B Flash interrupt because of Sequence Error is enabled

Field	Bits	Type	Description
PROERM	26	rw	**Protection Error Interrupt Mask** 0_B Interrupt not enabled 1_B Flash interrupt because of Protection Error is enabled
EOBM	31	rw	**End of Busy Interrupt Mask** 0_B Interrupt disabled. 1_B EOB interrupt is enabled.
PR5V	30	rw	**Programming Supply 5V** Selects the supply for programming. **Attention: In this 3.3 V device the setting "P5V" is forbidden!** 0_B **P3V**, The programming voltage is internally generated. 1_B **P5V**, As programming voltage the external 5 V supply is used. **Forbidden!**
0	[29:27]	r	**Reserved** Write 0; Read 0.

Note: The default numbers of wait states represent the slow cases. This is a general proceeding and additionally opens the possibility to execute higher frequencies without changing the configuration.

11.7.2.5 Flash Protection

Flash Protection Control and Status Register

This register reports the state of the Flash protection (see **Chapter 11.5.5.5**) and contains protection relevant control fields.

FPRO
Flash Protection Control and Status Register
($101C_H$) **Reset Value: $00XX\ 00A0_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								ENPE		0	DDFD	0	DDFPX	DDFP	DCFP
r								rw		r	rwh	r	rwh	rwh	rwh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					PROINHSM	PRODISDBG	PROINDBG	RES7	PROINOTP	RES5	PROINHSMCOTP	PRODISD	PROIND	PRODISP	PROINP
r					rh	rh	rh	r	rh	r	rh	rh	rh	rh	rh

Field	Bits	Type	Description
PROINP	0	rh	**PFlash Protection** This bit reflects the confirmed state of UCB_PFlash.
PRODISP	1	rh	**PFlash Protection Disabled**[1)] The protection configured by UCB_PFlash was successfully disabled by supplying the correct password to “Disable Protection”.
PROIND	2	rh	**DFlash Protection** This bit reflects the confirmed state of UCB_DFlash.
PRODISD	3	rh	**DFlash Protection Disabled**[1)] The protection configured by UCB_DFlash was successfully disabled by supplying the correct password to “Disable Protection”.
PROINHSMCOTP	4	rh	**HSM OTP Protection** This bit reflects the confirmed state of UCB_HSMCOTP.
RES5	5	rh	**Reserved** Read value don’t care, updated during startup; should be written with 0.
PROINOTP	6	rh	**OTP and Write-Once Protection** This bit reflects the confirmed state of UCB_OTP.

Field	Bits	Type	Description
RES7	7	rh	**Reserved** Read value don't care, updated during startup; should be written with 0.
PROINDBG	8	rh	**Debug Interface Password Protection** This bit reflects the confirmed state of UCB_DBG.
PRODISDBG	9	rh	**Debug Interface Password Protection Disabled**[1)] The password configured by UCB_DBG was correctly received with "Disable Protection". When PROCONHSMCOTP.DESTDBG is "destructive" then only the SSW can disable this protection.
PROINHSM	10	rh	**HSM Configuration** This bit reflects the confirmed state of UCB_HSM.
DCFP	16	rwh	**Disable Code Fetch from PFlash Memory for CPU0 PMI** This bit enables/disables the code fetch from the internal PFlash memory area for CPU0 PMI (see **Chapter 11.5.5.3**). Once set, this bit can only be cleared when FPRO.PRODISP or not PROCONP0.RPRO. This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash. 0_B Code fetching by CPU0 from the PFlash memory area is allowed. 1_B Code fetching by CPU0 from the PFlash memory area is not allowed.

Field	Bits	Type	Description
DDFP	17	rwh	**Disable Read from PFlash for CPU0 DMI** This bit enables/disables the read access to the PFlash memory area by for CPU0 DMI (see **Chapter 11.5.5.3**). Once set, this bit can only be cleared when FPRO.PRODISP or not PROCONP0.RPRO. This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash. 0_B Read access to the PFlash memory area is allowed. 1_B Read access to the PFlash memory area is not allowed.
DDFPX	18	rwh	**Disable Read from PFlash for Other Masters** This bit enables/disables the read access to PFlash for other masters (see **Chapter 11.5.5.3**). Once set, this bit can only be cleared when FPRO.PRODISP or not PROCONP0.RPRO. This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash. 0_B The read access by other masters to the PFlash memory area is allowed. 1_B The read access to the PFlash memory area is not allowed for other masters.
DDFD	20	rwh	**Disable Data Fetch from DFlash Memory** This bit enables/disables the data fetch from the internal DFlash memory area (see **Chapter 11.5.5.3**). Once set, this bit can only be cleared when FPRO.PRODISD or not PROCOND.RPRO. This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash. 0_B Data fetching from the DFlash memory area is allowed. 1_B Data fetching from the DFlash memory area is not allowed.

Field	Bits	Type	Description
ENPE	[23:22]	rw	**Enable Program/Erase** The field prevents any Flash program or erase directly in the FSI. It is set to Enabled by the SSW upon finishing the startup. 01_B **Enabled**, Program/Erase are enabled in the FSI. 10_B **Disabled**, Program/Erase are disabled in the FSI. others: Illegal values, disabled also Program/Erase. Once in “Enabled” state this field can’t be changed anymore.
0	[31:24], 21, 19, [15:11]	r	**Reserved** Always read as 0; should be written with 0.

1) Cleared with command “Resume Protection”.

Notes

After reset and execution of BootROM startup SW, the read protection control bits are set to the following values:

- Start not in internal Flash:
  - DCFP set to PROCONP0.RPRO.
  - DDFP set to PROCONP0.RPRO.
  - DDFPX set to PROCONP0.RPRO.
  - DDFD set to PROCOND.RPRO.
- Start in internal Flash:
  - DCFP, DDFP, DDFPX, DDFD set to 0.
- Independent of the start configuration: the PROIN fields are set depending on the content of their assigned UCB sectors.

Attention! Before disabling read access by setting any of the DCF* and DDF* flags all pending read accesses to the affected Flash ranges should have finished.

11.7.2.6 Protection Configuration

The configuration of read/write/OTP protection is indicated with registers PROCONP, PROCOND, PROCONHSMCOTP, PROCONOTP, PROCONWOP, PROCONHSM and PROCONDBG.

PFlash Protection Configuration

When UCB_PFlash is in errored state the initial value is “FFFF FFFF$_H$”, else the initial value after Flash startup reflects the UCB_PFlash content (**Table 11-8**).

PROCONPp (p=0-0)
PFlash Protection Configuration PFp

(1020$_H$+p*4$_H$) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

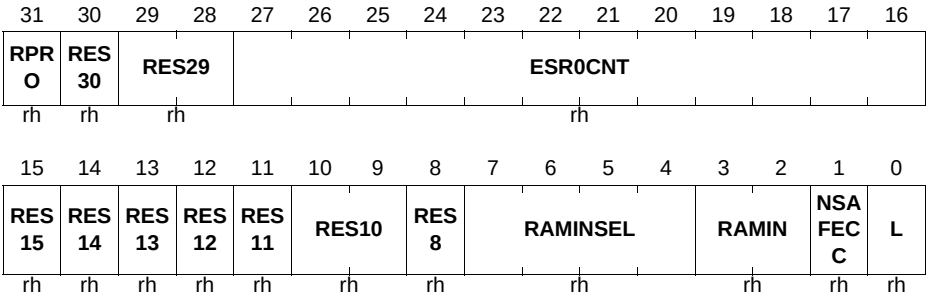
Field	Bits	Type	Description
SxL (x=0-26)	x	rh	**PFlash p Sector x Locked for Write Protection** These bits indicate whether PFLASH sector x is write-protected. 0_B No write protection is configured for sector x. 1_B Write protection is configured for sector x. In PMU0 PROCONP0 the S6L, S16L and S17L are only effective if these HSM code sectors are not HSM_exclusive.
RPRO	31	rh	**Read Protection Configuration** This bit indicates whether read protection is configured for PFLASH. This bit is only used in PROCONP0. In other PROCONPs it is reserved. 0_B No read protection configured 1_B Read protection and global write protection is configured.
RES	[30:27]	rh	**Reserved** Deliver the corresponding content of UCB_PFlash.

DFlash Protection Configuration

Only existing in PMUs with DFlash.

When UCB_DFlash is in errored state the initial value is “8000 0000$_H$”, else the initial value after Flash startup reflects the UCB_DFlash content (**Table 11-9**).

PROCOND
DFlash Protection Configuration (1030$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
L	0	rh	**DF_EEPROM Locked for Write Protection** This bit indicates whether the DFlash sectors EEPROMx are write protected. 0_B No write protection is configured. 1_B Write protection is configured.
NSAFECC	1	rh	**Non-Safety PFlash ECC** This bit indicates whether the SSW selects the “Safety” PFlash ECC algorithm or the “Legacy” ECC. 0_B Safety ECC is configured. 1_B Legacy ECC is configured.

Field	Bits	Type	Description
RAMIN	[3:2]	rh	**RAM Initialization by SSW Control** These bits defined whether the RAMs selected by the field RAMINSEL are initialized. 00_B **Init_All**, RAM initialization is performed after cold power-on resets and warm power-on resets. 01_B **Init_Warm**, RAM initialization is performed after warm power-on resets but not after cold power-on resets (not recommended). 10_B **Init_Cold**, RAM initialization is performed after cold power-on resets. 11_B **No_Init**, No RAM initialization is performed. This field determines also if a RAM is initialized before MBIST access is granted. In all “Init_*” cases a RAM is initialized before MBIST access is enabled, in the “No_Init” case a RAM is not erased. This is independent of the memory selection with RAMINSEL for initialization during startup (see MTU chapter).
RAMINSEL	[7:4]	rh	**RAM Initialization Selection** These bits select which memories are initialized when the RAM initialization is configured with RAMIN. Each bit with value ‘0’ selects the corresponding memory for initialization. $xxx0_B$ RAMs (PSPR, DSPR, PCACHE and DCACHE) in CPU0 are selected for initialization. $xx0x_B$ Reserved for CPU1. $x0xx_B$ Reserved for CPU2. $0xxx_B$ LMU RAMs are selected for initialization.
RESx(x=8-15)	x	rh	**Reserved** Deliver the corresponding content of UCB_DFlash.
ESR0CNT	[27:16]	rh	**ESR0 Prolongation Counter** Used to configure the ESR0 delay. Evaluation by SSW.
RES29	[29:28]	rh	**Reserved** Deliver the corresponding content of UCB_DFlash.

Field	Bits	Type	Description
RES30	30	rh	**Reserved** Deliver the corresponding content of UCB_DFlash.
RPRO	31	rh	**Read Protection Configuration** This bit indicates whether read protection is configured for DFlash sectors EEPROMx. 0_B No read protection configured 1_B Read protection and write protection is configured.

OTP Protection Configuration

After Flash startup this register represents the or-combination of all PROCONOTP entries of all confirmed configuration sets in UCB_OTP (**Table 11-10**).

When any OTP set is in the errored state the initial content is forced to "3FFF FFFF$_H$".

PROCONOTPp (p=0-0)
OTP Protection Configuration PFp

(1038_H+p*4_H) **Reset Value: 0000 0000$_H$**

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
SxROM (x=0-26)	x	rh	**PFlash p Sector x Locked Forever** These bits indicate whether PFlash p sector x is an OTP protected sector with read-only functionality. 0_B No OTP protection is configured for sector x. 1_B OTP protection is configured for sector x. In PMU0 PROCONOTP0 the S6ROM, S16ROM and S17ROM are not effective. These HSM code sectors are OTP protected by PROCONHSMCOTP.

Field	Bits	Type	Description
TP	31	rh	**Tuning Protection** This bit indicates whether tuning protection is installed or not. This bit is only evaluated in PMU0 PROCONOTP0. In other PMUs and PROCONOTPs it is reserved. 0_B Tuning protection is not configured. 1_B Tuning protection is configured and installed, if correctly confirmed.
RES	[28:27]	rh	**Reserved** Deliver the corresponding content of UCB_OTP.
BML	[30:29]	rh	**Boot Mode Lock** Only used in PMU0 PROCONOTP0, in other PROCONOTPs these bits are reserved. Used by the SSW to restrict the boot mode selection. 00_B Boot flow with standard evaluation of boot headers. 01_B Restricted boot flow, never evaluating HWCFG pins and without fallback to boot loader. 10_B Restricted boot flow, never evaluating HWCFG pins and without fallback to boot loader. 11_B Restricted boot flow, never evaluating HWCFG pins and without fallback to boot loader.

Write-Once Protection Configuration

After Flash startup this register represents the or-combination of all PROCONWOP entries of all confirmed configuration sets in UCB_OTP (**Table 11-10**).

When any OTP set is in the errored state the initial content is forced to “FFFF FFFF$_H$”.

PROCONWOPp (p=0-0)
Write-Once Protection Configuration PFp

(1048_H+p*4_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
SxWOP (x=0-26)	x	rh	**PFlash p Sector x Configured for Write-Once Protection** These bits indicate whether PFlash p sector x is an WOP protected sector. 0_B No WOP protection is configured for sector x. 1_B WOP protection is configured for sector x. In PMU0 PROCONWOP0 the S6WOP, S16WOP and S17WOP are not effective. These HSM code sectors are OTP protected by PROCONHSMCOTP.
DATM	31	rh	**Disable ATM** This bit indicates if the ATM “Application Test Mode” is disabled or not. 0_B ATM is enabled. 1_B ATM is disabled. This bit is only used in the PMU0 PROCONWOP0. In other PMUs and PROCONWOPs it is reserved.
RES	[30:27]	rh	**Reserved** Deliver the corresponding content of UCB_OTP.

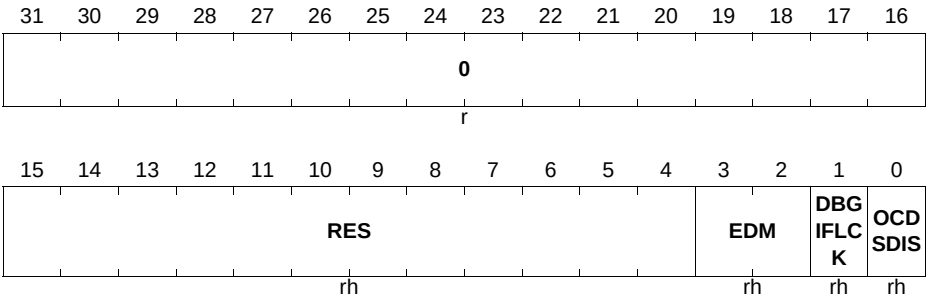
Debug Interface Protection Configuration

The debug interface and OCDS enable have a dedicated password protection logic.

When UCB_DBG is in errored state the initial value is “0000 $FFFF_H$”, else the initial value after Flash startup reflects the UCB_DBG content (**Table 11-12**).

PROCONDBG
Debug Interface Protection Configuration

(1058_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OCDSDIS	0	rh	**OCDS Disabled** This bit indicates whether the OCDS is configured as locked. 0_B No OCDS lock configured in UCB_DBG. 1_B OCDS lock configured in UCB_DBG.
DBGIFLCK	1	rh	**Debug Interface Locked** This bit indicates whether the debug interface is configured as locked. 0_B No debug interface lock configured in UCB_DBG. 1_B Debug interface lock configured in UCB_DBG.

Field	Bits	Type	Description
EDM	[3:2]	rh	**Entered Debug Mode** This bit indicates whether the debug interface has been opened via the "**Destructive Debug Entry**" (**Page 11-37**). Consequently the CAN and Flexray operation is made impossible! 00_B "Debug not entered", device operation not affected. 01_B "Debug not entered", device operation not affected. 10_B "Debug not entered", device operation not affected. 11_B "Debug entered", CAN and Flexray operation affected.
RES	[15:4]	rh	**Reserved** Deliver the corresponding content of UCB_DBG.
0	[31:16]	r	**Reserved** Always read as 0; should be written with 0.

HSM Code Flash OTP Protection Configuration

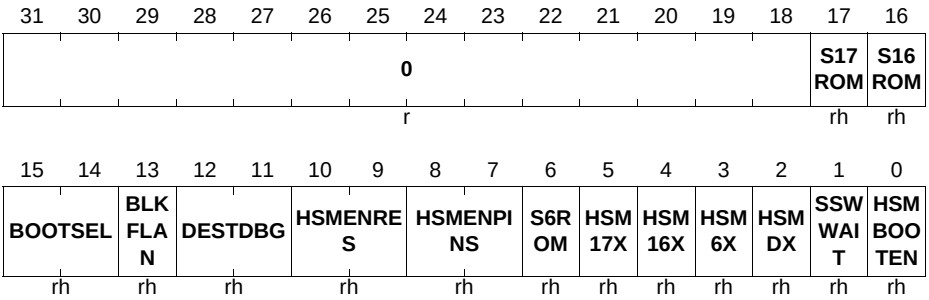
The HSM code sectors have also their own OTP protection configuration. This register represents after Flash startup the or-combination of all PROCONHSMCOTP entries of all confirmed configuration sets in UCB_HSMCOTP (see **Table 11-13**).

When any OTP set is in the errored state the initial content is forced to "0003 $007F_H$".

When configuring any HSM_exclusive protection it is strongly recommended to activate all four HSM_exclusive bits.

When enabling HSM boot with HSMBOOTEN is it strongly recommended to use all HSM code sectors only for HSM code but not for Tricore code or data.

PROCONHSMCOTP
HSM Code Flash OTP Protection Configuration
(1034_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
HSMBOOTEN	0	rh	**HSM Boot Enable** 0_B HSM Boot is not enabled. 1_B HSM Boot is enabled. HSMBOOTEN must not be set to 1 in devices without HSM.
SSWWAIT	1	rh	**SSW Wait** Defines if the SSW waits for the HSM to release the jump of CPU0 to user code. 0_B The SSW does not wait for HSM. 1_B SSW wait for acknowledge of HSM.
HSMDX	2	rh	**HSM Data Sectors Exclusive** This bit indicates whether the HSM data sectors HSMx are configured as “HSM_exclusive”. 0_B HSMx are not HSM_exclusive. 1_B HSMx are HSM_exclusive.
HSM6X	3	rh	**HSM Code Sector 6 Exclusive** This bit indicates whether the HSM code sector S6 is configured as “HSM_exclusive”. 0_B S6 is not HSM_exclusive. 1_B S6 is HSM_exclusive.

Field	Bits	Type	Description
HSM16X	4	rh	**HSM Code Sector 16 Exclusive** This bit indicates whether the HSM code sector S16 is configured as “HSM_exclusive”. 0_B S16 is not HSM_exclusive. 1_B S16 is HSM_exclusive.
HSM17X	5	rh	**HSM Code Sector 17 Exclusive** This bit indicates whether the HSM code sector S17 is configured as “HSM_exclusive”. 0_B S17 is not HSM_exclusive. 1_B S17 is HSM_exclusive.
S6ROM	6	rh	**HSM Code Sector 6 Locked Forever** This bit indicates whether PFlash sector 6 is an OTP protected sector with read-only functionality. 0_B No OTP protection is configured. 1_B OTP protection is configured.
HSMENPINS	[8:7]	rh	**Enable HSM Forcing of Pins HSM1/2** This bit indicates whether HSM may force the value of the pins HSM1/2 (i.e. overrule the value driven by the application). 00_B HSM can’t force pins. 01_B HSM can’t force pins. 10_B HSM can’t force pins. 11_B HSM can force pins.
HSMENRES	[10:9]	rh	**Enable HSM Triggering Resets** This bit indicates whether HSM may trigger application or system resets. 00_B HSM can’t trigger resets. 01_B HSM can’t trigger resets. 10_B HSM can’t trigger resets. 11_B HSM can trigger resets.
DESTDBG	[12:11]	rh	**Destructive Debug Entry** This field configures the destructive debug entry (see **Destructive Debug Entry** on **Page 11-37**). 00_B Debug entry is non-destructive. 01_B Debug entry is non-destructive. 10_B Debug entry is non-destructive. 11_B Debug entry is destructive.

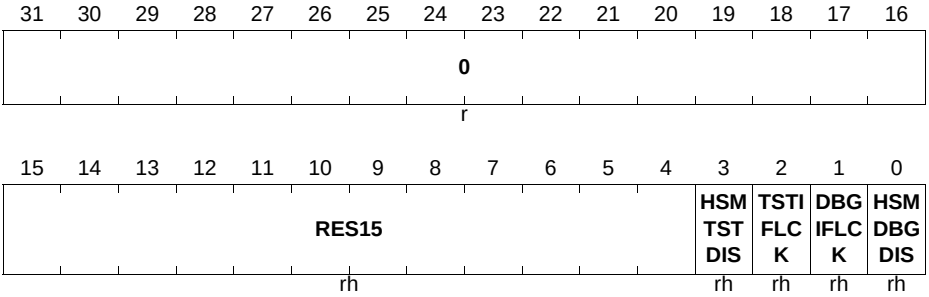
Field	Bits	Type	Description
BLKFLAN	13	rh	**Block Flash Analysis** This bit allows to block the command “Verify Erased Logical Sector Range” on certain HSM related Flash ranges as described on **Page 11-21**. 0_B Functions allowed on all Flash ranges. 1_B Functions blocked on HSM_exclusive Flash ranges.
BOOTSEL	[15:14]	rh	**Boot Sector Selection** This field controls which of the HSM code sectors S6, S16, S17 is searched for boot code. 00_B Sectors S6, S16 and S17 are searched. 01_B Sectors S6 and S16 are searched. 10_B Sector S6 is searched. 11_B Sector S17 is searched.
S16ROM	16	rh	**HSM Code Sector 16 Locked Forever** This bit indicates whether PFlash sector 16 is an OTP protected sector with read-only functionality. 0_B No OTP protection is configured. 1_B OTP protection is configured.
S17ROM	17	rh	**HSM Code Sector 17 Locked Forever** This bit indicates whether PFlash sector 17 is an OTP protected sector with read-only functionality. 0_B No OTP protection is configured. 1_B OTP protection is configured.
0	[31:18]	r	**Reserved** Always read as 0; should be written with 0.

HSM Interface Configuration

Only existing in PMU0. Content only evaluated in devices with activated HSM.

When UCB_HSM is in errored state the initial value is “0000 FFFF$_H$”, else the initial value after Flash startup reflects the UCB_HSM content (**Table 11-14**).

PROCONHSM
HSM Interface Configuration (105C$_H$) **Reset Value: 0000 0000$_H$**



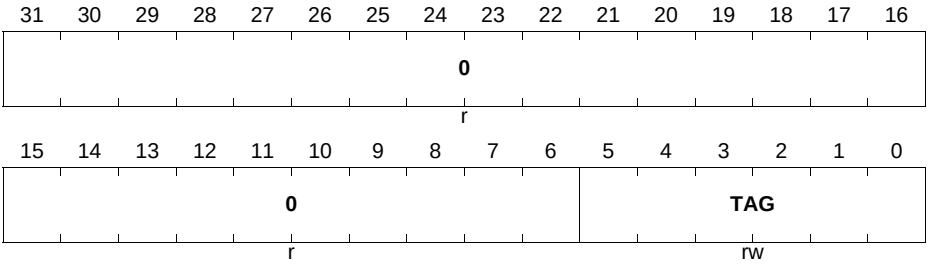
Field	Bits	Type	Description
HSMDBGDIS	0	rh	**HSM Debug Disable** This bit indicates whether HSM debug is configured as “disabled”. 0_B HSM debug is enabled. 1_B HSM debug is disabled.
DBGIFLCK	1	rh	**Debug Interface Locked** This bit indicates whether the chip debug interface is configured as “locked”. 0_B Debug is unlocked. 1_B Debug is locked.
TSTIFLCK	2	rh	**Test Interface Locked** This bit indicates whether the chip test interface is configured as “locked”. 0_B Test interface is unlocked. 1_B Test interface is locked.
HSMTSTDIS	3	rh	**HSM Test Disable** This bit indicates whether the HSM test is configured as “disabled”. 0_B HSM test is enabled. 1_B HSM test is disabled.
RES15	[15:4]	rh	**Reserved** Deliver the corresponding content of UCB_HSM.
0	[31:16]	r	**Reserved** Always read as 0; should be written with 0.

11.7.2.7 Flash Read Buffer Configuration

The RDBCFGp0–2 registers define the assignment of read buffers to masters for each PFlash p read port. The functionality of the read buffers is described in **Chapter 11.5.3**.

Assigning the same master tag to more than one of the 3 read buffers of one read port does not increase the performance further.

RDBCFGp0 (p=0-0)
Read Buffer Port p Cfg 0 **(1060_H+p*C_H)** **Reset Value: 0000 0000_H**
RDBCFGp1 (p=0-0)
Read Buffer Port p Cfg 1 **(1064_H+p*C_H)** **Reset Value: 0000 0002_H**
RDBCFGp2 (p=0-0)
Read Buffer Port p Cfg 2 **(1068_H+p*C_H)** **Reset Value: 0000 0004_H**



Field	Bits	Type	Description
TAG	[5:0]	rw	**Master Tag** This read buffer is assigned to the master with SRI tag = TAG.
0	[31:6]	r	**Reserved** Write 0, read 0.

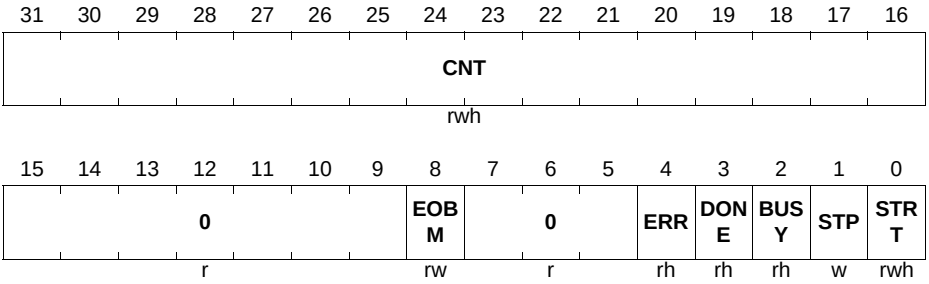
11.7.2.8 Requested Read Interface

The following registers can be used by any CPU to control the requested read interface and perform data transfers (see **Chapter 11.5.3.4**) from the EEPROMx sectors.

Requested Read Control

RRCT
Requested Read Control Register

(1140$_H$) Reset Value: 0000 0000$_H$



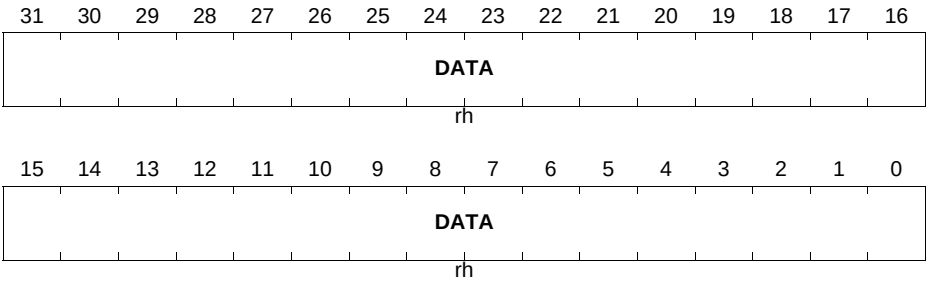
Field	Bits	Type	Description
STRT	0	rwh	**Start Request** Writing ‘1’ to this bit starts the next read process as configured by RRAD and RRCT.CNT. This bit is cleared by the PMU as soon the reading process starts executing.
STP	1	w	**Stop** Stops the read process.
BUSY	2	rh	**Flash Read Busy** 0_B The RRD registers contain the data addressed by RRAD (data ready). 1_B The Flash is busy reading the data addressed by RRAD.
DONE	3	rh	**Flash Read Done** 0_B The Flash read has not finished. 1_B The Flash read has finished, data is available.
ERR	4	rh	**Error** Cleared when starting a sequence with STRT, set when an error is detected. 0_B No error occurred. 1_B Error occurred.

Field	Bits	Type	Description
EOBM	8	rw	**End of Busy Interrupt Mask** Interrupt for RRCT.BUSY. 0_B Interrupt disabled. 1_B EOB interrupt is enabled.
CNT	[31:16]	rwh	**Count** Defines number of remaining data transfers.
0	[15:9], [7:5]	r	**Reserved** Always read as 0; should be written with 0.

Requested Read Data Registers

RRDx (x=0-1)
Requested Read Data Register x

(1144_H+x*4_H) **Reset Value: 0000 0000_H**

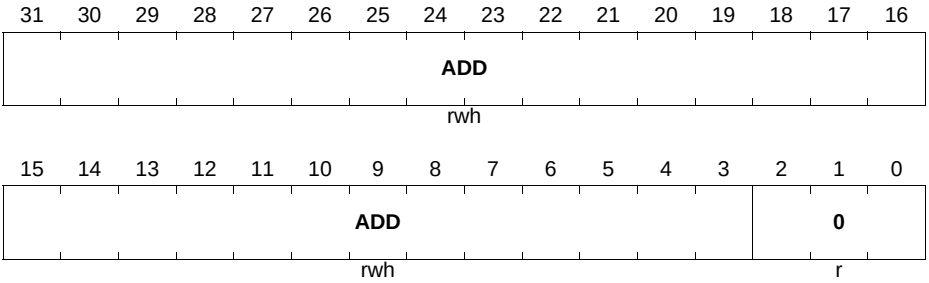


Field	Bits	Type	Description
DATA	[31:0]	rh	**Read Data** Read data.

Requested Read Address Register

RRAD
Requested Read Address Register

(114C$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
ADD	[31:3]	rwh	**Address** Start address/current address Can be written by software to define the next read address. Is automatically incremented by the requested read hardware when finishing the last read access. In case both writes happen concurrently the hardware update is performed, the software write is ignored.
0	[2:0]	r	**Reserved** Always read as 0; should be written with 0.

11.7.2.9 Flash ECC Access

ECC Write Register

The Error Correction Code Write register ECCW contains bits for disabling the ECC encoding separately for PFlash and DFlash.

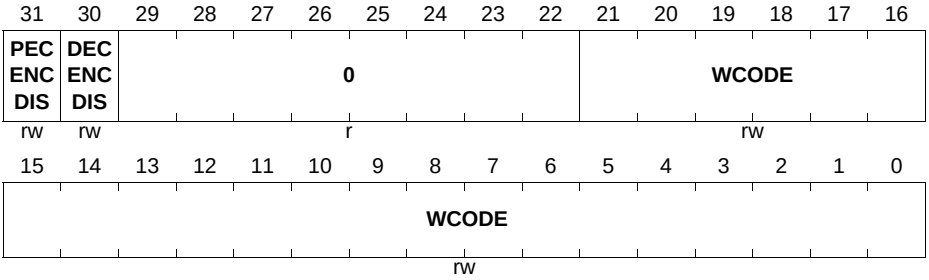
When disabling the ECC encoding for PFlash with PECENCDIS = ‘1’ the ECC code for the next 256-bit data block transferred from PMU to the Flash assembly buffer is taken from ECCW.WCODE.

When disabling the ECC encoding for DF_EEPROM with DECENCDIS = ‘1’ the ECC code for the next 64-bit data block transferred from PMU to the Flash assembly buffer is taken from ECCW.WCODE.

Because of internal dependencies only one of PECENCDIS or DECENCDIS may be set to ‘1’.

When any of PECENCDIS or DECENCDIS is set to ‘1’ the “Write Burst” command sequence is not allowed. Its use would cause unpredictable results.

ECCW
ECC Write Register **(1090_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
WCODE	[21:0]	rw	**Error Correction Write Code** 22-bit ECC code for the current 64-bit (for DFlash) or 256-bit (for PFlash) write buffer to be written into the assembly buffer instead of a generated ECC.
DECENCDIS	30	rw	**DF_EEPROM ECC Encoding Disable** 0_B The ECC code is automatically calculated. 1_B The ECC code is taken from WCODE.
PECENCDIS	31	rw	**PFlash ECC Encoding Disable** 0_B The ECC code is automatically calculated. 1_B The ECC code is taken from WCODE.
0	[29:22]	r	**Reserved** Always read as 0.

ECC Read Registers

For each Flash read path there is a separate Error Correction Code Read register. These allow disabling the ECC correction. The ECC decoding (i.e. the error detection) is not influenced. After reset ECC correction is enabled. If necessary the trap generation has to be separately disabled by MARP.TRAPDIS and MARD.TRAPDIS. Further on these registers allows to read the ECC code.

The ECC code of the last read access is stored in the RCODE field.

Note: After reading data with disabled ECC correction data buffers throughout the system (e.g. pre-fetch buffers in PMU and CPUs) may contain uncorrected data values. Therefore it is recommended to perform a reset to resume normal operation with ECC correction.

ECCRPp (p=0-0)
ECC Read Register PFp **(1094_H+p*4_H)** **Reset value: 0000 0000_H**
ECCRD
ECC Read Register DF **($10A4_H$)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	r						rh		rh					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RCODE															
rh															

Field	Bits	Type	Description
RCODE	[21:0]	rh	**Error Correction Read Code** ECC code, read from the Flash read buffer with last data read operation.
RES	[23:22]	rh	**Reserved** Internal data.
EDCERRINJ	30	rw	**EDC Error Injection** Setting this bit enforces an error in the ECC error detection supervision circuit. This can be used to check the correct function of this circuit. This bit is only implemented for the PFlash read paths (i.e. ECCRPp). In ECCRD this bit is read-only 0. 0_B EDC logic operates normally. 1_B An error is injected into the EDC logic.
ECCORDIS	31	rw	**ECC Correction Disable** 0_B ECC correction for this read path is enabled. 1_B ECC correction for this read path is disabled.

Field	Bits	Type	Description
0	[29:24]	r	**Reserved** Always read as 0.

11.7.2.10 HSM Command Interface

The following registers constitute the HSM command interface together with its reserved address range for command sequences.

In devices without DF_HSM these registers are existing but not functional.

HSM Flash Status Register

HSMFSR
Flash Status Register **(1200_H)** **Reset Value: $0000\ 0004_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	**0**	**0**	**0**	**SPND**	**EVER**	**PVER**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**
r	r	r	r	rwh	rwh	rwh	r	r	r	r	r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	**0**	**0**	**SQER**	**OPER**	**DFPAGE**	**0**	**ERASE**	**PROG**	**0**	**0**	**0**	**0**	**D1BUSY**	**0**	**0**
r	r	r	rwh	rwh	rh	r	rwh	rwh	r	r	r	r	rh	r	r

Field	Bits	Type	Description
D1BUSY	2	rh	**Data Flash Bank 1 Busy**[1)] HW-controlled status flag. 0_B DFlash1 ready, not busy; DFlash1 in read mode. 1_B DFlash1 busy; DFlash1 not in read mode. Indication of busy state of DFlash bank 1 because of active execution of an operation initiated by HSM; DFlash1 busy state is also indicated in sleep mode; while in busy state the DFlash1 is not in read mode.

Field	Bits	Type	Description
PROG	7	rwh	**Programming State** [2)3)] HW-controlled status flag. 0_B There is no program operation requested or in progress or just finished. 1_B Programming operation (write page) requested or in action or finished. Set with last cycle of Write Page/Burst command sequence, cleared with Clear Status command (if not busy) or with power-on reset. If one BUSY flag is coincidently set, PROG indicates the type of busy state. If OPER is coincidently set, PROG indicates the type of erroneous operation. Otherwise, PROG indicates, that operation is still requested or finished. Can be also cleared by writing ‘1’ to it.
ERASE	8	rwh	**Erase State** [2)3)] HW-controlled status flag. 0_B There is no erase operation requested or in progress or just finished 1_B Erase operation requested or in action or finished. Set with last cycle of Erase/Verify command sequence, cleared with Clear Status command (if not busy) or with power-on reset. Indications are analogous to PROG flag. Can be also cleared by writing ‘1’ to it.
DFPAGE	10	rh	**Data Flash in Page Mode**[1)4)] HW-controlled status flag. 0_B Data Flash not in page mode 1_B Data Flash in page mode Set with Enter Page Mode for DFlash, cleared with Write Page command. *Note: Concurrent page and read modes are allowed*

Field	Bits	Type	Description
OPER	11	rwh	**Flash Operation Error[2)3)4)]** 0_B No operation error. 1_B Flash array operation aborted, because of a Flash array failure, e.g. an ECC error in microcode. This bit is not cleared with application reset, but with power-on reset. Registered status bit; must be cleared per command or by writing ‘1’.
SQER	12	rwh	**Command Sequence Error[1)2)4)]** 0_B No sequence error 1_B Command state machine operation unsuccessful because of improper address or command sequence. A sequence error is not indicated if the Reset to Read command aborts a command sequence. Registered status bit; must be cleared per command or by writing ‘1’.
PVER	25	rwh	**Program Verify Error[1)2)4)]** A verify error was reported during a Flash program operation. 0_B The page is correctly programmed. All bits have full expected quality. 1_B A program verify error has been detected. Full quality of all bits cannot be guaranteed. Registered status bit; must be cleared per command or writing ‘1’.
EVER	26	rwh	**Erase Verify Error[1)2)4)]** A verify error was reported during a Flash erase operation. 0_B The sector is correctly erased. All erased bits have full expected quality. 1_B An erase verify error has been detected. Full quality erased bits cannot be guaranteed. Registered status bit; must be cleared per command or writing ‘1’.

Field	Bits	Type	Description
SPND	27	rwh	**Operation Suspended**[3)] Requested by HSMMARD.SPND a program or erase operation is suspended. 0_B No Flash operation is suspended. 1_B Suspended Flash operation. Can be also cleared by writing '1' to it to clean up after a reset that killed a suspended operation context.
0	[31:28], [24:13], 9, [6:3], 1, 0	r	**Reserved** Read zero, no write

1) Cleared with application reset
2) Cleared with command "Clear Status"
3) Cleared with power-on reset (PORST)
4) Cleared with command "Reset to Read"

Note: The xBUSY flags cannot be cleared with the "Clear Status" command or with the "Reset to Read" command. These flags are controlled by HW.

HSM Flash Configuration Register

HSMFCON
HSM Flash Configuration Register (1204_H) **Reset value: $0000\ 0001_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EOBM	**0**					**SQERM**	**VOPERM**	**0**							
rw	r					rw	rw	r							

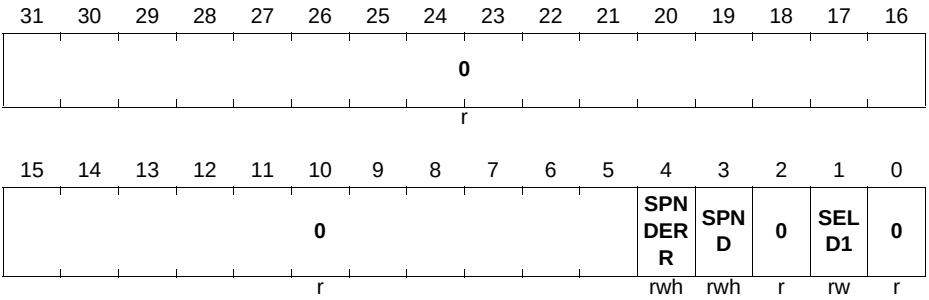
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														**LCK**	**HSMUCB**
r														rwh	

Field	Bits	Type	Description
LCKHSMUCB	[1:0]	rwh	**Lock Access to UCB_HSMCFG** Trap door register. This field can only be written to the "Locked" state. Other writes are ignored (see also **Page 11-31**) 01_B **Unlocked**, Reads by HSM to UCB_HSMCFG allowed. $..._B$ **Locked**, Reads to UCB_HSMCFG forbidden.
VOPERM	24	rw	**Verify and Operation Error Interrupt Mask** 0_B Interrupt not enabled 1_B HSM Flash interrupt because of Verify Error or Operation Error in Flash array (FSI) is enabled
SQERM	25	rw	**Command Sequence Error Interrupt Mask** 0_B Interrupt not enabled 1_B HSM Flash interrupt because of Sequence Error is enabled
EOBM	31	rw	**End of Busy Interrupt Mask** 0_B Interrupt disabled. 1_B EOB interrupt is enabled.
0	[30:26], [23:2]	r	**Reserved** Write 0; Read 0.

Margin Check Control HSM DFlash and Suspend

HSMMARD
Margin Control Register HSM DFlash

(1208_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SELD1	1	rw	**HSM DFLASH Bank Selection** Bank DF1 (HSM DFlash) is selected for reading with HMARGIN. 0_B Bank DF1 is read with the standard (default) margin independent of MARD.HMARGIN. 1_B Bank DF1 is read with the margin selected by MARD.HMARGIN.
SPND	3	rwh	**Suspend** 0_B No suspend requested or pending. 1_B Suspension of the ongoing program/erase process is requested or pending.
SPNDERR	4	rwh	**Suspend Error** 0_B No suspend error. 1_B Last suspend request via HSMMARD.SPND failed (see **Chapter 11.5.4.5**). Can be cleared by writing ‘1’.
0	0, 2, [15:4], [31:16]	r	**Reserved** Always read as 0; should be written with 0.

11.7.2.11 HSM Requested Read Interface

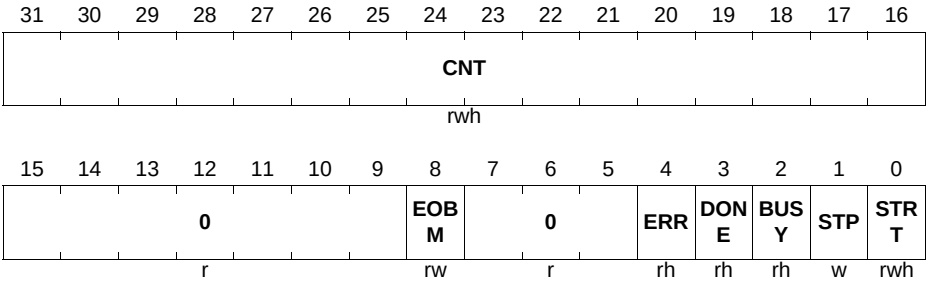
The following registers can be used by the HSM to control its requested read interface and perform data transfers (see **Chapter 11.5.3.4**) from the HSMx sectors.

In devices without DF_HSM these registers are existing but not functional.

HSM Requested Read Control

HSMRRCT
Requested Read Control Register HSM

(120C$_H$) Reset Value: 0000 0000$_H$



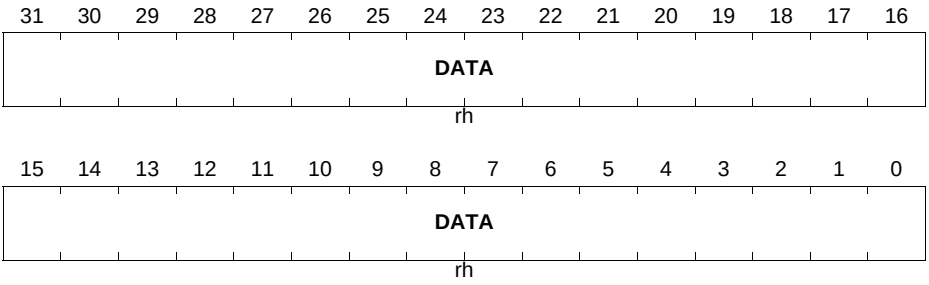
Field	Bits	Type	Description
STRT	0	rwh	**Start Request** Writing ‘1’ to this bit starts the read process as configured by HSMRRAD and HSMRRCT.CNT. This bit is cleared by the PMU as soon the reading process starts executing.
STP	1	w	**Stop** Stops the read process.
BUSY	2	rh	**Flash Read Busy** 0_B The HSMRRD registers contain the data addressed by HSMRRAD (data ready). 1_B The Flash is busy reading the data addressed by HSMRRAD.
DONE	3	rh	**Flash Read Done** 0_B The Flash read has not finished. 1_B The Flash read has finished, data is available.
ERR	4	rh	**Error** Cleared when starting a sequence with STRT, set when an error is detected. 0_B No error occurred in this sequence. 1_B Error occurred.

Field	Bits	Type	Description
EOBM	8	rw	**End of Busy Interrupt Mask** Interrupt for HSMRRCT.BUSY. 0_B Interrupt disabled. 1_B EOB interrupt is enabled.
CNT	[31:16]	rwh	**Count** Defines number of remaining data transfers.
0	[15:9], [7:5]	r	**Reserved** Always read as 0; should be written with 0.

HSM Requested Read Data Registers

HSMRRDx (x=0-1)
HSM Requested Read Data Register x

(1210_H+x*4_H) **Reset Value: 0000 0000_H**

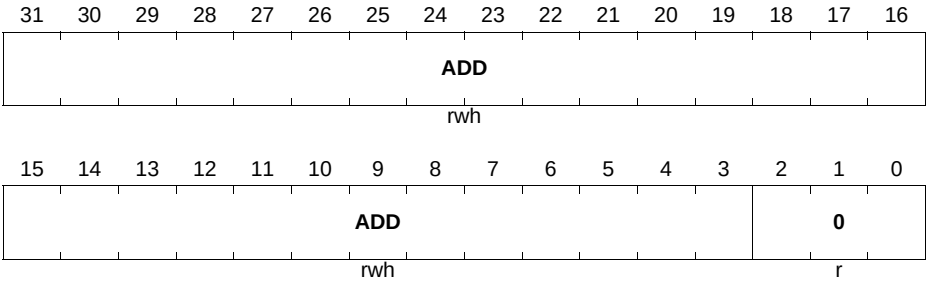


Field	Bits	Type	Description
DATA	[31:0]	rh	**Read Data** Read data.

HSM Requested Read Address Register

HSMRRAD
HSM Requested Read Address Register

(1218$_H$) **Reset Value: 0000 0000$_H$**



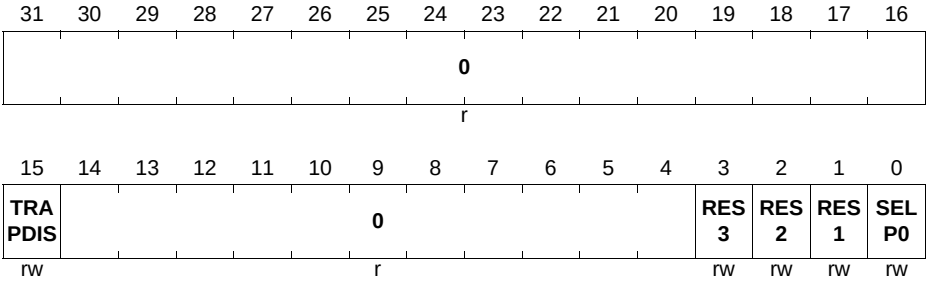
Field	Bits	Type	Description
ADD	[31:3]	rwh	**Address** Start address/current address. Must point to the DF1 address range starting at AN_DFlash_B1. The address range at AN_DFlash_B1F is not allowed (sets HSMRRCT.ERR). Can be written by software to define the next read address. Is automatically incremented by the requested read hardware when finishing the last read access. In case both writes happen concurrently the hardware update is performed, the software write is ignored.
0	[2:0]	r	**Reserved** Always read as 0; should be written with 0.

11.7.2.12 Margin Check Control

Note: Although uncorrectable error traps are disabled with reset, the traps are enabled by the startup SW (firmware) in Boot ROM before Boot ROM exit.

Margin Check Control PFlash

MARP
Margin Control Register PFlash (10A8$_H$) Reset Value: 0000 8000$_H$



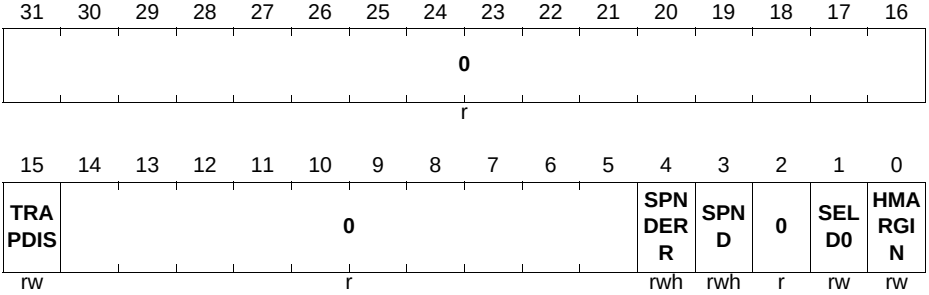
Field	Bits	Type	Description
SELPi(i=0-0)	i	rw	**PFLASH Bank PFi Selection** Bank PFi is selected for reading with MARD.HMARGIN. 0_B Bank PFi is read with the standard (default) margin independent of HMARGIN. 1_B Bank PFi is read with the margin selected by HMARGIN.
RES1	1	rw	**Reserved** Reserved for PFLASH Bank Selection SELP1.
RES2	2	rw	**Reserved** Reserved for PFLASH Bank Selection SELP2.
RES3	3	rw	**Reserved** Reserved for PFLASH Bank Selection SELP3.
TRAPDIS	15	rw	**PFLASH Uncorrectable Bit Error Trap Disable** 0_B If an uncorrectable error occurs in PFLASH (setting FSR.PFMBER), a bus error trap is generated[1)]. 1_B The uncorrectable error trap is disabled.

Field	Bits	Type	Description
0	[14:4], [31:16]	r	**Reserved** Always read as 0; should be written with 0.

1) After Boot ROM exit, uncorrectable bit error traps are enabled (TRAPDIS = 0_B).

Margin Check Control DFlash and Suspend

MARD
Margin Control Register DFlash (10AC$_H$) **Reset Value: 0000 8000$_H$**



Field	Bits	Type	Description
HMARGIN	0	rw	**Hard Margin Selection** Banks selected by MARD.SELi = 1 or MARP.SELi = 1 are read with: 0_B **Tight0**, Tight margin for 0 (low) level. Suboptimal 0-bits are read as 1s. 1_B **Tight1**, Tight margin for 1 (high) level. Suboptimal 1-bits are read as 0s. The concrete margin values are restored from the configuration sector and are determined by Infineon.
SELD0	1	rw	**DFLASH Bank Selection** Bank DF0 is selected for reading with HMARGIN. 0_B Bank DF0 is read with the standard (default) margin independent of HMARGIN. 1_B Bank DF0 is read with the margin selected by HMARGIN.

Field	Bits	Type	Description
SPND	3	rwh	**Suspend** 0_B No suspend requested or pending. 1_B Suspension of the ongoing program/erase process is requested or pending.
SPNDERR	4	rwh	**Suspend Error** 0_B No suspend error. 1_B Last suspend request via MARD.SPND failed (see **Chapter 11.5.4.5**). Can be cleared by writing ‘1’.
TRAPDIS	15	rw	**DFLASH Uncorrectable Bit Error Trap Disable** 0_B If an uncorrectable error occurs in DFLASH (setting FSR.DFMBER), a bus error trap is generated[1)]. 1_B The uncorrectable error trap is disabled.
0	2, [14:5], [31:16]	r	**Reserved** Always read as 0; should be written with 0.

1) After Boot ROM exit, uncorrectable bit error traps are enabled (TRAPDIS = 0_B).

11.7.2.13 Corrected Bits Address Buffer (CBAB)

When data is read from PFlash and the ECC decoder detects correctable bit errors those addresses are stored in the “corrected bits address buffer”. Each address is only entered once. Depending on its configuration 1-bit and 2-bit errors or only 2-bit errors are entered.

When CBAB becomes full the SMU is informed which can trigger an interrupt.

When the CBAB is full no further addresses are added. With CBABCFGp.CLR or CBABTOPp.CLR entries can be emptied.

There exists one CBAB per PFlash “p” SRI port.

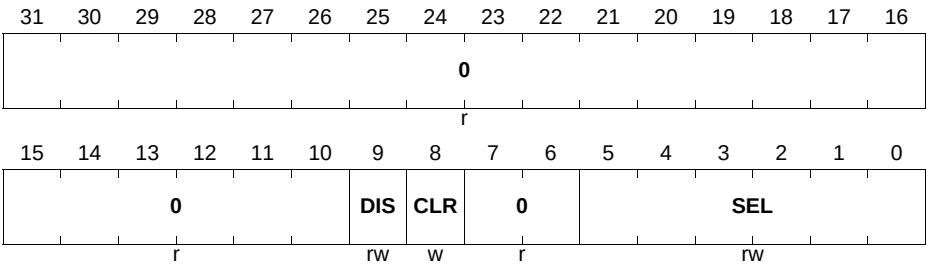
Each CBAB instance implements ten entries.

The CBAB is called in safety documentation “PFLASH Monitor”.

CBAB Configuration

Reset: power-on reset.

CBABCFGp (p=0-0)
CBAB Configuration Port p **($10B4_H+p*C_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SEL	[5:0]	rw	**Select Bit-Errors** This bit controls which type of errors are entered into the CBAB. 000000_BNo errors enter the CBAB. 000001_BCorrected single-bit errors enter the CBAB. 000010_BCorrected double-bit errors enter the CBAB. 000011_BCorrected single-bit and double-bit errors enter the CBAB. others: Reserved values.

Field	Bits	Type	Description
CLR	8	w	**Clear** Clears the complete CBABp.
DIS	9	rw	**Disable** This bit allows to disable this CBAB. This reduces the power consumption. The content of the CBAB stays unchanged. *Note: Due to race conditions switching this bit concurrently to Flash read accesses can cause an erroneous address to become registered twice.*
0	[7:6], [31:10]	r	**Reserved** Always read as 0; should be written with 0.

CBAB Status

Reset: power-on reset.

CBABSTATp (p=0-0)
CBAB Status Port p **($10B8_H+p*C_H$)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						**VLD 9**	**VLD 8**	**VLD 7**	**VLD 6**	**VLD 5**	**VLD 4**	**VLD 3**	**VLD 2**	**VLD 1**	**VLD 0**
r						rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

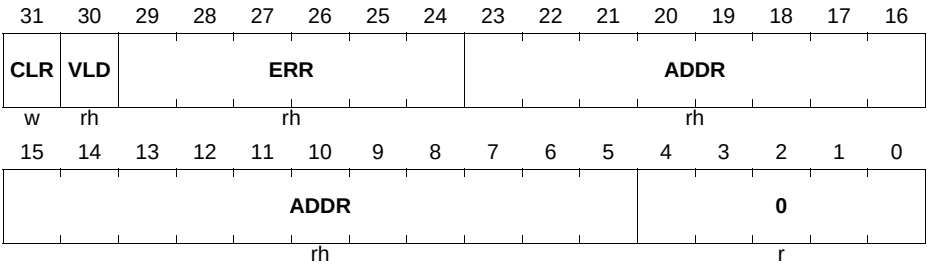
Field	Bits	Type	Description
VLDx (x=0-9)	x	rh	**Filling Level** Each VLDx indicates a valid entry. The complete set of VLD flags operates as thermometer code. Entry 0 is the top entry which is read in CBABTOP. The entry with the highest index number was entered last.
0	[31:10]	r	**Reserved** Always read as 0; should be written with 0.

CBAB FIFO Top Entry

This register displays the information of the top-most entry of the CBAB FIFO.

Reset: power-on reset (for the complete FIFO content).

CBABTOPp (p=0-0)
CBAB FIFO TOP Entry Port p ($10BC_H+p*C_H$) Reset Value: 0000 0000_H



Field	Bits	Type	Description
CLR	31	w	**Clear** Write-only trigger bit. Reading returns 0. 1_B Clears valid flag “VLD” of this entry and removes it from the FIFO. 0_B No operation.
VLD	30	rh	**Valid** Entry is valid.
ERR	[29:24]	rh	**Error Type** This field contains the error type found at ADDR. The bits correspond to CBABCFG.SEL. 000000_BNo error (reserved). 000001_BSingle-bit error. 000010_BDouble-bit error. others: Reserved.
ADDR	[23:5]	rh	**Address** Captured address (bits 23:5 of the SRI bus address) with detected error.
0	[4:0]	r	**Reserved** Always read as 0; should be written with 0.

11.7.2.14 Uncorrectable Bits Address Buffer (UBAB)

When data is read from PFlash and the ECC decoder detects uncorrectable bit errors those addresses are stored in the “uncorrected bits address buffer”. Each address is only entered once. Depending on its configuration selected failures can be entered.

When the UBAB is full no further addresses are added. With UBABCFGp.CLR or UBABTOPp.CLR entries can be emptied.

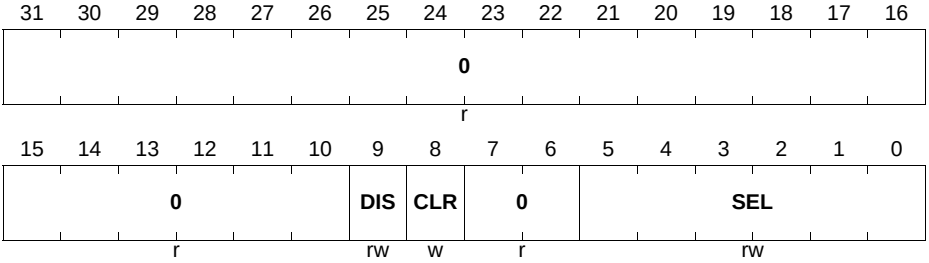
There exists one UBAB per PFlash “p” SRI port.

Each UBAB instance implements one entry.

UBAB Configuration

Reset: power-on reset.

UBABCFGp (p=0-0)
UBAB Configuration Port p **($10E4_H$+p*C_H)** **Reset Value: 0000 0000_H**



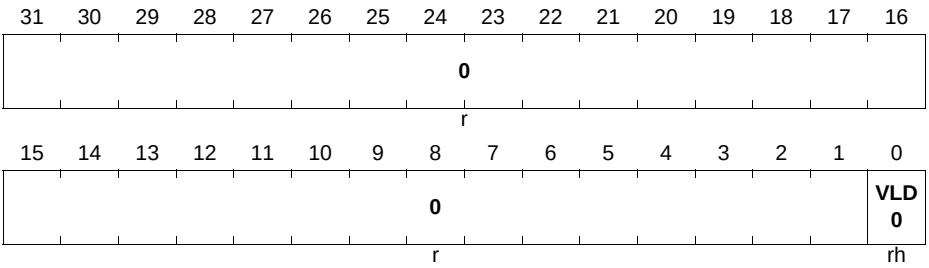
Field	Bits	Type	Description
SEL	[5:0]	rw	**Select Bit-Errors** This bit controls which type of errors are entered into the UBAB. 000000_BNo errors enter the UBAB. 000100_BDetected uncorrectable bit-errors (3-bit or more, address errors, all-0, all-1 enter the UBAB. others: Reserved values.
CLR	8	w	**Clear** Clears the complete UBABp.

Field	Bits	Type	Description
DIS	9	rw	**Disable** This bit allows to disable this UBAB. This reduces the power consumption. The content of the UBAB stays unchanged.
0	[31:10], [7:6]	r	**Reserved** Always read as 0; should be written with 0.

UBAB Status

Reset: power-on reset.

UBABSTATp (p=0-0)
UBAB Status Port p **($10E8_H+p*C_H$)** **Reset Value: 0000 0000$_H$**



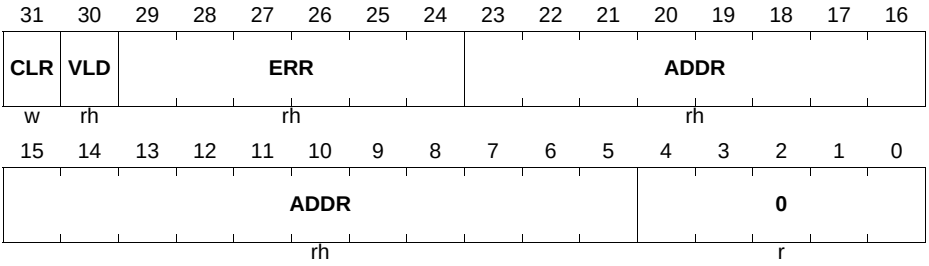
Field	Bits	Type	Description
VLD0	0	rh	**Filling Level** Each VLDi indicates a valid entry. The complete set of VLD flags operates as thermometer code. Entry 0 is the top entry which is read in UBABTOP. The entry with the highest index number was entered last.
0	[31:1]	r	**Reserved** Always read as 0; should be written with 0.

UBAB FIFO Top Entry

This register displays the information of the top-most entry of the UBAB FIFO.

Reset: power-on reset (for the complete FIFO content).

UBABTOPp (p=0-0)
UBAB FIFO TOP Entry Port p ($10EC_H+p*C_H$) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
CLR	31	w	**Clear** Write-only trigger bit. Reading returns 0. 1_B Clears valid flag “VLD” of this entry and removes it from the FIFO. 0_B No operation.
VLD	30	rh	**Valid** Entry is valid.
ERR	[29:24]	rh	**Error Type** This field contains the error type found at ADDR. The bits correspond to UBABCFG.SEL. 000000_BNo error (reserved). $XXX100_B$Uncorrectable error (3-bit or more, addressing error, all-0, all-1). others: Reserved.
ADDR	[23:5]	rh	**Address** Captured address (bits 23:5 of the SRI bus address) with detected error.
0	[4:0]	r	**Reserved** Always read as 0; should be written with 0.

11.7.2.15 Direct Flash Communication

These registers enable direct communication of software (e.g. a Flash driver running on TriCore) with the FSI specifically with its µCode.

Because of design particularities byte wide write accesses are not supported and cause unpredictable results. Only half-word (16-bit) wide writes shall be performed.

Read and write accesses during ongoing Flash operations (FSR shows BUSY flags) is forbidden. The PMU returns a bus error.

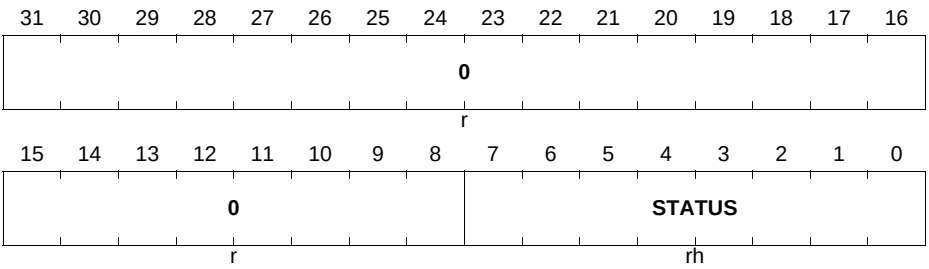
These registers shall be read or written in exceptional cases only when demanded by IFX for extended functions.

The behavior of these registers in specific Flash modes is special:

- During all FSI operations including Flash startup: the STATUS fields can deliver unpredictable data.
- When the Flash is in sleep mode: write and read accesses fail with a bus error.

Flash Communication Register 0

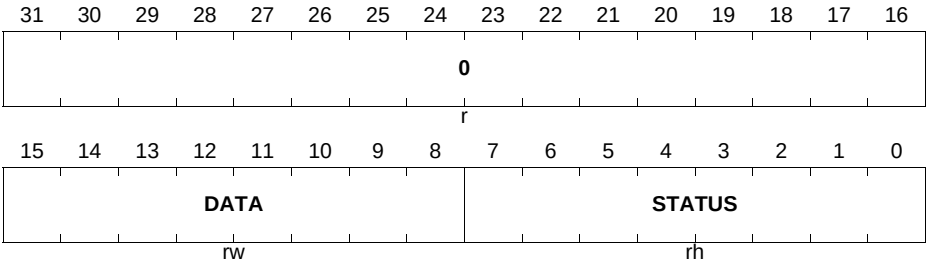
COMM0
FSI Communication Register 0 (0000_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
STATUS	[7:0]	rh	**Status** This field can be only written by the FSI.
0	[31:8]	r	**Reserved** Always read as 0.

Flash Communication Register

COMMx (x=1-2)
FSI Communication Register x **(0000_H+4*x)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
STATUS	[7:0]	rh	**Status** This field can be only written by the FSI.
DATA	[15:8]	rwh	**Data** This field can be only written by software not by the FSI.
0	[31:16]	r	**Reserved** Always read as 0.

11.8 Application Hints

The following application hints should support the user in using the PMU and Flash optimally.

11.8.1 Changes with Respect to Audo Families Audo-NG/F/S/Max

The following changes of the PMU with respect to Audo-NG/F/S/Max products are highlighted. With “Audo-Max” are changes noted with respect to SRI based Audo-Max products. The tag “All” indicates changes with respect to all Audo product generations:

- All: Flash cell concept is changed enabling many significant improvements:
  - Performance of programming significantly enhanced.
  - Burst programming feature with even higher programming throughput.
  - No over-erased state anymore.
  - Sector structure of PFlash enhanced with more small Flash sectors.
  - EEPROM emulation in DFlash improved by smaller pages.
  - Enhanced retention and endurance figures.
  - All logical sectors of PFlash (see **Table 11-2**) have the same endurance. “Second class” logical sectors with only 100 cycle endurance are not existing anymore.
- All: Changed PMU and FSI architecture (enabled by the increased programming performance). Now one FSI and PMU can serve several PFlash banks in addition to the DFlash banks.
- All: Due to this one PMU and FSI has to support several independent read paths with independent bus interfaces to the assigned PFlash banks.
- All: Changed command sequences. In Audo the SA and PA arguments were transmitted in the address phase, thus these command cycles had to be written to the target Flash range. Now SA and PA are transmitted in the data phase. Only writes into the DFlash address range are interpreted as command sequences.
- Audo-NG/F/S: Enhanced Flash read buffer concept with master specific read buffers.
- Audo-NG/F/S: Changed bus interface from LMB to SRI.
- All: Changed supply concept supporting EVR. Dedicated programming modes for 3.3V only supply or 5V supply.
- Audo-NG/F/S: The wait-state settings in FCON don’t relate by default to the bus clock as in Audo-NG/F/S (i.e. the LMB clock) but to the FSI and FSI2 clocks. These clocks have their own divider from the PLL clock which need to be configured in SCU_CCUCON0.FSIDIV and SCU_CCUCON0.FSI2DIV. They have to be configured to have a relation $f_{SRI}/f_{FSI(2)}$ of n/1.
- All: Explicit suspend to read feature replacing automatic “program while erase” of the Audo generation.
- Audo-NG/F/S: The OVRAM and the EMEM were moved to a different module “LMU”.
- All: The register field FCON.STALL configures the behavior when reading busy Flash banks. Either “ready” is suppressed or a bus error is generated.
- Audo-NG/F/S: TP: changed addresses RTPWT and RPSSW.

- Audo-NG/F/S: Programming and reading data with disabled ECC generation and correction allows customers to program data with invalid ECC.
- Audo-NG/F/S: Error flags in FSR can be selectively cleared to enable easier flag handling for concurrent operations.
- Audo-Max: Dropped extended status register XSFR.
- All: Protection fields assembled in new register FPRO.
- All: Changed protection concept:
  - Only one protection “user” in PFlash.
  - Separate protection with password for DFlash.
  - Password width increased from 64 bits to 256 bits.
  - More flexible OTP configuration that allows adding OTP.
  - New write-once protection enabling “automatic” OTP protection.
  - All UCBs realized as part of DFlash instead of PFlash.
  - Confirmation concept for UCB blocks changed. Now an erased confirmation code activates complete protection and locks the UCB.
  - New password protected debug lock.
- All: Support for HSM:
  - Dedicated protection for HSM code sectors.
  - HSM related UCBs for configuring HSM Flash protection.
- All: New erase counters.
- All: Changed base addresses of all Flash modules.
- All: Changed base address of BootROM.
- All: TEC-QED ECC algorithm in DFlash.
- All: DEC-TED ECC algorithm in PFlash with specific safety features for 99% white noise coverage, detection of all-0/all-1 inducing faults and addressing errors.
  - As in Audo-Max the ECC algorithm can be switched between safety and non-safety mode.
  - Attention: switching the algorithm with FCON.NSAFECC may only be done while no Flash accesses are performed. This feature may conflict with Audo-F Flash driver software.
- All: New “Erase Verify” functionality.
- All: New multiple sector erase command sequence “Erase Logical Sector Range”.
- All: Extended safety protection of registers with ACCEN and “Safety ENDINIT”.
- All: FIFOs that store uniquely addresses in PFlash read with corrected and uncorrectable bit errors.

11.8.2 Performing Flash Operations

This section offers advice for programming command sequences.

General Advice

- Please remember to disable the Safety ENDINIT protection before executing program and erase commands for the PFlash (see **Chapter 11.5.5.2**).

- Code that performs PFlash programming or erasing should not be executed from the same PFlash.
- The command cycles shall address the non-cached address range of the Flash (otherwise the data may stay in the cache or could be received by the PMU in an incorrect order).
- The non-cached Flash range is not regarded as peripheral address space by the TriCore. This means that a read (notably reading the FSR for checking the flags) placed behind the last command cycle write in program order might be executed before this last write.
  The FSR flags xFPAGE, PROG, ERASE can be used to ensure that polling for a cleared BUSY starts only after the command was accepted by the PMU.
  Additionally it is recommended to place a “DSYNC” instruction between a command sequence and read accesses to depending data including affected registers.
- The caches (data cache in DMI “DCache” and program cache in PMI “PCACHE”) as well as the data line buffer in the DMI “DLB” are not automatically invalidated nor updated after changing Flash content by erasing or programming. It is therefore recommended to either invalidate them actively or read the Flash content via the non-cached address range. Otherwise old data might be delivered from these buffers.
  The DMI cache and line buffer can be invalidated by writing OVCCON.DCINVAL to ‘1’. The PCACHE can be invalidated by writing PCON1.PCINV to ‘1’. All buffers are invalidated by a reset.
- The PMU and Flash work with the SRI, FSI and FSI2 clocks. When changing the divider values of these clocks in SCU_CCUCON0 the following rules apply:
  – The only allowed PMU/Flash “operation” when switching is reading from Flash memory. Programming or erasing the Flash is forbidden.
  – It must be ensured that before, during and after the divider change the configured number of Flash wait-cycles is sufficient for the selected clock frequency. Remember that the wait-cycles are counted with f_{FSI2} for PFlash and f_{FSI} for DFlash.
  – After System Resets and Power-On Resets the wait cycle values are configured to a value only sufficient for the clock frequencies used during startup (i.e. 100 MHz). So basically always changes to the clock configuration must be preceded by changes to the wait cycles.

Sequence for Programming

The following sequence is the most defensive one for programming a page. It is however acceptable to skip some checks when the programmed data is later verified:

- “Clear Status” to clear flags.
- “Enter Page Mode”.
- DSYNC.
- Wait until FSR.xFPAGE = ‘1’ or fail if FSR.SQER = ‘1’ or FSR.PROER = ‘1’.
- Repeat “Load Page” until the page is filled.

- “Write Page”.
- DSYNC.
- Wait until FSR.PROG = ‘1’ or fail if FSR.SQER = ‘1’ or FSR.PROER = ‘1’.
- Wait until FSR.xBUSY = ‘0’ or enable the interrupt.
  – While FSR.xBUSY is ‘1’ the flags FSR.OPER can be checked for ‘1’ as abort criterion to protect against hardware failures causing BUSY to stay ‘1’.
- Check for FSR.PVER flag.
- Fail if FSR.OPER = ‘1’.
- Recommended: check programmed content, evaluate FSR.xMBER and possibly count correctable errors.
- Clear error flags either with “Clear Status” or by directly writing to FSR.

Sequence for Erasing

The following sequence is the most defensive one for erasing a range of sectors. It is however acceptable to skip some checks when the programmed data is verified after programming (or the flag FSR.PVER is checked as described above):

- “Clear Status” to clear flags.
- “Erase Logical Sector Range”.
- DSYNC.
- Wait until FSR.ERASE = ‘1’ or fail if FSR.SQER = ‘1’ or FSR.PROER = ‘1’.
- Wait until FSR.xBUSY = ‘0’ or enable the interrupt.
  – While FSR.xBUSY is ‘1’ the flags FSR.OPER can be checked for ‘1’ as abort criterion to protect against hardware failures causing BUSY to stay ‘1’.
- Check for FSR.EVER/PVER flags.
- Fail if FSR.OPER = ‘1’.
- Clear error flags either with “Clear Status” or by directly writing to FSR.

An analog sequence can be used for “Verify Erased Logical Sector Range”.

11.8.3 EEPROM Emulation With DFlash

The term “EEPROM emulation” designates an algorithm with the following features:

- It increases the effective endurance by spreading the EEPROM write accesses over a larger range of Flash memory.
- It ensures that all Flash cells incur a similar number of cycles independent of the update frequency of the EEPROM data (“wear levelling”).
- It manages the allocation of EEPROM data to Flash ranges so that stale data can be erased.

A popular emulation algorithm is the “two sector” emulation, which splits the complete DFlash in two equally sized ranges:

- The EEPROM writes are performed in one range, the “active” one. The other range stays erased.

- The data is stored so that several writes of the same EEPROM address can be performed in one DFlash range. The position of the latest data version and the original EEPROM address can be determined from the address in Flash and additional administrative data (e.g. all data is pushed to a stack and the pushed data contains the EEPROM address).
- At a certain range fill level a range switch is performed. This moves all active data to the erased range. After that the active range is erased and the other range becomes the active one.

With the 6 erasable DFlash ranges of the TC21x/TC22x/TC23x other more efficient algorithms are possible. However the algorithm must ensure that all sectors are used equally, e.g. it is not allowed to keep static data in certain sectors and often updated data in other sectors. The sectors with static data would incur too many disturbs.

One specific requirement for an EEPROM emulation algorithm is the resistance against aborts during its operation. In any case the algorithm must be able after device startup to recover without data loss, determine the active data and resume operation.

In many applications even resistance against aborted Flash processes (program, erase) is needed. See details in **Chapter 11.8.5.2**.

11.8.3.1 Robust EEPROM Emulation

A key requirement for an EEPROM emulation algorithm is the reliability of the stored data. The DFlash with its TEC-QED ECC algorithm protects perfectly against bit or bit-line oriented failures.

However, ECC mechanisms do not protect against word-line oriented failures. Word-line failure modes may result in a complete word-line which can no longer be programmed or erased, and the data within the failed word-line may not be able to be read correctly. Word-line failures are most likely to occur during the high voltage conditions present during programming or erase operations. Therefore, a robust EEPROM emulation algorithm must tolerate word-line failures, and must protect against data loss in case the word-line fails during an erase or programming operation.

The following steps shall be followed to achieve the necessary robustness:

- Before programming a page save the content of all other pages on the same word-line that contain active data to SRAM.
- Program the new page and compare the content of this page and of the saved pages with their reference data. This can be done with normal read margins. Ignore correctable bit-errors.
- If the data comparison fails or the programming returned with PVER error program this page and the saved content of the other pages to a different word-line.
- This procedure can be repeated if the data comparison fails again. The number of repetitions should be limited (e.g. to 3) in case the programming fails because of out-of-spec operating conditions.

- Word-line oriented fails can also have the effect that the affected word-lines can not be erased anymore, yet the contents of the word-line data could still be read without any error indication. Sequence counters for the data blocks or other means must be used to identify old data blocks in word-lines with this type of failure mode.

For the TC21x/TC22x/TC23x this robust EEPROM algorithm is required for the usage of the DFlash.

Due to the specificity of each application the appropriate usage and implementation of these measures must be chosen according to the context of the application.

11.8.4 Handling Errors

The earlier sections described shortly the functionality of “error indicating” bits in the flash status register **FSR**. This section elaborates on this with more in-depth explanation of the error conditions and recommendations how these should be handled by customer software.

11.8.4.1 Handling Errors During Operation

This first part handles error conditions occurring during operation (i.e. after issuing command sequences) and the second part (**Section 11.8.4.2**) error conditions detected during startup.

SQER “Sequence Error”

Fault conditions:

- Improper command cycle address or data, i.e. incorrect command sequence.
- New “Enter Page” in Page Mode.
- “Load Page” and not in Page Mode.
- “Load Page” results in buffer overflow.
- “Load Page” with mixed 32/64-bit transfers.
- First “Load Page” addresses 2. word.
- “Write Page” with buffer underflow.
- “Write Page” and not in Page Mode.
- “Write Page” to unavailable Flash range.
- Command sequence with address not pointing to a legal start address (e.g. page, UCB or sector).
- “Write Page Once” targeting DFlash.
- Byte transfer to password or data.
- “Erase Logical Sector Range” or “Verify Erased Logical Sector Range” with range leaving a physical sector.
- “Resume Prog/Erase” with arguments not matching the suspended command.
- “Resume Prog/Erase” when there is no suspended operation.

- Any programming or erase command when there is a suspended programming command.
- Any erase command when there is a suspended erase command, including “Verify Erased Logical Sector Range”.
- Programming to the target range of a suspended erase command.
- Unsupported command sequence for the HSM command interpreter.

New state:

Read mode is entered with following exceptions:

- “Enter Page” in Page Mode re-enters Page Mode.
- “Write Page” with buffer underflow is executed.
- After “Load Page” causing a buffer overflow the Page Mode is not left, a following “Write Page” is executed.

Proposed handling by software:

Usually this bit is only set due to a bug in the software. Therefore in development code the responsible error tracer should be notified. In production code this error will not occur. It is however possible to clear this flag with “Clear Status” or “Reset to Read” and simply issue the corrected command sequence again.

OPER “Operation Error”

Fault conditions:

ECC double-bit error detected in Flash microcode SRAM during an operation or the microcode has detected another significant failure. This can be a transient event due to alpha-particles or illegal operating conditions or it is a permanent error due to a hardware defect. This situation will practically not occur.

Attention: these bits can also be set during startup (see **Chapter 11.8.4.2**).

New state:

The Flash operation is aborted, the BUSY flag is cleared and read mode is entered.

Proposed handling by software:

The last operation can be determined from the PROG and ERASE flags. In case of an erase operation the affected physical sector must be assumed to be in an invalid state, in case of a program operation only the affected page. Other sectors can still be read. New Flash commands (Write*, Erase*, Verify*, Resume*) must not be issued before the next system or power-on reset. “Clear Status” can be used to clear the OPER flag, however this doesn’t resolve the corrupted state of the FSI.

Attention: New FSI operations in this state can cause corruption of Flash content, which might even prevent the device from booting.

The next system or power-on reset performs a new Flash startup with initialization of the microcode SRAM. A power-on reset clears additionally the OPER flag. The application must determine from the context which operation failed and react accordingly. Mostly

erasing the addressed sector and re-programming its data is most appropriate. If a “Program Page” command was affected and the sector can not be erased (e.g. in Flash EEPROM emulation) the word-line could be invalidated if needed by marking it with all-one data and the data could be programmed to another empty word-line.

Only in case of a defective microcode SRAM the next program or erase operation will incur again this error.

PROER “Protection Error”

Fault conditions:

- Password failure.
- Erase/Write to protected sector.
- Erase/Write of protected UCB.
- “Verify Erased Logical Sector Range” to blocked addresses.
- Program or erase targeting PFlash with active Safety ENDINIT protection.

New state:

Read mode is entered. The protection violating command is not executed.

Proposed handling by software:

Usually this bit is only set during runtime due to a bug in the software. In case of a password failure a reset must be performed in the other cases the flag can be cleared with “Clear Status” or “Reset to Read”. After that the corrected sequence can be executed.

EVER “Erase Verify Error”

Fault conditions:

This flag is set by the erase commands when they don’t achieve an optimum result.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This bit should be cleared with “Clear Status” or “Reset to Read”.

The operating conditions should be checked. The following advice assumes correct operating conditions and a correctly configured device.

In the PFlash an EVER can be regarded as device failure.

In the DFlash an EVER is a warning which doesn’t require immediate action. The robust EEPROM emulation will detect during programming the corresponding word-lines and “jump” over them.

*Note: Even when this flag is ignored it is recommended to clear it. Otherwise all following operations — including “sleep” — could trigger an interrupt even when they are successful (see **Chapter 11.5.7**, interrupt because of verify error).*

PVER "Program Verify Error"

Fault conditions:

This flag is set by the program commands when they don't achieve an optimum result.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This bit should be cleared with "Clear Status" or "Reset to Read".

The operating conditions should be checked. The following advice assumes correct operating conditions and a correctly configured device.

In the PFlash a PVER can be regarded as device failure. However due to the high correction capability of the ECC customers may choose to check the amount of corrected and uncorrectable errors and decide on this basis if the device can stay in operation.

In the DFlash a PVER is a signal for the robust EEPROM emulation that programming on the current word-line failed. The algorithm has to "jump" over this word-line and programs its data to the next word-line.

*Note: Even when this flag is ignored it is recommended to clear it. Otherwise all following operations — including "sleep" — could trigger an interrupt even when they are successful (see **Chapter 11.5.7**, interrupt because of verify error).*

PFSBER, PFDBER, DFSBER, DFDBER, DFTBER "Single/Double/Triple-Bit Error"

Fault conditions:

When reading data or fetching code from PFlash or DFlash the ECC evaluation detected an error which was corrected.

This flag is a warning indication and not an error. A certain amount of correctable errors must be expected because of known physical effects.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This flag can be used to analyze the state of the Flash memory. During normal operation it should be ignored. High counts of correctable errors can indicate that the Flash is operated outside of the defined operating conditions (e.g. temperature, voltage, endured p/e cycles, configured wait-states).

When programming the PFlash (end-of-line programming or SW updates) customers can count the number of correctable errors using the CBAB or rely on the PVER indication.

In case of EEPROM emulation using DFlash the verification of programmed data should be done with the normal read level and correctable errors should be ignored. Further advice can be found in **Chapter 11.8.3**.

11.8.4.2 Handling Errors During Startup

The FSR flags are not only used to inform about the success of Flash command sequences but they are also used to inform (1) the startup software and (2) the user software about special situations incurred during startup. In order to react on this information these flags must be evaluated after reset before performing any flag clearing sequence as “Clear Status” or “Reset to Read”.

The following two levels of situations are separated:

- Fatal level: the user software is not started. A WDT reset is performed.
- Warning level: the user software is started but a warning is issued.

Fatal Level (WDT Reset)

These error conditions are evaluated by the startup software which decides that the Flash is not operable and thus waits for a WDT reset. The application sees only a longer startup time followed by a WDT reset.

The reason for a failed Flash startup can be a hardware error or damaged configuration data.

Warning Level

These conditions inform the user software about an internally corrected or past error condition.

Leftover OPER:

FSR bits set: OPER.

The OPER flag are only cleared by the command sequence “Clear Status” or with a power-on reset. After any other reset a OPER flag can still be set when the user software is started.

Correctable error in UCB or configuration sector:

FSR bits set: PFSBER/PFDBER, DFSBER, DFDBER, DFTBER or ORIER.

An correctable ECC error was detected during installation of the protection or of the configuration sector content.

11.8.5 Resets During Flash Operation

A reset or power failure during an ongoing Flash operation (i.e. program or erase) must be considered as violation of stable operating conditions. However the Flash was designed to prevent damage to non-addressed Flash ranges when the reset is applied

as defined in the data sheet. The addressed Flash range is left in an undefined state. Additional means are implemented that help to prevent aborting programming processes in the DFlash.

11.8.5.1 General Advice

When an erase operation is aborted the previously programmed bits (‘1’) in the addressed Flash range can be in any state between ‘0’ and ‘1’. When reading this range all-0 can be returned, the old data, or something in between. The result can be instable. Due to the ECC correction there may even appear ‘1’ bits at positions which contained ‘0’ bits before erase start.

When a page programming operation is aborted the page can still appear as erased (but contain slightly programmed bits), it can appear as being correctly programmed (but the data has a lowered retention) or the page contains garbage data. It is also possible that the read data is instable so that depending on the operating conditions different data is read.

For the detection of an aborted Flash process the flags FSR.PROG and FSR.ERASE could be used as indicator but only when the reset was an application reset. When Flash processes are aborted by power-on resets this is not indicated by any flags. It is not possible to detect an aborted operation simply by reading the Flash range (please note that the ECC is not a reliable means to detect an aborted Flash operation). Even the margin reads don’t offer a reliable indication.

When erasing or programming the PFlash usually an external instance can notice the reset and restart the operation by erasing the Flash range and programming it again.

11.8.5.2 Advice for EEPROM Emulation

However for the case of EEPROM emulation in the DFlash this external instance is not existing. A common solution is detecting an abort by performing two operations in sequence and determine after reset from the correctness of the second the completeness of the first operation.

E.g. after erasing a DFlash sector a page is programmed. After reset the existence of correct data in this page proves that the erase process was performed completely.

The detection of aborted programming processes can be handled similarly. After programming a block of data an additional page is programmed as marker. When after reset the block of data is readable and the marker is existent it is ensured that the block of data was programmed without interruption.

In very specific cases it is allowed to repair data left from an aborted programming operation: if the algorithm can detect that an abort occurred and the algorithm knows which data must be present in the page it is possible to simply redo the programming by programming the same data again.

In the AURIX family the probability of aborting a programming process can be minimized by the following means:

- In case of a reset with stable power supply (“warm resets”) the Flash gets automatically a request to enter safe state before the reset is applied. Due to their short duration single “Write Page” operations are finished correctly by this process. “Write Burst” operations however are interrupted after the current page programming has finished.
- The voltage monitoring (see SCU chapter) can be used to get an under voltage warning early enough that an ongoing programming process can be finished and no new one is started.
- By selecting an internally generated programming voltage (see **Chapter 11.5.4.6**) the needed voltage at V_{EXT} is reduced giving more headroom for an early warning by the voltage monitors.

11.8.6 ECC

For special applications the ECC features need to be considered.

Using the PFlash Safety ECC

The PFlash Safety ECC is a vital part of the safe fetch path needed for safety applications. The difference between Legacy ECC and Safety ECC is explained in **Chapter 11.5.6.2**.

The calculation of the Safety ECC is done over 256 data bits, the address bits 22:5 and the configuration area selection signal. As side effect erased PFlash ranges or PFlash ranges programmed with the Legacy ECC will be read with ECC errors.

Thus the installation of an application using the Safety ECC should be done as follows:

- By default (delivery state) the device starts with the Safety ECC enabled.
- The Flash loader can execute from RAM. Erased PFlash ranges shall not be read.
- A sector should be programmed completely to ensure that it can be read without ECC errors.
- When changing the UCB_DFlash it is important to keep the ECC configuration flag PROCOND.NSAFECC = 0.

The installation of an application using the Legacy ECC should be done as follows:

- By default (delivery state) the device starts with the Safety ECC enabled.
- The Flash loader can execute from RAM.
- By writing FCON.NSAFECC to 1 the ECC algorithm is switched to Legacy ECC.
- Afterwards the PFlash programming is performed with the Legacy ECC.
- Erased PFlash ranges can be read without error.
- In UCB_DFlash the ECC configuration flag PROCOND.NSAFECC shall be programmed to 1 to ensure that the device starts after next reset with the Legacy ECC. It must be ensured that is kept when changing later the UCB_DFlash.

Attention: Changing FCON.NSAFECC while accessing the Flash (reading, programming, erasing) is forbidden.

Attention: Reading PFlash ranges with the incorrect ECC (e.g. Flash was programmed with Legacy ECC but reading with setting of NSAFECC=0) must not done although it might seem to work when the uncorrectable error traps are disabled.
On certain address/data combinations mis-corrections will happen and single and double-bit errors in PFlash will not be corrected because for the wrong ECC algorithm nearly all addresses will have uncorrectable errors resulting in the delivery of the raw data.

Creating Incorrect ECC

In safety applications error detection features are usually checked at each startup. In order to check the detection logic for ECC errors addresses in PFlash need to be programmed with erroneous data.

The automatic ECC generation can be disabled with ECCW.PECENCDIS. With this feature any combination of data and ECC bits can be programmed.

The ECC code causing the required error type (e.g. triple-bit error) can be determined by first programming the data with automatic ECC generation on. When reading this data the corresponding ECC code can be found in ECCRPp.RCODE. After erasing this range of Flash a modified data/ECC combination can be programmed with automatic ECC generation switched off (ECCW.PECENCDIS = 1).

It is also possible to create ECC incorrect patterns by programming twice with enabled automatic ECC generation.

Ready-to-use programming routines for the creation of ECC errors are part of the Infineon safety software “SafeTlib”.

11.8.7 Startup Tests of ECC Logic

As described in **Chapter 11.6** the ECC logic of the PFlash is protected by special hardware means, the “ECC Monitor” and the “EDC Comparator”. Depending on the targeted ASIL level these units, their error signals and generally the ECC error signaling to the SMU has to be tested during each startup after reset.

The Infineon safety software “SafeTlib” contains routines to perform these tests.

11.8.7.1 Testing ECC Alarms and Error Flags

In order to test if each type of ECC error is correctly reported to the SMU and PMU status registers a pattern with this error needs to be stored in PFlash and read during startup after reset.

Such patterns can be created as described in **Chapter 11.8.6**.

Test Pattern

As the patterns stored in PFlash might change their error signature over life-time (e.g. a single-bit error becomes a double-bit error due to a single bit toggling) each pattern needs to be stored redundantly (we propose 4 times).
As the ECC logic of each PFlash bank has separate paths the patterns have to be stored in each PFlash bank and tested in each PFlash bank.

Patterns for the following types of errors should be stored and read:

- No error (valid data). This data could be shared with the one for **Chapter 11.8.7.2**.
- 1-bit error.
- 2-bit error.
- 3-bit error to trigger an uncorrectable error.
- Address error (can be created by generating an ECC for an address that is different by 1 or 2 address bits). This test pattern is optional. It is not needed for sufficient test coverage.
- All-0 in data and ECC. This test pattern is optional. It is not needed for sufficient test coverage.
- All-1 in data and ECC. This test pattern is optional. It is not needed for sufficient test coverage.

In sum these 7 pattern (each covering one 32-byte page) are stored 4 times per PFlash bank.

For best possible robustness 2 of the 4 pattern sets shall be inverse to the other 2.

Test Flow

For each error type its 4 patterns are read. The corresponding error flag and SMU alarm should occur at least once.

11.8.7.2 Testing the “ECC Monitor”

As the ECC Monitor is always in use its logic is usually tested sufficiently during startup of the application, simply by performing read accesses to the PFlash banks.

However in order to achieve a defined error coverage a dedicated test procedure recommended.

Test Pattern

In each PFlash bank a set of 32 valid pages (i.e. containing no intentional ECC error) is stored. These patterns are chosen by IFX to ensure >90% stuck-at coverage of the ECC Monitor logic.

Test Flow

The 32 pages of each PFlash bank are read by any master e.g. the CPU.

The ECC monitor logic is working correctly if during this test the alarm “PFLASH ECC monitor error” at the SMU is not activated.

11.8.7.3 Testing the SMU Alarm of the “ECC Monitor”

In order to test that the “PFLASH ECC monitor error” alarm to the SMU can be activated the ECC monitor has to receive a pattern with incorrect ECC for which the ECC correction logic states that a correction was performed.

Test Pattern

In each PFlash bank a pattern with a correctable error has to be read, e.g. the ones used in **Chapter 11.8.7.1**.

Test Flow

The ECC correction has to be disabled for the tested PFlash bank “p” with ECCRPp.ECCORDIS. After that read 4 patterns from this bank with a correctable error. This shall trigger at least once the PFLASH ECC Error alarm in the SMU. Clear the alarm, clear ECCRPp.ECCORDIS for this bank and repeat the test for the other PFlash banks.

11.8.7.4 Testing the “EDC Comparator”

The EDC comparator compares the output of two error checking units. In case of a difference the SMU alarm “PFLASH EDC comparator error” is activated. This error can be enforced by setting for a PFlash bank “p” by setting ECCRPp.EDCERRINJ.

Test Pattern

The test patterns of **Chapter 11.8.7.1** can be used.

Test Flow

The test patterns are read with ECCRPp.EDCERRINJ = 0. This is already part of the test in **Chapter 11.8.7.1**. The “PFLASH EDC comparator error” alarm must not be activated.

The test patterns are read with ECCRPp.EDCERRINJ = 1. This shall trigger the “PFLASH EDC comparator error” alarm in the SMU.

Repeat this test for all PFlash banks.

11.8.7.5 General Advice for Startup Tests

The previously described tests need to be executed under controlled conditions:

- Only a single master with blocked interrupts should execute these tests. This is mandatory for tests with disabled ECC correction (**Chapter 11.8.7.3**) because other masters might receive uncorrected Flash data during that time.
- For the same reason the Flash test code should execute from RAM. Especially it must not execute from a PFlash bank with disabled ECC correction (**Chapter 11.8.7.3**).
- It has to be taken into account that internal pre-fetching of the PMU can trigger the “PFLASH ECC monitor error” and the “PFLASH EDC comparator error” before the corresponding Flash read access is issued by the CPU. For the ECC alarms and error flags of **Chapter 11.8.7.1** this issue is not existing as the PMU activates these errors only when the respective data is read from the bus.
- The alarms activation in the SMU has a latency of several clock cycles.
- The software executing these tests has to cope with all consequent actions like activated error flags, entries in error buffers, bus-errors, SMU alarms. Before normal execution continues these mechanisms have to be cleared.
- The existence of Flash addresses with correctable and uncorrectable errors has to be respected by the application software. Interpretation as real error has to be prevented.

12 Local Memory Unit (LMU)

The Local Memory Unit is an SRI peripheral providing access to volatile memory resources. It's primary purpose is to provide 32 kbytes of local memory for general purpose usage but it will also provide access to the separate block of emulation and debug memory (EMEM) provided in the Emulation Devices.

Data stored in the local memory is protected by ECC at all points within the LMU. Areas of local memory can be write protected by configuring up to eight address ranges using SFRs in the LMU. Each of these ranges can be sized in thirty-two byte increments and has its own, independent list of Master Tag IDs permitted write access. Read accesses are not protected.

The LMU also provides OnLine Data Acquisition (OLDA) region support. This provides an address space where writes complete without error but no memory is addressed. This allows production code to be written which writes data to memory which is only present in the Emulation Device. When running in the Emulation Device, the code maps EMEM to the OLDA region address space using the memory overlay feature and the writes are stored in the EMEM. when running in the Production Device, the LMU terminates writes to the OLDA address space without error, even though no memory exists at the target address, but the write data is discarded.

For ADAS variants of the device, the LMU acts as the interface to the hardware FFT accelerator. It allows the registers of the accelerator to be updated. and provides a data port to allow transfer of parameters.

12.1 Feature List

An overview of the features implemented in the LMU follows:

- 32 kbytes of SRAM
  - organized as 64 bit words
  - support for byte, half word and word accesses as well as double-word and burst accesses
  - memory can be used as overlay memory
- Access to the hardware FFT engine
- Protection of LMU SRAM contents
  - eight, programmable address regions can be protected
  - each address range has a programmable list of bus masters permitted write access based on the Unique master Tag ID
- Interface to the EMEM of the Emulation Device.
- Interface to the hardware FFT accelerator
- OLDA region support.

12.2 Local Memory (LMU SRAM)

The LMU SRAM can be used for code execution, data storage or overlay memory. The address range of the memory is 90000000_H to $90007FFF_H$. As well as being accessed via cached (segment 9_H), the memory can be accessed via non-cached (segment B_H) memory addresses.

The memory implements memory integrity checking for error detection and correction. This means that the memory must be initialized before reads are attempted with the integrity checking enabled to avoid generating spurious data corruption errors. Initializing before enabling the memory integrity logic allows the LMU SRAM to support initialisation using word (32 bit) or smaller writes as well as 64 bit writes. (The compiler does not support double-word memory accesses at present. Requiring double-word accesses for memory initialization requires a software workaround which it would be useful to avoid.)

If memory integrity checking is enabled, a read access which fails the integrity check will be terminated with an SRI error condition. This behavior can be changed by setting the **LMU_MEMCON.ERRDIS** bit to 1_B. If the bit is set then an SRI error will not occur.

An ECC error will also be reported to the SMU. The SMU will use this signal for error indication and triggering of an NMI trap (if enabled).

The LMU SRAM is internally organized as a 64 bit memory without the possibility of sub-word accesses. This means that any write access of less than 64 bits of data needs an internal Read-Modify-Write (iRMW) operation to correctly write the data and update the ECC data. This happens transparently to rest of the system unless an uncorrected ECC error is detected during the read phase of the iRMW. This ECC error will be flagged in the same way as a data ECC error occurring during a normal read. In addition the **LMU_MEMCON.RMWERR** flag will be set. The write operation will not take place as this would write incorrect ECC data to the memory (the ECC would match the written data but the data would potentially contain an uncorrected error).

LMU SRAM performance will be the same as, or better than, the performance of the embedded flash. This applies to both the initial latency of the first word returned and also the incremental latency for each word in the same cache line fetched.

If the CPU access can't be handled by the LMU SRAM (e.g. an unsupported SRI opcode has been received), an SRI bus error is reported by the LMU. This will cause a DSE trap.

Some bitfields of the **LMU_MEMCON** register are protected by **LMU_MEMCON.PMIC** bit. If the data written to the register has the bitfield set to 0_B, no change will be made to bits 15_D to 9_D of the register regardless of the data written to these fields.

12.2.1 LMU SRAM Read Buffers

The LMU SRAM interface implements read buffers to optimize use of the LMU SRAM. The read buffer will store the last 64 bit word accessed from the LMU SRAM. The buffer is predominantly useful when sequential, 32 bit accesses are being performed.

One read buffer will be available for every processor instance in the system. Each buffer will be controlled by an instance of the **LMU_BUFCONx (x=0-2)** register. The read buffer can be enabled using the **LMU_BUFCONx (x=0-2).TAG1** or **LMU_BUFCONx (x=0-2).TAG2** bits. Setting either of the bits to 1_B will enable the associated buffer. Each buffer can be associated with one or two Unique Master Tag IDs (**LMU_BUFCONx (x=0-2).TAG1** and **LMU_BUFCONx (x=0-2).TAG2**) and an update of the buffer will only be triggered when an access to the LMU SRAM uses an enabled tag. The tags are independently enabled using two control bits, **LMU_BUFCONx (x=0-2).EN1** for **TAG1** and **LMU_BUFCONx (x=0-2).EN2** for **TAG2**.[1)]

12.3 Memory Protection

The LMU allows for the definition of eight, protected regions of SRAM memory. The protection applies only to write accesses to SRAM included in the LMU (including atomic read-modify-write operations), not EMEM or registers. SRAM read accesses are not protected.

The protection scheme is based on the use of Unique Master Tag IDs to identify the master attempting the access and allows for a six bit tag individually identifying up to 64 masters. 32 masters are supported in the current implementation.

Each region is defined using four registers, **LMU_RGNLAx (x=0-7)** to define the lower address of the region, **LMU_RGNUAx (x=0-7)** to define the upper address of the region and **LMU_RGNACCENAx (x=0-7)** and **LMU_RGNACCENBx (x=0-7)** to individually select the master tags permitted write access to the defined address range. The scheme is compatible with the Tricore implementation so **LMU_RGNLAx (x=0-7)** defines the first address in the region

After reset, the region address registers will be set to include the whole of the LMU, SRAM address space and write access by all masters will be enabled.

The registers implementing the memory protection scheme are protected by the “safety endinit” function.

If overlapping regions are defined, then a write access only needs to be permitted by one of the overlapping regions for it to succeed.

Legal addresses for write accesses are those to a defined address region with a permitted master tag. The memory protection scheme will block write accesses to an address falling outside all of the defined address ranges

When altering protection settings, it should be noted that, due to access pipelining in the LMU and resynchronization delays in the register block, a write to a memory address affected by the protection change occurring immediately after the register write initiating the change may, or may not, be affected by the changed settings.

1) Multiple buffers should not be configured to respond to the same Master Tag ID. LMU behaviour in this case is undefined.

12.4 FFT Accelerator Interface

The LMU provides maps the resources of the hardware based FFT accelerator into the system address space. For full information on using the FFT accelerator, see the dedicated chapter of this specification.

Accesses to the registers and the data load/unload ports of the FFT accelerator are handled separately.

The LMU provides two functions related to the data load/unload ports:

- Any access to the data load/unload ports which is not completed by the FFT accelerator will time out after 255 clock cycles
- Read accesses to the data unload port are augmented by a prefetch function. Any read access using a BTR4, SSI opcode will automatically trigger another access of the same size to the next contiguous address. The prefetch is enabled by writing bit 10 (FFTPFT) of the MEMCON register.

12.5 Emulation Memory (EMEM)

In the Emulation Device , an area of Emulation Memory (EMEM) is provided, which can be used for either calibration via overlay of non-volatile memory or overlay of the OLDA address space (see **Chapter 1.8** below). The address range allocated for the memory is $9F000000_H$ to $9F3FFFFF_H$ which allows the maximum EMEM size fitted in any of the derivative products to be addressed.

As well as the cached addresses (segment 9_H), noncached address (segment B_H) accesses can be used for EMEM accesses via the LMU.

The Emulation Memory interface controls the CPU-accesses to the Emulation Memory in the Emulation Device. All widths of write accesses are supported (byte, halfword, word, double-word).

CPU-controlled Load-Modify-Store accesses (with LDMST instruction) are supported as separate read and write instructions not as an atomic operation.

In the production device, the EMEM interface is always disabled. A CPU read access from the Emulation Memory region causes a DSE trap by returning an SRI bus error. If the Emulation Memory region read access is initiated by a SPB master (e.g. PCP), additionally a SPB error interrupt can be generated.

By default, write accesses to the Emulation Memory by any master will cause an SRI bus error trap in the production device.

In the Emulation Device, a SRI bus error is returned by the LMU if a read access can’t be handled by the EMEM, for example, when the CPU accesses a trace memory tile in EMEM. In this case, the EMEM access is aborted by the LMU.

Write accesses which cannot be handled by the EMEM will fail silently as the write access is completed on the SRI bus before being passed to the EMEM. Therefore any error condition encountered by the EMEM will occur after the SRI access has completed.

A status bit **LMU_MEMCON.EWERR** will be set if an error occurs on an EMEM write. This bit can be cleared by writing 0_B.

Wait states can be manually added to EMEM memory accesses using the **LMU_MEMCON.WSTATES** field. This can be programmed with a counter preload value. A counter is loaded with this value every time the LMU starts a read access to the EMEM. Data returned by the EMEM will be delayed until the counter reaches a count of zero. The counter is decremented by one every SRI clock cycle.

12.5.1 EMEM Memory Read Buffers

Accesses to the EMEM address space can be stored to read buffers. One read buffer will be instantiated for each CPU in the system. Each of these buffers will store 256 bits of data. Buffering of read data is controlled by the **LMU_BUFCONx (x=0-2).EREN** bit and will be enabled when **EREN** is 1_B. Speculative prefetch is available only if buffering of read data is enabled and is controlled by the **LMU_BUFCONx (x=0-2).EPEN** bit. Setting **EPEN** to 1_B will allow prefetch if **EREN** is also 1_B. Two Unique Master Tag IDs can be manually associated with each CPU using the **LMU_BUFCONx (x=0-2).TAG1** and **LMU_BUFCONx (x=0-2).TAG2**. Each tag field can be individually enabled using the **LMU_BUFCONx (x=0-2).EN1** and **LMU_BUFCONx (x=0-2).EN2** fields respectively.[1)]

If read buffering is enabled, then all reads to the EMEM not using the BTR4 opcode will be mapped to BTR4 equivalent read accesses to the EMEM and the data returned stored in the related buffer while the requested data is returned to the SRI interface. Any further reads to the address range of the data stored in the buffer will be returned directly from the buffer.

If prefetch is enabled, then two conditions will trigger a prefetch:

- any SDTW read to the EMEM will cause a speculative read of the next BTR4 address range to be triggered if the address of the read corresponds to the highest 32 bit address of a BTR4[2)] (even if the data for the read is already stored in the buffer).
- Any BTR4 read to the cached segment address of the EMEM (9_H) will trigger a prefetch (even if the data for the read is already stored in the buffer).

The prefetched data will be stored in the related buffer and any reads to the address range of the prefetch will be returned directly from the buffer. A prefetch will not occur if another read to EMEM is already required. Write accesses will be scheduled after the prefetch has completed.

Prefetch takes priority over read buffering.

1) Multiple buffers should not be configured to respond to the same Master Tag ID. LMU behaviour in this case is undefined.

2) A BTR4 access requires 256 bits of data or 8, 32 bit words. These words always have $A_{SRI}[4:2] = 000_B$, 001_B, 010_B, 011_B, 100_B, 101_B, 110_B, 111_B. An 32 bit access with $A_{SRI}[4:2] = 111_B$ will trigger a prefetch

Any write access to EMEM which collides with the address range stored in a buffer will invalidate that buffer. Read accesses to the Emulation Device register space will not be buffered.

12.5.2 Access to Emulation Device Register Space

In addition to accessing EMEM, the EMEM interface in the LMU is also used to access configuration registers in the Emulation Device. To allow this accesses to the address range $F9000000_H$ to $F90FFFFF_H$ are directed to the ED register address space via the EMEM interface.

The interface to the ED register space only supports 32 bit accesses. Any other size of access will be errored.

12.6 Error Detection and Signalling

The LMU will detect several different classes of error which cannot be signalled on the SRI during the associated transaction. These will cause a flag to be set in the **LMU_MEMCON** register and a trigger will be sent to either the SMU or the Interrupt system for processing. In general ECC errors will be processed by the SMU and other errors will be passed to the Interrupt Router. Unless explicitly stated below, the access will complete. The following list details the detected error conditions:

12.6.1 EMEM Read Error

An error signalled by the EMEM on the second data phase of a 256 bit access cannot be signalled on the SRI as this would violate the protocol or, in the case of a 32 bit read, occur after the SRI access has completed. In this event, the LMU_MEMCON.ERERR bit will set and a trigger will be sent to the Interrupt Router.

12.6.2 EMEM Write Error

All errors signalled by the EMEM during a write access will, by definition in the SRI protocol, occur after the access has been accepted from the SRI. These errors will set the LMU_MEMCON.EWERR bit and send a trigger to the Interrupt router

12.6.3 Internal ECC Error

Internal registers used to transfer data between the RAM and the SRI interface are ECC protected. In the event of this ECC detecting an error, the LMU_MEMCON.INTERR bit will be set and an error will be signalled to the SMU.

12.6.4 Internal SRAM Read Error

The LMU will perform a internal Read-Modify-Write (iRMW) access when a write of less than 64 bits of data is performed. An ECC error reported by the RAM on the read phase

will cause the LMU_MEMCON.RMWERR bit to be set and an error will be signalled to the SMU. The write phase of the iRMW will not take place.

12.6.5 ECC check failure

The hardware used to check and correct the read data from the SRAM is replicated and the output from the two instances is compared. In the event of a difference between the two outputs, an error condition will be signalled to the SMU. The second instance will use inverted logic to eliminate common failure modes.

12.6.6 SRI write access data phase error

If an ECC error occurs on the data phase of an SRI write access then the LMU_MEMCON.DATAERR bit will be set and an error will be signalled to the SMU

12.6.7 SRI access address phase error

If an ECC error occurs on the address phase of an SRI access then the LMU_MEMCONADDERR bit will be set and an error will be signalled to the SMU. The SRI access will terminate with an error.

12.7 Online Data Acquisition (OLDA) and its Overlay

Calibration is additionally supported by an OLDA memory range of up to 32 Kbyte, which is a virtual memory and physically only available if it is redirected (by the overlay feature of the processor) to internal or external physical memory or to the EMEM in the Emulation Device.

If OLDA support is enabled in the LMU, direct write accesses (without redirection) to the OLDA range are not really executed, and they do not generate a bus error trap[1)]. If OLDA support is not enabled, write accesses will generate a bus error trap. OLDA support is enabled by setting LMU_MEMCON.OLDAEN to 1_B.

Note that switching on or off the OLDA function takes a finite amount of time after the register write completes. It is therefore possible for an immediately following access pipelined into the LMU SRI interface to be acknowledged with either the "on" or "off" behaviour.

Read accesses to the OLDA range generate a bus error trap, if not redirected to a physically available overlay block. Successful accesses to the OLDA memory range will only take place when the accesses are redirected to real, physical memory.

1) Write accesses to a cached memory address will trigger a read to fill the cache line before the data is written to the cache. This read will trigger a bus error.

The base address of the virtual OLDA memory range is A/8FE7 0000_H, the end address is A/8FE7 $7FFF_H$. Accesses to the OLDA range are also supported in cached address space.

Note: In OTARx registers, any target address can be selected for redirection, thus also addresses in the OLDA range. However, the handling of direct accesses to the OLDA range is completely controlled in the LMU.

12.8 Clock Control

The LMU contains a clock control register, **LMU_CLC**, which allows the LMU to be put into a power saving mode.

If LMU_CLC.DISR is set then the LMU will be disabled and all accesses will be errored unless they are addressed to a register.

12.9 LMU Register Protection

The LMU implements the standard memory protection scheme for peripheral registers using the **LMU_ACCEN0** and **LMU_ACCEN1** registers. This allows the LMU control registers to be protected from corruption by untrusted masters. Masters are identified using the SRI tag of the access and, if the appropriate bit is not set in the access enable registers, write accesses will be disconnected with error acknowledge. See the On Chip Bus chapter for the product's master Tag ID to master peripheral mapping. This protection scheme does not apply to the **LMU_ACCEN0** and **LMU_ACCEN1** themselves.

LMU_ACCEN0 and **LMU_ACCEN1** are protected by Safe Endinit while all other registers are Endinit protected. The Endinit and Safe Endinit system status is defined by different Watchdog Units in the System Control Unit (SCU).

12.10 LMU Registers

The LMU registers are mapped into a 256 byte address space which allows for 64 registers. Accesses to unused register space will cause an SRI bus error.

Table 12-1 Registers Address Space

Module	Base Address	End Address	Note

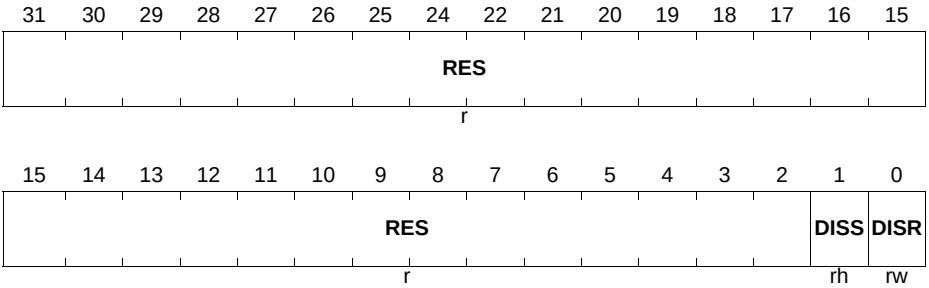
1) The absolute register address is calculated as follows:
Module Base Address (**Table 1-5**) + Offset Address (shown in this column)

LMU Clock Control Register

LMU_CLC

LMU Clock Control Register **(000_H)** **Reset Value: 0000 0000_H**

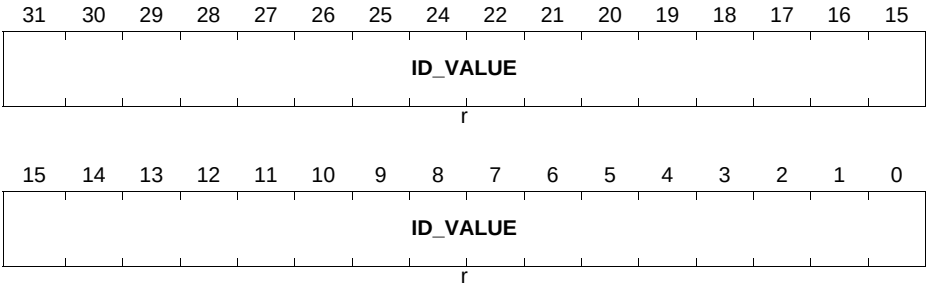


Field	Bits	Type	Description
DISR	0	rw	**LMU Disable Request Bit** This bit is used for enable/disable control of the LMU. 0_B LMU disable is not requested 1_B LMU disable is requested
DISS	1	rh	**LMU Disable Status Bit** Current state of LMU. 0_B LMU is enabled (default after reset) 1_B LMU is disabled
RES	31:2	r	**Reserved**

LMU Module ID Register

LMU_MODID

LMU Module ID Register **(008_H)** **Reset Value: $0088\ C002_H$**



Field	Bits	Type	Description
ID_VALUE	31:0	r	**Module Identification Value**

LMU Access Enable Register 0

The Access Enable Register 0 controls write access for transactions to registers with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The LMU is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... ,EN31 -> TAG ID 011111_B.

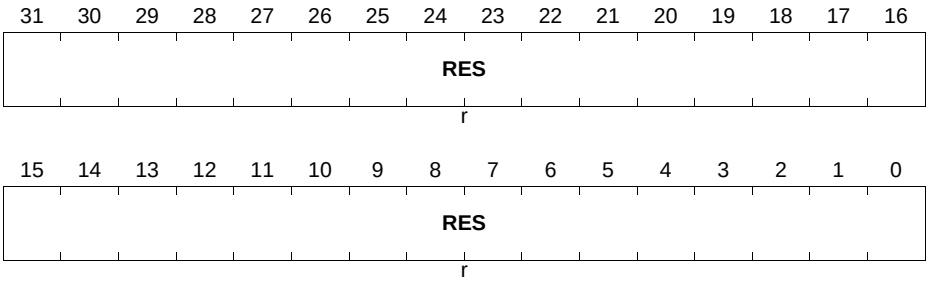
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the LMU register addresses for transactions with the Master TAG ID n 0_B Write access will not be executed. Read accesses will be executed. 1_B Write and read accesses will be executed

LMU Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). These tags are not used in this system and so no programmable bits are provided.

LMU_ACCEN1

LMU Access Enable Register 1 (14_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RES	31:0	r	**Reserved** Read as 0; should be written with 0.

LMU Memory Control Register

Provides Control of the memory integrity error checking, error signalling to the SMU and error injection for ECC logic test. Also control of the OLDA function. The register is cleared by an application reset.

LMU_MEMCON
LMU Memory Control Register (020$_H$) Reset Value: 0000 0000$_H$

Field	Bits	Type	Description
OLDAEN	0	rw	**Online Data Acquisition Enabled** This bit is used to control trap generation for write accesses to the OLDA address range. 0_B Trap generation on write access to OLDA memory range is enabled 1_B No trap generated on write access to OLDA memory range.
POLDAEN	1	w	**Protection Bit for OLDAEN** This bit always returns 0_B when read. 0_B Bit Protection: Bit OLDAEN remains unchanged after LMU_MEMCON write. 1_B OLDAEN can be changed by current write to LMU_MEMCON
INTERR	2	rwh	**Internal ECC Error** Flag set by hardware when the LMU logic detects an ECC error while accessing the RAM. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An error has been observed during a RAM access.

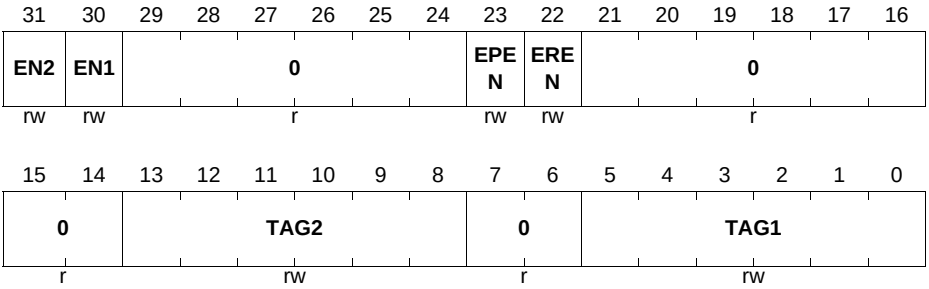
Field	Bits	Type	Description
ERERR	3	rwh	**EMEM Read Error** Flag set by hardware when the LMU logic detects an error on an EMEM read transaction which cannot be reported on the SRI bus. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An unreportable error has been observed on an EMEM read transaction.
RMWERR	4	rwh	**Internal Read Modify Write Error** Flag set by hardware when the LMU logic detects an ECC error on the read phase of an internal RMW operation. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An error has been observed during an iRMW operation.
EWERR	5	rwh	**EMEM Write Error** Flag set by hardware when the LMU logic detects an error on an EMEM write transaction. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An error has been observed on an EMEM write transaction.
DATAERR	6	rwh	**SRI Data Phase ECC Error** Flag set by hardware when the SRI interface detects an ECC error in the data phase of an incoming write transaction. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An ECC error has been observed on an SRI transaction addressed to the LMU
ADDERR	7	rwh	**SRI Address Phase ECC Error** Flag set by hardware when the SRI interface detects an ECC error in the address phase of an incoming transaction. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An ECC error has been observed on an SRI transaction addressed to the LMU

Field	Bits	Type	Description
PMIC	8	w	**Protection Bit for Memory Integrity Control Bit** Will always return 0_B when read 0_B Bit Protection: Bit 9 remains unchanged after LMU_MEMCON write. 1_B Bit 9 will be updated by the current write to LMU_MEMCON
ERRDIS	9	rw	**ECC Error Disable** When set SRI bus errors caused by ECC errors in data read from the SRAM will be disabled 0_B Normal behavior. SRI error will occur on SRAM ECC errors. Default after reset 1_B Test Mode. SRI errors will not be generated on an SRAM ECC error. This does not affect the generation of interrupts.
FFTPFT	10	rw	**FFT Accelerator Prefetch Disable** 0_B Read accesses to FFT accelerator data port using a BTR4, SRI opcode trigger prefetch of the next data. 1_B No prefetch on accesses to FFT accelerator data port
0	11	r	**Reserved** Read as 0_H, must be written as 0_H
WSTATES	15:12	rw	**EMEM Wait States** Wait State Counter for EMEM accesses. See **“Emulation Memory (EMEM)” on Page 4-6** for operational details.
0	31:16	r	**Reserved** Read as 0_H, must be written as 0_H

LMU Buffer Control Register

Enables control of a read buffer. The register is cleared by an application reset.

LMU_BUFCONx (x=0-2)
LMU Buffer Control Register **(030_H+x*04_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TAG1	5:0	rw	**Master Tag ID 1** This field should store the Master Tag ID of accesses which are required to trigger an update of the read and prefetch buffers.
0	7:6	r	**Reserved** Read as 0_B, should be written with 0_B.
TAG2	13:8	rw	**Master Tag ID 2** This field should store the Master Tag ID of accesses which are required to trigger an update of the read and prefetch buffers.
0	21:14	r	**Reserved** Read as 0_B, should be written with 0_B.
EREN	22	rw	**EMEM Read Buffer Enable** Enable bit for the read buffer function on EMEM reads 0_B Do not buffer reads from the EMEM 1_B Read buffer is enabled.
EPEN	23	rw	**EMEM Prefetch Enable** Enable bit for the prefetch function on EMEM reads 0_B Do not prefetch from the EMEM 1_B Prefetch is enabled.

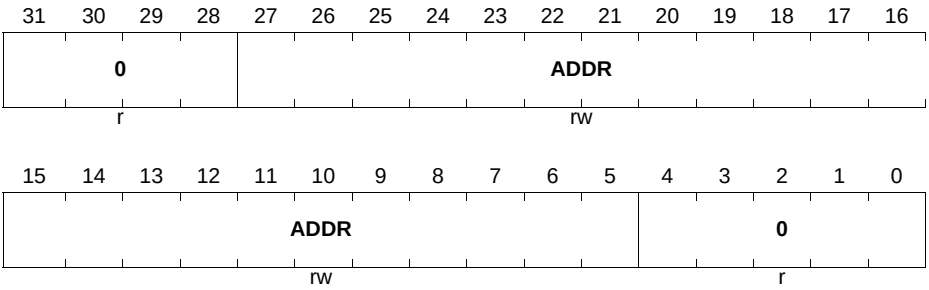
Field	Bits	Type	Description
0	29:24	r	**Reserved** Read as 0_B, should be written with 0_B.
EN1	30	rw	**TAG1 Field Enable** Enable bit for the TAG1 field 0_B TAG1 does not contain a valid Unique Master Tag ID value and should be ignored. 1_B TAG1 does contain a valid Unique Master Tag ID value and should be used when triggering an update for the read buffer. Local SRAM Read buffer is enabled.
EN2	31	rw	**TAG2 Field Enable** Enable bit for the TAG1 field 0_B TAG2 does not contain a valid Unique Master Tag ID value and should be ignored. 1_B TAG2 does contain a valid Unique Master Tag ID value and should be used when triggering an update for the read buffer. Local SRAM Read buffer is enabled.

LMU Region Lower Address Register

In conjunction with the associated RGNUA and RGNACCENx registers, the RGNLA register provides control of a memory protection region. The register is cleared by a application (Class 3) reset. RGNLA defines the lower address of a region of memory, RGNUA defines the upper address and the RGNACCENx registers define the Unique Master Tag IDs allowed to access the region. Address ranges can bet set to be larger than the LMU address space but only accesses to the LMU are affected by these registers. Bits 31_D to 28_D are ignored as they define the segment address and the minimum resolution of the comparison logic is 32_D bytes so address bits 4_D down to 0_D are similarly not used. Bit 28 of RGNUA.ADDR can be set if all addresses in the segment greater than or equal to RGNLA.ADDR are to be considered valid

LMU_RGNLAx (x=0-7)

LMU Region Lower Address Register(050_H+x*10_H) **Reset Value: 0000 0000_H**



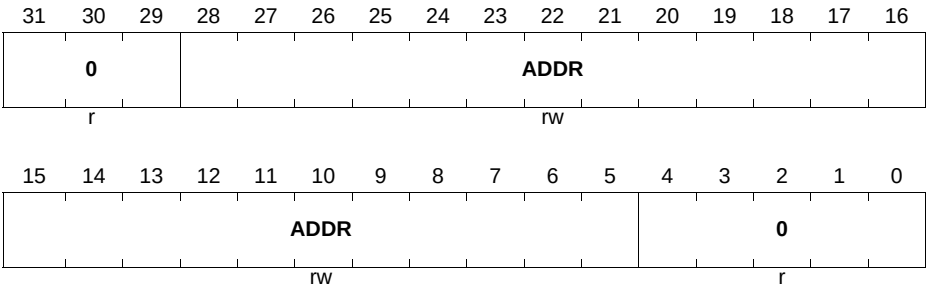
Field	Bits	Type	Description
0	4:0	r	**Unused** Read as 0_B, should be written with 0_B although written value will be ignored.
ADDR	27:5	rw	**Region Lower Address** Bits 27 to 5 of the SRI address which is the lower bound of the defined memory region
0	31:28	r	**Unused** Read as 0_B, should be written with 0_B although written value will be ignored.

LMU Region Upper Address Register

In conjunction with the associated RGNLA and RGNACCENx registers, the RGNUA register provides control of a memory protection region. The register is cleared by an application (Class 3) reset. RGNUA defines the upper address of the memory region and will contain the first address outside the protected region.

LMU_RGNUAx (x=0-7)

LMU Region Upper Address Register(054_H+x*10_H) **Reset Value: 1000 0000_H**



Field	Bits	Type	Description
1	4:0	r	**Unused** Read as 0_B, should be written with 0_B although written value will be ignored.
ADDR	28:5	rw	**Region Lower Address** Bits 27 to 5 of the SRI address which is the upper bound of the defined memory region. i.e. the first address outside the protected region. Set bit 28 if all addresses in the segment greater than the lower address are to be accepted
0	31:28	r	**Unused** Read as 0_B, should be written with 0_B although written value will be ignored.

LMU Region Access Enable Register A

The Access Enable Register A controls write access for transactions to the protected memory region with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The LMU is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... ,EN31 -> TAG ID 011111_B.

LMU_RGNACCENAx (x=0-7)

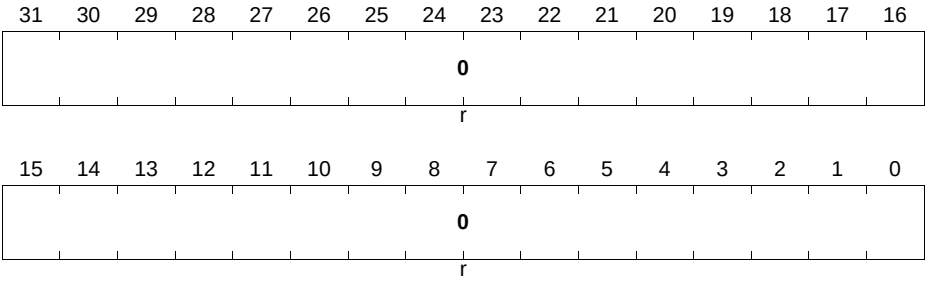
LMU Region Access Enable Register B

The Access Enable Register B controls write access for transactions to the protected memory region with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The LMU is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... ,EN31 -> TAG ID 111111_B.

LMU_RGNACCENBx (x=0-7)

LMU Region Access Enable Register 1($05C_H$+x*10_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

13 Data Access Overlay (OVC)

The data overlay provides the capability to redirect selected data accesses to the Overlay memory. Data accesses made by the TriCore to Program Flash, Online Data Acquisition space, or EBU space can be redirected. Overlay memory may be located in the Local Memory (if present), in the Emulation Memory (Emulation Device only), or in the DPSR/PSPR memory. Overlay functionality makes it possible, for example, to modify the application's test and calibration parameters (which are typically stored in Flash memory) during run time of a program. Note that only read and write data accesses are redirected. The access redirection is executed without performance penalty.

Attention: As the address translation is implemented in the DMI it is only effective for data accesses by the TriCore. Instruction fetches by the TriCore or accesses by any other master (including the debug interface) are not effected!

Summary of Features and Functions

- Redirecting data accesses addressed to Program Flash, OLDA or External EBU Space.
- Support redirection to Overlay memory located in:
  - Local Memory (LMU) (if present)
  - Emulation Memory (Emulation Device only)
  - DSPR or PSPR memory
- Support of up to 4 MB overlay memory address range;
- Up to 8 overlay ranges ("blocks") available;
- Overlay block size from 32 byte to 128 Kbyte;
- Up to 1 MB of redirected space (8 ranges x 128 Kbyte);
- Overlay memory location and block size selected individually for every overlay block;
- Multiple overlay blocks can be enabled or disabled with one register write access;
- Programmable flush (invalidate) control for data cache in DMI.
- Overlay start/stop synchronised against data load.

13.1 Data Access Redirection

The principle of redirecting data access from the original target memory (“Target Address”) to overlay memory (“Redirected Address”) is shown below.

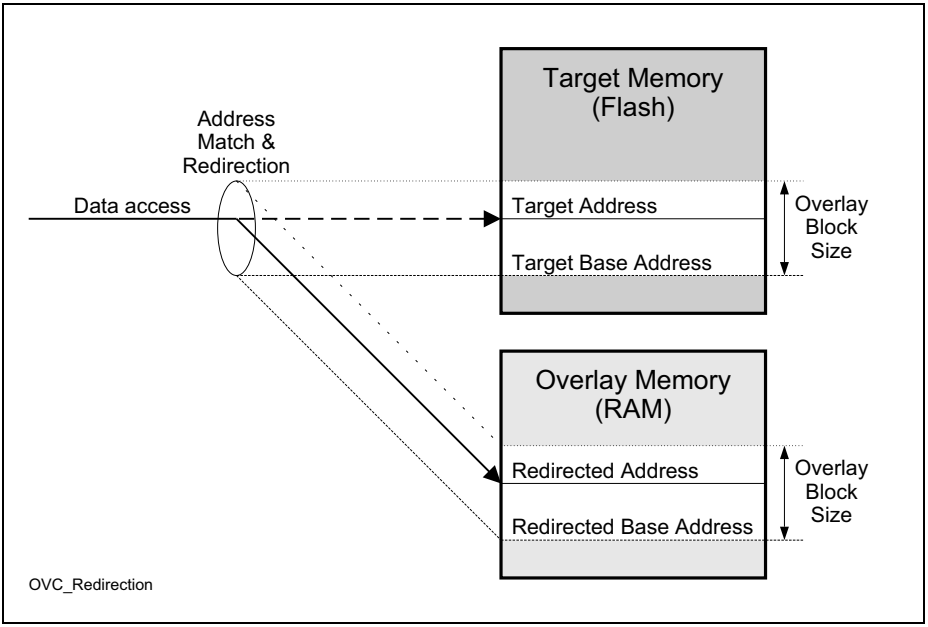


Figure 13-1 Data Access Redirection

Data access overlay is defined using overlay ranges (“overlay blocks”). Each overlay block defines one continuous range of address space for which the accesses are redirected. Each overlay block is configured with the following parameters:

- Overlay Block Target Base Address - the start address for the range of the target addresses to be redirected;
- Overlay Block Size - the size of the range of the addresses to be redirected;
- Overlay Block Redirection Base Address - the start address for redirection.

In TC21x/TC22x/TC23x up to 8 overlay ranges can be used in each TriCore instance.

Each overlay block has 3 associated registers for independent configuration of these parameters. The overlay parameters are configured as follows:

- Target Base Address is configured with OTARx register (**“OTARx (x=0-7)” on Page 13-13**),
- Overlay Block Size is configured with OMASKx register (**“OMASKx (x=0-7)” on Page 13-14**),

- Redirection Base Address is configured with RABRx register (**"RABRx (x=0-7)" on Page 13-11**).

The size of the overlay memory blocks can be 2^n x 32 bytes, with n = 0 to 12. This gives the block size range from 32 bytes to 128 Kbytes. The start address of the block can only be an integer multiple of the programmed block size (natural alignment boundary). If OTAR register value, or RABR register value is not aligned with the block size, the least significant bit values are ignored and treated as zero.

The Redirection Base Address is determined by two fields in RABRx register:

- RABRx.OMEM selecting the Overlay Memory, and
- RABRx.OBASE selecting the base address within this memory.

Each overlay block can be activated or deactivated with its RABRx.OVEN bit. Overlay blocks can be activated and deactivated independently, by directly accessing RABRx register, or in groups, where multiple configured blocks are activated of deactivated concurrently. For information on concurrent block activation see **Chapter13.4.1**.

The address redirection process is shown in the following figure.

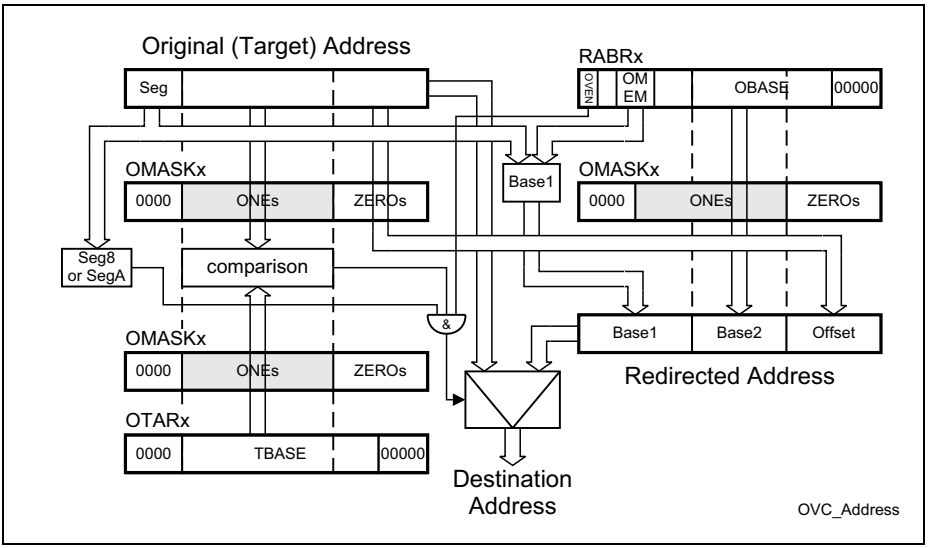

Figure 13-2 Address Redirection Process

Any data access to segment 8_H or segment A_H is checked against all the activated overlay blocks. For each activated overlay block, address bits 27..5 are compared with the target base address (OTARx), and this bit-wise comparison is qualified by the content of OMASKx register. Address bits participate in the comparison if the

corresponding OMASKx bits are set to one. The access is redirected, if all the address bits selected by OMASKx equal to the corresponding bits in OTARx register.

The address for redirection is constructed as follows:

- Address bits 31..22 are set according to the overlay memory selection (RABRx.OMEM) and the cache-ability of the original address.
- For address bits 21..5:
  - If the corresponding OMASKx bit is set, the address bit value is taken from RABRx.OBASE field;
  - If the corresponding OMASKx bit is cleared, the address bit value is taken from the original address.
- Address bits 4..0 are always taken directly from the original address.

If there is no redirection, the original address is used to perform the access.

Target address ranges for activated overlay blocks should not overlap or an exception may occur, see **Chapter13.6**.

13.2 Target Memories

Data access to any memory within the segment 8_H or segment A_H may be redirected to overlay memory. In particular, access to the following memories may be redirected:

- Program Flash;
- Data Flash;
- OLDA space;
- External EBU space.

13.2.1 Online Data Acquisition (OLDA) Space

Calibration is additionally supported by virtual OLDA memory range. The base address of the virtual OLDA memory range is A/8FE7 0000_H.

13.3 Overlay Memories

In the following, all the supported overlay memories are described. Note, that depending on the device type only a subset of the listed overlay memories is available. Overlay memory is selected independently for each block by RABRx.OMEM field value.

13.3.1 Local Memory

If present, the Local Memory (LMU) can be selected for overlay. The Local Memory is selected for overlay block x redirection, if RABRx.OMEM value is 6. The base address of the LMU is B/9000 0000_H. During address translation, the upper 10 address bits are set to $B0_H00_B$ (for target segment A_H) or to 90_H00_B (for target segment 8_H).

13.3.2 Emulation Memory

If present, the Emulation Memory (EMEM) can be selected for overlay. The Emulation Memory is selected for overlay block x redirection, if RABRx.OMEM value is 7. The base address of the Emulation Memory is B/9F00 0000_H. During address translation, the upper 10 address bits are set to BF_H00_B (for target segment A_H) or to $9F_H00_B$ (for target segment 8_H).

13.3.3 DSPR & PSPR Memory

Data Scratch Memory (DSPR) or Program Scratch Memory (PSPR) can be selected for overlay. The DSPR or PSPR is selected for overlay block x redirection, if RABRx.OMEM value is 0, 1, or 2. The base address is 7000 0000_H, 6000 0000_H, or 5000 0000_H. During address translation, the upper 10 address bits are set to 70_H00_B, 60_H00_B, or 50_H00_B. Depending on the value set in RABRx.OBASE either DSPR memory (starting at offset 0_H) or PSPR memory (starting at offset 10 0000_H) can be used.

13.4 Global Overlay Control

Overlay can be disabled or enabled individually for each core with OVCENABLE register. If OVCENABLE.OVENx bit is cleared no address redirection is permitted on Core x regardless of the remaining register settings. A write to OVCENABLE register does not change any of the remaining register values.

While each overlay block can be activated and deactivated individually by writing its RABRx.OVEN bit, a dedicated functionality is provided for concurrently activating and deactivating multiple blocks. This can be useful in maintaining data consistency across several memory regions. For the purpose of concurrent activation and deactivation overlay blocks are selected in two stages:

- The individual blocks for activation and deactivation are selected with OVCx_OSEL registers, for each core x independently;
- The set of cores is selected with OVCCON.CSEL field.

Multiple overlay blocks can be simultaneously activated or deactivated with OVCCON.OVSTRT bit. When OVCCON.OVSTRT bit is written with one:

- If OVCCON.CSELx bit is written with one, and OVCx_OSEL.SHOVENy bit value is one, overlay block y in core x is activated, and OVCx_RABRy.OVEN bit is set;
- If OVCCON.CSELx bit is written with one, and OVCx_OSEL.SHOVENy bit value is zero, overlay block y in core x is deactivated, and OVCx_RABRy.OVEN bit is cleared;
- If OVCCON.CSELx bit is written with zero, the overlay configuration in core x is not effected.

The actions listed above are executed concurrently. The overlay configuration is not changed otherwise. With this function it is possible to switch directly from one set of overlay blocks to another set of overlay blocks.

Multiple overlay blocks can be simultaneously deactivated with OVCCON.OVSTP bit. When OVCCON.OVSTP is written with one:

- If OVCCON.CSELx bit is written with one, all the overlay blocks in core x are deactivated, and all OVCx_RABRy.OVEN bits are cleared;
- If OVCCON.CSELx bit is written with zero, the overlay configuration in core x is not effected.

The actions listed above are executed concurrently. The overlay configuration is not changed otherwise.

Note: Overlay should not be enabled or disabled using global OVCENABLE register if any of the blocks are enabled with RABRx.OVEN. Instead, OVSTRT or OVSTP should be used if concurrent block enabling or disabling is required.

When OVCCON.DCINVAL is written with one, all the unmodified (clean) data cache lines in the selected cores are invalidated. The data cache lines containing modified (dirty) data are not effected. The cores not selected with OVCCON.CSEL field are not effected. Data Cache invalidation can be combined with OVSTRT or OVSTP action. This function helps to assure that the CPU can access the new data after the overlay blocks have been activated or deactivated.

Note: OVCCON.CSEL field is written together with OVSTRT, OVSTP and DCINVAL bits in the same register, and only impacts any action triggered by the same write. CSEL, OVSTRT, OVSTP and DCINVAL do not retain the written value and always read as zero.

The OVCCON.OVCONF user control flag is provided, together with its protection bit OVCCON.POVCONF. These bits do not impact the overlay functionality.

When OVCCON register is written with CSELx set and either OVSTRT or OVSTP set, and at the same time OVCx_RABRy register is written, the resulting value of OVCx_RABRy.OVEN bit is not defined. Possibility of such simultaneous access should be avoided.

OVSTRT, OVSTP and DCINVAL actions are not performed when TriCore is in IDLE state.

13.4.1 Global Overlay Control Synchronisation

When OVSTRT, OVSTP or DCINVAL action is requested its execution may be delayed to prevent changing Overlay configuration during an ongoing data load.

Sufficient time should be allowed after an action request, before another action is requested. If a new action is requested while previous action is still pending (due to synchronisation with CPU loads) some actions may be lost.

13.5 Overlay Configuration Change

Overlay block should be disabled, by clearing its RABRx.OVEN bit, before any changes are made to OTARx, OMASKx or RABRx registers. Otherwise, unintended access redirections may occur. Overlay block should only be enabled, if the target address, the overlay memory selection, the redirection address and the mask have all been configured with intended values.

Note: The Overlay Control does not prevent configuring the translation logic incorrectly. In particular, redirection to not implemented or forbidden address range is not prevented.

Special care needs to be taken to synchronise Overlay redirection change to the executed instruction stream if data consistency is required.

External accesses may be buffered in the CPU. External accesses that have not been completed may still be affected by overlay configuration changes. Therefore, it is advised to ensure completion of all pending accesses (for example, by executing DSYNC instruction) before any overlay range is acitvated of deactivated.

When overlay block is enabled and the same memory location is written through the target address space and read through the redirected address space, or vice-versa, the access synchronisation need to be enforced (with DSYNC and data cache writeback if applicable).

13.6 Access Protection, Attributes, Concurrent Matches

When data access is redirected by Overlay, access protection is applied as follows:

- Target address is subject to CPU Memory Protection (MPU) validation;
- Redirected address is subject to Safety Protection validation.

Physical Memory Attributes for the redirected access are determined basing on the Target Address segment (see CPU Physical Memory Attributes chapter).

Concurrent matches in more than one enabled overlay block are not supported. When an address matches two, or more, of the enabled overlay blocks, an exception is raised and the memory access is not performed. A load operation with multiple matches on overlay ranges, raises a Data Access Synchronous Error (DSE) trap, and a store operation raises Data Access Asynchronous Error (DAE) trap. In such case, relevant trap information registers: Data Synchronous Trap Register (DSTR), Data Asynchronous Trap Register (DATR), and Data Error Address Register (DEADD) are updated, see DMI Registers chapter for more information.

13.7 Overlay Control Registers

OVC block control registers are located in each module that supports data access overlay. OVC global control registers are located in SCU. OVC register access can be restricted by Safety Register Protection.

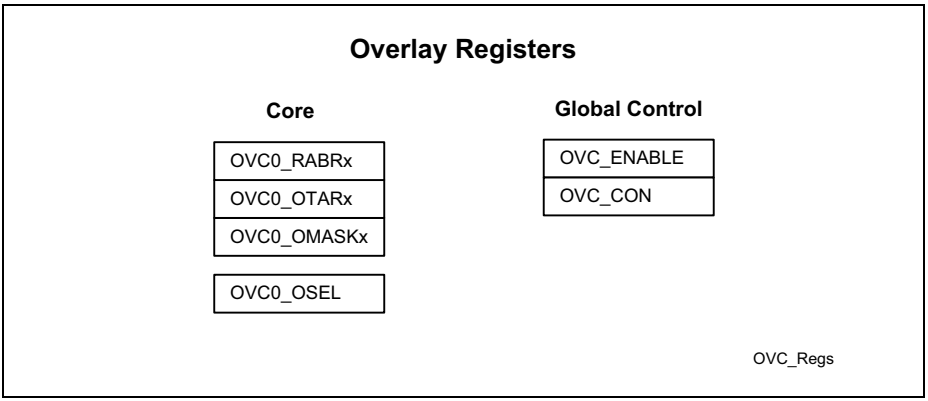

Figure 13-3 Overlay Register Overview

Registers OVCENABLE and OVCCON are described in SCU Chapter.

Table 13-1 Registers Address Space of OVC Registers

Module	Base Address	End Address	Note
OVC0	F880 FB00$_H$	F880 FCFF$_H$	Core0 Overlay

Table 13-2 Registers Overview, Overlay Block Control

Register[1] Short Name	Register Long Name	Offset Address	Access Mode[2]		Descript-ion see
			Read	Write	
OSEL	Overlay Range Select Register	0000_H	U, SV, 32	P, SV, 32	Page 13-10
RABRx	Redirected Address Base Register x (x = 0-7)	$0010_H + x * C_H$	U, SV, 32	P, SV, 32	Page 13-11
OTARx	Overlay Target Address Register x (x = 0-7)	$0014_H + x * C_H$	U, SV, 32	P, SV, 32	Page 13-13
OMASKx	Overlay Mask Register x (x = 0-7)	$0018_H + x * C_H$	U, SV, 32	P, SV, 32	Page 13-14

1) The OVC register short names are extended with the module name prefix “OVCi_”, where i is core number.

2) Symbol P: Write access protected with Safety Protection
Symbol SV: Access permitted in Supervisor Mode
Symbol U: Access permitted in User Mode 0 or 1
Symbol 32: Only 32-bit word access is permitted

13.7.1 Block control registers

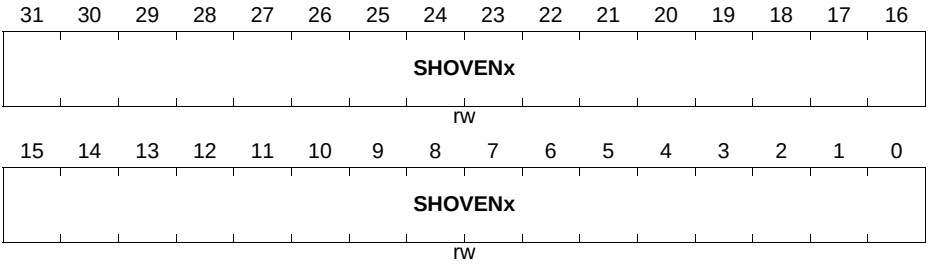
For each of the 8 overlay memory blocks (indicated by index x), three registers control the overlay operation and the memory selection:

- Redirected Address Base Register RABRx, which selects the overlay memory, holds the block base address within this memory, and contains block enable bit.
- Overlay Target Address Register OTARx, which holds the base address of the memory block being overlaid.
- Overlay Mask Register OMASKx, which determines which bits (from RABRx) are used for the base address (of overlay memory and block) and which bits (of original data address) are directly used as offset within the block.

Additionally, Overlay Range Select Registers OSEL determines which blocks are to be enabled and which blocks are to be disabled when OVCCON.OVSTRT bit is set.

All overlay block control registers are reset to their default values with the application reset. A special debug reset is not considered.

OSEL
Overlay Range Select Register (0000_H) Reset Value: $0000\ 0000_H$

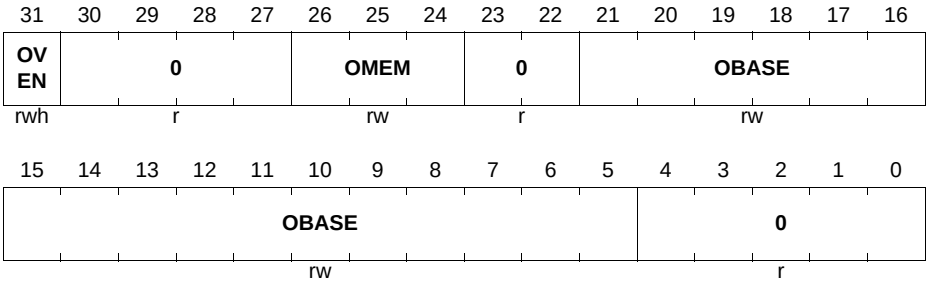


Field	Bits	Type	Description
SHOVENx (x=0-7)	x	rw	**Shadow Overlay Enable x** 0_B Overlay block x is disabled when OVCCON.OVSTRT is set. 1_B Overlay block x is enabled when OVCCON.OVSTRT is set. One enable bit is provided for each of the 8 overlay blocks (indicated by index x).

*Note: See **Chapter13.4.1** for more information on using OSEL register.*

RABRx (x=0-7)
Redirected Address Base Register x

(10_H+x*C_H) **Reset Value: 0000 0000_H**

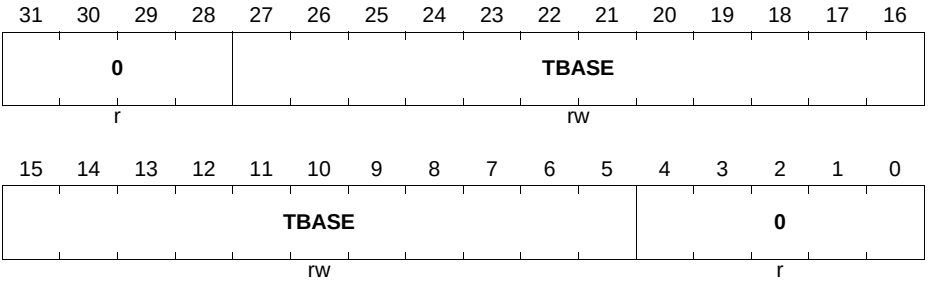


Field	Bits	Type	Description
OVEN	31	rwh	**Overlay Enabled** This bit controls whether the overlay function of overlay block x is enabled. 0_B Overlay function of block x is disabled. 1_B Overlay function of block x is enabled. This bit can also be changed when OVCCON.OVSTP or OVCCON.OVSTRT is set. See OVCCON register description.
OMEM	[26:24]	rw	**Overlay Memory Select** Selects overlay memory used for redirection. 0_H Redirection to Core 0 DSPR/PSPR memory $1..5_H$ Reserved, do not use 6_H Redirection to LMU 7_H Redirection to EMEM
OBASE	[21:5]	rw	**Overlay Block Base Address** Bits 21..5 of the base address the overlay memory block in the overlay memory. If the corresponding bit in OMASK register is set to one, OBASE bit value is used in the redirection address. If the corresponding bit in OMASK register is set to zero, OBASE bit value is ignored.

Field	Bits	Type	Description
0	[30:27] [23:22] [4:0]	r	**Fixed Value** Read as 0; should be written with 0.

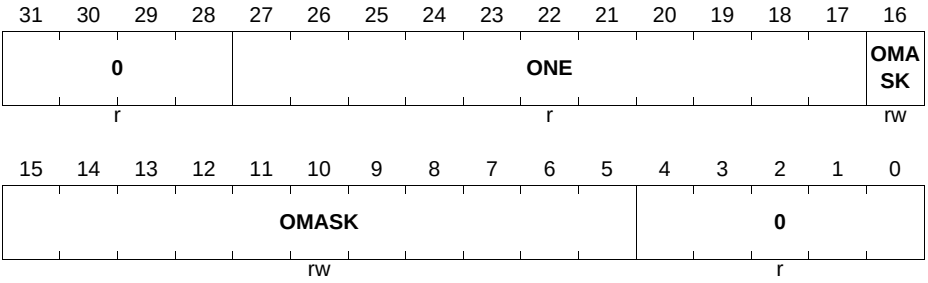
OTARx (x=0-7)
Overlay Target Address Register x

(14_H+x*C_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TBASE	[27:5]	rw	**Target Base** This field holds the base address of the overlay memory block in the target memory. If the corresponding bit in OMASK register is set to one TBASE bit value is used in the address match. If the corresponding bit in OMASK register is set to zero TBASE bit value is ignored.
0	[31:28] [4:0]	r	**Reserved** Reads as 0; should be written with 0.

OMASKx (x=0-7)
Overlay Mask Register x **(18_H+x*C_H)** **Reset Value: 0FFF FFE0$_H$**



Field	Bits	Type	Description
OMASK	[16:5]	rw	**Overlay Address Mask** This bitfield determines the overlay block size and the bits used for address comparison and translation. 000000000000_B, 128 Kbyte block size 100000000000_B, 64 Kbyte block size 110000000000_B, 32 Kbyte block size [...] 111111111110_B, 64 byte block size 111111111111_B, 32 byte block size “Zero” bits determine the corresponding address bits which are not used in the address comparison and thus determine the block size; corresponding final address bits are derived from the original data address. “One” bits determine the corresponding address bits which are used for the address comparison; corresponding final address bits are derived from RABRx register in case of address match.
ONE	[27:17]	r	**Fixed “1” Values** Corresponding address bits are participating in the address comparison. Corresponding final address bits are taken from RABRx.

Field	Bits	Type	Description
0	[4:0] [31:28]	r	**Fixed “0” Values** Corresponding address bits are not used in the address comparison. Corresponding final address bits are taken from the original data address.

13.8 Global overlay control registers

Two registers globally control the overlay operation for all the cores:

- Overlay Enable Register OVCENABLE can be used to disable or enable data access overlay individually for each core;
- Overlay Control Register OVCCON can be used to perform the following action on selected set of cores:
  – concurrently enable / disable selected overlay blocks,
  – concurrently disable overlay blocks,
  – invalidate data cache.

.

14 General Purpose I/O Ports and Peripheral I/O Lines (Ports)

The TC21x/TC22x/TC23x has digital General Purpose Input/Output (GPIO) port lines which are connected to the on-chip peripheral units.

Attention: Please refer to the pin definition and functions chapters for port input and output signal mapping.

14.1 Basic Port Operation

Figure 14-1 is a general block diagram of a TC21x/TC22x/TC23x GPIO port slice.

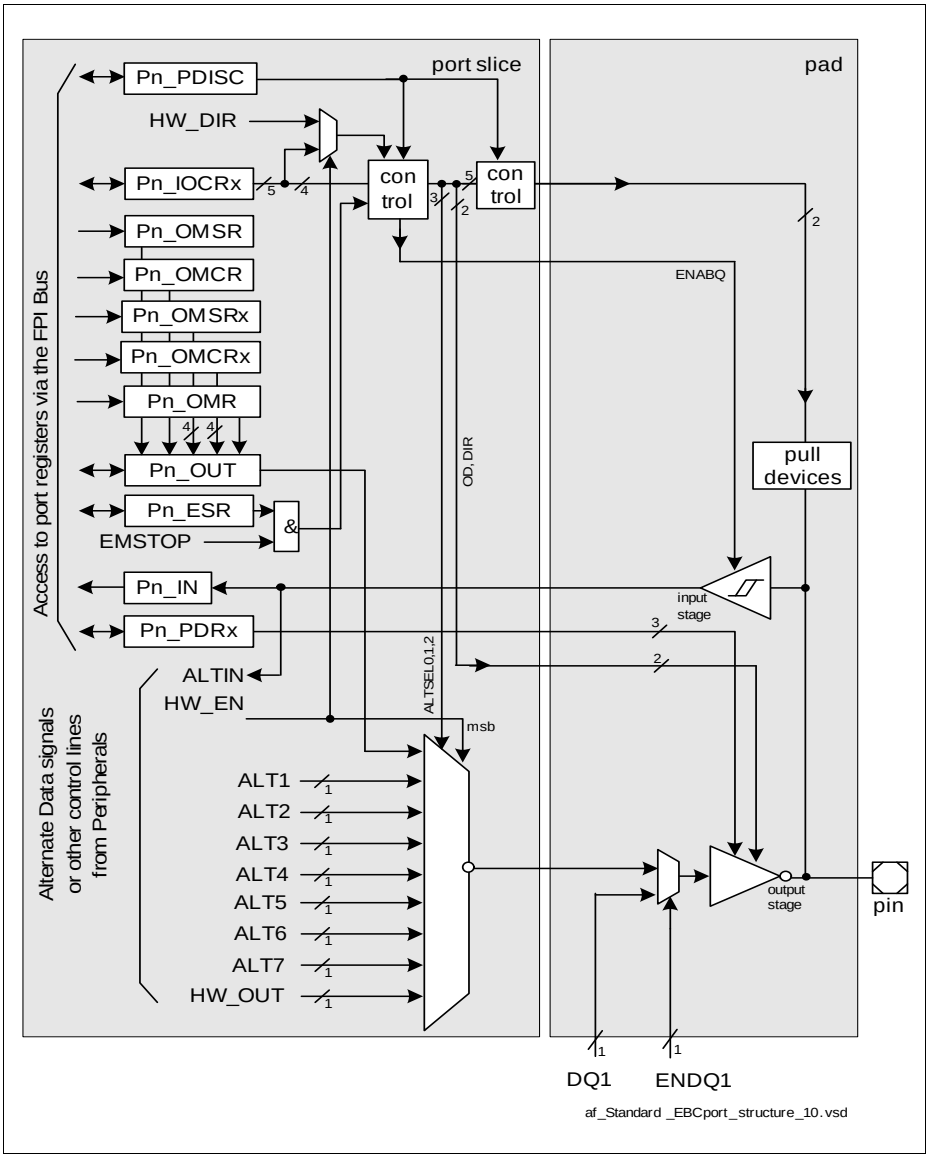


Figure 14-1 General Structure of a Port Pin

Each port line has a number of control and data bits, enabling very flexible usage of the line. Each port pin can be configured for input or output operation. In input mode (default after reset), the output driver is switched off (high-impedance). The actual voltage level present at the port pin is translated into a logical 0 or 1 via a Schmitt-Trigger device and can be read via the read-only register Pn_IN. Input signals are connected directly to the various inputs of the peripheral units (AltDataIn). The function of the input line from the pin to the input register Pn_IN and to AltDataIn is independent of whether the port pin operates as input or output. This means that when the port is in output mode, the level of the pin can be read by software via Pn_IN or a peripheral can use the pin level as an input.

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. Switching between input and output mode is accomplished through the Pn_IOCR register, which enables or disables the output driver. If a peripheral unit uses a GPIO port line as a bi-directional I/O line, register Pn_IOCR has to be written for input or output selection. The Pn_IOCR register further controls the driver type of the output driver, and determines whether an internal weak pull-up, pull-down, or without input pull device is alternatively connected to the pin when used as an input. This offers additional advantages in an application.

The output multiplexer in front of the output driver selects the signal source for the GPIO line when used as output. If the pin is used as general-purpose output, the multiplexer is switched by software (Pn_IOCR register) to the Output Data Register Pn_OUT. Software can set or clear the bit in Pn_OUT through separate Pn_OMSR or Pn_OMCR registers. The set or clear operations for the bits in Pn_OUT can also be done for up to four bits per register in Pn_OMSRx and Pn_OMCRx (x=0,4,8,12). Alternatively, the set, clear or toggle function can be achieved through Pn_OMR, where adjacent pins within the same port can be set, cleared or toggled within one write operation. The manipulation of the control bits in these registers can directly influence the state of the port pin. If the on-chip peripheral units use the pin for output signals, the alternate output lines ALT1 to ALT7 can be switched via the multiplexer to the output driver. The data written into the output register Pn_OUT by software can be used as input data to an on-chip peripheral. This enables, for example, peripheral tests via software without external circuitry.

When selected as general-purpose output line, the logic state of each port pin can be changed individually by programming the pin-related bits in the Output Modification Set Register Pn_OMSR, Output Modification Set Register x Pn_OMSRx (x=0,4,8,12), Output Modification Clear Register Pn_OMCR, Output Modification Clear Register x Pn_OMCRx (x=0,4,8,12) or Output Modification Register, OMR. The bits in Pn_OMSR/Pn_OMSRx and Pn_OMCR/Pn_OMCRx make it possible to set and clear the bits in the Pn_OUT register. While the bits in Pn_OMR allows the bits in Pn_OUT to be set, cleared, toggled or remain unchanged.

When selected as general-purpose output line, the actual logic level at the pin can be examined through reading Pn_IN and compared against the applied output level (either applied through software via the output register Pn_OUT, or via an alternate output

function of a peripheral unit). This can be used to detect some electrical failures at the pin caused through external circuitry. In addition, software-supported arbitration schemes can be implemented in this way using the open-drain configuration and an external wired-And circuitry. Collisions on the external communication lines can be detected when a high level (1) is output, but a low level (0) is seen when reading the pin value via the input register Pn_IN.

All digital GPIO lines of the TC21x/TC22x/TC23x has an emergency stop logic. This logic makes it possible to individually disconnect outputs and put them onto a well defined logic state in an emergency case. In an emergency case, the pin is switched to input function in tri-state mode. The Emergency Stop Register Pn_ESR determines whether an output is enabled or disabled in an emergency case.

14.2 Description Scheme for the Port IO Functions

The following two general building block can be used to describe each GPIO pin:

Table 14-1 Port x Input/Output Functions

Port Pin	I/O	Select	Connected Signal(s)	From / to Module
Px.y	Input		Signal(s)	module(s)
	Output	GPIO	Signal	module
		ALT1	Signal	module
		ALT2	Signal	module
		ALT3	Signal	module
		ALT4	Signal	module
		ALT5	Signal	module
		ALT6	Signal	module
		ALT7	Signal	module
	HW_DIR	HW_Out	Signal	module; group En

or:

Table 14-2 Port x Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
Px.y	I	GPIO	Px_IN.Py	Px_IOCRz. PC0	$0XXX0_B$
	O	GPIO	Px_OUT.Py		$1X000_B$
					$1X001_B$
					$1X010_B$
					$1X011_B$
					$1X100_B$
					$1X101_B$
					$1X110_B$
					$1X111_B$
	HW_DIR	module; group En	Signal		HW_DIR

- HW_DIR:
  The type Alternate Direction signal which is needed if HW_En is active:
  – Out -always output
    DIRx - the pins in one port having the same DIRx (x=0, 1, 2, ...), are controlled as a group by a dedicated HW_DIR signal.
    SDIR- Single DIR- the pin is controlled by its own, dedicated, single HW_DIR signal.
- grouping indicates if the respective pin is controlled by hardware:
  – ENx - the pins in one port having the same ENx (x=0, 1, 2, ...), are controlled as a group by a dedicated HW_EN signal.
  – SEN - Single EN - the pin is controlled by its own, dedicated, single HW_EN signal
- Digital port slices with HW_DIR defined are the ports described in **Figure 14-1**.

Note: Emergency Stop has higher priority than the HW_EN signal. Emergency Stop is functional when the pins are set in the GPIO mode.

Note: HW_DIR signal, output case, switches the pad to push-pull output state.
HW_DIR signal, input case, switches the pad to the input state with pull-up/down setting as defined by the IOCR register.

14.3 Port Register Description

The individual control and data bits of each GPIO port are implemented in a number of registers. The registers are used to configure and use the port as general-purpose I/O or alternate function input/output. For some ports, not all registers are implemented. The availability of the registers in the specific ports is described separately.

Note: Parallel requests from on chip bus masters to the ports module are executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the ports module in between the operations.

Port Register Overview

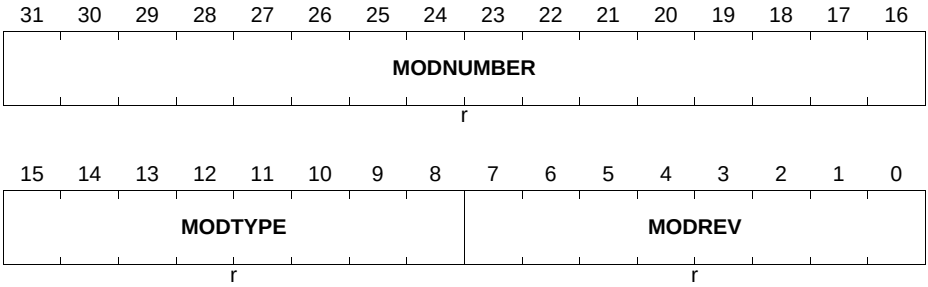
14.3.1 Module Identification Register

The module Identification Register ID contains read-only information about the module version.

ID
Identification Register **(08_H)** **Reset Value: $00C8\ C0XX_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field indicates the revision number of the TC21x/TC22x/TC23x module (01_H = first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines a 32-bit module
MODNUMBER	[31:16]	r	**Module Number** This bit field defines the module identification number. The value for the Ports module is $00C8_H$

14.3.2 Port Input/Output Control Registers

The port input/output control registers select the digital output and input driver functionality and characteristics of a GPIO port pin. Port direction (input or output), pull-up, pull-down, or no pull devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-15). Each 32-bit wide port input/output control register controls four GPIO port lines:

Register Pn_IOCR0 controls the Pn.[3:0] port lines
Register Pn_IOCR4 controls the Pn.[7:4] port lines
Register Pn_IOCR8 controls the Pn.[11:8] port lines
Register Pn_IOCR12 controls the Pn.[15:12] port lines

The diagrams below show the register layouts of the port input/output control registers with the PCx bit fields. One PCx bit field controls exactly one port line Pn.x.

P00_IOCR0
Port 00 Input/Output Control Register 0
(10_H) Reset Value: 0000 0000$_H$

P02_IOCR0
Port 02 Input/Output Control Register 0

11011_B			Alternate output function 3
11100_B			Alternate output function 4
11101_B			Alternate output function 5
11110_B			Alternate output function 6
11111_B			Alternate output function 7

1) Only input functions apply for P40 and P41.

14.3.3 Pad Driver Mode Register

Overview

The pad structure of the TC21x/TC22x/TC23x GPIO lines offers the possibility to select the output driver strength, the slew rate / edge control. These two parameters are controlled by the PDx bit fields in the pad driver mode registers Pn_PDR0/1 for output modes..

The assignment of each port pin to one of these pad classes is shown in the port configuration figures. Further details about pad driver classes that are available in the TC21x/TC22x/TC23x are summarized in the Target Data Sheet/Data Sheet (TBD).

Depending on the assigned pad class, the 3-bit wide pad driver mode selection bit fields PDx in the pad driver mode registers Pn_PDRx make it possible to select the port line functionality as shown in **Table 14-6**.

Table 14-6 Pad Driver Mode Selection

PDx.2	PDx.1	PDx.0	Functionality
X	0	0	Speed grade 1
X	0	1	Speed grade 2
X	1	0	Speed grade 3
X	1	1	Speed grade 4

Note: TC21x/TC22x/TC23x Data Sheet describes the DC characteristics of all pad classes.

Pad Driver Mode Registers

This is the general description of the PDR registers. Each port contains its own specific PDR registers, described additionally at each port, that can contain between one and eight PDx fields for PDR0 and PDR1 registers, respectively. Each PDx field controls 1 pin. For coding of PDx, see **Table 14-6**.

The reset value of Pn_PDR0/1registers is 3333 3333_H.

P00_PDR0
Port 00 Pad Driver Mode 0 Register (40_H) Reset Value: 3333 3333$_H$
P02_PDR0

14.3.4 Pin Function Decision Control Register

Pin Function Decision Control Register

The pad structure of the TC21x/TC22x/TC23x GPIO lines offers the possibility to select digital input or analog ADC input functionalities. For the selection of digital input, the parameters defined for Class S pads must be met. This feature can be controlled by individual bits in the Pn_PDISC register, independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_IOCR register. One Pn_PDISC register is assigned to each port.

P40_PDISC
Port 40 Pin Function Decision Control Register(60_H) **Reset Value: 0000 0FFF$_H$**
P41_PDISC
Port 41 Pin Function Decision Control Register(60_H) **Reset Value: 0000 0FFF$_H$**

Field	Bits	Type	Description
SELx (x = 0-15)	x	rw	**Pin Controller Select for Pin x** This bit enables or disables the VADC Multiplexer Diagnostics (MD) feature. 0_B Disable VADC MD feature of pin x. 1_B Enable VADC MD feature of pin x.
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus has no effect. In this device without function (LCK stays 0_B). 0_B The register is unlocked and can be updated. 1_B The register is locked and can not be updated.
0	[30:16]	r	**Reserved** Read as 0; should be written with 0.

14.3.6 Port Output Register

The port output register determines the value of a GPIO pin when it is selected by Pn_IOCRx as output. Writing a 0 to a Pn_OUT.Px (x = 0-15) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of Pn_OUT.Px can be individually set or cleared by writing appropriate values into the port output modification set register Pn_OMSR or port output modification clear register Pn_OMCR, respectively. The Pn_OUT.Px bits can also be set, cleared or toggled with register Pn_OMR within the same write operation.

P00_OUT
Port 00 Output Register **(00_H)** **Reset Value: 0000 0000_H**
P02_OUT
Port 02 Output Register **(00_H)** **Reset Value: 0000 0000_H**
Pn_OUT (n=10-11)

14.3.11 Port Output Modification Clear Registers x

The port output modification clear register x, (x = 0, 4, 8, 12) contains control bits to individually clear the logic state of a single port line by manipulating the output register.

Register Pn_OMCR0 clears the logic state of Pn.[3:0] port lines

Register Pn_OMCR4 clears the logic state of Pn.[7:4] port lines

Register Pn_OMCR8 clears the logic state of Pn.[11:8] port lines

Register Pn_OMCR12 clears the logic state of Pn.[15:12] port lines

P00_OMCR0
Port 00 Output Modification Clear Register 0(80_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
PCLx (x = 15-12)	x + 16	w	**Port n Clear Bit x** Setting this bit will clear the corresponding bit in the port output register Pn_OUT. Read as 0. 0_B No operation 1_B Clears Pn_OUT.Px
0	[27:0]	r	**Reserved** Read as 0; should be written with 0.

14.3.12 Emergency Stop Register

All digital GPIO lines have an emergency stop logic implemented (see **Figure 14-1**).

Each of these GPIO lines has its own emergency stop enable bit ENx that is located in the emergency stop register Pn_ESR of Port n. If the emergency stop signal becomes active, one of two states can be selected:

- Emergency stop function disabled (ENx = 0):
  The output line remains connected (alternate function).
- Emergency stop function enabled (ENx = 1):
  The mapped output function is disconnected and the safe state is entered by switching to the reset state, input function in tri-state mode or input pull-up. (the content of the corresponding PCx bit fields in register Pn_IOCR will not be considered).

P00_ESR
Port 00 Emergency Stop Register (50_H) Reset Value: 0000 0000_H
P02_ESR
Port 02 Emergency Stop Register (50_H) Reset Value: 0000 0000_H
Pn_ESR (n=10-11)
Port n Emergency Stop Register ($F003\ A650_H + n*100_H$) Reset Value: 0000 0000_H
Pn_ESR (n=13-15)
Port n Emergency Stop Register ($F003\ A650_H + n*100_H$) Reset Value: 0000 0000_H
Pn_ESR (n=20-23)
Port n Emergency Stop Register ($F003\ AC50_H + n*100_H$) Reset Value: 0000 0000_H
Pn_ESR (n=33-34)
Port n Emergency Stop Register ($F003\ B250_H + n*100_H$) Reset Value: 0000 0000_H

Field	Bits	Type	Description
ENx (x = 0-15)	x	rw	**Emergency Stop Enable for Port n Pin x** This bit enables the emergency stop function for all GPIO lines. If the emergency stop condition is met and enabled, the output selection is automatically switched from alternate output function to GPIO input function with tri-state. See **Page 14-38**. 0_B Emergency stop function for Pn.x is disabled. 1_B Emergency stop function for Pn.x is enabled.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

14.3.13 Port Input Register

The logic level of a GPIO pin can be read via the read-only port input register Pn_IN. Reading the Pn_IN register always returns the current logical value at the GPIO pin independently whether the pin is selected as input or output.

P00_IN
Port 00 Input Register **(24_H)** **Reset Value: 0000 XXXX$_H$**
P02_IN
Port 02 Input Register **(24_H)** **Reset Value: 0000 XXXX$_H$**
Pn_IN (n=10-11)
Port n Input Register **(F003 A624$_H$ + n*100$_H$)** **Reset Value: 0000 XXXX$_H$**
Pn_IN (n=13-15)
Port n Input Register **(F003 A624$_H$ + n*100$_H$)** **Reset Value: 0000 XXXX$_H$**
Pn_IN (n=20-23)
Port n Input Register **(F003 AC24$_H$ + n*100$_H$)** **Reset Value: 0000 XXXX$_H$**
Pn_IN (n=33-34)
Port n Input Register **(F003 B224$_H$ + n*100$_H$)** **Reset Value: 0000 XXXX$_H$**
P40_IN
Port 40 Input Register **(24_H)** **Reset Value: 0000 XXXX$_H$**
P41_IN
Port 41 Input Register **(24_H)** **Reset Value: 0000 XXXX$_H$**

Px **(x = 0-15)**	x	rh	**Port n Input Bit x** This bit indicates the level at the input pin Pn.x. 0_B The input level of Pn.x is 0. 1_B The input level of Pn.x is 1.
0	[31:16]	r	**Reserved** Read as 0.

14.3.14 Access Protection Registers

The Access Enable Register 0 controls write[1)] access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 and ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B , ... ,EN31 -> TAG ID 011111_B.

Each port has its own dedicated ACCEN0 and ACCEN1 registers.

P00_ACCEN0
Port 00 Access Enable Register 0 (FC_H) Reset Value: FFFF FFFF$_H$
P02_ACCEN0
Port 02 Access Enable Register 0 (FC_H) Reset Value: FFFF FFFF$_H$
Px_ACCEN0 (x=10-11)
Port x Access Enable Register 0($F003\ A6FC_H + x*100_H$) Reset Value: FFFF FFFF$_H$
Px_ACCEN0 (x=13-15)
Port x Access Enable Register 0($F003\ A6FC_H + x*100_H$) Reset Value: FFFF FFFF$_H$
Px_ACCEN0 (x=20-23)
Port x Access Enable Register 0($F003\ ACFC_H + x*100_H$) Reset Value: FFFF FFFF$_H$
Px_ACCEN0 (x=33-34)
Port x Access Enable Register 0($F003\ B2FC_H + x*100_H$) Reset Value: FFFF FFFF$_H$
P40_ACCEN0
Port 40 Access Enable Register 0 (FC_H) Reset Value: FFFF FFFF$_H$
P41_ACCEN0
Port 41 Access Enable Register 0 (FC_H) Reset Value: FFFF FFFF$_H$

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

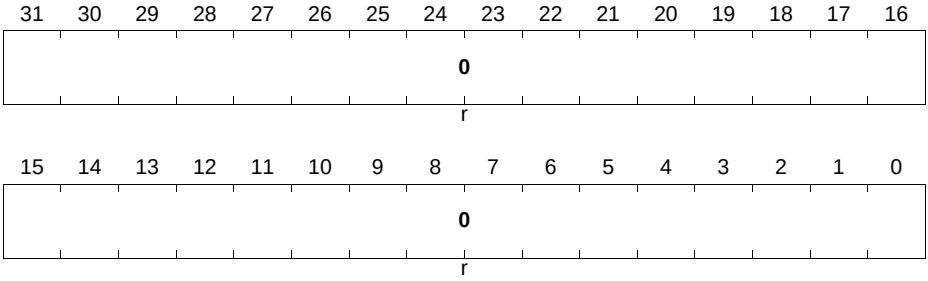
1) The BPI_FPI Access Enable functionality controls only write transactions to the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

Field	Bits	Type	Description
ENx (x = 0-31)	x	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

The Access Enable Register 1 controls write[1)] access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... ,EN31 -> TAG ID 111111B.

P00_ACCEN1
Port 00 Access Enable Register 1 ($F8_H$) Reset Value: 0000 0000$_H$
P02_ACCEN1
Port 02 Access Enable Register 1 ($F8_H$) Reset Value: 0000 0000$_H$
Px_ACCEN1 (x=10-11)
Port x Access Enable Register 1($F003\ A6F8_H + x*100_H$) Reset Value: 0000 0000$_H$
Px_ACCEN1 (x=13-15)
Port x Access Enable Register 1($F003\ A6F8_H + x*100_H$) Reset Value: 0000 0000$_H$
Px_ACCEN1 (x=20-23)
Port x Access Enable Register 1($F003\ ACF8_H + x*100_H$) Reset Value: 0000 0000$_H$
Px_ACCEN1 (x=33-34)
Port x Access Enable Register 1($F003\ B2F8_H + x*100_H$) Reset Value: 0000 0000$_H$
P40_ACCEN1
Port 40 Access Enable Register 1 ($F8_H$) Reset Value: 0000 0000$_H$
P41_ACCEN1
Port 41 Access Enable Register 1 ($F8_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

14.4 Port 00

This section describes the Port 00 functionality.

14.4.1 Port 00 Registers

The following registers are available on Port 00:

Table 14-8 Port 00 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P00_OUT	Port 00 Output Register	0000_H	Page 14-46[2]
P00_OMR	Port 00 Output Modification Register	0004_H	Page 14-46[2]
P00_IOCR0	Port 00 Input/Output Control Register 0	0010_H	Page 14-14
P00_IOCR4	Port 00 Input/Output Control Register 4	0014_H	Page 14-15
P00_IOCR8	Port 00 Input/Output Control Register 8	0018_H	Page 14-16
P00_IOCR12	Port 00 Input/Output Control Register 12	$001C_H$	Page 14-47[2]
P00_IN	Port 00 Input Register	0024_H	Page 14-47[2]
P00_PDR0	Port 00 Pad Driver Mode 0 Register	0040_H	Page 14-20
P00_PDR1	Port 00 Pad Driver Mode 1 Register	0044_H	Page 14-48[2]
P00_ESR	Port 00 Emergency Stop Register	0050_H	Page 14-48[2]
P00_OMSR0	Port 00 Output Modification Set Register 0	0070_H	Page 14-29
P00_OMSR4	Port 00 Output Modification Set Register 4	0074_H	Page 14-30
P00_OMSR8	Port 00 Output Modification Set Register 8	0078_H	Page 14-31
P00_OMSR12	Port 00 Output Modification Set Register 12	$007C_H$	Page 14-46[2]
P00_OMCR0	Port 00 Output Modification Clear Register 0	0080_H	Page 14-34
P00_OMCR4	Port 00 Output Modification Clear Register 4	0084_H	Page 14-35
P00_OMCR8	Port 00 Output Modification Clear Register 8	0088_H	Page 14-36
P00_OMCR12	Port 00 Output Modification Clear Register 12	$008C_H$	Page 14-46[2]
P00_OMSR	Port 00 Output Modification Set Register	0090_H	Page 14-46[2]
P00_OMCR	Port 00 Output Modification Clear Register	0094_H	Page 14-46[2]
P00_ACCEN1	Port 00 Access Enable Register 1	$00F8_H$	Page 14-43
P00_ACCEN0	Port 00 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 14-3)

2) These registers are listed and noted here in the Port 00 section because they differ from the general port register description given in Section 14.3.

14.4.1.1 Port 00 Output Register

The basic P00_OUT register functionality is described on **Page 14-24**. Port lines P00.[15:13] are not connected. Reading the P00_OUT bits P[15:13] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P00_OMR, P00_OMSR, P00_OMCR, P00_OMSRx (x=0,4,8,12), P00_OMCRx (x=0,4,8,12).

14.4.1.2 Port 00 Output Modification Register

The basic P00_OMR register functionality is described on **Page 14-26**. However, port lines P00.[15:13] are not connected. The P00_OMR bits PS[15:13] and PCL[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

14.4.1.3 Port 00 Output Modification Set Register

The basic P00_OMSR register functionality is described on **Page 14-28**. However, port lines P00.[15:13] are not connected. The P00_OMSR bits PS[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

14.4.1.4 Port 00 Output Modification Set Register 12

The basic P00_OMSR12 register functionality is described on **Page 14-32**. However, port lines P00.[15:13] are not connected. The P00_OMSR12 bits PS[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

14.4.1.5 Port 00 Output Modification Clear Register

The basic P00_OMCR register functionality is described on **Page 14-33**. However, port lines P00.[15:13] are not connected. The P00_OMCR bits PCL[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

14.4.1.6 Port 00 Output Modification Clear Register 12

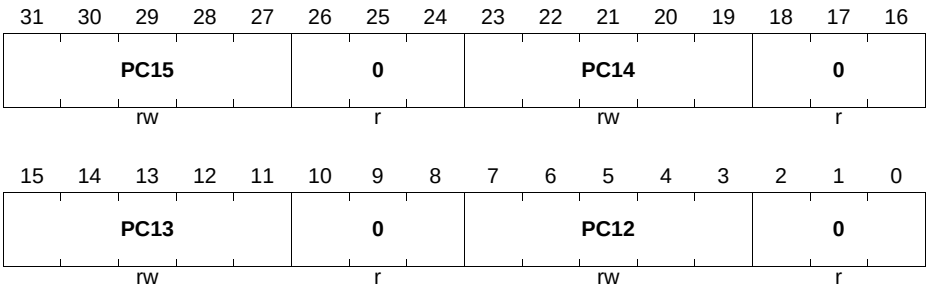
The basic P00_OMCR12 register functionality is described on **Page 14-37**. However, port lines P00.[15:13] are not connected. The P00_OMCR12 bits PCL[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

14.4.1.7 Port 00 Input/Output Control Register 12

The PC13, PC14 and PC15 bit fields in register P00_IOCR12 are not connected.

P00_IOCR12
Port 00 Input/Output Control Register 12

($1C_H$) **Reset Value: $0000\ 0000_H$**



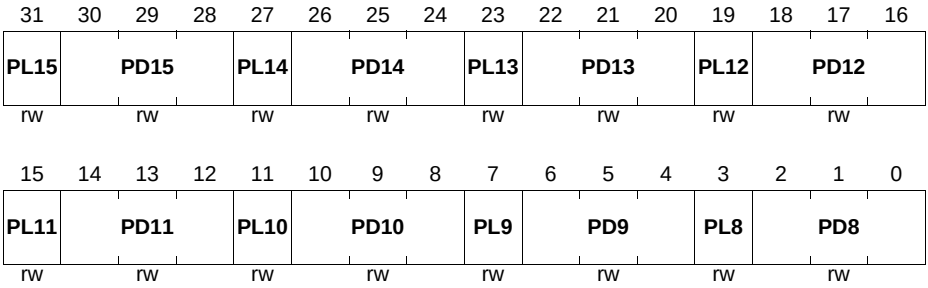
Field	Bits	Type	Description
PC13	[15:11]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC14	[23:19]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC15	[31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC12	[7:3]	rw	**Port Control for Port 00.12** (coding see **Table 14-5**)
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.4.1.8 Port 00 Input Register

The basic P00_IN register functionality is described on **Page 14-40**. However, port lines P00.[15:13] are not connected. Therefore, bits P[15:13] in register P00_IN are always read as 0.

14.4.1.9 Port 00 Pad Driver Mode 1 Register

P00_PDR1
Port 00 Pad Driver Mode 1 Register (44$_H$) **Reset Value: 3333 3333$_H$**



Field	Bits	Type	Description
PD8	[2:0]	rw	**Pad Driver Mode for Port 00 Pin 8**
PD9	[6:4]	rw	**Pad Driver Mode for Port 00 Pin 9**
PD10	[10:8]	rw	**Pad Driver Mode for Port 00 Pin 10**
PD11	[14:12]	rw	**Pad Driver Mode for Port 00 Pin 11**
PD12	[18:16]	rw	**Pad Driver Mode for Port 00 Pin 12**
PD13, **PD14,** **PD15**	[22:20], [26:24], [30:28]	rw	**Reserved** Read as 011$_B$ after reset; returns value that was written, must be written with reset value.
PL8, **PL9,** **PL10,** **PL11,** **PL12,** **PL13,** **PL14,** **PL15**	3, 7, 11, 15, 19, 23, 27, 31	rw	**Reserved** Read as 0, returns values last written, must be written with 0.

14.4.1.10 Port 00 Emergency Stop Register

The basic P00_ESR register functionality is described on **Page 14-38**. Port lines P00.[15:13] are not connected. Reading the P00_ESR bits EN[15:13] returns the value that was last written.

14.5 Port 02

This section describes the Port 02 functionality.

14.5.1 Port 02 Registers

The following registers are available on Port 02:

Table 14-9 Port 02 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P02_OUT	Port 02 Output Register	0000_H	Page 14-51 [2]
P02_OMR	Port 02 Output Modification Register	0004_H	Page 14-51 [2]
P02_IOCR0	Port 02 Input/Output Control Register 0	0010_H	Page 14-14
P02_IOCR4	Port 02 Input/Output Control Register 4	0014_H	Page 14-15
P02_IOCR8	Port 02 Input/Output Control Register 8	0018_H	Page 14-52 [2]
P02_IN	Port 02 Input Register	0024_H	Page 14-52 [2]
P02_PDR0	Port 02 Pad Driver Mode 0 Register	0040_H	Page 14-20
P02_PDR1	Port 02 Pad Driver Mode 1 Register	0044_H	Page 14-53 [2]
P02_ESR	Port 02 Emergency Stop Register	0050_H	Page 14-53 [2]
P02_OMSR0	Port 02 Output Modification Set Register 0	0070_H	Page 14-29
P02_OMSR4	Port 02 Output Modification Set Register 4	0074_H	Page 14-30
P02_OMSR8	Port 02 Output Modification Set Register 8	0078_H	Page 14-51 [2]
P02_OMCR0	Port 02 Output Modification Clear Register 0	0080_H	Page 14-34
P02_OMCR4	Port 02 Output Modification Clear Register 4	0084_H	Page 14-35
P02_OMCR8	Port 02 Output Modification Clear Register 8	0088_H	Page 14-51 [2]
P02_OMSR	Port 02 Output Modification Set Register	0090_H	Page 14-51 [2]
P02_OMCR	Port 02 Output Modification Clear Register	0094_H	Page 14-51 [2]
P02_ACCEN1	Port 02 Access Enable Register 1	$00F8_H$	Page 14-43
P02_ACCEN0	Port 02 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see **Table 14-3**)
2) These registers are listed and noted here in the Port 02 section because they differ from the general port register description given in **Section 14.3**.

14.5.1.1 Port 02 Output Register

The basic P02_OUT register functionality is described on **Page 14-24**. Port lines P02.[15:9] are not connected. Reading the P02_OUT bits P[15:12] always return 0. Reading P[11:9] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P02_OMR, P02_OMSR, P02_OMCR, P02_OMSRx (x=0,4,8), P02_OMCRx (x=0,4,8).

14.5.1.2 Port 02 Output Modification Register

The basic P02_OMR register functionality is described on **Page 14-26**. However, port lines P02.[15:9] are not connected. The P02_OMR bits PS[11:9] and PCL[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

14.5.1.3 Port 02 Output Modification Set Register

The basic P02_OMSR register functionality is described on **Page 14-28**. However, port lines P02.[15:9] are not connected. The P02_OMSR bits PS[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

14.5.1.4 Port 02 Output Modification Set Register 8

The basic P02_OMSR8 register functionality is described on **Page 14-31**. However, port lines P02.[11:9] are not connected. The P02_OMSR8 bits PS[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

14.5.1.5 Port 02 Output Modification Clear Register

The basic P02_OMCR register functionality is described on **Page 14-33**. However, port lines P02.[15:9] are not connected. The P02_OMCR bits PCL[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

14.5.1.6 Port 02 Output Modification Clear Register 8

The basic P02_OMCR8 register functionality is described on **Page 14-36**. However, port lines P02.[11:9] are not connected. The P02_OMCR8 bits PCL[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

14.5.1.7 Port 02 Input/Output Control Register 8

The PC[11:9] bit fields in register P02_IOCR8 are not connected.

P02_IOCR8
Port 02 Input/Output Control Register 8

(18_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PC11					0			PC10					0		
rw					r			rw					r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PC9					0			PC8					0		
rw					r			rw					r		

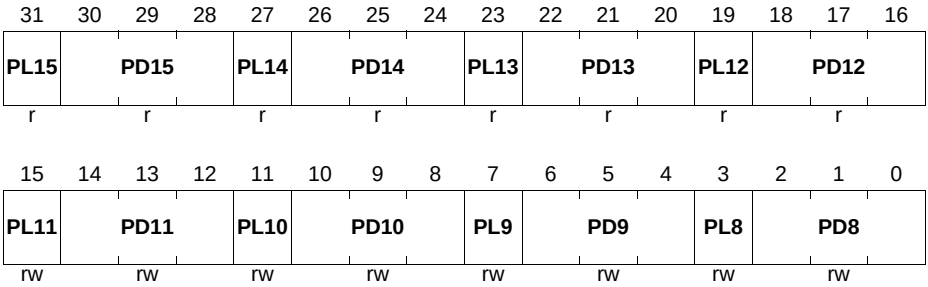
Field	Bits	Type	Description
PC8	[7:3]	rw	**Port Control for Port 02 Pin 8** Coding see **Table 14-5**.
PC9, PC10, PC11	[15:11], [23:19], [31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.5.1.8 Port 02 Input Register

The basic P02_IN register functionality is described on **Page 14-40**. However, port lines P02.[15:9] are not connected. Therefore, bits P[15:9] in register P02_IN are always read as 0.

14.5.1.9 P02 Pad Driver Mode 1 Register

P02_PDR1
Port 02 Pad Driver Mode 1 Register (44_H) **Reset Value: $0000\ 3333_H$**



Field	Bits	Type	Description
PD8	[2:0]	rw	**Pad Driver Mode for Port n Pin 8**
PD9, PD10, PD11	[6:4], [10:8], [14:12]	rw	**Reserved** Read as 011_B after reset; returns value that was written, must be written with reset value.
PD12, PD13, PD14, PD15	[18:16], [22:20], [26:24], [30:28]	r	**Reserved** Read as 000_B after reset; should be written as 0.
PL8, PL9, PL10, PL11	3, 7, 11, 15	rw	**Reserved** Read as 0_B after reset; returns value that was written, have to be written with 0.
PL12, PL13, PL14, PL15	19, 23, 27, 31	r	**Reserved** Read as 0_B after reset; should be written as 0.

14.5.1.10 Port 02 Emergency Stop Register

The basic P02_ESR register functionality is described on **Page 14-38**. Port lines P02.[15:9] are not connected. Reading the P02_ESR bits EN[15:12] always returns 0. Reading the P02_ESR bits EN[11:9] returns value that was last written.

14.6 Port 10

This section describes the Port 10 functionality.

14.6.1 Port 10 Registers

The following registers are available on Port 10:

Table 14-10 Port 10 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P10_OUT	Port 10 Output Register	0000_H	Page 14-55[2]
P10_OMR	Port 10 Output Modification Register	0004_H	Page 14-56[2]
P10_IOCR0	Port 10 Input/Output Control Register 0	0010_H	Page 14-57[2]
P10_IOCR4	Port 10 Input/Output Control Register 4	0014_H	Page 14-58[2]
P10_IN	Port 10 Input Register	0024_H	Page 14-58[2]
P10_PDR0	Port 10 Pad Driver Mode 0 Register	0040_H	Page 14-59[2]
P10_ESR	Port 10 Emergency Stop Register	0050_H	Page 14-59[2]
P10_OMSR0	Port 10 Output Modification Set Register 0	0070_H	Page 14-56[2]
P10_OMSR4	Port 10 Output Modification Set Register 4	0074_H	Page 14-56[2]
P10_OMCR0	Port 10 Output Modification Clear Register 0	0080_H	Page 14-56[2]
P10_OMCR4	Port 10 Output Modification Clear Register 4	0084_H	Page 14-56[2]
P10_OMSR	Port 10 Output Modification Set Register	0090_H	Page 14-56[2]
P10_OMCR	Port 10 Output Modification Clear Register	0094_H	Page 14-56[2]
P10_ACCEN1	Port 10 Access Enable Register 1	$00F8_H$	Page 14-43
P10_ACCEN0	Port 10 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 14-3)

2) These registers are listed and noted here in the Port 10 section because they differ from the general port register description given in Section 14.3.

14.6.1.1 Port 10 Output Register

The basic P10_OUT register functionality is described on Page 14-24. Port lines P10.0, P10.4, P10.[15:7] are not connected. Reading the P10_OUT bits P10.0, P10.4, P10.7 returns the value that was last written. Reading P10.[15:8] returns 0. These connected bits can be also set/reset by the corresponding bits in P10_OMR, P10_OMSR, P10_OMCR, P10_OMSRx (x=0,4), P10_OMCRx (x=0,4).

14.6.1.2 Port 10 Output Modification Register

The basic P10_OMR register functionality is described on **Page 14-26**. However, port lines P10.0, P10.4, P10.[15:7] are not connected. The P10_OMR bits PS0, PS4, PS[15:7] and PCL0, PCL4, PCL7 have no direct effect on port lines but only on register bits P10_OUT.P0, P4 and P7.

14.6.1.3 Port 10 Output Modification Set Register

The basic P10_OMSR register functionality is described on **Page 14-28**. However, port lines P10.0, P10.4, P10.[15:7] are not connected. The P10_OMSR bits PS0, PS4, PS7 have no direct effect on port lines but only on register bits P10_OUT.P0, P4 and P7.

14.6.1.4 Port 10 Output Modification Set Register 0

The basic P10_OMSR0 register functionality is described on **Page 14-29**. However, port lines P10.0 is not connected. The P10_OMSR0 bits PS0 has no direct effect on port lines but only on register bits P10_OUT.P0.

14.6.1.5 Port 10 Output Modification Set Register 4

The basic P10_OMSR4 register functionality is described on **Page 14-30**. However, port lines P10.4 and P10.7 are not connected. The P10_OMSR4 bits PS4 and PS7 have no direct effect on port lines but only on register bits P10_OUT.P4 and P7.

14.6.1.6 Port 10 Output Modification Clear Register

The basic P10_OMCR register functionality is described on **Page 14-33**. However, port lines P10.0, P10.4, P10.7 are not connected. The P10_OMCR bits PCL0, PCL4, PCL7 have no direct effect on port lines but only on register bits P10_OUT.P0, P4 and P7.

14.6.1.7 Port 10 Output Modification Clear Register 0

The basic P10_OMCR0 register functionality is described on **Page 14-34**. However, port lines P10.0 is not connected. The P10_OMSR0 bits PCL0 has no direct effect on port lines but only on register bits P10_OUT.P0.

14.6.1.8 Port 10 Output Modification Clear Register 4

The basic P10_OMCR4 register functionality is described on **Page 14-35**. However, port lines P10.4 and P10.7 are not connected. The P10_OMCR4 bits PCL4 and PCL7 have no direct effect on port lines but only on register bits P10_OUT.P4 and P7.

14.6.1.9 Port 10 Input/Output Control Register 0

The PC0 bit field in register P10_IOC04 is not connected.

P10_IOCR0
Port 10 Input/Output Control Register 0

(10_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PC3					**0**			**PC2**					**0**		
rw					r			rw					r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PC1					**0**			**PC0**					**0**		
rw					r			rw					r		

Field	Bits	Type	Description
PC0	[7:3]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC1, PC2, PC3	[15:11], [23:19], [31:27]	rw	**Port Control for Port 10 Pin 1 to 3** (coding see **Table 14-5**)
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.6.1.10 Port 10 Input/Output Control Register 4

The PC4 and PC7 bit fields in register P10_IOCR4 are not connected.

P10_IOCR4
Port 10 Input/Output Control Register 4

(14_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PC7					**0**			**PC6**					**0**		
rw					r			rw					r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PC5					**0**			**PC4**					**0**		
rw					r			rw					r		

Field	Bits	Type	Description
PC4, PC7	[7:3], [31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC5, PC6	[15:11], [23:19]	rw	**Port Control for Port 10 Pin 5 to 6** (coding see **Table 14-5**)
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.6.1.11 Port 10 Input Register

The basic P10_IN register functionality is described on **Page 14-40**. However, port lines P10.0, P10.4, P10.[15:7] are not connected. Therefore, bits P0, P4, P[15:7] in register P10_IN are always read as 0.

14.6.1.12 Port 10 Pad Driver Mode 0 Register

The basic P10_PDR0 register functionality is described on **Page 14-20**.

P10_PDR0
Port 10 Pad Driver Mode 0 Register (40$_H$) **Reset Value: 3333 3333$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PL7		PD7		PL6		PD6		PL5		PD5		PL4		PD4	
rw		rw		rw		rw		rw		rw		rw		rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PL3		PD3		PL2		PD2		PL1		PD1		PL0		PD0	
rw		rw		rw		rw		rw		rw		rw		rw	

Field	Bits	Type	Description
PD1	[6:4]	rw	**Pad Driver Mode for Port 20 Pin 1**
PD2	[10:8]	rw	**Pad Driver Mode for Port 20 Pin 2**
PD3	[14:12]	rw	**Pad Driver Mode for Port 20 Pin 3**
PD5	[22:20]	rw	**Pad Driver Mode for Port 20 Pin 5**
PD6	[26:24]	rw	**Pad Driver Mode for Port 20 Pin 6**
PD0, **PD4,** **PD7**	[2:0], [18:16], [30:28]	rw	**Reserved** Read as 011_B after reset; returns value that was written, must be written with reset value.
PL0, **PL1,** **PL2,** **PL3,** **PL4,** **PL5,** **PL6,** **PL7**	3, 7, 11, 15, 19, 23, 27, 31	rw	**Reserved** Read as 0, returns values last written, must be written with 0.

14.6.1.13 Port 10 Emergency Stop Register

The basic P10_ESR register functionality is described on **Page 14-38**. Port lines P10.0, P10.4, P[15:7] are not connected. Reading the P10_ESR bits EN[15:8] always returns 0. Reading the P10_ESR bits EN0, EN4, EN7 returns value that was last written.

14.7 Port 11

This section describes the Port 11 functionality.

14.7.1 Port 11 Registers

The following registers are available on Port 11:

Table 14-11 Port 11 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P11_OUT	Port 11 Output Register	0000_H	Page 14-62[2]
P11_OMR	Port 11 Output Modification Register	0004_H	Page 14-62[2]
P11_IOCR0	Port 11 Input/Output Control Register 0	0010_H	Page 14-64[2]
P11_IOCR4	Port 11 Input/Output Control Register 4	0014_H	Page 14-65[2]
P11_IOCR8	Port 11 Input/Output Control Register 8	0018_H	Page 14-16
P11_IOCR12	Port 11 Input/Output Control Register 12	$001C_H$	Page 14-66[2]
P11_IN	Port 11 Input Register	0024_H	Page 14-66[2]
P11_PDR0	Port 11 Pad Driver Mode 0 Register	0040_H	Page 14-67[2]
P11_PDR1	Port 11 Pad Driver Mode 1 Register	0044_H	Page 14-68[2]
P11_ESR	Port 11 Emergency Stop Register	0050_H	Page 14-68[2]
P11_OMSR0	Port 11 Output Modification Set Register 0	0070_H	Page 14-62[2]
P11_OMSR4	Port 11 Output Modification Set Register 4	0074_H	Page 14-62[2]
P11_OMSR8	Port 11 Output Modification Set Register 8	0078_H	Page 14-31
P11_OMSR12	Port 11 Output Modification Set Register 12	$007C_H$	Page 14-62[2]
P11_OMCR0	Port 11 Output Modification Clear Register 0	0080_H	Page 14-63[2]
P11_OMCR4	Port 11 Output Modification Clear Register 4	0084_H	Page 14-63[2]
P11_OMCR8	Port 11 Output Modification Clear Register 8	0088_H	Page 14-36
P11_OMCR12	Port 11 Output Modification Clear Register 12	$008C_H$	Page 14-63[2]
P11_OMSR	Port 11 Output Modification Set Register	0090_H	Page 14-62[2]
P11_OMCR	Port 11 Output Modification Clear Register	0094_H	Page 14-62[2]
P11_ACCEN1	Port 11 Access Enable Register 1	$00F8_H$	Page 14-43
P11_ACCEN0	Port 11 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 14-3)

2) These registers are listed and noted here in the Port 10 section because they differ from the general port register description given in Section 14.3.

14.7.1.1 Port 11 Output Register

The basic P11_OUT register functionality is described on **Page 14-24**. Port lines P11.[15:13], P11.7, P11.[5:4], P11.[1:0] are not connected. Reading the P11_OUT P[15:13], 7, [5:4], [1:0] bits return the value that was last written (0 after reset). These connected bits can be also set/reset by the corresponding bits in P10_OMR, P11_OMSR, P11_OMCR, P11_OMSRx (x=0,4,8,12), P11_OMCRx (x=0,4,8,12).

14.7.1.2 Port 11 Output Modification Register

The basic P11_OMR register functionality is described on **Page 14-26**. However, port lines P11.[15:13], P11.7, P11.[5:4], P11.[1:0] are not connected. The P11_OMR bits PS[15:13], PS7, PS[5:4], PS[1:0] and PCL[15:13], PCL7, PCL[5:4], PCL[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[15:13], P7,P[5:4],P[1:0].

14.7.1.3 Port 11 Output Modification Set Register

The basic P11_OMSR register functionality is described on **Page 14-28**. However, port lines P11.[15:13], P11.7, P11.[5:4], P11.[1:0] are not connected. The P11_OMSR bits PS[15:13], PS7, PS[5:4], PS[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[15:13], P7,P[5:4],P[1:0].

14.7.1.4 Port 11 Output Modification Set Register 0

The basic P11_OMSR0 register functionality is described on **Page 14-29**. However, port lines P11.[1:0] are not connected. The P11_OMSR0 bits PS[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[1:0].

14.7.1.5 Port 11 Output Modification Set Register 4

The basic P11_OMSR4 register functionality is described on **Page 14-30**. However, port lines P11.[5:4], P11.7 are not connected. The P11_OMSR4 bits PS[5:4], PS7 have no direct effect on port lines but only on register bits P11_OUT.P[5:4], P11_OUT.P7.

14.7.1.6 Port 11 Output Modification Set Register 12

The basic P11_OMSR12 register functionality is described on **Page 14-32**. However, port lines P11.[15:13] are not connected. The P11_OMSR12 bits PS[15:13] have no direct effect on port lines but only on register bits P11_OUT.P[15:13].

14.7.1.7 Port 11 Output Modification Clear Register

The basic P11_OMCR register functionality is described on **Page 14-33**. However, port lines P11.[15:13], P11.7, P11.[5:4], P11.[1:0] are not connected. The P11_OMCR bits

PCL[15:13], PCL7, PCL[5:4], PCL[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[15:13], P7,P[5:4],P[1:0].

14.7.1.8 Port 11 Output Modification Clear Register 0

The basic P11_OMCR0 register functionality is described on **Page 14-34**. However, port lines P11.[1:0] are not connected. The P11_OMCR0 bits PCL[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[1:0].

14.7.1.9 Port 11 Output Modification Clear Register 4

The basic P11_OMCR4 register functionality is described on **Page 14-30**. However, port lines P11.[5:4], P11.7 are not connected. The P11_OMCR4 bits PCL[5:4], PCL7 have no direct effect on port lines but only on register bits P11_OUT.P[5:4], P11_OUT.P7.

14.7.1.10 Port 11 Output Modification Clear Register 12

The basic P11_OMCR12 register functionality is described on **Page 14-37**. However, port lines P11.[15:13] are not connected. The P11_OMCR12 bits PCL[15:13] have no direct effect on port lines but only on register bits P11_OUT.P[15:13].

14.7.1.11 Port 11 Input/Output Control Register 0

The PC[1:0] bit fields in register P11_IOCR0 are not connected.

P11_IOCR0
Port 11 Input/Output Control Register 0

(10_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PC3					**0**			**PC2**					**0**

PC1					**0**			**PC0**					**0**		
rw					r			rw					r		

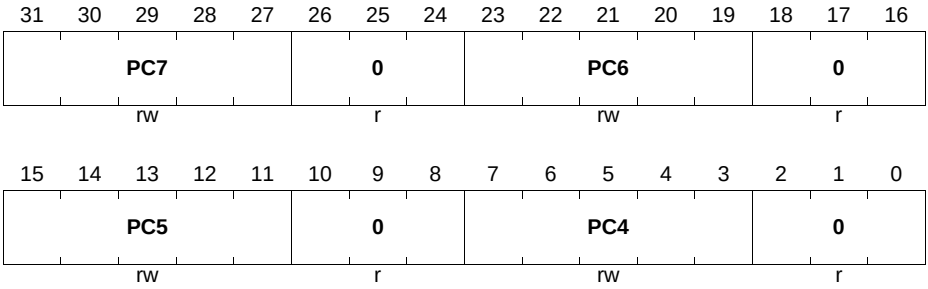
Field	Bits	Type	Description
PC2	[23:19]	rw	**Port Control for Port 11 Pin 2**
PC3	[31:27]	rw	**Port Control for Port 11 Pin 3**
PC0, PC1	[7:3], [15:11]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.7.1.12 Port 11 Input/Output Control Register 4

The PC[5:4] and PC7 bit fields in register P11_IOCR4 are not connected.

P11_IOCR4
Port 11 Input/Output Control Register 4

(14_H) **Reset Value: 0000 0000$_H$**



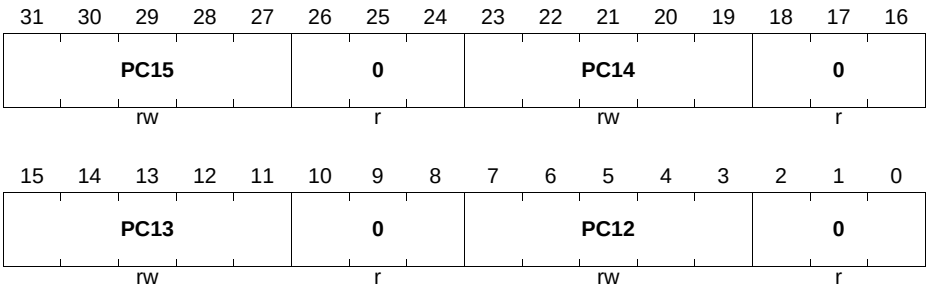
Field	Bits	Type	Description
PC4, PC5, PC7	[7:3], [15:11], [31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC6	[23:19]	rw	**Port Control for Port 11 Pin 6** (coding see **Table 14-5**)
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.7.1.13 Port 11 Input/Output Control Register 12

The PC13, PC14 and PC15 bit fields in register P00_IOCR12 are not connected.

P11_IOCR12
Port 11 Input/Output Control Register 12

($1C_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
PC13, PC14, PC15	[15:11], [23:19], [31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC12	[7:3]	rw	**Port Control for Port 11.12** (coding see **Table 14-5**)
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.7.1.14 Port 11 Input Register

The basic P11_IN register functionality is described on **Page 14-40**. However, port lines P11.[15:13] are not connected. Therefore, bits P[15:9] in register P10_IN are always read as 0.

14.7.1.15 Port 11 Pad Driver Mode 0 Register

The basic P11_PDR0 register functionality is described on **Page 14-20**.

P11_PDR0
Port 11 Pad Driver Mode 0 Register (40_H) **Reset Value: $3333\ 3333_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PL11	15	rw	**Pad Level Selection for Port 11 Pin 11**
PL12	19	rw	**Pad Level Selection for Port 11 Pin 12**
PD13, PD14, PD15	[22:20], [26:24], [30:28]	rw	**Reserved** Read as 011_B after reset; returns value that was written, must be written with reset value.
PL8, PL13, PL14, PL15	3, 23, 27, 31	rw	**Reserved** Read as 0, returns values last written, must be written with 0.

14.7.1.17 Port 11 Emergency Stop Register

The basic P11_ESR register functionality is described on **Page 14-38**. Port lines P11.[15:13], P11.7, P11.[5:4], P11.[1:0] are not connected. Reading the P10_ESR bits EN[15:13], EN7, EN[5:4], EN[1:0] returns value that was last written..

14.8 Port 13

This section describes the Port 13 functionality.

Port 13 is an 4-bit GPIO port.

14.8.1 Port 13 Registers

The following registers are available on Port 13:

Table 14-12 Port 13 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P13_OUT	Port 13 Output Register	0000_H	Page 14-70[2]
P13_OMR	Port 13 Output Modification Register	0004_H	Page 14-70[2]
P13_IOCR0	Port 13 Input/Output Control Register 0	0010_H	Page 14-14
P13_IN	Port 13 Input Register	0024_H	Page 14-71[2]
P13_PDR0	Port 13 Pad Driver Mode 0 Register	0040_H	Page 14-72[2]
P13_ESR	Port 13 Emergency Stop Register	0050_H	Page 14-72[2]
P13_OMSR0	Port 13 Output Modification Set Register 0	0070_H	Page 14-29
P13_OMCR0	Port 13 Output Modification Clear Register 0	0080_H	Page 14-34
P13_OMSR	Port 13 Output Modification Set Register	0090_H	Page 14-71[2]
P13_OMCR	Port 13 Output Modification Clear Register	0094_H	Page 14-71[2]
P13_ACCEN1	Port 13 Access Enable Register 1	$00F8_H$	Page 14-43
P13_ACCEN0	Port 13 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 14-3)

2) These registers are listed and noted here in the Port 13 section because they differ from the general port register description given in Section 14.3.

14.8.1.1 Port 13 Output Register

The basic P13_OUT register functionality is described on Page 14-24. Port line P13.[15:4] are not connected. Reading the P13_OUT bit P[15:4] always return 0. These connected bits can be also set/reset by the corresponding bits in P13_OMR, P13_OMSR, P13_OMCR, P13_OMSR0, P13_OMCR0.

14.8.1.2 Port 13 Output Modification Register

The basic P13_OMR register functionality is described on Page 14-26. However, port lines P13.[15:4] are not connected.

14.8.1.3 Port 13 Output Modification Set Register

The basic P13_OMSR register functionality is described on **Page 14-28**. However, port lines P13.[15:4] are not connected.

14.8.1.4 Port 13 Output Modification Clear Register

The basic P13_OMCR register functionality is described on **Page 14-33**. However, port lines P13.[15:4] are not connected.

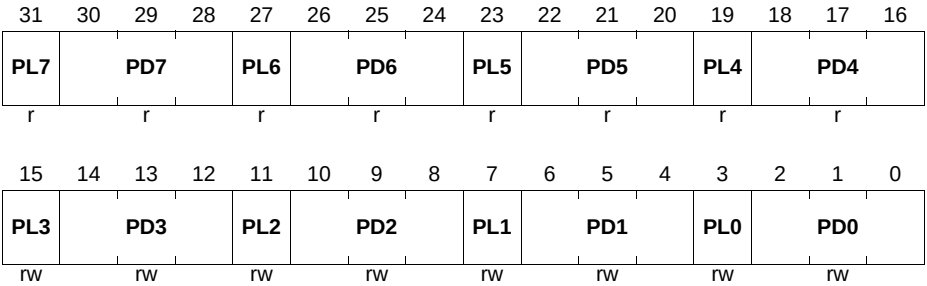
14.8.1.5 Port 13 Input Register

The basic P13_IN register functionality is described on **Page 14-40**. However, port lines P13.[15:4] are not connected. Therefore, bits P[15:4] in register P13_IN are always read as 0.

14.8.1.6 Port 13 Pad Driver Mode 0 Register

The basic P13_PDR0 register functionality is described on **Page 14-20**.

P13_PDR0
Port 13 Pad Driver Mode 0 Register (40_H) **Reset Value: $0000\ 3333_H$**



Field	Bits	Type	Description
PD0, **PD1,** **PD2,** **PD3**	[2:0], [6:4], [10:8], [14:12]	rw	**Pad Driver Mode for Port 13 Pin 0 to 3**
PL0, **PL1,** **PL2,** **PL3**	3, 7, 11, 15	rw	**Reserved** Read as 0, returns values last written, must be written with 0.
PD4, **PD5,** **PD6,** **PD7**	[18:16], [22:20], [26:24], [30:28]	r	**Reserved** Read as 000_B after reset; should be written with 0.
PL4, **PL5,** **PL6,** **PL7**	19, 23, 27, 31	r	**Reserved** Read as 0_B after reset; should be written with 0.

14.8.1.7 Port 13 Emergency Stop Register

The basic P13_ESR register functionality is described on **Page 14-38**. Port lines P13.[15:4] are not connected. Reading the P13_ESR bits EN[15:4] always returns 0.

14.9 Port 14

This section describes the Port 14 functionality.

14.9.1 Port 14 Registers

The following registers are available on Port 14:

Table 14-13 Port 14 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P14_OUT	Port 14 Output Register	0000_H	Page 14-51 [2]
P14_OMR	Port 14 Output Modification Register	0004_H	Page 14-51 [2]
P14_IOCR0	Port 14 Input/Output Control Register 0	0010_H	Page 14-14
P14_IOCR4	Port 14 Input/Output Control Register 4	0014_H	Page 14-15
P14_IOCR8	Port 14 Input/Output Control Register 8	0018_H	Page 14-52 [2]
P14_IN	Port 14 Input Register	0024_H	Page 14-52 [2]
P14_PDR0	Port 14 Pad Driver Mode 0 Register	0040_H	Page 14-20
P14_PDR1	Port 14 Pad Driver Mode 1 Register	0044_H	Page 14-53 [2]
P14_ESR	Port 14 Emergency Stop Register	0050_H	Page 14-53 [2]
P14_OMSR0	Port 14 Output Modification Set Register 0	0070_H	Page 14-29
P14_OMSR4	Port 14 Output Modification Set Register 4	0074_H	Page 14-30
P14_OMSR8	Port 14 Output Modification Set Register 8	0078_H	Page 14-51 [2]
P14_OMCR0	Port 14 Output Modification Clear Register 0	0080_H	Page 14-34
P14_OMCR4	Port 14 Output Modification Clear Register 4	0084_H	Page 14-35
P14_OMCR8	Port 14 Output Modification Clear Register 8	0088_H	Page 14-51 [2]
P14_OMSR	Port 14 Output Modification Set Register	0090_H	Page 14-51 [2]
P14_OMCR	Port 14 Output Modification Clear Register	0094_H	Page 14-51 [2]
P14_ACCEN1	Port 14 Access Enable Register 1	$00F8_H$	Page 14-43
P14_ACCEN0	Port 14 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see **Table 14-3**)
2) These registers are listed and noted here in the Port 14 section because they differ from the general port register description given in **Section 14.3**.

14.9.1.1 Port 14 Output Register

The basic P14_OUT register functionality is described on **Page 14-24**. Port lines P14.[15:9] are not connected. Reading the P14_OUT bits P[15:12] always return 0. Reading P[11:9] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P14_OMR, P14_OMSR, P14_OMCR, P14_OMSRx (x=0,4,8), P14_OMCRx (x=0,4,8).

14.9.1.2 Port 14 Output Modification Register

The basic P14_OMR register functionality is described on **Page 14-26**. However, port lines P14.[15:9] are not connected. The P14_OMR bits PS[11:9] and PCL[11:9] have no direct effect on port lines but only on register bits P14_OUT.P[11:9].

14.9.1.3 Port 14 Output Modification Set Register

The basic P14_OMSR register functionality is described on **Page 14-28**. However, port lines P14.[15:9] are not connected. The P14_OMSR bits PS[11:9] have no direct effect on port lines but only on register bits P14_OUT.P[11:9].

14.9.1.4 Port 14 Output Modification Set Register 8

The basic P14_OMSR8 register functionality is described on **Page 14-31**. However, port lines P14.[11:9] are not connected. The P14_OMSR8 bits PS[11:9] have no direct effect on port lines but only on register bits P14_OUT.P[11:9].

14.9.1.5 Port 14 Output Modification Clear Register

The basic P14_OMCR register functionality is described on **Page 14-33**. However, port lines P14.[15:9] are not connected. The P14_OMCR bits PCL[11:9] have no direct effect on port lines but only on register bits P14_OUT.P[11:9].

14.9.1.6 Port 14 Output Modification Clear Register 8

The basic P14_OMCR8 register functionality is described on **Page 14-36**. However, port lines P14.[11:9] are not connected. The P14_OMCR8 bits PCL[11:9] have no direct effect on port lines but only on register bits P14_OUT.P[11:9].

14.9.1.7 Port 14 Input/Output Control Register 8

The PC[11:9] bit fields in register P14_IOCR8 are not connected.

P14_IOCR8
Port 14 Input/Output Control Register 8

(18_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PC11					0			PC10					0		
rw					r			rw					r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PC9					0			PC8					0		
rw					r			rw					r		

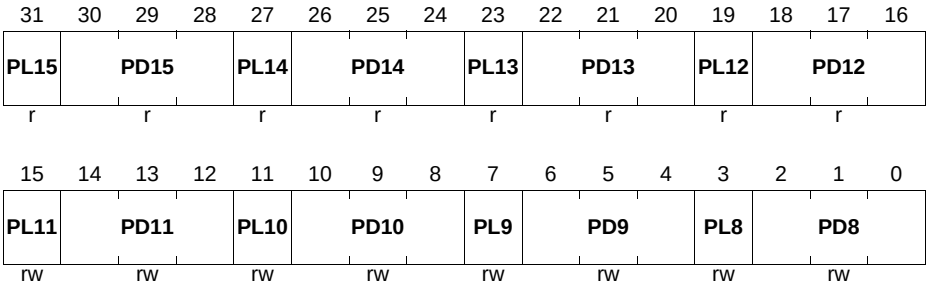
Field	Bits	Type	Description
PC8	[7:3]	rw	**Port Control for Port 14 Pin 8** Coding see **Table 14-5**.
PC9, PC10, PC11	[15:11], [23:19], [31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.9.1.8 Port 14 Input Register

The basic P14_IN register functionality is described on **Page 14-40**. However, port lines P14.[15:9] are not connected. Therefore, bits P[15:9] in register P14_IN are always read as 0.

14.9.1.9 P14 Pad Driver Mode 1 Register

P14_PDR1
Port 14 Pad Driver Mode 1 Register (44_H) **Reset Value: $0000\ 3333_H$**



Field	Bits	Type	Description
PD8	[2:0]	rw	**Pad Driver Mode for Port n Pin 8**
PD9, PD10, PD11	[6:4], [10:8], [14:12]	rw	**Reserved** Read as 011_B after reset; returns value that was written, must be written with reset value.
PD12, PD13, PD14, PD15	[18:16], [22:20], [26:24], [30:28]	r	**Reserved** Read as 000_B after reset; should be written as 0.
PL8, PL9, PL10, PL11	3, 7, 11, 15	rw	**Reserved** Read as 0_B after reset; returns value that was written, have to be written with 0.
PL12, PL13, PL14, PL15	19, 23, 27, 31	r	**Reserved** Read as 0_B after reset; should be written as 0.

14.9.1.10 Port 14 Emergency Stop Register

The basic P14_ESR register functionality is described on **Page 14-38**. Port lines P14.[15:9] are not connected. Reading the P14_ESR bits EN[15:12] always returns 0. Reading the P14_ESR bits EN[11:9] returns value that was last written.

14.10 Port 15

This section describes the Port 15 functionality.

14.10.1 Port 15 Registers

The following registers are available on Port 15:

Table 14-14 Port 14 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P15_OUT	Port 15 Output Register	0000_H	Page 14-51 [2]
P15_OMR	Port 15 Output Modification Register	0004_H	Page 14-51 [2]
P15_IOCR0	Port 15 Input/Output Control Register 0	0010_H	Page 14-14
P15_IOCR4	Port 15 Input/Output Control Register 4	0014_H	Page 14-15
P15_IOCR8	Port 15 Input/Output Control Register 8	0018_H	Page 14-52 [2]
P15_IN	Port 15 Input Register	0024_H	Page 14-52 [2]
P15_PDR0	Port 15 Pad Driver Mode 0 Register	0040_H	Page 14-20
P15_PDR1	Port 15 Pad Driver Mode 1 Register	0044_H	Page 14-53 [2]
P15_ESR	Port 15 Emergency Stop Register	0050_H	Page 14-53 [2]
P15_OMSR0	Port 15 Output Modification Set Register 0	0070_H	Page 14-29
P15_OMSR4	Port 15 Output Modification Set Register 4	0074_H	Page 14-30
P15_OMSR8	Port 15 Output Modification Set Register 8	0078_H	Page 14-51 [2]
P15_OMCR0	Port 15 Output Modification Clear Register 0	0080_H	Page 14-34
P15_OMCR4	Port 15 Output Modification Clear Register 4	0084_H	Page 14-35
P15_OMCR8	Port 15 Output Modification Clear Register 8	0088_H	Page 14-51 [2]
P15_OMSR	Port 15 Output Modification Set Register	0090_H	Page 14-51 [2]
P15_OMCR	Port 15 Output Modification Clear Register	0094_H	Page 14-51 [2]
P15_ACCEN1	Port 15 Access Enable Register 1	$00F8_H$	Page 14-43
P15_ACCEN0	Port 15 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see **Table 14-3**)
2) These registers are listed and noted here in the Port 14 section because they differ from the general port register description given in **Section 14.3**.

14.10.1.1 Port 15 Output Register

The basic P15_OUT register functionality is described on **Page 14-24**. Port lines P15.[15:9] are not connected. Reading the P15_OUT bits P[15:12] always return 0. Reading P[11:9] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P15_OMR, P15_OMSR, P15_OMCR, P15_OMSRx (x=0,4,8), P15_OMCRx (x=0,4,8).

14.10.1.2 Port 15 Output Modification Register

The basic P15_OMR register functionality is described on **Page 14-26**. However, port lines P15.[15:9] are not connected. The P15_OMR bits PS[11:9] and PCL[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

14.10.1.3 Port 15 Output Modification Set Register

The basic P15_OMSR register functionality is described on **Page 14-28**. However, port lines P15.[15:9] are not connected. The P15_OMSR bits PS[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

14.10.1.4 Port 15 Output Modification Set Register 8

The basic P15_OMSR8 register functionality is described on **Page 14-31**. However, port lines P15.[11:9] are not connected. The P15_OMSR8 bits PS[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

14.10.1.5 Port 15 Output Modification Clear Register

The basic P15_OMCR register functionality is described on **Page 14-33**. However, port lines P15.[15:9] are not connected. The P15_OMCR bits PCL[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

14.10.1.6 Port 14 Output Modification Clear Register 8

The basic P15_OMCR8 register functionality is described on **Page 14-36**. However, port lines P15.[11:9] are not connected. The P15_OMCR8 bits PCL[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

14.10.1.7 Port 14 Input/Output Control Register 8

The PC[11:9] bit fields in register P15_IOCR8 are not connected.

P15_IOCR8
Port 15 Input/Output Control Register 8

(18_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PC11					0			PC10					0		
rw					r			rw					r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PC9					0			PC8					0		
rw					r			rw					r		

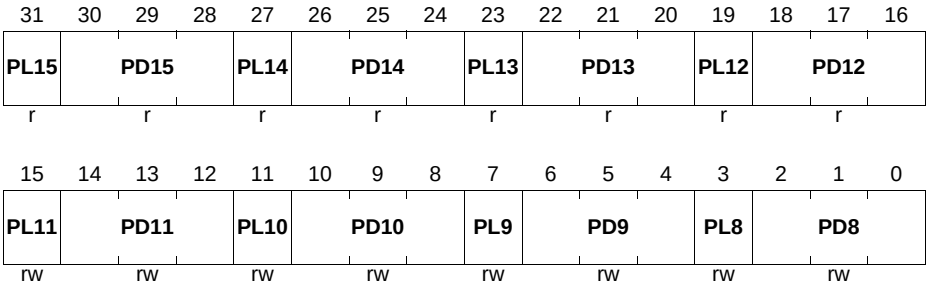
Field	Bits	Type	Description
PC8	[7:3]	rw	**Port Control for Port 15 Pin 8** Coding see **Table 14-5**.
PC9, PC10, PC11	[15:11], [23:19], [31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.10.1.8 Port 15 Input Register

The basic P15_IN register functionality is described on **Page 14-40**. However, port lines P15.[15:9] are not connected. Therefore, bits P[15:9] in register P15_IN are always read as 0.

14.10.1.9 P15 Pad Driver Mode 1 Register

P15_PDR1
Port 15 Pad Driver Mode 1 Register (44$_H$) **Reset Value: 0000 3333$_H$**



Field	Bits	Type	Description
PD8	[2:0]	rw	**Pad Driver Mode for Port n Pin 8**
PD9, PD10, PD11	[6:4], [10:8], [14:12]	rw	**Reserved** Read as 011_B after reset; returns value that was written, must be written with reset value.
PD12, PD13, PD14, PD15	[18:16], [22:20], [26:24], [30:28]	r	**Reserved** Read as 000_B after reset; should be written as 0.
PL8, PL9, PL10, PL11	3, 7, 11, 15	rw	**Reserved** Read as 0_B after reset; returns value that was written, have to be written with 0.
PL12, PL13, PL14, PL15	19, 23, 27, 31	r	**Reserved** Read as 0_B after reset; should be written as 0.

14.10.1.10Port 15 Emergency Stop Register

The basic P15_ESR register functionality is described on **Page 14-38**. Port lines P15.[15:9] are not connected. Reading the P15_ESR bits EN[15:12] always returns 0. Reading the P15_ESR bits EN[11:9] returns value that was last written.

14.11 Port 20

This section describes the Port 20 functionality.

14.11.1 Port 20 Registers

The following registers are available on Port 20:

Table 14-15 Port 20 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P20_OUT	Port 20 Output Register	0000_H	Page 14-85[2]
P20_OMR	Port 20 Output Modification Register	0004_H	Page 14-85[2]
P20_IOCR0	Port 20 Input/Output Control Register 0	0010_H	Page 14-87[2]
P20_IOCR4	Port 20 Input/Output Control Register 4	0014_H	Page 14-88[2]
P20_IOCR8	Port 20 Input/Output Control Register 8	0018_H	Page 14-16
P20_IOCR12	Port 20 Input/Output Control Register 12	$001C_H$	Page 14-89[2]
P20_IN	Port 20 Input Register	0024_H	Page 14-89[2]
P20_PDR0	Port 20 Pad Driver Mode 0 Register	0040_H	Page 14-90[2]
P20_PDR1	Port 20 Pad Driver Mode 1 Register	0044_H	Page 14-91[2]
P20_ESR	Port 20 Emergency Stop Register	0050_H	Page 14-92[2]
P20_OMSR0	Port 20 Output Modification Set Register 0	0070_H	Page 14-85[2]
P20_OMSR4	Port 20 Output Modification Set Register 4	0074_H	Page 14-85[2]
P20_OMSR8	Port 20 Output Modification Set Register 8	0078_H	Page 14-31
P20_OMSR12	Port 20 Output Modification Set Register 12	$007C_H$	Page 14-85[2]
P20_OMCR0	Port 20 Output Modification Clear Register 0	0080_H	Page 14-86[2]
P20_OMCR4	Port 20 Output Modification Clear Register 4	0084_H	Page 14-86[2]
P20_OMCR8	Port 20 Output Modification Clear Register 8	0088_H	Page 14-36
P20_OMCR12	Port 20 Output Modification Clear Register 12	$008C_H$	Page 14-86[2]
P20_OMSR	Port 20 Output Modification Set Register	0090_H	Page 14-85[2]
P20_OMCR	Port 20 Output Modification Clear Register	0094_H	Page 14-86[2]
P20_ACCEN1	Port 20 Access Enable Register 1	$00F8_H$	Page 14-43
P20_ACCEN0	Port 20 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 14-3)

2) These registers are listed and noted here in the Port 20 section because they differ from the general port register description given in Section 14.3.

14.11.1.1 Port 20 Output Register

The basic P20_OUT register functionality is described on **Page 14-24**. Port line P20.1, P20.[5:4] and P20.15 are not connected. Reading the P20_OUT bits P1, P[5:4] and P15 returns the value that was last written (0 after reset). These connected bits can be also set/reset by the corresponding bits in P20_OMR, P20_OMSR, P20_OMCR, P20_OMSRx (x=0, 4,12), P20_OMCRx (x=0, 4,12). P20_OUT.P2 does not determine the level at P20.2, returns the value that was last written.

14.11.1.2 Port 20 Output Modification Register

The basic P20_OMR register functionality is described on **Page 14-26**. However, port lines P20.1, P20.[5:4] and P20.15 are not connected. The P20_OMR bits PS1, PS[5:4], PS15 and PCL1, PCL[5:4], PCL15 have no direct effect on port lines but only on register bits P20_OUT P1, P[5:4] and P15. P20_OMR bit PS2 and PCL2 has no effect on P20_OUT.P2.

14.11.1.3 Port 20 Output Modification Set Register

The basic P20_OMSR register functionality is described on **Page 14-28**. However, port lines P20.1, P20.[5:4], P20.15 is not connected. The P20_OMSR bits PS1, PS.[5:4], PS15 has no direct effect on port line but only on register bits P20_OUT.P1, P[5:4], P15. P20_OMSR bit PS2 has no effect on P20_OUT.P2.

14.11.1.4 Port 20 Output Modification Set Register 0

The basic P20_OMSR0 register functionality is described on **Page 14-29**. However, port lines P20.1 are not connected. The P20_OMSR0 bits PS1 has no direct effect on port lines but only on register bits P20_OUT.P1. P20_OMSR0 bit PS2 has no effect on P20_OUT.P2.

14.11.1.5 Port 20 Output Modification Set Register 4

The basic P20_OMSR4 register functionality is described on **Page 14-30**. However, port lines P20.[5:4] are not connected. The P20_OMSR4 bits PS[5:4] has no direct effect on port lines but only on register bits P20_OUT.P[5:4].

14.11.1.6 Port 20 Output Modification Set Register 12

The basic P20_OMSR12 register functionality is described on **Page 14-32**. However, port lines P20.15 is not connected. The P20_OMSR12 bits PS15 has no direct effect on port lines but only on register bits P20_OUT.P15.

14.11.1.7 Port 20 Output Modification Clear Register

The basic P20_OMCR register functionality is described on **Page 14-33**. However, port lines P20.1, P20.[5:4] and P20.15 are not connected. The P20_OMCR bits PCL1, PCL[5:4], PCL15 has no direct effect on port lines but only on register bits P20_OUT.P1, P[5:4] and P15. P20_OMCR bit PCL2 has no effect on P20_OUT.P2.

14.11.1.8 Port 20 Output Modification Clear Register 0

The basic P20_OMCR0 register functionality is described on **Page 14-34**. However, port lines P20.1 are not connected. The P20_OMCR0 bits PCL1 has no direct effect on port lines but only on register bits P20_OUT.P1. P20_OMCR0 bit PCL2 has no effect on P20_OUT.P2.

14.11.1.9 Port 20 Output Modification Clear Register 4

The basic P20_OMCR4 register functionality is described on **Page 14-35**. However, port lines P20.[5:4] are not connected. The P20_OMCR4 bits PCL[5:4] has no direct effect on port lines but only on register bits P20_OUT.P[5:4].

14.11.1.10Port 20 Output Modification Clear Register 12

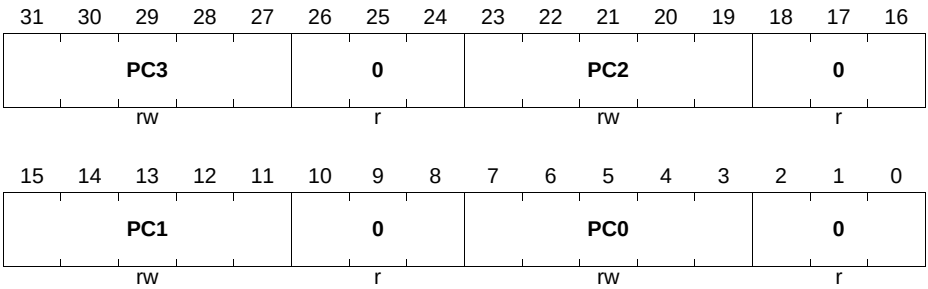
The basic P20_OMCR12 register functionality is described on **Page 14-37**. However, port lines P20.15 are not connected. The P20_OMCR12 bits PCL15 has no direct effect on port lines but only on register bits P20_OUT.P15.

14.11.1.11Port 20 Input/Output Control Register 0

The PC1 bit field in register P20_IOCR0 are not connected.

P20_IOCR0
Port 20 Input/Output Control Register 0

(10_H) **Reset Value: $0010\ 0000_H$**



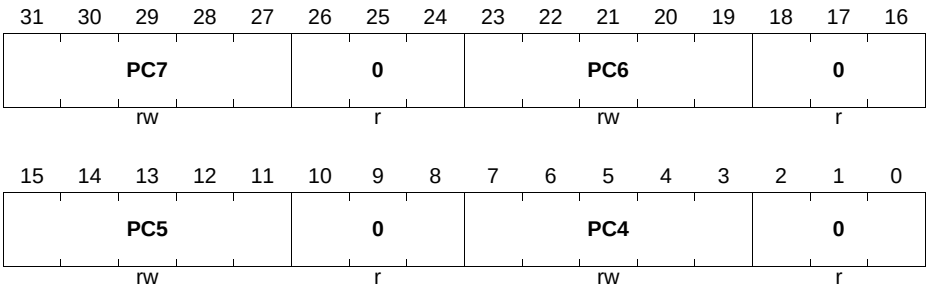
Field	Bits	Type	Description
PC1	[15:11]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC0	[7:3]	rw	**Port Control for Port 20 Pin 0** (coding see **Table 14-5**)
PC2	[23:19]	rw	**Reserved** Read as 00010_B after reset; returns value that was written.
PC3	[31:27]	rw	**Port Control for Port 20 Pin 3** (coding see **Table 14-5**)
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.11.1.12Port 20 Input/Output Control Register 4

The PC[5:4] bit fields in register P20_IOCR4 are not connected.

P20_IOCR4
Port 20 Input/Output Control Register 4

(14_H) **Reset Value: 0000 0000$_H$**



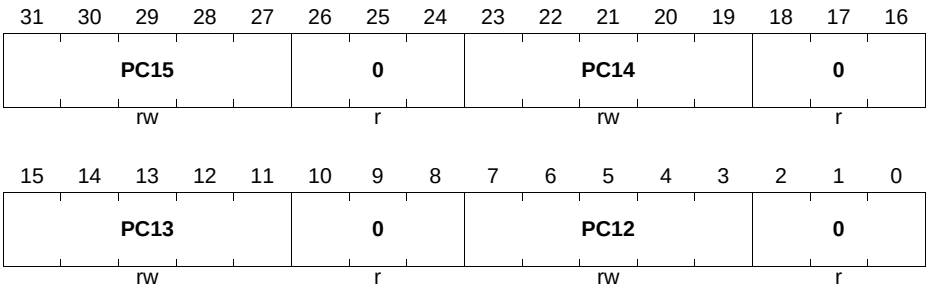
Field	Bits	Type	Description
PC4, PC5	[7:3], [15:11]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC6	[23:19]	rw	**Port Control for Port 20 Pin 6** (coding see **Table 14-5**)
PC7	[31:27]	rw	**Port Control for Port 20 Pin 7** (coding see **Table 14-5**)
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.11.1.13Port 20 Input/Output Control Register 12

The PC15 bit fields in register P20_IOCR12 is not connected.

P20_IOCR12
Port 20 Input/Output Control Register 12

($1C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PC15	[31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC12	[7:3]	rw	**Port Control for Port 20 Pin 12** (coding see **Table 14-5**)
PC13	[15:11]	rw	**Port Control for Port 20 Pin 13** (coding see **Table 14-5**)
PC14	[23:19]	rw	**Port Control for Port 20 Pin 14** (coding see **Table 14-5**)
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.11.1.14Port 20 Input Register

The basic P20_IN register functionality is described on **Page 14-40**. However, port lines P20.1, P20.[5:4] and P20.15 are not connected. Therefore, bits P1, P[5:4] and P15 in register P20_IN are always read as 0.

14.11.1.15Port 20 Pad Driver Mode 0 Register

The basic P20_PDR0 register functionality is described on **Page 14-20**.

P20_PDR0
Port 20 Pad Driver Mode 0 Register (40_H) **Reset Value: $3333\ 3333_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PL7	**PD7**			**PL6**	**PD6**			**PL5**	**PD5**			**PL4**	**PD4**		
rw	rw			rw	rw			rw	rw			rw	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PL3	**PD3**			**PL2**	**PD2**			**PL1**	**PD1**			**PL0**	**PD0**		
rw	rw			rw	rw			rw	rw			rw	rw		

Field	Bits	Type	Description
PD0	[2:0]	rw	**Pad Driver Mode for Port 20 Pin 0**
PD3	[14:12]	rw	**Pad Driver Mode for Port 20 Pin 3**
PD6	[26:24]	rw	**Pad Driver Mode for Port 20 Pin 6**
PD7	[30:28]	rw	**Pad Driver Mode for Port 20 Pin 7**
PD1, **PD2,** **PD4,** **PD5**	[6:4], [10:8], [18:16], [22:20]	rw	**Reserved** Read as 011_B after reset; returns value that was written, must be written with reset value.
PL0, **PL1,** **PL2,** **PL3,** **PL4,** **PL5,** **PL6,** **PL7**	3, 7, 11, 15, 19, 23, 27, 31	rw	**Reserved** Read as 0, returns values last written, must be written with 0.

14.11.1.16Port 20 Pad Driver Mode 1 Register

P20_PDR1
Port 20 Pad Driver Mode 1 Register (44$_H$) **Reset Value: 3333 3333$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PL15		PD15		PL14		PD14		PL13		PD13		PL12		PD12	
rw		rw		rw		rw		rw		rw		rw		rw

PL11		PD11		PL10		PD10		PL9		PD9		PL8		PD8	
rw		rw		rw		rw		rw		rw		rw		rw	

Field	Bits	Type	Description
PD8	[2:0]	rw	**Pad Driver Mode for Port 20 Pin 8**
PD9	[6:4]	rw	**Pad Driver Mode for Port 20 Pin 9**
PD10	[10:8]	rw	**Pad Driver Mode for Port 20 Pin 10**
PD11	[14:12]	rw	**Pad Driver Mode for Port 20 Pin 11**
PD12	[18:16]	rw	**Pad Driver Mode for Port 20 Pin 12**
PD13	[22:20]	rw	**Pad Driver Mode for Port 20 Pin 13**
PD14	[26:24]	rw	**Pad Driver Mode for Port 20 Pin 14**
PD15	[30:28]	rw	**Reserved** Read as 011$_B$ after reset; returns value that was written, must be written with reset value.
PL8, **PL9,** **PL10,** **PL11,** **PL12,** **PL13,** **PL14,** **PL15**	3, 7, 11, 15, 19, 23, 27, 31	rw	**Reserved** Read as 0, returns values last written, must be written with 0.

14.11.1.17Port 20 Emergency Stop Register

The basic P20_ESR register functionality is described on **Page 14-38**. Port lines P20.1, P20.[5:4] and P20.15 are not connected. Reading the EN1, EN2, EN[5:4], EN15 returns value that was last written.

14.12 Port 21

This section describes the Port 21 functionality.

Port 21 is an 8-bit GPIO port.

14.12.1 Port 21 Registers

The following registers are available on Port 21:

Table 14-16 Port 21 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P21_OUT	Port 21 Output Register	0000_H	Page 14-94[2]
P21_OMR	Port 21 Output Modification Register	0004_H	Page 14-95[2]
P21_IOCR0	Port 21 Input/Output Control Register 0	0010_H	Page 14-96[2]
P21_IOCR4	Port 21 Input/Output Control Register 4	0014_H	Page 14-15
P21_IN	Port 21 Input Register	0024_H	Page 14-98[2]
P21_PDR0	Port 21 Pad Driver Mode 0 Register	0040_H	Page 14-97[2]
P21_ESR	Port 21 Emergency Stop Register	0050_H	Page 14-98[2]
P21_OMSR0	Port 21 Output Modification Set Register 0	0070_H	Page 14-95[3]
P21_OMSR4	Port 21 Output Modification Set Register 4	0074_H	Page 14-30
P21_OMCR0	Port 21 Output Modification Clear Register 0	0080_H	Page 14-95[4]
P21_OMCR4	Port 21 Output Modification Clear Register 4	0084_H	Page 14-35
P21_OMSR	Port 21 Output Modification Set Register	0090_H	Page 14-95[5]
P21_OMCR	Port 21 Output Modification Clear Register	0094_H	Page 14-95[6]
P21_ACCEN1	Port 21 Access Enable Register 1	$00F8_H$	Page 14-43
P21_ACCEN0	Port 21 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 14-3)

2) These registers are listed and noted here in the Port 21 section because they differ from the general port register description given in Section 14.3.

3) These registers are listed and noted here in the Port 21 section because they differ from the general port register description given in Section 14.3.

4) These registers are listed and noted here in the Port 21 section because they differ from the general port register description given in Section 14.3.

5) These registers are listed and noted here in the Port 21 section because they differ from the general port register description given in Section 14.3.

6) These registers are listed and noted here in the Port 21 section because they differ from the general port register description given in Section 14.3.

14.12.1.1 Port 21 Output Register

The basic P21_OUT register functionality is described on Page 14-24. Port line P21.[1:0], [15:8] are not connected. Reading the P21_OUT bit P[15:8] always return 0,

reading P21_OUT bit P[1:0] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P21_OMR, P21_OMSR, P21_OMCR, P21_OMSRx (x=0,4), P21_OMCRx (x=0,4).

14.12.1.2 Port 21 Output Modification Register

The basic P21_OMR register functionality is described on **Page 14-26**. However, port lines P21.[1:0], P21.[15:8] are not connected. The P21_OMR bits PS[1:0] and PCL[1:0] have no direct effect on port lines but only on register bits P21_OUT.P[1:0].

14.12.1.3 Port 21 Output Modification Set Register

The basic P21_OMSR register functionality is described on **Page 14-28**. However, port lines P21.[1:0], P21.[15:8] is not connected. The P21_OMR bits PS[1:0] have no direct effect on port lines but only on register bits P21_OUT.P[1:0].

14.12.1.4 Port 21 Output Modification Set Register 0

The basic P21_OMSR0 register functionality is described on **Page 14-29**. However, port lines P21.[1:0] are not connected. The P21_OMSR0 bits PS[1:0] have no direct effect on port lines but only on register bits P21_OUT.P[1:0].

14.12.1.5 Port 21 Output Modification Clear Register

The basic P21_OMCR register functionality is described on **Page 14-33**. However, port lines P21.[15:8] are not connected. The P21_OMCR bits PCL[1:0] have no direct effect on port lines but only on register bits P21_OUT.P[1:0].

14.12.1.6 Port 21 Output Modification Clear Register 0

The basic P21_OMCR0 register functionality is described on **Page 14-29**. However, port lines P21.[1:0] are not connected. The P21_OMCR0 bits PCL[1:0] have no direct effect on port lines but only on register bits P21_OUT.P[1:0].

14.12.1.7 Port 21 Input/Output Control Register 0

The PC[1:0] bit fields in register P21_IOCR0 are not connected.

P21_IOCR0
Port 21 Input/Output Control Register 0

(10_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PC3					**0**			**PC2**					**0**

rw	rw			rw	rw			rw	rw			rw	rw		

Field	Bits	Type	Description
PD2	[10:8]	rw	**Pad Driver Mode for Port 21 Pin 2**
PD3	[14:12]	rw	**Pad Driver Mode for Port 21 Pin 3**
PD4	[18:16]	rw	**Pad Driver Mode for Port 21 Pin 4**
PD5	[22:20]	rw	**Pad Driver Mode for Port 21 Pin 5**
PD6	[26:24]	rw	**Pad Driver Mode for Port 21 Pin 6**
PD7	[30:28]	rw	**Pad Driver Mode for Port 21 Pin 7**
PD0, **PD1**	[2:0], [6:4]	rw	**Reserved** Read as 011_B after reset; returns value that was written, must be written with reset value.
PL0, **PL1,** **PL2,** **PL3,** **PL4,** **PL5,** **PL6,** **PL7**	3, 7, 11, 15, 19, 23, 27, 31	rw	**Reserved** Read as 0, returns values last written, must be written with 0.

14.12.1.9 Port 21 Input Register

The basic P21_IN register functionality is described on **Page 14-40**. However, port lines P21.[1:0], P21.[15:8] are not connected. Therefore, bits P[1:0], P[15:8] in register P21_IN are always read as 0.

14.12.1.10 Port 21 Emergency Stop Register

The basic P21_ESR register functionality is described on **Page 14-38**. Port lines P21.[1:0], P21.[15:8] are not connected. Reading the P15_ESR bits EN[15:8] always returns 0, reading EN[1:0] returns value that was last written. EN2 is reserved and has no influence on the emergency control function of P21.2, should be written with 0.

14.13 Port 22

This section describes the Port 22 functionality.

Port 22 is an 5-bit GPIO port.

14.13.1 Port 22 Registers

The following registers are available on Port 22:

Table 14-17 Port 22 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P22_OUT	Port 22 Output Register	0000_H	**Page 14-101** 2)
P22_OMR	Port 22 Output Modification Register	0004_H	**Page 14-101** 2)
P22_IOCR0	Port 22 Input/Output Control Register 0	0010_H	**Page 14-14**
P22_IOCR4	Port 22 Input/Output Control Register 4	0014_H	**Page 14-102** 2)
P22_IN	Port 22 Input Register	0024_H	**Page 14-101** 2)
P22_PDR0	Port 22 Pad Driver Mode 0 Register	0040_H	**Page 14-103** 2)
P22_ESR	Port 22 Emergency Stop Register	0050_H	**Page 14-103** 2)
P22_OMSR0	Port 22 Output Modification Set Register 0	0070_H	**Page 14-29**
P22_OMSR4	Port 22 Output Modification Set Register 4	0074_H	**Page 14-101** 2)
P22_OMCR0	Port 22 Output Modification Clear Register 0	0080_H	**Page 14-34**
P22_OMCR4	Port 22 Output Modification Clear Register 4	0084_H	**Page 14-101** 2)
P22_OMSR	Port 22 Output Modification Set Register	0090_H	**Page 14-101** 2)
P22_OMCR	Port 22 Output Modification Clear Register	0094_H	**Page 14-101** 2)
P22_ACCEN1	Port 22 Access Enable Register 1	$00F8_H$	**Page 14-43**
P22_ACCEN0	Port 22 Access Enable Register 0	$00FC_H$	**Page 14-41**

1) The absolute addresses are calculated by adding the offset address to the module base address (see **Table 14-3**)

2) These registers are listed and noted here in the Port 22 section because they differ from the general port register description given in **Section 14.3**.

14.13.1.1 Port 22 Output Register

The basic P22_OUT register functionality is described on **Page 14-24**. Port line P22.[15:5] are not connected. Reading P22_OUT bit P[15:8] always return 0, reading P[7:5] returns value that was last written.These connected bits can be also set/reset by the corresponding bits in P22_OMR, P22_OMSR, P22_OMCR, P22_OMSRx, P22_OMCRx (x=0,4).

14.13.1.2 Port 22 Output Modification Register

The basic P22_OMR register functionality is described on **Page 14-26**. However, port lines P22.[15:5] are not connected. The P22_OMR bits PS[7:5] and PCL[7:5], have no direct effect on port lines but only on register bits P22_OUT P[7:5].

14.13.1.3 Port 22 Output Modification Set Register

The basic P22_OMSR register functionality is described on **Page 14-28**. However, port lines P22.[15:5] are not connected.The P22_OMR bits PS[7:5] have no direct effect on port lines but only on register bits P22_OUT P[7:5].

14.13.1.4 Port 22 Output Modification Set Register 4

The basic P22_OMSR4 register functionality is described on **Page 14-30**. However, port lines P22.[7:5] are not connected.The P22_OMR bits PS[7:5] have no direct effect on port lines but only on register bits P22_OUT P[7:5].

14.13.1.5 Port 22 Output Modification Clear Register

The basic P22_OMCR register functionality is described on **Page 14-34**. However, port lines P22.[15:5] are not connected.The P22_OMR bits PCL[7:5], have no direct effect on port lines but only on register bits P22_OUT P[7:5].

14.13.1.6 Port 22 Output Modification Clear Register 4

The basic P22_OMCR4 register functionality is described on **Page 14-35**. However, port lines P22.[7:5] are not connected.The P22_OMR bits PCL[7:5], have no direct effect on port lines but only on register bits P22_OUT P[7:5].

14.13.1.7 Port 22 Input Register

The basic P22_IN register functionality is described on **Page 14-40**. However, port lines P22.[15:5] are not connected. Therefore, bits P[15:5] in register P22_IN are always read as 0.

14.13.1.8 Port 22 Input/Output Control Register 4

The PC[7:5] bit fields in register P22_IOCR4 are not connected.

P22_IOCR4
Port 22 Input/Output Control Register 4

(14_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PL3	PD3			PL2	PD2			PL1	PD1			PL0	PD0		
rw	rw			rw	rw			rw	rw			rw	rw		

Field	Bits	Type	Description
PD0	[2:0]	rw	**Pad Driver Mode for Port 22 Pin 0**
PD1	[6:4]	rw	**Pad Driver Mode for Port 22 Pin 1**
PD2	[10:8]	rw	**Pad Driver Mode for Port 22 Pin 2**
PD3	[14:12]	rw	**Pad Driver Mode for Port 22 Pin 3**
PD4	[18:16]	rw	**Pad Driver Mode for Port 22 Pin 4**
PD5, PD6, PD7	[22:20], [26:24], [30:28]	rw	**Reserved** Read as 011_B after reset; returns value that was written, must be written with reset value.
PL0, PL1, PL2, PL3, PL4, PL5, PL6, PL7	3, 7, 11, 15, 19, 23, 27, 31	rw	**Reserved** Read as 0, returns values last written, must be written with 0.

14.13.1.10 Port 22 Emergency Stop Register

The basic P22_ESR register functionality is described on **Page 14-38**. Port lines P22.[15:5] are not connected. Reading EN[15:8] always returns 0, reading EN[7:5] returns value that was last written.

14.14 Port 23

This section describes the Port 23 functionality.

14.14.1 Port 23 Configuration

Port 23 is a 1-bit bi-directional general-purpose I/O port.

14.14.2 Port 23 Registers

The following registers are available on Port 23:

Table 14-18 Port 23 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P23_OUT	Port 23 Output Register	0000_H	**Page 14-105** 2)
P23_OMR	Port 23 Output Modification Register	0004_H	**Page 14-108** 2)
P23_IOCR0	Port 23 Input/Output Control Register 0	0010_H	**Page 14-107** 2)
P23_IN	Port 23 Input Register	0024_H	**Page 14-109** 2)
P23_PDR0	Port 23 Pad Driver Mode 0 Register	0040_H	**Page 14-108** 2)
P23_ESR	Port 23 Emergency Stop Register	0050_H	**Page 14-109** 2)
P23_OMSR0	Port 23 Output Modification Set Register 0	0070_H	**Page 14-109** 2)
P23_OMCR0	Port 23 Output Modification Clear Register 0	0080_H	**Page 14-109** 2)
P23_OMSR	Port 23 Output Modification Set Register	0090_H	**Page 14-109** 2)
P23_OMCR	Port 23 Output Modification Clear Register	0094_H	**Page 14-109** 2)
P23_ACCEN1	Port 23 Access Enable Register 1	$00F8_H$	**Page 14-43**
P23_ACCEN0	Port 23 Access Enable Register 0	$00FC_H$	**Page 14-41**

1) The absolute addresses are calculated by adding the offset address to the module base address (see **Table 14-3**)

2) These registers are listed and noted here in the Port 23 section because they differ from the general port register description given in **Section 14.3**.

14.14.2.1 Port 23 Output Register

The basic P23_OUT register functionality is described on **Page 14-24**. Port line P23.0, P23.[15:2] are not connected. Reading the P23_OUT bit P0,P[3:2] returns the value that was last written (0 after reset). Reading the P23_OUT bit P[15:4] always return 0. These

connected bits can be also set/reset by the corresponding bits in P23_OMR, P23_OMSR, P23_OMCR, P23_OMSR0, P23_OMCR0.

14.14.2.2 Port 23 Input/Output Control Register 0

The PC0, PC[3:2] bit fields in register P23_IOCR0 are not connected.

P23_IOCR0
Port 23 Input/Output Control Register 0

(10_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PC3					**0**			**PC2**					**0**		
rw					r			rw					r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PC1					**0**			**PC0**					**0**		
rw					r			rw					r		

Field	Bits	Type	Description
PC1	[15:11]	rw	**Port Control for Port 23 Pin 1**
PC0, PC2, PC3	[7:3], [23:19], [31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.14.2.3 Port 23 Pad Driver Mode 0 Register

The basic P23_PDR0 register functionality is described on **Page 14-20**.

P23_PDR0
Port 23 Pad Driver Mode 0 Register (40_H) **Reset Value: $0000\ 3333_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PL7	**PD7**			**PL6**	**PD6**			**PL5**	**PD5**			**PL4**	**PD4**		
r	r			r	r			r	r			r	r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PL3	**PD3**			**PL2**	**PD2**			**PL1**	**PD1**			**PL0**	**PD0**		
rw	rw			rw	rw			rw	rw			rw	rw		

Field	Bits	Type	Description
PD1	[6:4]	rw	**Pad Driver Mode for Port 23 Pin 1**
PL1	7	rw	**Pad Level Selection for Port 23 Pin 1**
PD0, PD2, PD3	[2:0], [10:8], [14:12]	rw	**Reserved** Read as 011_B after reset; returns value that was written, must be written with reset value.
PD4, PD5, PD6, PD7	[18:16], [22:20], [26:24], [30:28]	r	**Reserved** Read as 000_B after reset; should be written with 0.
PL0, PL2, PL3	3, 11, 15	rw	**Reserved** Read as 0_B after reset; returns value that was written, must be written with 0.
PL4, PL5, PL6, PL7	19, 23, 27, 31	r	**Reserved** Read as 0_B after reset; should be written with 0.

14.14.2.4 Port 23 Output Modification Register

The basic P23_OMR register functionality is described on **Page 14-26**. However, port lines P23.0, P23.[15:2] are not connected. The P23_OMR bits PS0, PS[3:2] and PCL0, PCL[3:2] have no direct effect on port lines but only on register bits P23_OUT.P0, P[3:2].

14.14.2.5 Port 23 Output Modification Set Register

The basic P23_OMSR register functionality is described on **Page 14-28**. However, port lines P23.0, P23.[15:2] is not connected. The P23_OMSR bits PS0, PS[15:2] have no direct effect on port lines but only on register bits P23_OUT.P0, P[15:2].

14.14.2.6 Port 23 Output Modification Set Register 0

The basic P23_OMSR0 register functionality is described on **Page 14-29**. However, port lines P23.0, P23.[3:2] are not connected. The P23_OMSR0 bits PS0, PS[3:2] have no direct effect on port lines but only on register bits P23_OUT.P0, P[3:2].

14.14.2.7 Port 23 Output Modification Clear Register

The basic P23_OMCR register functionality is described on **Page 14-33**. However, port lines P23.0, P23.[3:2] are not connected. The P23_OMCR bits PCL0, PCL[3:2] have no direct effect on port lines but only on register bits P23_OUT.P0, P[3:2].

14.14.2.8 Port 23 Output Modification Clear Register 0

The basic P23_OMCR0 register functionality is described on **Page 14-34**. However, port lines P23.0, P23.[3:2] are not connected. The P23_OMCR0 bits PCL0, PCL[3:2] have no direct effect on port lines but only on register bits P23_OUT.P0, P[3:2].

14.14.2.9 Port 23 Input Register

The basic P23_IN register functionality is described on **Page 14-40**. However, port lines P23.0, P23.[15:2] are not connected. Therefore, bits P0, P[15:2] in register P23_IN are always read as 0.

14.14.2.10Port 23 Emergency Stop Register

The basic P23_ESR register functionality is described on **Page 14-38**. Port lines P23.0, P23.[15:2] are not connected. Reading the EN0, EN[3:2] returns value that was last written.Reading EN[15:4] always returns 0.

14.15 Port 33

This section describes the Port 33 functionality.

14.15.1 Port 33 Registers

The following registers are available on Port 33:

Table 14-19 Port 00 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P33_OUT	Port 33 Output Register	0000_H	Page 14-46[2]
P33_OMR	Port 33 Output Modification Register	0004_H	Page 14-46[2]
P33_IOCR0	Port 33 Input/Output Control Register 0	0010_H	Page 14-14
P33_IOCR4	Port 33 Input/Output Control Register 4	0014_H	Page 14-15
P33_IOCR8	Port 33 Input/Output Control Register 8	0018_H	Page 14-16
P33_IOCR12	Port 33 Input/Output Control Register 12	$001C_H$	Page 14-47[2]
P33_IN	Port 33 Input Register	0024_H	Page 14-47[2]
P33_PDR0	Port 33 Pad Driver Mode 0 Register	0040_H	Page 14-20
P33_PDR1	Port 33 Pad Driver Mode 1 Register	0044_H	Page 14-48[2]
P33_ESR	Port 33 Emergency Stop Register	0050_H	Page 14-48[2]
P33_OMSR0	Port 33 Output Modification Set Register 0	0070_H	Page 14-29
P33_OMSR4	Port 33 Output Modification Set Register 4	0074_H	Page 14-30
P33_OMSR8	Port 33 Output Modification Set Register 8	0078_H	Page 14-31
P33_OMSR12	Port 33 Output Modification Set Register 12	$007C_H$	Page 14-46[2]
P33_OMCR0	Port 33 Output Modification Clear Register 0	0080_H	Page 14-34
P33_OMCR4	Port 33 Output Modification Clear Register 4	0084_H	Page 14-35
P33_OMCR8	Port 33 Output Modification Clear Register 8	0088_H	Page 14-36
P33_OMCR12	Port 33 Output Modification Clear Register 12	$008C_H$	Page 14-46[2]
P33_OMSR	Port 33 Output Modification Set Register	0090_H	Page 14-46[2]
P33_OMCR	Port 33 Output Modification Clear Register	0094_H	Page 14-46[2]
P33_ACCEN1	Port 33 Access Enable Register 1	$00F8_H$	Page 14-43
P33_ACCEN0	Port 33 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 14-3)

2) These registers are listed and noted here in the Port 33 section because they differ from the general port register description given in Section 14.3.

14.15.1.1 Port 33 Output Register

The basic P33_OUT register functionality is described on **Page 14-24**. Port lines P33.[15:13] are not connected. Reading the P33_OUT bits P[15:13] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P33_OMR, P33_OMSR, P33_OMCR, P33_OMSRx (x=0,4,8,12), P33_OMCRx (x=0,4,8,12).

14.15.1.2 Port 33 Output Modification Register

The basic P33_OMR register functionality is described on **Page 14-26**. However, port lines P33.[15:13] are not connected. The P33_OMR bits PS[15:13] and PCL[15:13] have no direct effect on port lines but only on register bits P33_OUT.P[15:13].

14.15.1.3 Port 33 Output Modification Set Register

The basic P33_OMSR register functionality is described on **Page 14-28**. However, port lines P33.[15:13] are not connected. The P33_OMSR bits PS[15:13] have no direct effect on port lines but only on register bits P33_OUT.P[15:13].

14.15.1.4 Port 33 Output Modification Set Register 12

The basic P33_OMSR12 register functionality is described on **Page 14-32**. However, port lines P33.[15:13] are not connected. The P33_OMSR12 bits PS[15:13] have no direct effect on port lines but only on register bits P33_OUT.P[15:13].

14.15.1.5 Port 33 Output Modification Clear Register

The basic P33_OMCR register functionality is described on **Page 14-33**. However, port lines P33.[15:13] are not connected. The P33_OMCR bits PCL[15:13] have no direct effect on port lines but only on register bits P33_OUT.P[15:13].

14.15.1.6 Port 33 Output Modification Clear Register 12

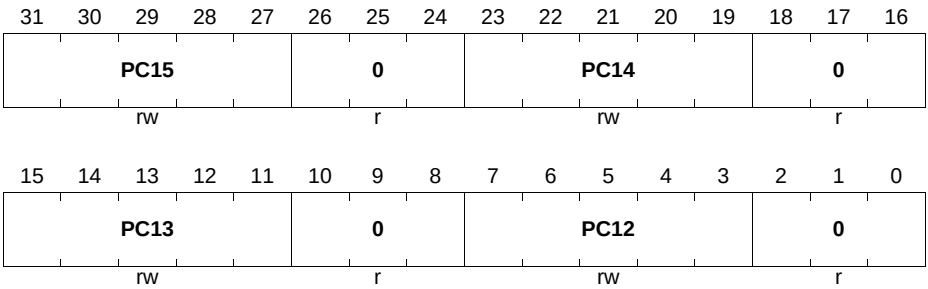
The basic P33_OMCR12 register functionality is described on **Page 14-37**. However, port lines P33.[15:13] are not connected. The P33_OMCR12 bits PCL[15:13] have no direct effect on port lines but only on register bits P33_OUT.P[15:13].

14.15.1.7 Port 33 Input/Output Control Register 12

The PC13, PC14 and PC15 bit fields in register P33_IOCR12 are not connected.

P33_IOCR12
Port 33 Input/Output Control Register 12

($1C_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
PC13	[15:11]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC14	[23:19]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC15	[31:27]	rw	**Reserved** Read as 00000_B after reset; returns value that was written.
PC12	[7:3]	rw	**Port Control for Port 33.12** (coding see **Table 14-5**)
0	[2:0], [10:8], [18:16], [26:24]	r	**Reserved** Read as 0; should be written with 0.

14.15.1.8 Port 33 Input Register

The basic P33_IN register functionality is described on **Page 14-40**. However, port lines P33.[15:13] are not connected. Therefore, bits P[15:13] in register P33_IN are always read as 0.

14.15.1.9 Port 33 Pad Driver Mode 1 Register

P33_PDR1
Port 33 Pad Driver Mode 1 Register (44$_H$) **Reset Value: 3333 3333$_H$**

PD10	[10:8]	rw	**Pad Driver Mode for Port 33 Pin 10**
PD11	[14:12]	rw	**Pad Driver Mode for Port 33 Pin 11**
PD12	[18:16]	rw	**Pad Driver Mode for Port 33 Pin 12**
PD13, PD14, PD15	[22:20], [26:24], [30:28]	rw	**Reserved** Read as 011$_B$ after reset; returns value that was written, must be written with reset value.
PL8, PL9, PL10, PL11, PL12, PL13, PL14, PL15	3, 7, 11, 15, 19, 23, 27, 31	rw	**Reserved** Read as 0, returns values last written, must be written with 0.

14.15.1.10Port 33 Emergency Stop Register

The basic P33_ESR register functionality is described on **Page 14-38**. Port lines P33.[15:13] are not connected. Reading the P33_ESR bits EN[15:13] returns the value that was last written. EN8 is reserved and has no influence on the emergency control function of P33.8, should be written with 0.

14.16 Port 34

This section describes the Port 34 functionality.

Port 34 is an 4-bit GPIO port.

14.16.1 Port 34 Registers

The following registers are available on Port 34:

Table 14-20 Port 13 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P34_OUT	Port 34 Output Register	0000_H	Page 14-70[2]
P34_OMR	Port 34 Output Modification Register	0004_H	Page 14-70[2]
P34_IOCR0	Port 34 Input/Output Control Register 0	0010_H	Page 14-14
P34_IN	Port 34 Input Register	0024_H	Page 14-71[2]
P34_PDR0	Port 34 Pad Driver Mode 0 Register	0040_H	Page 14-72[2]
P34_ESR	Port 34 Emergency Stop Register	0050_H	Page 14-72[2]
P34_OMSR0	Port 34 Output Modification Set Register 0	0070_H	Page 14-29
P34_OMCR0	Port 34 Output Modification Clear Register 0	0080_H	Page 14-34
P34_OMSR	Port 34 Output Modification Set Register	0090_H	Page 14-71[2]
P34_OMCR	Port 34 Output Modification Clear Register	0094_H	Page 14-71[2]
P34_ACCEN1	Port 34 Access Enable Register 1	$00F8_H$	Page 14-43
P34_ACCEN0	Port 34 Access Enable Register 0	$00FC_H$	Page 14-41

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 14-3)

2) These registers are listed and noted here in the Port 34 section because they differ from the general port register description given in Section 14.3.

14.16.1.1 Port 34 Output Register

The basic P34_OUT register functionality is described on Page 14-24. Port line P34.[15:4] are not connected. Reading the P34_OUT bit P[15:4] always return 0. These connected bits can be also set/reset by the corresponding bits in P34_OMR, P34_OMSR, P34_OMCR, P34_OMSR0, P34_OMCR0.

14.16.1.2 Port 34 Output Modification Register

The basic P34_OMR register functionality is described on Page 14-26. However, port lines P34.[15:4] are not connected.

14.16.1.3 Port 34 Output Modification Set Register

The basic P34_OMSR register functionality is described on **Page 14-28**. However, port lines P34.[15:4] are not connected.

14.16.1.4 Port 34 Output Modification Clear Register

The basic P34_OMCR register functionality is described on **Page 14-33**. However, port lines P34.[15:4] are not connected.

14.16.1.5 Port 34 Input Register

The basic P34_IN register functionality is described on **Page 14-40**. However, port lines P34.[15:4] are not connected. Therefore, bits P[15:4] in register P34_IN are always read as 0.

14.16.1.6 Port 34 Pad Driver Mode 0 Register

The basic P34_PDR0 register functionality is described on **Page 14-20**.

P34_PDR0
Port 34 Pad Driver Mode 0 Register (40_H) **Reset Value: $0000\ 3333_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PL7	**PD7**			**PL6**	**PD6**			**PL5**	**PD5**			**PL4**	**PD4**		
r	r			r	r			r	r			r	r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PL3	**PD3**			**PL2**	**PD2**			**PL1**	**PD1**			**PL0**	**PD0**		
rw	rw			rw	rw			rw	rw			rw	rw		

Field	Bits	Type	Description
PD0, PD1, PD2, PD3	[2:0], [6:4], [10:8], [14:12]	rw	**Pad Driver Mode for Port 34 Pin 0 to 3**
PL0, PL1, PL2, PL3	3, 7, 11, 15	rw	**Reserved** Read as 0, returns values last written, must be written with 0.
PD4, PD5, PD6, PD7	[18:16], [22:20], [26:24], [30:28]	r	**Reserved** Read as 000_B after reset; should be written with 0.
PL4, PL5, PL6, PL7	19, 23, 27, 31	r	**Reserved** Read as 0_B after reset; should be written with 0.

14.16.1.7 Port 34 Emergency Stop Register

The basic P34_ESR register functionality is described on **Page 14-38**. Port lines P34.[15:4] are not connected. Reading the P34_ESR bits EN[15:4] always returns 0.

14.17 Port 40

This section describes the Port 40 functionality in detail.

14.17.1 Port 40 Configuration

Port 40 is a 12-bit input port.

14.17.2 Port 40 Registers

The following registers are available on Port 40:

Table 14-21 Port 40 Registers

Register Short Name	Register Long Name	Offset [1] Address	Description see
P40_IOCR0	Port 40 Input/Output Control Register 0	0010_H	Page 14-121 [2]
P40_IOCR4	Port 40 Input/Output Control Register 4	0014_H	Page 14-121 [2]
P40_IOCR8	Port 40 Input/Output Control Register 8	0018_H	Page 14-121 [2]
P40_IN	Port 40 Input Register	0024_H	Page 14-40
P40_PDISC	Port 40 Pin Function Decision Control Register	0060_H	Page 14-123 [2]
P40_PCSR	Port 40 Pin Controller Select Register	0064_H	Page 14-126 [2]
P40_ACCEN1	Port 40 Access Enable Register 1	$00F8_H$	Page 14-43 [2]
P40_ACCEN0	Port 40 Access Enable Register 0	$00FC_H$	Page 14-41 [2]

1) The absolute addresses are calculated by adding the offset address to the module base address (see **Table 14-3**)

2) These registers are listed here in the Port 40 section because they differ from the general port register description given in **Section 14.3**.

14.17.3 Port 40 Input/Output Control Registers

P40_IOCR0
Port 40 Input/Output Control Register 0

(10_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
PDIS0	0	rw	**Pin Function Decision Control for Pin 0** The bit selects the function of P40.0 The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 0. 1_B Pad is used for ADC analog input x.
PDIS1	1	rw	**Pin Function Decision Control for Pin 1** The bit selects the function of P40.1 The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 1. 1_B Pad is used for ADC analog input x.
PDIS2	2	rw	**Pin Function Decision Control for Pin 2** The bit selects the function of P40.2. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 2 1_B Pad is used for ADC analog input x.
PDIS3	3	rw	**Pin Function Decision Control for Pin 3** The bit selects the function of P40.3. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 3. 1_B Pad is used for ADC analog input x.

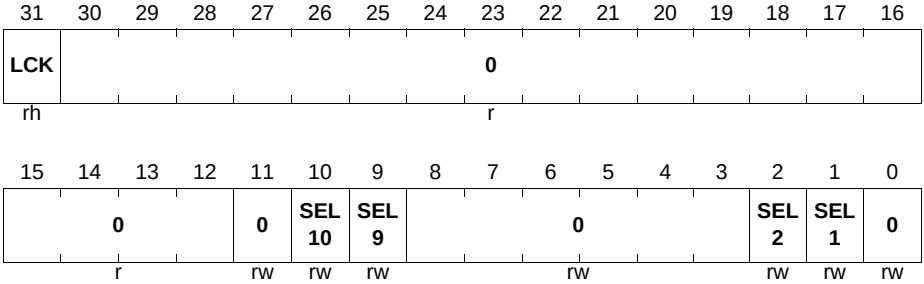
Field	Bits	Type	Description
PDIS4	4	rw	**Pin Function Decision Control for Pin 4** The bit selects the function of P40.4. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 4. 1_B Pad is used for ADC analog input x.
PDIS5	5	rw	**Pin Function Decision Control for Pin 5** The bit selects the function of P40.5. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 5. 1_B Pad is used for ADC analog input x.
PDIS6	6	rw	**Pin Function Decision Control for Pin 6** The bit selects the function of P40.6. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 6. 1_B Pad is used for ADC analog input x.
PDIS7	7	rw	**Pin Function Decision Control for Pin 7** The bit selects the function of P40.7. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 7. 1_B Pad is used for ADC analog input x.
PDIS8	8	rw	**Pin Function Decision Control for Pin 8** The bit selects the function of P40.8. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 8. 1_B Pad is used for ADC analog input x.
PDIS9	9	rw	**Pin Function Decision Control for Pin 9** The bit selects the function of P40.9. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 9. 1_B Pad is used for ADC analog input x.
PDIS10	10	rw	**Pin Function Decision Control for Pin 10** The bit selects the function of P40.10. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 10. 1_B Pad is used for ADC analog input x.

Field	Bits	Type	Description
PDIS11	11	rw	**Pin Function Decision Control for Pin 11** The bit selects the function of P40.11. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 11. 1_B Pad is used for ADC analog input x.
0	[15:12]	rw	**Reserved** Read as 0; should be written with 0.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

14.17.5 Port 40 Pin Controller Select Register

P40_PCSR enables or disables the VADC Multiplexer Diagnostics (MD) feature.

P40_PCSR
Port 40 Pin Controller Select Register (64_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SELx (x = 2-1)	0 + x	rw	**Pin Controller Select for Pin x** This bit enables or disables the VADC Multiplexer Diagnostics (MD) feature. For the respective analog signal connection, see analog connections table in VADC chapter. 0_B Disables VADC MD feature. 1_B Enables VADC MD feature.
SELx (x = 10-9)	0 + x	rw	**Pin Controller Select for Pin x** This bit enables or disables the VADC Multiplexer Diagnostics (MD) feature. For the respective analog signal connection, see analog connections table in VADC chapter. 0_B Disables VADC MD feature. 1_B Enables VADC MD feature.
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus has no effect. 0_B The register is unlocked and can be updated. 1_B The register is locked and can not be updated.

Field	Bits	Type	Description
0	0, [8:3], 11	rw	**Reserved** Read as 0; returns value last written, must be written with 0.
0	[30:16], [15:12]	r	**Reserved** Read as 0; should be written with 0.

14.18 Port 41

This section describes the Port 41 functionality in detail.

14.18.1 Port 41 Configuration

Port 41 is a 12-bit input port.

14.18.2 Port 41 Registers

The following registers are available on Port 41:

Table 14-22 Port 40 Registers

Register Short Name	Register Long Name	Offset [1] Address	Description see
P41_IOCR0	Port 41 Input/Output Control Register 0	0010_H	Page 14-130 [2]
P41_IOCR4	Port 41 Input/Output Control Register 4	0014_H	Page 14-130 [2]
P41_IOCR8	Port 41 Input/Output Control Register 8	0018_H	Page 14-130 [2]
P41_IN	Port 41 Input Register	0024_H	Page 14-40
P41_PDISC	Port 41 Pin Function Decision Control Register	0060_H	Page 14-132 [2]
P41_PCSR	Port 41 Pin Controller Select Register	0064_H	Page 14-132 [2]
P41_ACCEN1	Port 41 Access Enable Register 1	$00F8_H$	Page 14-43 [2]
P41_ACCEN0	Port 41 Access Enable Register 0	$00FC_H$	Page 14-41 [2]

1) The absolute addresses are calculated by adding the offset address to the module base address (see **Table 14-3**)

2) These registers are listed here in the Port 41 section because they differ from the general port register description given in **Section 14.3**.

14.18.3 Port 41 Input/Output Control Registers

P41_IOCR0
Port 41 Input/Output Control Register 0

(10_H) **Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
PDIS0	0	rw	**Pin Function Decision Control for Pin 0** The bit selects the function of P41.0 The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 0. 1_B Pad is used for ADC analog input x.
PDIS1	1	rw	**Pin Function Decision Control for Pin 1** The bit selects the function of P41.1 The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 1. 1_B Pad is used for ADC analog input x.
PDIS2	2	rw	**Pin Function Decision Control for Pin 2** The bit selects the function of P41.2. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 2 1_B Pad is used for ADC analog input x.
PDIS3	3	rw	**Pin Function Decision Control for Pin 3** The bit selects the function of P41.3. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 3. 1_B Pad is used for ADC analog input x.

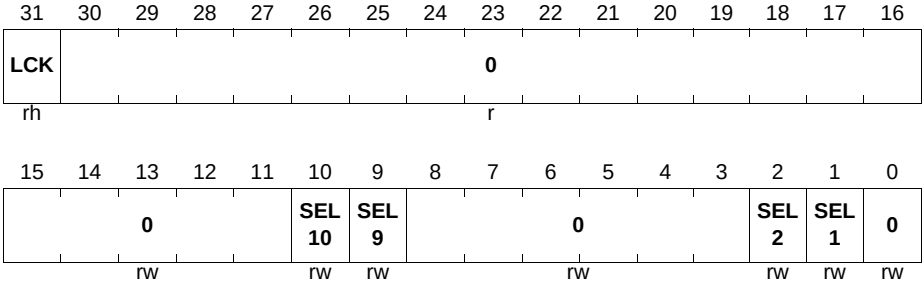
Field	Bits	Type	Description
PDIS4	4	rw	**Pin Function Decision Control for Pin 4** The bit selects the function of P41.4. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 4. 1_B Pad is used for ADC analog input x.
PDIS5	5	rw	**Pin Function Decision Control for Pin 5** The bit selects the function of P41.5. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 5. 1_B Pad is used for ADC analog input x.
PDIS6	6	rw	**Pin Function Decision Control for Pin 6** The bit selects the function of P41.6. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 6. 1_B Pad is used for ADC analog input x.
PDIS7	7	rw	**Pin Function Decision Control for Pin 7** The bit selects the function of P41.7. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 7. 1_B Pad is used for ADC analog input x.
PDIS8	8	rw	**Pin Function Decision Control for Pin 8** The bit selects the function of P41.8. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 8. 1_B Pad is used for ADC analog input x.
PDIS9	9	rw	**Pin Function Decision Control for Pin 9** The bit selects the function of P41.9. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 9. 1_B Pad is used for ADC analog input x.
PDIS10	10	rw	**Pin Function Decision Control for Pin 10** The bit selects the function of P41.10. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 10. 1_B Pad is used for ADC analog input x.

Field	Bits	Type	Description
PDIS11	11	rw	**Pin Function Decision Control for Pin 11** The bit selects the function of P41.11. The default state of the pad selects the ADC analog input. 0_B Pad is used for digital input 11. 1_B Pad is used for ADC analog input x.
0	[15:12]	rw	**Reserved** Read as 0; should be written with 0.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

14.18.5 Port 41 Pin Controller Select Register

P41_PCSR enables or disables the VADC Multiplexer Diagnostics (MD) feature.

P41_PCSR
Port 41 Pin Controller Select Register (64_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SELx (x = 2-1)	0 + x	rw	**Pin Controller Select for Pin x** This bit enables or disables the VADC Multiplexer Diagnostics (MD) feature. For the respective analog signal connection, see analog connections table in VADC chapter. 0_B Disables VADC MD feature. 1_B Enables VADC MD feature.
SELx (x = 10-9)	0 + x	rw	**Pin Controller Select for Pin x** This bit enables or disables the VADC Multiplexer Diagnostics (MD) feature. For the respective analog signal connection, see analog connections table in VADC chapter. 0_B Disables VADC MD feature. 1_B Enables VADC MD feature.
LCK	31	rh	**Lock Status** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus has no effect. 0_B The register is unlocked and can be updated. 1_B The register is locked and can not be updated.

Field	Bits	Type	Description
0	0, [8:3], [15:11]	rw	**Reserved** Read as 0; returns value last written, must be written with 0.
0	[30:16]	r	**Reserved** Read as 0; should be written with 0.

14.19 Register Behavior for Unavailable Port Pins

Table 14-23 Register Behavior of unavailable pins

Register	Behavior
Pn_OUT, Pn_ESR, Pn_PDR0, Pn_PDR1, Pn_IOCRx (x=0-3), Pn_PDISC	The unused control fields within the same nibble pin group as available pins are "rw", returns value that was last written and must be written with reset value. Otherwise, these unused control fields are 'r', read as 0 and should be written with reset value.
Pn_OMR, Pn_OMSR, Pn_OMSRx, Pn_OMCR, Pn_OMCRx, (x=0-3)	The unused control fields within the same nibble pin group as available pins are able to control Pn_OUT. Otherwise, these unused control fields do not have an influence on Pn_OUT.

15 Direct Memory Access (DMA)

This chapter describes the DMA Controller. It contains the following sections:

- Features (see **Section 15.2**)
- Block Diagram (see **Section 15.3**)
- Functional Description (see **Section 15.4**)
- Power Modes (see **Section 15.5**)
- Functional Safety Features (see **Section 15.6**)
- Debug Features (see **Section 15.7**)
- Register Description (see **Section 15.8**)
- Use Cases (see **Section 15.9**)

*Note: The DMA kernel register names described in **Section 15.8** are referenced in the TC21x/TC22x/TC23x User's Manual by the module name prefix "DMA_".*

15.1 What is new

Major differences of the RAM based AURIX DMA compared to the register based AURIX DMA are

- Any DMA move engine can service a DMA request from any DMA channel. There is no fixed mapping of DMA channels to move engines. DMA requests from the highest number DMA channel are serviced first by the DMA controller. The DMA move engine is the module that executes DMA channel requests.
- The DMA channel transaction control set is stored in the DMARAM.The move engines uses a copy of the DMARAM channel transaction control set to service DMA requests.
- DMA channels can be assigned to one of four hardware resource partitions that determine access protection of the DMARAM channel transaction control set.
- DMA channels can be daisy chained. On completing a DMA transaction a DMA channel can initiate a DMA transaction in the immediate next lower priority channel.
- DMA channel source and address pointers are 32-bit wide address counters. The source and destination wrap buffers are optionally selectable.
- Support for DMA Linked Lists. The current DMA transaction can load the next DMA transaction control set into the DMARAM by overwriting the existing channel transaction control set. It can optionally auto start the next DMA transaction.
- Support for DMA Double Buffering. The DMA transaction can execute read or fill DMA transfer from one of two source or destination buffers. A control bit allows the re-direction of DMA transfers from the one buffer to the other buffer.
- All DMA channels support safe DMA operation by the addition of logic to calculate checksums during DMA Moves.
- The move engine supports 64-bit data transfers to SRI addresses. Each move engine has its own 256-bit read buffer to access resources in the cached address ranges.
- The DMA kernel is clocked at the SRI clock frequency.

15.2 Features

The DMA controller is a fast and flexible DMA controller that has the following features:

- The DMA controller supports 16 DMA channels:
  - DMA channel 015 has the highest priority.
  - DMA channel 000 has the lowest priority.
- DMA channel hardware requests are sourced from the Interrupt Router (IR) Interrupt Control Unit (ICU). The system architecture defines a dedicated ICU to arbitrate between peripheral interrupt triggers and generate a DMA hardware request.
  - Any peripheral that can trigger an interrupt can initiate a DMA transfer.
- DMA channel software requests.
- The DMA controller supports 2 move engines for the parallel execution of DMA requests:
  - 1 X DMA sub-block (move engine) services 1 X active DMA channel.
  - DMA sub-blocks (move engines) work in parallel.
- The DMA can be hardware configured to support three programmable levels of System Peripheral Bus (SPB) bus priority through the single on chip bus data path to support the optional addition of a Debug Interface.
  - Setting high priority supports enhanced debug access. The debugger wins arbitration at the internal DMA bus switch and over all other bus master requests in order to gain immediate access to the SPB. There is a potential impact on performance.
  - Setting low priority supports non intrusive debugging. The debugger only wins arbitration when no other DMA access requesters or bus masters are requesting access to the bus. There is minimal performance impact.
- Individually programmable operation modes for each DMA channel
- Full 32-bit addressing capability of each DMA channel
  - 4 Gbyte address range.
  - Circular buffer addressing mode with flexible circular buffer sizes
- Data block move throughput
  - DMA transaction moving data from an SRI-source to an SRI-destination supports >8 Mbyte moves per DMA transaction.
  - DMA transaction moving data either from an FPI-source or to an FPI-destination supports >1 Mbyte moves per DMA transaction.
- The DMA transaction control set is stored in the DMARAM.
- DMA read move and DMA write moves are directed by the DMA switch to different sources and destinations depending on the source or destination address.
- Buffer capability for move actions on the buses (at least 1 move per bus is buffered)
- Programmable data width of DMA moves:
  - SPB master interface: 8-bit, 16-bit, or 32-bit.
  - SRI master interface: 8-bit, 16-bit, 32-bit, 64-bit, 128-bit or 256-bit.
- Interrupt Triggers:

  - Each DMA channel generates one traffic management interrupt trigger with an unique interrupt vector and priority level.
  - The DMA generates one error interrupt trigger.
- Operating frequencies:
  - The DMA controller kernel (active channel, move engine and SRI master interface) work at the SRI clock frequency in order to maximise the data throughput for DMA moves from SRI source addresses to SRI destination addresses.
  - The DMA controller configuration sector (slave interface, DMARAM, ICU interface and SPB Master interface) work at the SPB clock frequency.
- Slave based access protection:
  - DMA channel transaction control sets are access protected.
  - Each DMA channel is assigned to a hardware resource partition.
  - Access control to a hardware partition is via enabling of individual Master TAG IDs to have write access to the hardware partition.
  - Each DMA hardware resource partition has an unique Master TAG IDs and is configured to make accesses in supervisor or user mode.

15.3 Block Diagram

The DMA Controller transfers data from data source locations to data destination locations without intervention of the CPU or other on chip devices. One data move operation is controlled by an active DMA channel. A DMA sub-block can service DMA requests from any of the DMA channels. The Bus Switch provides the connection between a DMA sub-block and on chip bus interfaces.

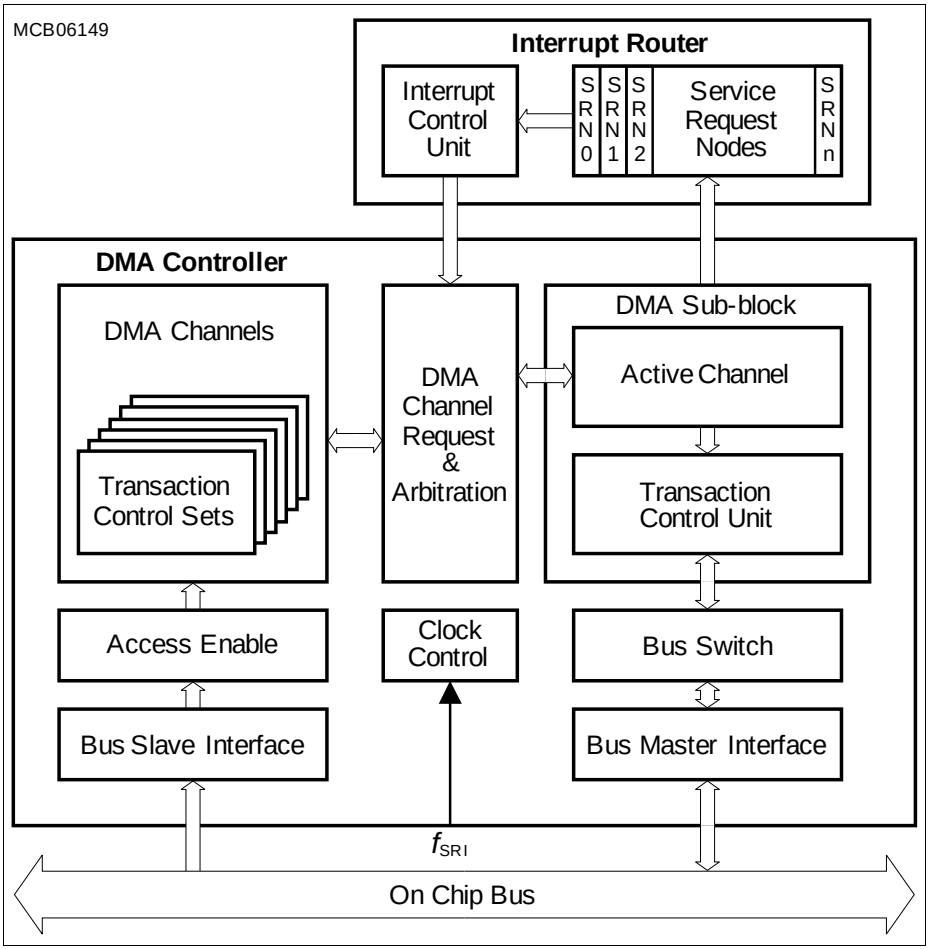


Figure 15-1 DMA Block Diagram

Programming of the DMA transaction control sets is via a bus slave interface. The slave interface supports clock control and access protection to the DMA controller. The Access

Enable registers are safe endinit protected and support register monitoring safety measures.

Address decoding and DMA request wiring are managed outside the DMA controller.

15.4 Functional Description

15.4.1 Definition of Terms

Some basic terms must be defined for the functional description of the DMA controller.

DMA Move

A DMA move is an operation that always consists of two parts:

1. A read move that loads data from a data source into the DMA controller
2. A write move that puts data from the DMA controller to a data destination

Within a DMA move, data is always moved from the data source via the DMA controller to the data destination. Data is temporarily stored in the DMA controller. The data widths of read move and write move are typically identical (8-bit, 16-bit, 32-bit, 64-bit, 128-bit or 256-bit).

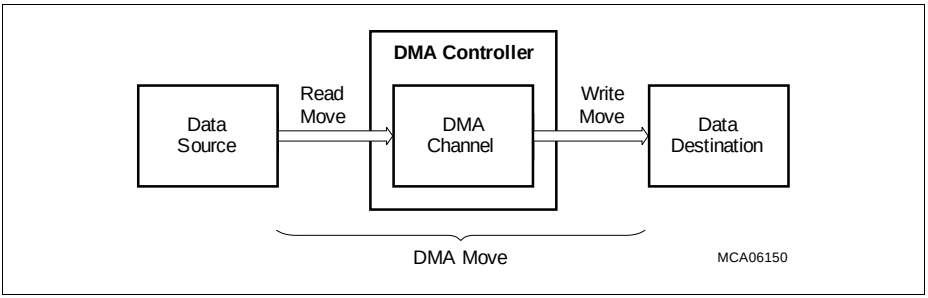

Figure 15-2 DMA Definition of Terms

DMA Transfer

A DMA transfer can be composed of 1, 2, 3, 4, 5, 8, 9 or 16 DMA moves.

DMA Transaction

A DMA transaction is composed of several (at least one) DMA transfers. The Transfer Count determines the number of DMA transfers within one DMA transaction.

Example:
1024 word (32-bit wide) transactions can be composed of 256 transfers of four DMA word moves, or 128 transfers of eight DMA word moves.

Linked List

A linked list is a series of DMA transactions executed in the same DMA channel.

15.4.2 DMA Principles

The DMA controller supports DMA moves from one address location to another location.

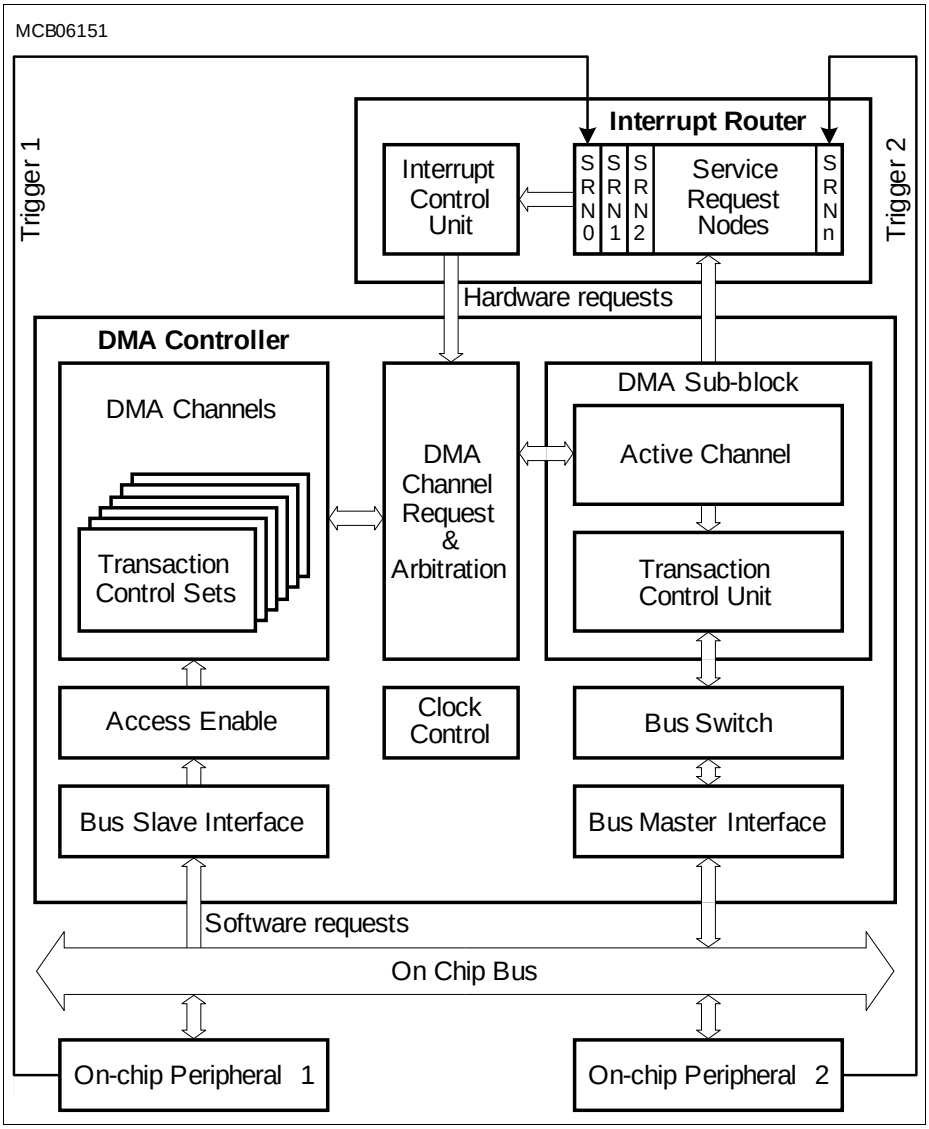

Figure 15-3 DMA System Overview

DMA moves can be requested either by hardware or by software. DMA hardware requests are triggered by specific request lines from the Interrupt Control Unit (ICU) or from other DMA channels (see **Figure 15-3**). Typically, the parallel occurrence of DMA requests and interrupts requests for DMA channels is possible. Therefore, the ICU and the DMA controller can react independently to interrupt DMA requests that have been generated by one source.

The DMA controller primarily consists of DMA channels, sub-blocks (move engines) and a bus switch. Once configured, the DMA sub-blocks are able to act as a master on the SPB Bus and on the SRI Bus.

15.4.3 DMA Channel Functionality

The transaction control set of each DMA channel is stored in the DMARAM in an array of 8 X 32-bit words. When a DMA request is serviced the associated transaction control set is copied from the DMARAM to the active DMA channel register set within a DMA sub-block. The transaction control set of a DMA channel includes functionality to support the calculation of Cyclic Redundancy Checker (CRC) checksums for source and destination addresses and read data to support enhanced data integrity checking. The index “z” refers to the channel number (z = 000 to a maximum of z = 015) within the DMA controller.

DMA channels are associated with a hardware resource partition.The index “y” refers to the hardware resource number (y = 0-3). The move engine and error registers located in the DMA sub-block use the index “x” to refer to the DMA sub-block number (x = 0-1).

When a DMA sub-block x services a DMA request from DMA channel z then the transaction control set (8 X 32-bit words) is copied from the DMARAM to the following active channel register set in DMA sub-block x:

- Channel x Status Register MExCHSR (for details, see **Page 15-108**)
- Channel x Control Register MExCHCR (for details, see **Page 15-112**)
- Channel x Address and Interrupt Control Register MExADICR (for details, see **Page 15-116**)
- Channel x Shadow Address Register MExSHADR (for details, see **Page 15-111**)
- Channel x Destination Address Register MExDADR (for details, see **Page 15-126**)
- Channel x Source Address Register MExSADR (for details, see **Page 15-127**)
- Channel x Source and Destination Address CRC Register MExSDCRC (for details, see **Page 15-128**)
- Channel x Read Data CRC Register MExRDCRC (for details, see **Page 15-129**)

15.4.3.1 Shadowed Source or Destination Address

As a typical application, an ASC module that receives data (fixed source address) has to deliver it to a memory buffer using a DMA transaction (variable destination address). After a certain amount of data has been transferred, a new DMA transaction should be

initiated to deliver further ASC data into another memory buffer. While the destination address register is updated during a running DMA transaction with the actual destination address, a shadow mechanism allows programming of a new destination address without disturbing the content of the destination address register. In this case, the new destination address is written into a buffer register, i.e. the shadow address register. At the start of the next DMA transaction, the new address is transferred from this shadow address register to the destination address register without CPU intervention. This shadow mechanism avoids the CPU having to check for the end of a DMA transaction before reprogramming address registers.

The shadow address register can be used also to store a source address. However, it cannot store source and destination address at the same time. This means that the shadow mechanism makes it possible to automatically update either a new source address, or a new destination address at the start of a DMA transaction. If both address registers (for source and destination address) have to be updated for the next DMA transaction, a running DMA transaction for this channel must be finished. After that, source and destination address registers can be written before the next DMA transaction is started.

Only one address register can be shadowed while a transaction is running, because the shadow register can only be assigned either to the source or to the destination address. Note that the shadow address transfer mechanism has the same behavior in Single and Continuous Mode.

When the shadow mechanism is disabled the DMA sub-block active channel shadow address register MExSHADR is always read as 0000 0000_H.

DMA Channel Idle

If no DMA transaction is running and a new source or destination address is written to DMA channel z then the new address value is directly written into the DMARAM source address word (SADRz) or destination address word (DADRz). Writes to the shadow address word (SHADRz) are as follows:

- Read Only Mode: the shadow address is not writable (ADICRz.SHCT = 0001_B or 0010_B) and a write to the shadow address word SHADRz will result in a bus error.
- Direct Write Mode: the shadow address is directly writable (ADICRz.SHCT = 0101_B or 0110_B) and the shadow address word SHADRz is updated.

DMA Channel Active

In the case when move engine x is servicing a DMA request from DMA channel z and a DMA transfer is in progress then address updates are dependent on the shadow control settings:

- Read Only Mode: **Figure 15-4** shows the actions that take place when a source address register is updated (destination register update happens in an equivalent

manner). The shadow address is not directly writable (ADICRz.SHCT = 0001_B or 0010_B).
  – For source shadow addressing (ADICRz.SHCT = 0001_B) the new source address is written to the shadow address register MExSHADR in DMA sub-block x.
  – For destination shadow addressing (ADICRz.SHCT = 0010_B) the new destination address is written to the shadow address register MExSHADR in DMA sub-block x.
  – Direct writes to the shadow address register will result in a bus error.
  – When the current DMA transaction completes and the final write back to DMARAM occurs the MExSHADR value is written to either SADRz or DADRz and the SHADRz is set to 00000000_H.
- Direct Write Mode: the shadow address is directly writable (ADICRz.SHCT = 0101_B or 0110_B) and the shadow address register MExSHADR in DMA sub-block x is directly written.
  – The SHADRz value stored in the DMARAM is updated to the MExSHADR value on the write back.
  – At the start of a new DMA transaction the source address register (MExSADR) or the destination address register (MExDADR) is updated with the SHADRz value. MExADICR.SHCT must be set accordingly.
  – The shadow transfer will be repeated until DMA channel z is reset or until the value in MExSHADR is $0000\ 0000_H$.

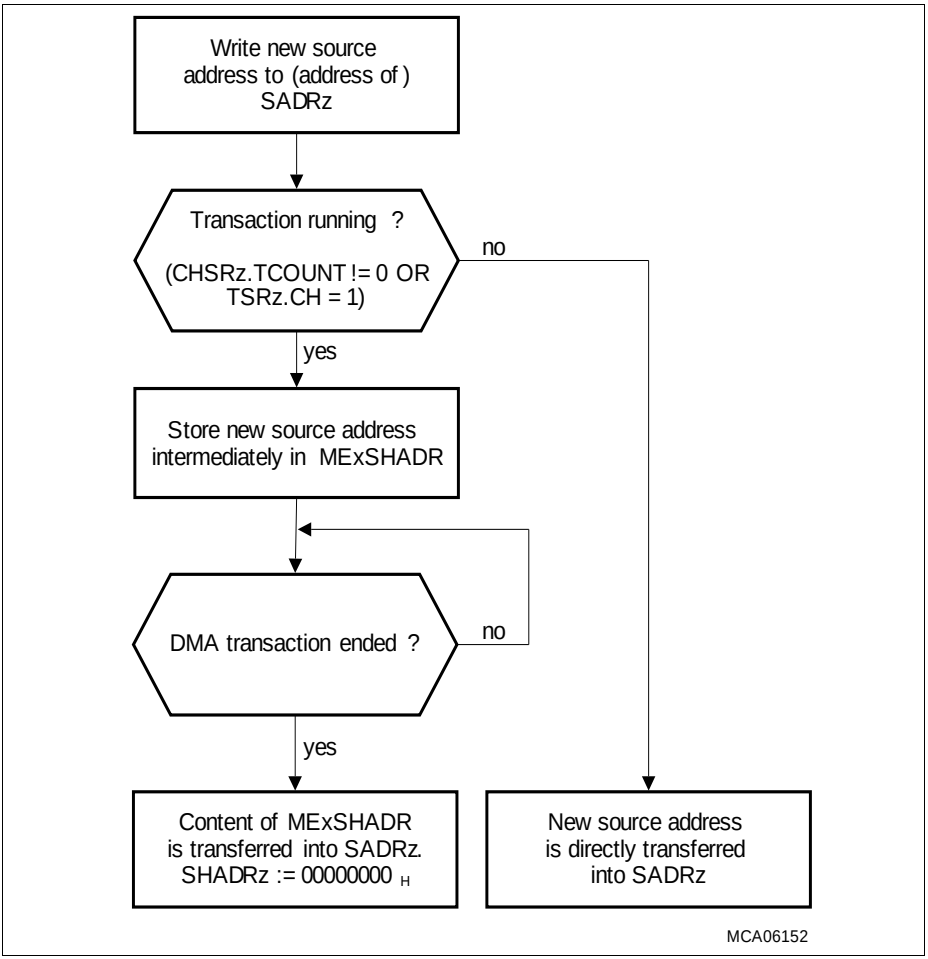

Figure 15-4 Source Address Update (ADICRz.SHCT = 0001_B)

Transfer Count Update

The transfer count of a DMA transaction, stored in bit field CHCFGRz.TREL, can also be programmed if the DMA transaction is running. At the start of a DMA transaction, CHCFGRz.TREL is transferred to bit field MExCHSR.TCOUNT. TCOUNT is updated during the DMA transaction.

No reload of address or counter will be done if MExCHSR.TCOUNT is not equal to 0.

The reprogramming of channel specific values (except for the selected shadow address register) must be avoided while a DMA channel is active as the data transfer maybe corrupted.

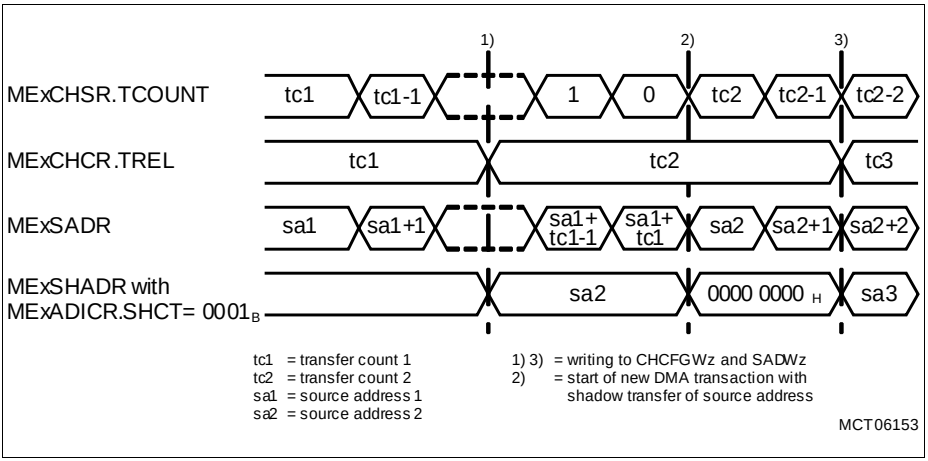

Figure 15-5 Shadow Source Address and Transfer Count Update with MExADICR.SHCT = 0001_B (Shadow Read Only Mode)

Figure 15-5 shows how the contents of the source address register MExSADR and the transfer count MExCHSR.TCOUNT are updated during two DMA transactions with a shadowed source address and transfer count update.

At reference point 2) the DMA transaction 1 is finished and DMA transaction 2 is started. At 1) the DMA channel is reprogrammed with two new parameters for the next DMA transaction: Transfer count tc2 and source address sa2. Source address sa2 is buffered in MExSHADR and transferred to MExSADR when the new DMA transaction is started at 2). At this time, transfer count tc2 is also transferred to MExCHSR.TCOUNT. Note that the shadow address register is only reset by hardware to 0000 0000_H as shown in this example, if the write enable bit is set to 0 (ADICRz.SHCT = 0001_B or 0010_B).

In the event that CHCFGRz.TREL is written while DMA channel z is active:

- A write to CHCFGRz.TREL will update the MExCHCR.TREL value in the DMA sub-block x.
- On write back CHCFGRz.TREL is updated with the latest MExCHCR.TREL value.
- MExCHSR.TCOUNT is updated to the new CHCFGRz.TREL value at the start of the next DMA transaction.

15.4.3.2 DMA Channel Request Control

Figure 15-6 shows the control logic for DMA requests that is implemented for each DMA channel.

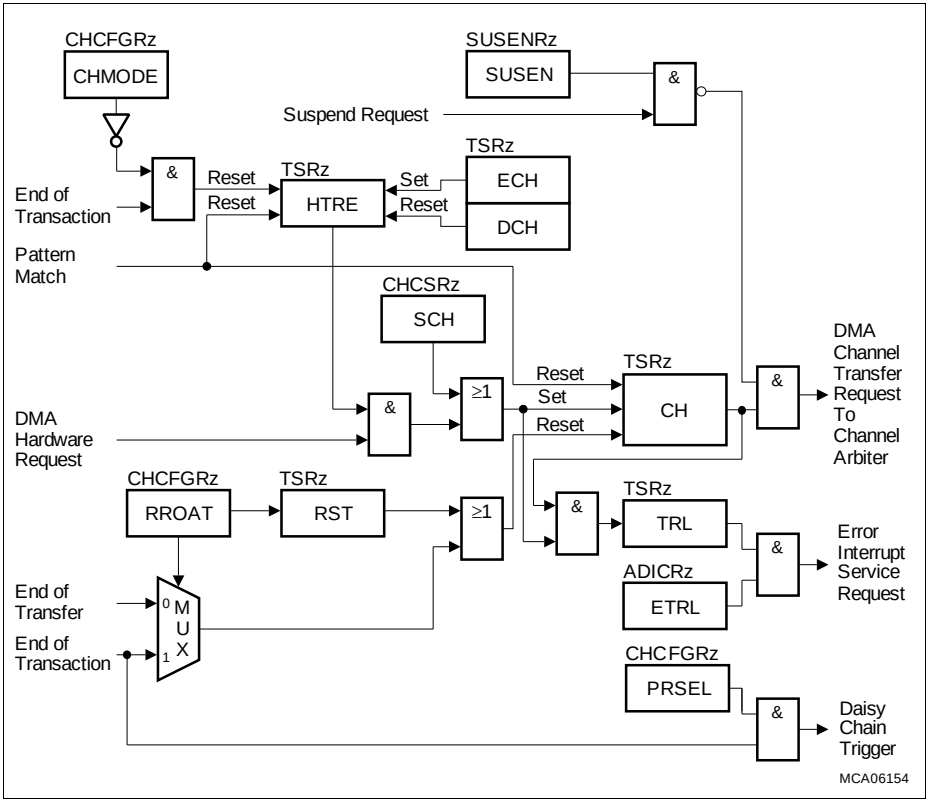

Figure 15-6 Channel Request Control

Two different types of DMA requests are possible:

- Hardware DMA requests
- Software DMA requests

DMA hardware requests (CHz_REQ) are triggered by the Interrupt Control Unit (ICU).

If CHCFGRz.PRSEL = 1 in the current DMA channel z can bypass the ICU and trigger a DMA hardware request in the next lower DMA channel z-1. The latency to service a DMA channel z-1 request is reduced. DMA channel z interrupt service requests are disabled.

Hardware requests are enabled/disabled by status bit TSRz.HTRE. HTRE can be set/reset by software or by hardware in Single Mode at the end of a DMA transaction. A software request can be generated by setting bit CHCSRz.SCH.

Status flag TSRz.CH indicates whether or not a software or hardware generated DMA request for DMA channel z is pending. TSRz.CH is cleared when the DMA transfer starts (RROAT = 0) or at the end of a DMA transaction (RROAT = 1).

If a software or a hardware DMA request is detected for channel z while TSRz.CH is set, a request lost event occurs. This error event indicates that the DMA is already processing a transfer and that another transfer has been requested before the end of the previous one. In this case, bit TSRz.TRL will be set. If ADICRz.ETRL is set then a transfer lost interrupt trigger will be generated when DMA channel z becomes active.

15.4.3.3 DMA Channel Operation Modes

The operation mode of a DMA channel is individually programmable for each DMA channel z. In basic terms, a DMA channel can operate in the following modes:

- Software controlled mode
- Hardware controlled mode, in Single Mode, Continuous Mode or Linked List.

In software-controlled mode, a DMA channel request is generated by setting a control bit. In hardware-controlled mode, a DMA channel request is generated by the ICU servicing an interrupt trigger generated by an on chip peripheral unit.

In hardware-controlled Single Mode, a DMA channel z becomes disabled by hardware after the last DMA transfer of its DMA transaction. In hardware-controlled Continuous Mode, a DMA channel z remains enabled after the last DMA transfer of its DMA transaction.

In linked list mode the DMA channel is loaded with the new transaction control set on completion of the current DMA transaction. The next DMA transaction can optionally be auto started by a software request.

In hardware- and software-controlled mode, a DMA request signal can be configured to trigger a complete DMA transaction or one single transfer.

Software-controlled Modes

In software-controlled mode, one software request starts one complete DMA transaction or one single DMA transfer. Software-controlled modes are selected by writing TSRz.DCH = 1. This forces status flag TSRz.HTRE = 0 (hardware request of DMA channel z is disabled).

The software-controlled mode that initiates one complete DMA transaction to be executed is selected for DMA channel z by the following write operations:

- CHCFGRz.RROAT = 1
- CHCSRz.SCH = 1

Setting CHCSRz.SCH to 1 (this is the software request) causes the DMA transaction of DMA channel z to be started and TSRz.CH to be set. At the start of the DMA transaction, the value of CHCFGRz.TREL is loaded into MExCHSR.TCOUNT (transfer count or tc) and the DMA transfers are executed. After each DMA transfer, TCOUNT becomes decremented and next source and destination addresses are calculated. When TCOUNT reaches the 0, DMA channel z becomes disabled and status flag TSRz.CH is reset. Setting CHCSRz.SCH again starts a new DMA transaction of DMA channel z with the parameters as currently defined in the channel register set.

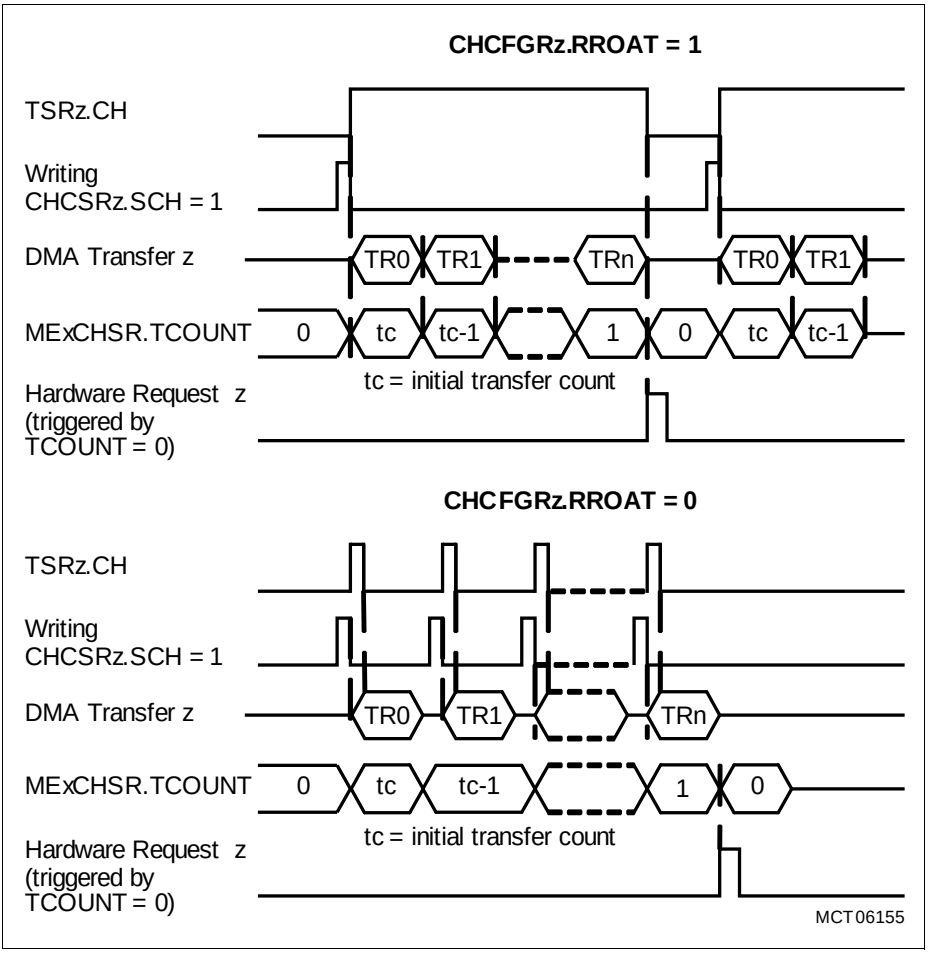

Figure 15-7 Software Controlled Mode Operation

The software-controlled mode that initiates a single DMA transfer to be executed is selected for DMA channel z by the following write operations:

- CHCFGRz.RROAT = 0
- CHCSRz.SCH = 1, repeated for each DMA transfer

When CHCFGRz.RROAT = 0, TSRz.CH is cleared when a DMA transfer starts and a new software request (writing CHCSRz.SCH = 1) must be generated for starting the next DMA transfer.

Hardware-controlled Modes

In hardware-controlled modes, a hardware request signal starts a DMA transaction or a single DMA transfer. There are two hardware-controlled modes available:

- **Single Mode:**
  Hardware requests are disabled by hardware after a DMA transaction
- **Continuous Mode:**
  Hardware requests are not disabled by hardware after a DMA transaction

Hardware-controlled Single Mode

In hardware-controlled Single Modes, one hardware request starts one complete DMA transaction or one single DMA transfer. The hardware-controlled Single Mode that initiates one complete DMA transaction to be executed for DMA channel z is selected by the following operations:

- CHCFGRz.CHMODE = 0
- CHCFGRz.RROAT = 1
- CHCFGRz.PRSEL = 0
- TSRz.ECH = 1

Setting TSRz.ECH to 1 enables hardware transfer requests (TSRz.HTRE = 1) for DMA channel z. When the ICU generates a DMA hardware request CHz_REQ then TSRz.CH is set high. If DMA channel z wins channel arbitration then DMA channel z becomes a move engine active channel. The value of CHCFGRz.TREL is loaded into MExCHSR.TCOUNT and the DMA transaction is started by executing its first DMA transfer. After each DMA transfer, TCOUNT is decremented and next source and destination addresses are calculated. When TCOUNT reaches the 0, DMA channel z becomes disabled and status flags TSRz.CH and TSRz.HTRE are reset. In order to start a new hardware-controlled DMA transaction, hardware requests must be enabled again by setting TSRz.HTRE through TSRz.ECH = 1. The hardware request disable function in Single Mode is typically needed when a reprogramming of the DMA channel register set (addresses, transfer count) is required before the next hardware triggered DMA transaction is started.

The hardware-controlled Single Mode in which each single DMA transfer has to be requested by a hardware request signal is selected as described above, with one difference:

- CHCFGRz.RROAT = 0

In this operation mode, TSRz.CH is cleared when a new DMA transfer starts, and a new hardware request at CHz_REQ must be generated for starting the next DMA transfer.

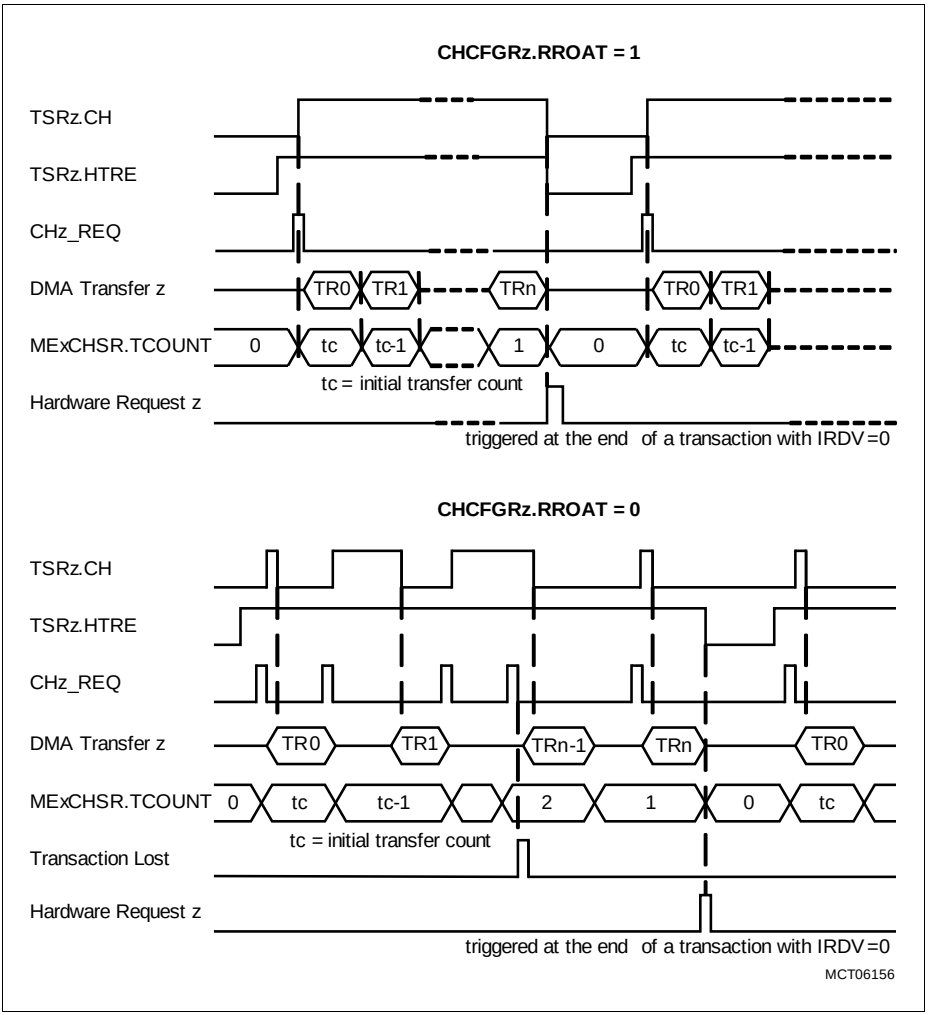

Figure 15-8 Hardware-controlled Single Mode Operation

Hardware-controlled Continuous Mode

In hardware-controlled Continuous Mode (CHCFGRz.CHMODE = 1), the hardware transaction request enable bit TSRz.HTRE is not reset at the end of a DMA transaction. A new transaction of DMA channel z with the parameters actually stored in the transaction control set of DMA channel z is started each time when CHCSRz.TCOUNT = 0 at the end of the DMA transaction. No software re-enable for a hardware request at CHz_REQ is required.

Combined Software/Hardware-controlled Mode

Figure 15-9 shows how software- and hardware-controlled modes can be combined. In the example, the first DMA transfer is triggered by software when setting CHCSRz.SCH. Hardware requests are still disabled. After hardware requests have been enabled by setting TSRz.ECH, subsequent DMA transfers are triggered now by hardware request coming from the CHz_REQ line.

In the example, DMA channel z operates in Single Mode (CHCFGRz.CHMODE = 0). In this mode, TSRz.HTRE becomes reset by hardware when CHCSRz.TCOUNT = 0 at the end of the DMA transaction.

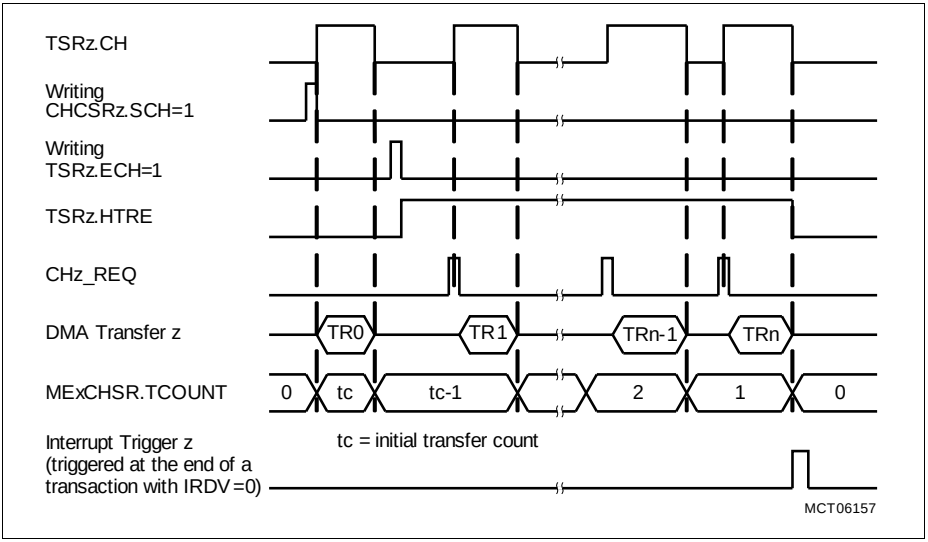

Figure 15-9 Transaction Start by Software, Continuation by Hardware

If a DMA channel is configured to be triggered by parallel hardware and software requests then if the requests collide in the same clock cycle the DMA move will be executed and a Transaction/Transfer Request Lost event will be flagged in the TSRz.TRL bit.

15.4.3.4 DMA Service Requests

Interrupt Requests are prioritized by the Interrupt Router and processed by one of the Service Providers (CPU or DMA). Each DMA peripheral interfaces to a dedicated Interrupt Control Unit (ICU) instantiated in the Interrupt Router (IR).

DMA channels are associated with the Service Request Priority Number bit field programmed in the Service Request Control Register SRC.SRPN. For example:

- DMA Channel 000 equates to SRC.SRPN = 0 programmed in IR.
- DMA Channel 001 equates to SRC.SRPN = 1 programmed in IR.
- DMA Channel 002 equates to SRC.SPRN = 2 programmed in IR.
- DMA Channel 003 equates to SRC.SRPN = 3 programmed in IR.
- DMA Channel 004 equates to SRC.SPRN = 4 programmed in IR.

The routing of a hardware Service Request to a service provider destination is determined by the IR Type of Service Control bit field SRC.TOS. The DMA will acknowledge all Service Requests. If the value programmed in the SRC.SRPN is for an Invalid Channel then the DMA Controller will take no action.

The user must programme valid SRC.SRPN values for a DMA peripheral.

Daisy Chain

DMA Channels can be daisy chained by setting the bit CHCFGRz.PRSEL.

When a higher priority DMA channel completes a DMA transaction then it will initiate a DMA transaction on the next lower priority DMA channel by setting the access pending bit TSRz.CH bit. Daisy chaining is limited to a higher priority DMA channel initiating the next lower priority DMA Channel.

Enabling the daisy chain disables the channel transfer interrupt trigger in the next higher priority channel. In a typical DMA daisy chain application only the lowest priority DMA channel is required to generate a channel transfer interrupt trigger. When the sequence of DMA transactions from the highest to lowest priority DMA channel has completed then the lowest priority DMA channel in the daisy chain will generate a channel transfer interrupt trigger to signal the end of the DMA operation.

Only the Service Request for the highest priority DMA Channel in the daisy chain is initiated by the ICU. The lower priority Service Requests bypass the ICU in order to improve interrupt latency.

15.4.3.5 Channel Reset Operation

A DMA transaction of DMA channel z can be stopped (channel is reset) by setting bit TSRz.RST. If a read or write on chip bus access of DMA channel z is executed at the time when TSRz.RST is set then the On Chip Bus access is finished normally. This behavior guarantees data consistency.

When a channel reset is applied to an active DMA channel, the on-going DMA transfer executing in the move engine will complete before the DMA channel transitions to the reset state. A pending DMA channel must become active and service its pending request before making a transition to the channel reset state.

DMA Channel Reset State

On completion of a DMA channel reset:

- Bits TSRz.HTRE, TSRz.CH, TSRz.TRL, CHCSRz.ICH, CHCSRz.IPM, CHCSRz.WRPD, CHCSRz.WRPS, CHCSRz.LXO, and bit field CHCSRz.TCOUNT are reset.
- If a circular buffer ADICRz.SCBE and/or ADICRz.DCBE is enabled then the source and/or destination address register will be set to the wrap boundary else the address registers are cleared. SHADRz will be cleared.
- All automatic functions are stopped for channel z.

Resetting a DMA Channel

A user program must execute the following steps to reset a DMA channel:

1. If hardware requests are enabled for the DMA channel z, disable the DMA channel z hardware requests by setting TSRz.DCH = 1.
2. Writing a 1 to TSRz.RST.
3. Waiting (polling) until TSRz.RST = 0 to indicate the reset has completed.

During a DMA channel reset operation, software requests must not be initiated by setting CHCSRz.SCH = 1.

Restarting a DMA Channel

A user program must execute the following steps for restarting a DMA channel after it was reset:

1. Optionally (re-)configuring the address and other channel registers.
2. Restarting the DMA channel z by setting TSRz.ECH = 1 for hardware requests or CHCSRz.SCH = 1 for software requests.

15.4.3.6 Channel Halt Operation

A DMA channel can be halted during a DMA transaction and the state frozen to allow a background RAM test to be run over a destination memory in order to detect stuck bits and distinguish between static errors and transient errors. On completion of the RAM test the DMA channel can be re-started and the DMA transaction completed.

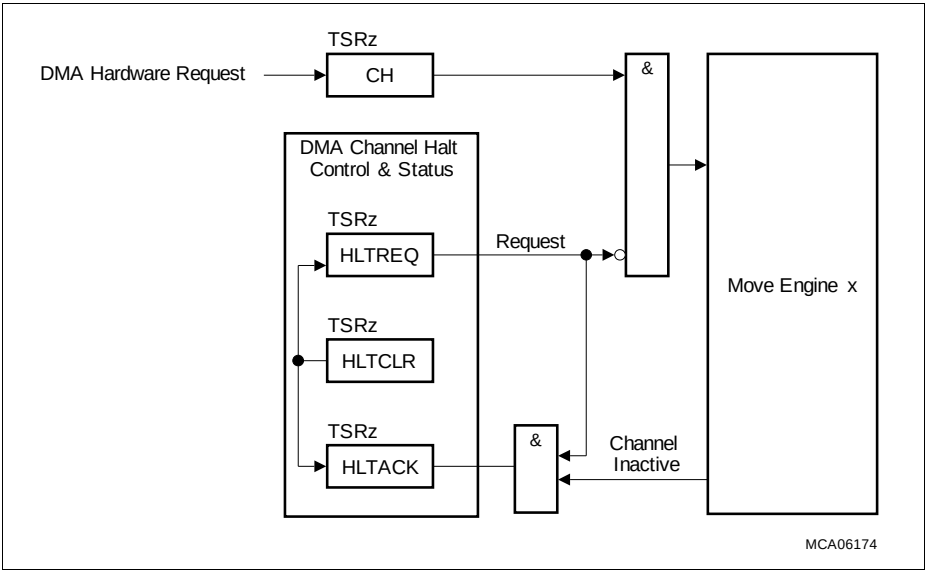

Figure 15-10 DMA Channel Halt Control

The halt control utilizes a set/clear mechanism to request the channel transitions to and from the HALT state on completion of the current DMA transfer. Only writing a logic ‘1’ to set or clear a halt request to a DMA channel has an effect and the status of other channels can be ignored.

The DMA channel halt operation is shown in **Figure 15-11**.

Entering DMA Channel Halt

Channel Halt Mode of DMA channel z is entered if the halt request bit TSRz.HLTREQ is set by software. The DMA channel enters the halt state mode automatically after the current DMA transfer is completed. The DMA channel z halt state is signalled by the halt acknowledge status flag TSRz.HLTACK.

When the DMA channel is in the halt state the transaction control set can be modified. These modifications are taken into account for further DMA transactions or DMA transfers of the related DMA channel after Halt Mode has been left again.

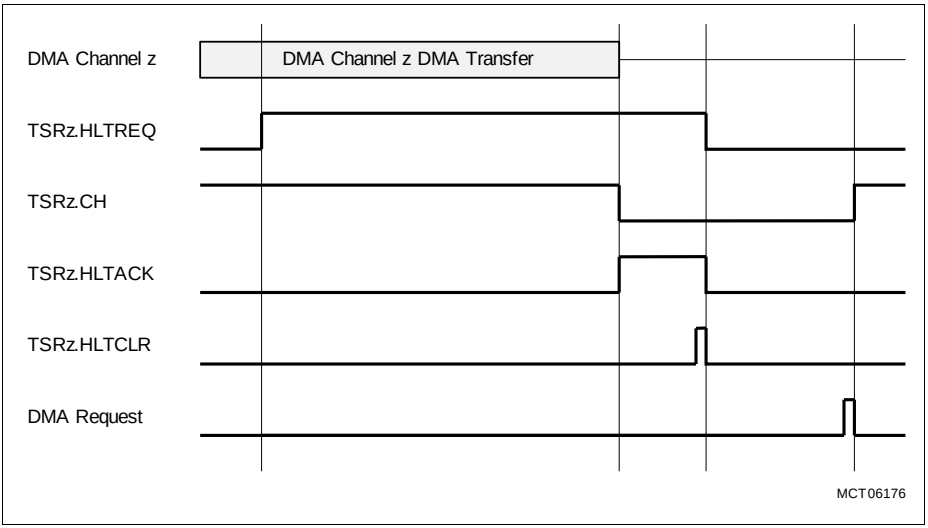

Figure 15-11 DMA Channel Halt Operation

Exiting Channel Halt Mode

DMA channel z is released from the halt state by software setting the halt clear bit TSRz.HLTCLR. Normal DMA operation is resumed.

DMA Hardware Request during Channel Halt Mode

If DMA channel z is in the halt state (TSRz.HLTACK = 1_B) and the hardware transaction request enable bit TSRz.HTRE is set then the DMA channel z will respond to DMA hardware request service requests as follows:

- Idle channel (TSRz.CH = 0_B): the access pending bit will be set and the DMA hardware request will be serviced when DMA channel z exits halt mode.
- Active channel (TSRz.CH = 1_B): the TSRz.TRL bit is set as the transaction will be lost. If the enable transaction request lost interrupt bit ADICRz.ETRL is set then an interrupt will be generated for a transaction request lost event.

15.4.3.7 Transfer Count and Move Count

The move count determines the number of moves (consisting of one read and one write each) to be done in each DMA transfer. It allows the user to indicate to the DMA the number of moves to be done after one request. The number of DMA moves per DMA transfer is selected by the block mode settings (CHCFGRz.BLKM).

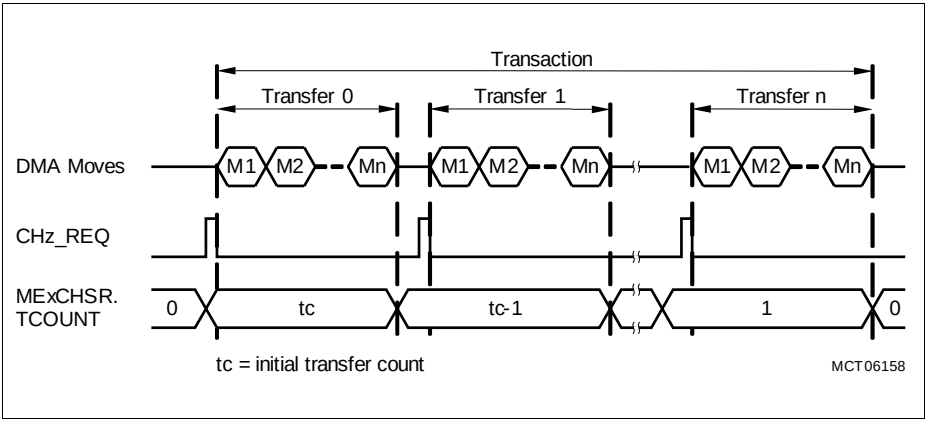

Figure 15-12 Transfer and Move Count

After a DMA move, the next source and destination addresses are calculated. Source and destination addresses are calculated independently of each other. The following address calculation parameters can be selected:

- The address offset, which is a multiple of the selected data width
- The offset direction: addition, subtraction, or none (unchanged address)

Control bits in address and interrupt control word ADICRz determine how the addresses are incremented/decremented. Further, the data width as defined in CHCFGRz.CHDW is taken into account for the address calculation.

Figure 15-13 and **Figure 15-14** show two examples of address calculation. In both examples, a data width of 16-bit (CHCFGRz.CHDW = 001_B) is assumed.

Programmable Address Modification - Example 1

In **Figure 15-13**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 10_H to a destination memory with decrementing destination addresses offset of 08_H.

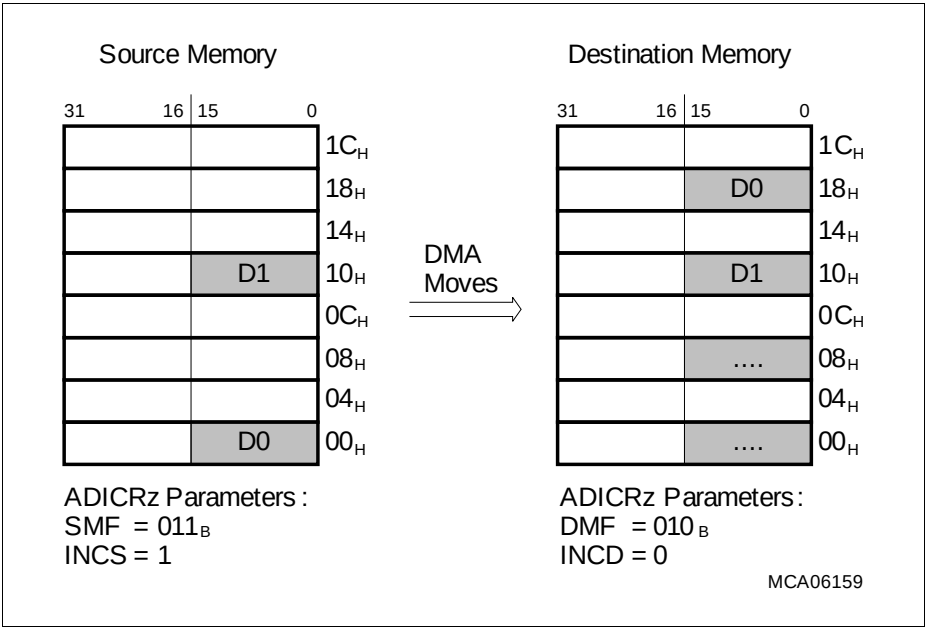

Figure 15-13 Programmable Address Modification - Example 1

Programmable Address Modification - Example 2

In **Figure 15-14**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 02_H to a destination memory with incrementing destination addresses offset of 04_H.

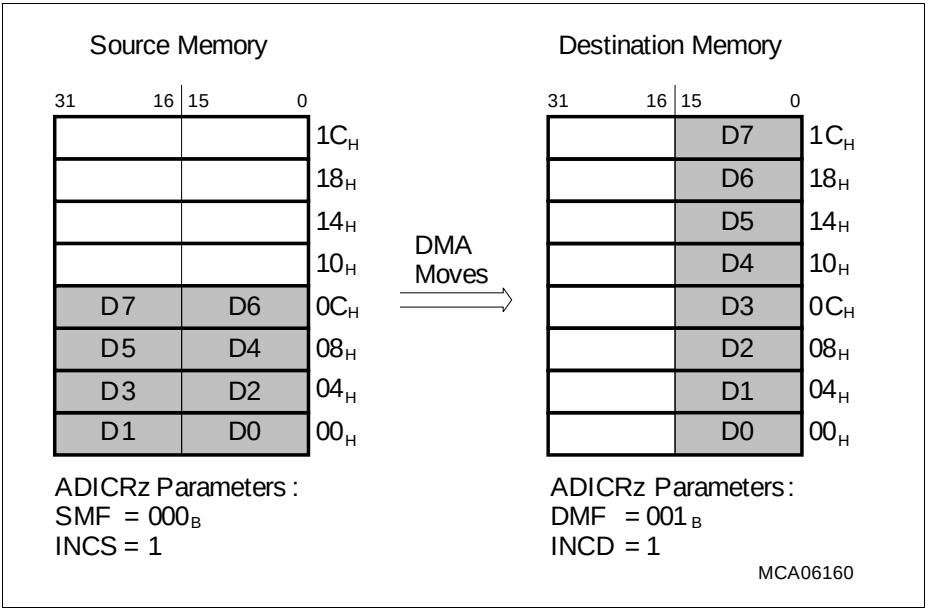

Figure 15-14 Programmable Address Modification - Example 2

15.4.3.8 Circular Buffer

Destination and source address can be configured to build a circular buffer separately for source and destination data. Within this circular buffer, addresses are updated as defined in **Figure 15-13** and **Figure 15-14** with a wrap-around at the buffer limits. The circular buffer length is determined by bit fields ADICRz.CBLS (for the source buffer) and ADICRz.CBLD (for the destination buffer). These 4-bit wide bit fields determine which bits of the 32-bit address remain unchanged at an address update. Possible buffer sizes of the circular buffers can be 2^{CBLS} or 2^{CBLD} bytes (= 1, 2, 4, 8, 16, … up to 64k bytes).

Source and destination addresses are updated (incremented or decremented) during a DMA move, all upper bits [31:CBLS] of source address and [31:CBLD] of destination address are frozen and remain unchanged, even if a wrap-around from the lower address bits [CBLS-1:0] or [CBLD-1:0] occurred. This address-freezing mechanism always causes the circular buffers to be aligned to a multiple integer value of its size.

If the circular buffer size is less or equal than the selected address offset (see **Figure 15-13**), the same circular buffer address will always be accessed.

The source and destination circular buffers are enabled by setting the circular buffer enable bits ADICRz.SCBE and ADICRz.DCBE respectively.

15.4.3.9 Address Counter

If ADICRz.SCBE = 0 then the source circular buffer is not enabled and the address will increment/decrement determined by ADICRz.INCS across the entire 32-bit address field. The address offset is determined by CHCFGRz.CHDW. The source address will wrap around on the 32-bit address boundary:

- If incrementing will wrap from $FFFFFFFF_H$ to 00000000_H.
- If decrementing will wrap from 00000000_H to $FFFFFFFF_H$.

15.4.3.10 Flow Control

A timestamp can optionally be attached at the end a DMA transaction to record the occurrence of the event. The timestamp is the time at which the event was recorded by the DMA controller and not the real time.

Timestamp Generation

The timestamp is generated from a 32-bit binary upwards synchronous counter clocked by the SPB clock divided by 8 as shown in **Figure 15-15**. The counting starts automatically after an application reset. It is not possible to affect the counter during normal operation.

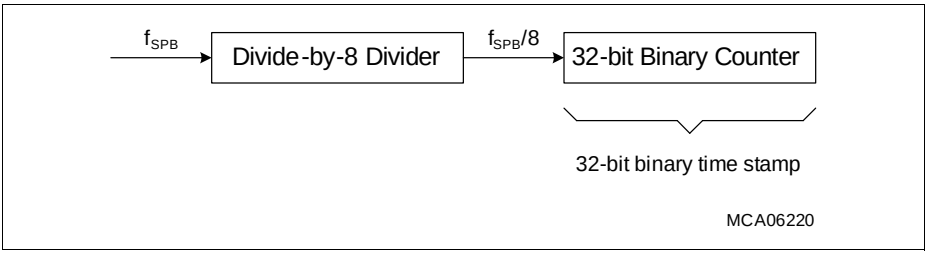

Figure 15-15 Timestamp Generation

The current 32-bit count value can be read through the DMA_TIME register.

Timestamp Appendage

The appendage of a timestamp to the destination data at the end of a DMA transaction is controlled by the ADICRz.STAMP bit. If enabled then a 32-bit timestamp will be appended by a DMA write move to the next word aligned address in the destination data

sequence. If the address control increment of destination address bit ADICRz.INCD = 1_B then the timestamp will be written at the next higher word aligned destination address and if ADICRz.INCD = 0_B then the timestamp will be written at the next lower word aligned destination address.

If a DMA channel is configured to support circular buffer operation then the timestamp must be appended at the next word aligned address above the circular buffer (ADICRz.INCD = 1_B) or below the circular buffer (ADICRz.INCD = 0_B). The appendage of the timestamp must not overwrite or change the destination address of circular buffer DMA move data.

Appendage of Timestamp - Example 1

In **Figure 15-16**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 10_H to a destination memory with decrementing destination addresses offset of 08_H.

The destination address is incrementing (ADICRz.INCD = 1_B) and the timestamp is appended above the destination data.

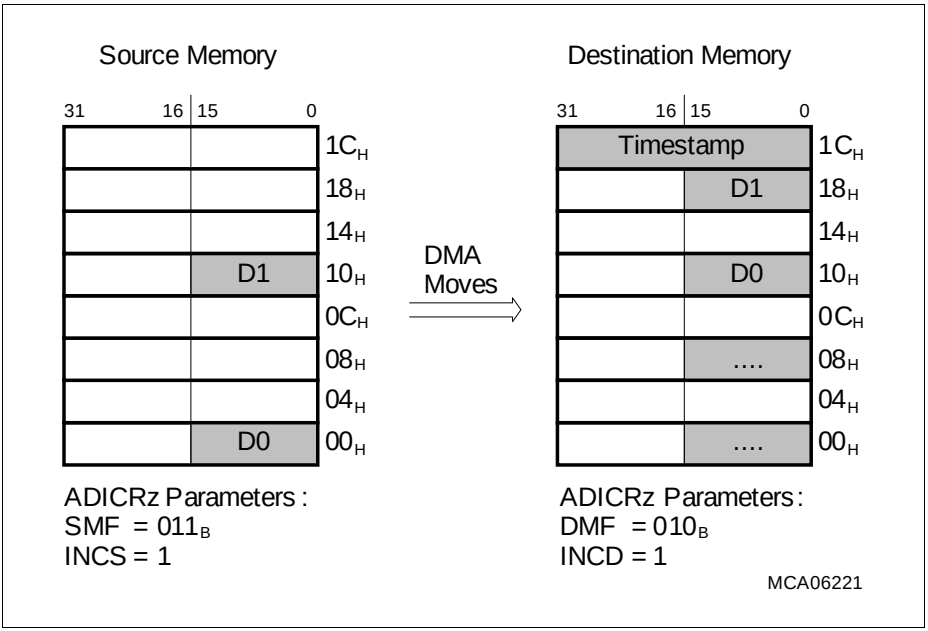

Figure 15-16 Appendage of Timestamp - Example 1 (ADICRz.INCD = 1)

Appendage of Timestamp - Example 2

In **Figure 15-17**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 02_H to a destination memory with decrementing destination addresses offset of 04_H.

The destination address is decrementing (ADICRz.INCD = 0) and the timestamp is appended below the destination data.

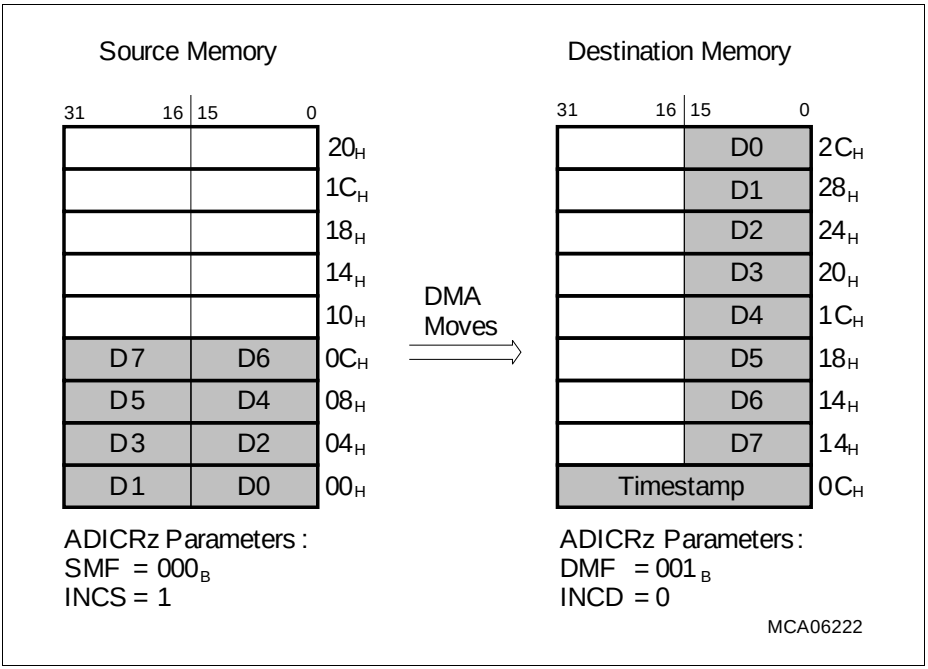

Figure 15-17 Appendage of Timestamp - Example 2 (ADICRz.INCD = 0)

Flow Control

The appendage of timestamps to the end of DMA transactions support flow control. The relative count value of the timestamp can be used to determine the sequence of DMA writes to different destination addresses.

15.4.3.11 Double Buffering Operation

The DMA supports double buffering **Figure 15-18** shows an example of double destination buffering. DMA read moves transfer a continuous data stream from a peripheral to the DMA controller and DMA write moves transfer the read data from the DMA controller to one of two destination buffers stored in memory. The data stream can be re-directed via a software switch. The dormant data buffer can be frozen and be available for cyclic software tasks while the other data buffer continues to be filled.

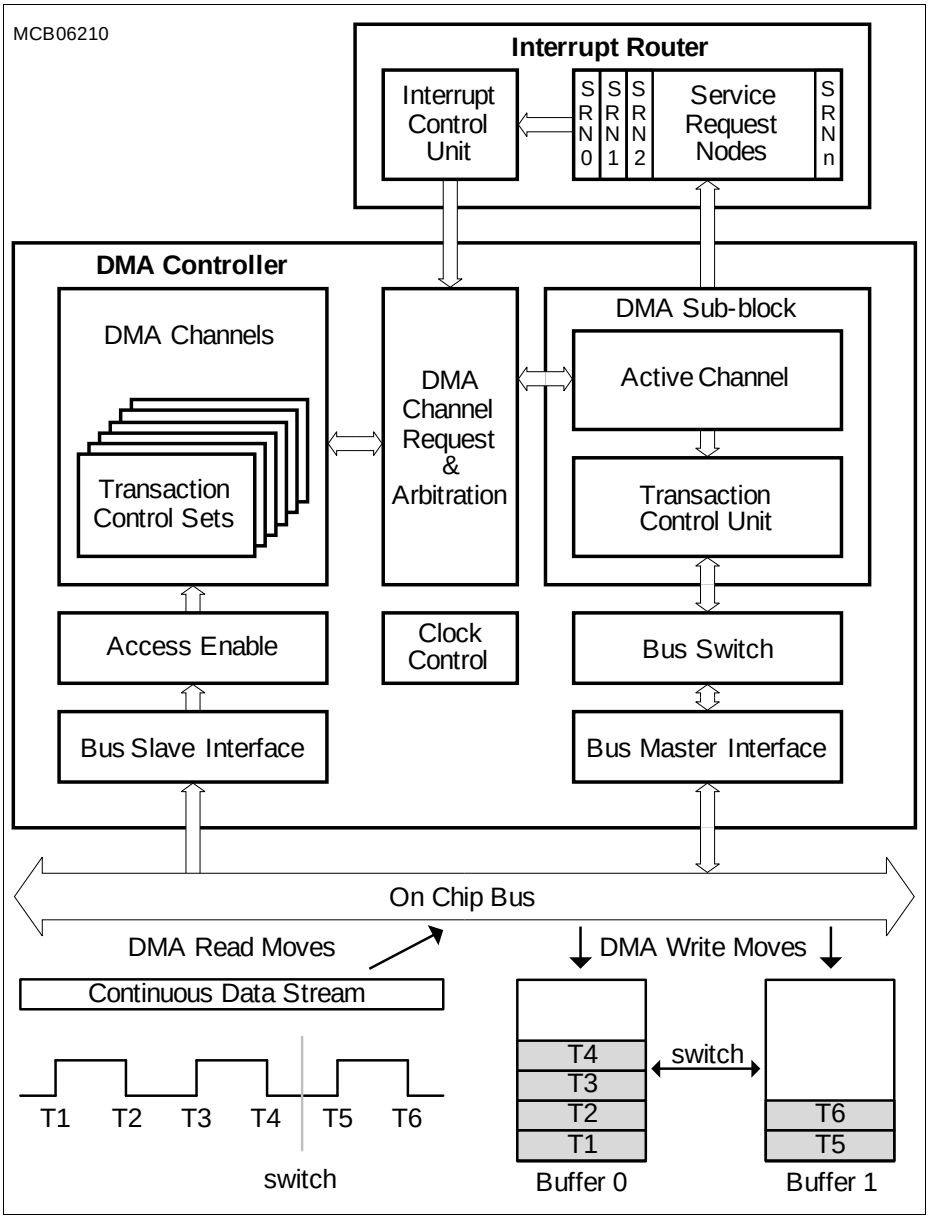

Figure 15-18 DMA Double Buffering

Double Source Addressing

A DMA Channel can be configured to support double source addresses (ADICRz.SHCT[3:1] = 100_B).

Data is streamed by the DMA from one of two data buffers (buffer 0 and buffer 1) stored in memory to a continuous output data stream. Double buffer source addresses:

- The source address SADRz is used to address buffer 0.
- The shadow address SHADRz is used as a source address to address buffer 1.

The size of the two source double buffers is equal and determined by the following DMA transaction control parameters:

- The channel data width (CHCFGRz.CHDW).
- The source circular buffer enable/disable control (ADICRz.SCBE).
- The source address modification factor (ADICRz.SMF).
- The increment of the source address (ADICRz.INCS).
- The block mode value (CHCFGRz.BLKM).
- The transfer reload value (CHCFGRz.TREL).

The size of one source buffer is equal to the size of one DMA transaction.

Double Destination Addressing

A DMA Channel can be configured to support double destination addresses (ADICRz.SHCT[3:1] = 101_B).

A continuous input data stream is directed by the DMA to one of two data buffers (buffer 0 and buffer 1) stored in memory. Double buffer destination addresses:

- The destination address DADRz is used to address buffer 0.
- The shadow address SHADRz is used as a destination address to address buffer 1.

The size of the two destination double buffers is equal and determined by the following DMA transaction parameters:

- The channel data width (CHCFGRz.CHDW).
- The destination circular buffer enable/disable control (ADICRz.DCBE).
- The destination address modification factor (ADICRz.DMF).
- The increment of the destination address (ADICRz.INCD).
- The block mode value (CHCFGRz.BLKM).
- The transfer reload value (CHCFGRz.TREL).

The size of one destination buffer is equal to the size of one DMA transaction.

Active Buffer

During DMA double buffering the CHCSRz.BUFFER status bit is used to indicate which buffer is active.

- MExCHSR.BUFFER = 0_B: buffer 0 is read or filled by the DMA.

- MExCHSR.BUFFER = 1_B: buffer 1 is read or filled by the DMA.

Buffer Switching

The re-direction of the data stream from one buffer to the other can be controlled by software and additionally automatically by hardware. Automatic hardware switching is selected by setting ADICRz.SHCT[0] = 1_B. The different DMA double buffering modes are shown in **Table 15-1**.

Table 15-1 DMA Double Buffering Modes

SHCT	Description
1000_B	**DMA Double Source Buffering** **Software Switch Only** Switching from the current source buffer to the other source buffer is controlled by the software switch CHCSRz.SWB
1001_B	**DMA Double Source Buffering** **Automatic Hardware and Software Switch** DMA controller automatically switches source buffers when current source buffer is emptied. Software source buffer switching controlled by CHCSRz.SWB
1010_B	**DMA Double Destination Buffering** **Software Switch Only** Switching from the current destination buffer to the other destination buffer is controlled by the software switch CHCSRz.SWB
1011_B	**DMA Double Destination Buffering** **Automatic Hardware and Software Switch** DMA controller automatically switches destination buffers when current destination buffer is full. Software destination buffer switching controlled by CHCSRz.SWB

Software Buffer Switch

Before a DMA transaction completes and the active buffer is full software can re-direct the data stream from the active buffer to the other buffer by setting CHCSRz.SWB. If a move engine is actively servicing a DMA channel z configured for double buffering then the current DMA transfer completes before the buffer switch is made.

On completion of the DMA transfer the DMA controller will:

- Automatically re-load MExCHSR.TCOUNT with CHCFGRz.TREL
- Switch the address pointer between the source/destination address and the shadow
  - Buffer 0 address pointer (source or destination address).
  - Buffer 1 address pointer (shadow address).

The address control factors remain the same. The next DMA transaction controlling the filling or reading of the new buffer will start when a DMA request is received.

During a software buffer switch no DMA requests are lost by the DMA controller and there is no loss, duplication or split of data across the two buffers.

Buffer Empty or Full

If the current buffer is emptied (in the case of DMA double source buffering) or filled (in the case of DMA double destination buffering) before a software buffer switch is received then the DMA channel will stop and no more DMA transfers are made. The transaction control set is frozen. The transfer count status (MExCHSR.TCOUNT and CHCSRz.TCOUNT) when the DMA channel is stopped is equal to 0000_H.

The signalling of a buffer empty or full event can be generated by using the DMA channel traffic interrupt service request. The interrupt control ADICRz.INTCT is set to 10_B and the interrupt raise detect value ADICRz.IRDV set to 0000_B. When the transfer count equals zero then the DMA channel will raise a DMA channel interrupt service request.

The DMA channel interrupt handler can interrogate the DMA channel transaction control set to identify which empty or full buffer generated the interrupt. Software can reset the channel ready to restart DMA double buffering operations.

Fast Data Rate

If the data rate is faster than the DMA controller is able to transfer the data to one of the buffers then a transaction request lost event will occur.

If the DMA controller is servicing a DMA access pending request (TSRz.CH = 1_B) and a DMA hardware request is detected then the transaction request lost bit TSRz.TRL will be set. If the enable transaction request lost bit is set (ADICRz.ETRL = 1_B) then a DMA error interrupt service request will be generated.

The DMA error interrupt handler can interrogate the DMA channels and identify the source of the error. Software can reset the DMA channel and restart DMA double buffer operations.

Automatic Hardware Buffer Switch

The DMA controller will automatically switch from the active buffer to the other buffer when the DMA transaction reading or filling the active buffer completes. On switching buffers the MExCHSR.FROZEN bit is set to indicate that one buffer is frozen and available for cyclic software tasks. The interrupt control bits ADICRz.INTCT and interrupt raise detect value MExADICR.IRDV can be used to generate a DMA channel interrupt service request.

On completion of the DMA transaction when MExCHSR.TCOUNT equals 0000_H the DMA controller will:

- Automatically re-load MExCHSR.TCOUNT with CHCFGRz.TREL
- Switch the address pointer between the source/destination address and the shadow address:
  – Buffer 0 address pointer (source or destination address).
  – Buffer 1 address pointer (shadow address).

The address control factors remain the same. The next DMA transaction controlling the filling or reading of the new buffer will start when a DMA request is received.

During an automatic hardware buffer switch no DMA requests are lost by the DMA controller and there is no loss, duplication or split of data across the two buffers.

Frozen Buffer

When the DMA controller switches buffer the frozen bit MExCHSR.FROZEN is set. The frozen buffer is then available for a cyclic software task. On completion of the software task the status bit MExCHSR.FROZEN is cleared by software and the buffer address pointer is re-programmed to the start address ready for the next DMA transaction that reads/fills the buffer.

Transaction Request Lost

If MExCHSR.FROZEN is equal to 1_B then the automatic hardware switch buffer will not occur and the DMA controller will stop. If a DMA hardware request is detected before MExCHSR.FROZEN is cleared then the transaction request lost bit TSRz.TRL is set and a DMA error interrupt service request will be generated if ADICRz.ETRL is 1_B.

DMA Double Buffer Operation

A typical DMA double buffer application is shown in **Figure 15-19**:

- A DMA read move loads a continuous stream of 32-bit data words from an SPB connected peripheral into the DMA controller.
- A DMA write move stores the data from the DMA controller into one of two destination data buffers.

Double destination buffering with software buffer switch only is selected by using the shadow operation control bits (ADICRz.SHCT = 1010_B) as shown in **Table 15-1**. The shadow mechanism is not available.

Transaction Control Set

The DMA active channel points at the two buffers as follows:

- The destination address register MExDADR.DADR is the address pointer to buffer 0.
- The shadow address register MExSHADR.SHADR is the address pointer to buffer 1.

The transfer count (CHCFGRz.TREL), block mode (CHCFGRz.BLKM) and address modification factors (CHCFGRz.CHDW, ADICRz.DCBE, ADICRz.DMF and ADICRz.INCD) are the same for the two buffers.

The buffer depth of the two data buffers is identical and is equal to one DMA transaction. The size of the buffer depth is a multiple of the address modification factors, the DMA transfer block mode and the DMA transaction transfer count.

DMA Operation

The DMA channel z configured for double destination buffering is programmed to execute DMA transfers of 2 X 32-bit words from a source peripheral to one of two destination buffers.

The DMA channel receives a DMA request and on winning arbitration executes a DMA transfer. During the second DMA transfer, the DMA channel z receives a swap buffer command. On completion of the current DMA transfer the frozen buffer bit MExCHSR.FROZEN is set.

At the start of the next DMA transfer the incoming data stream is re-directed to buffer 1. No data is lost, duplicated or split between the buffers. MExCHSR.TCOUNT is reloaded with CHCFGRz.TREL and executes DMA moves to the buffer 1 starting at the address stored in MExSHADR. The status bit MExCHSR.BUFFER switches state to indicate that the DMA controller is filling buffer 1. The cyclic software task operates on buffer 0 and on completion clears MExCHSR.FROZEN and re-programmes the destination address register to the buffer 0 start address. Buffer 0 is now available to receive data and the software will issue a switch buffer instruction and in turn buffer 1 will become available for a cyclic software task.

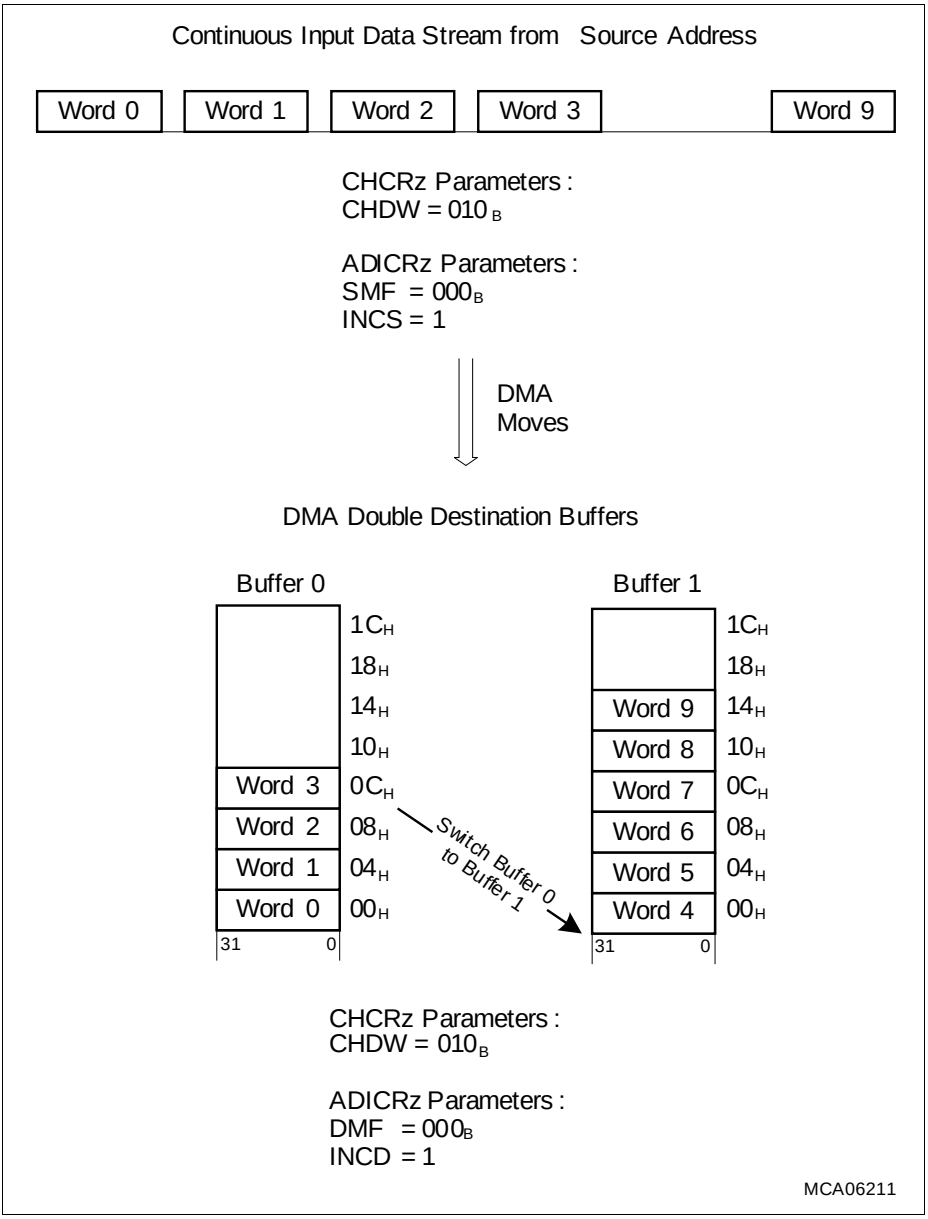

Figure 15-19 DMA Double Destination Buffering

15.4.3.12 Linked Lists

Linked lists are an extension of the DMA channel functionality. Linked lists consist of a series of DMA transactions executed by the same DMA channel z. Each DMA transaction has a unique transaction control set. The source and destination areas do not have to exist in contiguous areas of memory. The new DMA transaction can issue a DMA software request and auto start the DMA transaction bypassing the Interrupt Router and so reducing the cumulative latency over a number of DMA transactions.

In a linked list, the current DMA channel transaction control set defines the shadow register as an address pointer to read the next 32-byte transaction control set from anywhere in memory and overwrite the current transaction control set in the DMARAM.

The following types of linked lists are supported:

- DMA Linked List (see **Section 15.4.3.13**)
- Accumulated Linked List (see **Section 15.4.3.14**)
- Safe Linked List (see **Section 15.4.3.15**)
- Conditional Linked List (see **Section 15.4.3.16**)

Linked lists support greater flexibility in the use of the DMA controller.

Circular Operation of Linked List

Linked lists may be configured for circular operation when the same series of DMA transactions in the linked list are endlessly repeated.

Pattern Detection During a Linked List

If a DMA transaction in a DMA, Accumulated or Safe Linked List is configured for pattern detection then a pattern match (see **Section 15.4.7**) will terminate linked list operation. If the pattern match occurs during the last DMA move of the DMA transaction then the current DMA move status is preserved and the next transaction control set is not loaded. Software must reconfigure the DMA channel.

Software Termination of a Linked List

If the linked list is terminated by software then the current DMA transaction is completed and the linked list is disabled.

15.4.3.13 DMA Linked List

A DMA channel z supports a DMA linked list consisting of 32-Byte transaction control sets by using the shadow operation control bits (ADICRz.SHCT = 1100_B) as shown in **Table 15-15**.

If DMA channel z is configured to support a DMA linked list then when the DMA move engine x completes the servicing of a DMA request from DMA channel z it will read the next transaction control set from memory and overwrite the DMARAM channel z with the new transaction control set. The current DMA transaction uses the shadow address as an address pointer to the next transaction control set. The address pointer to the next transaction control set must be mapped to a 32-byte aligned address in either internal or external memory and configured as shown in **Figure 15-20**. A BTR4 access can be used to read the new transaction control set. The DMA controller will start reading the new transaction control set from the RDCRCRz word upwards.The last word to be read is CHCSRz.

If CHCSRz.SCH is set to 1 then the new transaction control set will auto start and initiate a new transaction request for DMA channel z. The access pending bit TSRz.CH will be set. The DMA controller will arbitrate against other pending requests on completion of the current DMA transfer. When DMA channel z wins arbitration the new DMA transaction will be serviced. There is no limit to the number of DMA transactions in a DMA linked list.

The DMA transactions in the linked list can be started by hardware or software requests. Auto start of a new DMA channel z transaction control set is limited to software requests.

Last DMA Transaction in DMA Linked List

The DMA traffic management interrupt service requests may be used to signal the completion of the last DMA transaction in the DMA linked list. The last DMA transaction will load a new transaction control set. The auto start is not to be set.

Loading Non Linked List Transaction Control Set

If a DMA linked list loads a non linked list transaction control set then the DMA channel exits linked list mode. The non linked list transaction control set will not auto start.

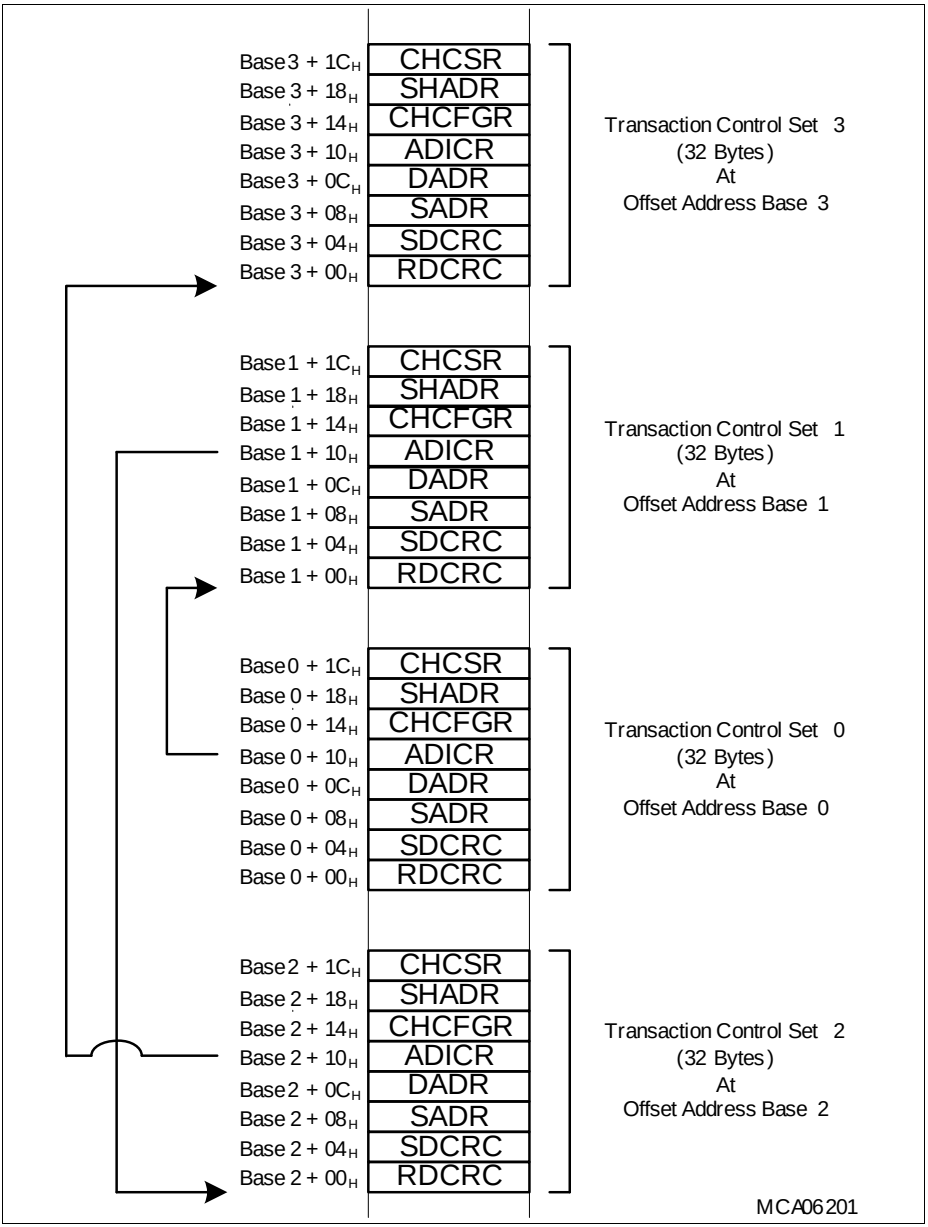

Figure 15-20 DMA Linked List

15.4.3.14 Accumulated Linked List

A DMA channel z supports an accumulated linked list by using the shadow operation control bits (ADICRz.SHCT = 1101_B) as shown in **Table 15-15**. The accumulated linked list is a variant of the DMA linked list and has an identical footprint in memory (size and structure). The SDCRCRz and RDCRCRz words are not overwritten when the new transaction control set is written into the DMARAM channel z and are accumulated across DMA transactions.

SDCRC & RDCRC Checksums

The SDCRC and RDCRC checksums are not overwritten when the new transaction control set is loaded into the DMA channel. On completion of the linked list operation (on completion of the last DMA transaction) the SDCRC and RDCRC checksums are the values calculated across all DMA transactions.

15.4.3.15 Safe Linked List

A Safe linked list provides protection against software errors. If the shadow address in the linked list is incorrectly written then a link address pointer could point to any random area of memory and load a new transaction control set and execute it. A DMA channel z supports a safe linked list by using the shadow operation control bits (ADICRz.SHCT = 1110_B) as shown in **Table 15-15**.

Proceeding from one DMA transaction to the next DMA transaction in the linked list sequence is dependent on the current SDCRC checksum matching the expected SDCRC checksum stored in the next transaction control set.

SDCRC Checksum

The user is required to load the SDCRC word with an expected CRC checksum value. When the safe link list reads the new transaction control set from memory the SDCRC checksum generated by the running DMA transaction is compared against the new expected SDCRC checksum. If the checksums match then the DMA controller proceeds with the execution of the new transaction control set. And if not then a DMA error service interrupt request is triggered, error flag ERRxSR.SLLER set and the DMA stops the execution of the linked list. Assuming all the SDCRC checksum values match at the end of the linked list then the checksum is the value calculated across all DMA transactions.

RDCRC Checksum

The RDCRC checksum word is not overwritten when the new transaction control set is loaded into the DMA channel. The RDCRC checksum value at the end of the linked list is the accumulated checksum across the read data for all DMA transactions.

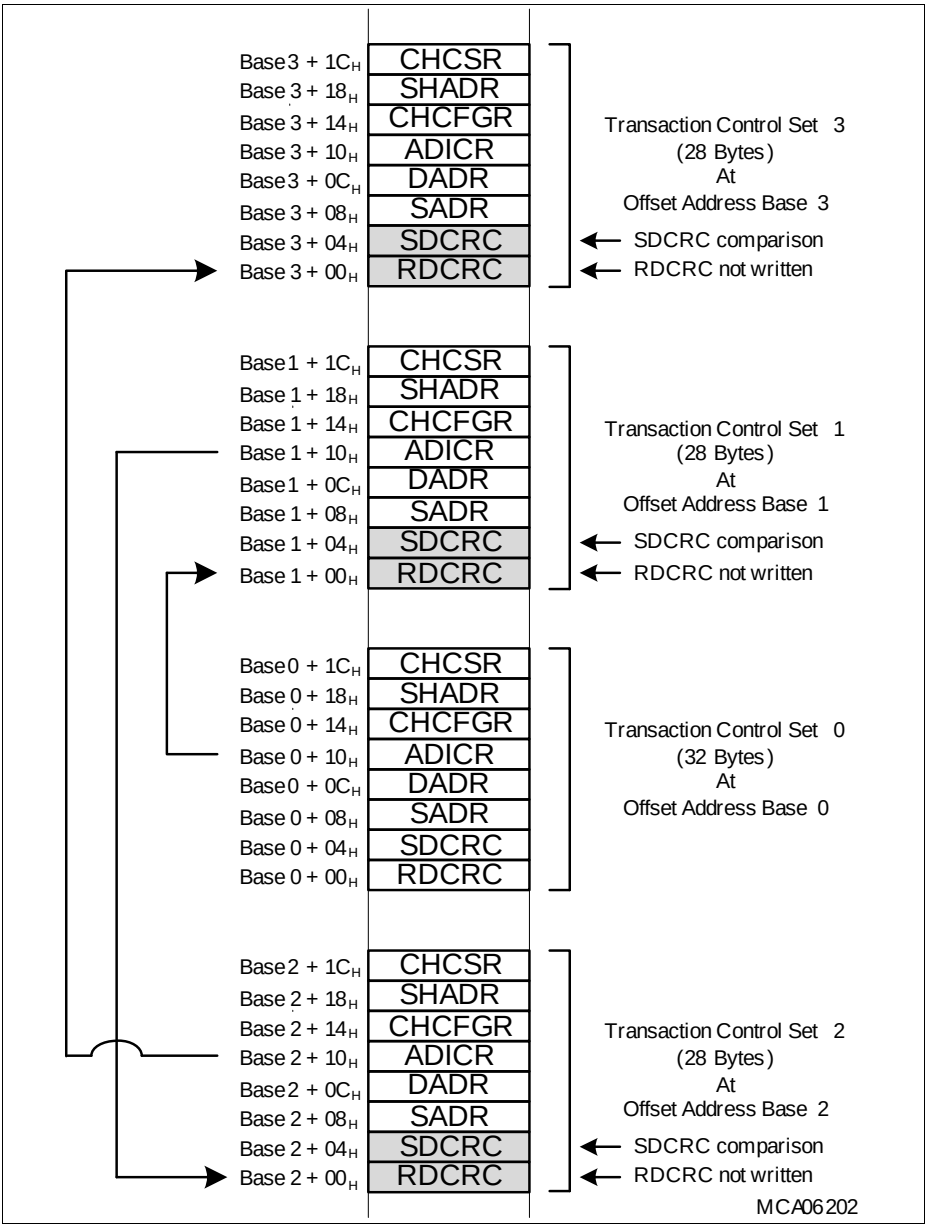

Figure 15-21 Safe Linked List

15.4.3.16 Conditional Linked List

A special use of linked lists is the Conditional Linked Lists (CLL) as shown in **Figure 15-22**. Selection of the address pointer is determined by a conditional state.

A DMA channel supports a Conditional Linked List by using the shadow operation control bits (ADICRz.SHCT = 1111_B) as shown in **Table 15-15**. DMA usage of CLL is limited to 8-bit DMA read moves (CHCFGRz.CHDW = 000_B). CLL does not support the appendage of timestamps (ADICRz.STAMP = 0_B).

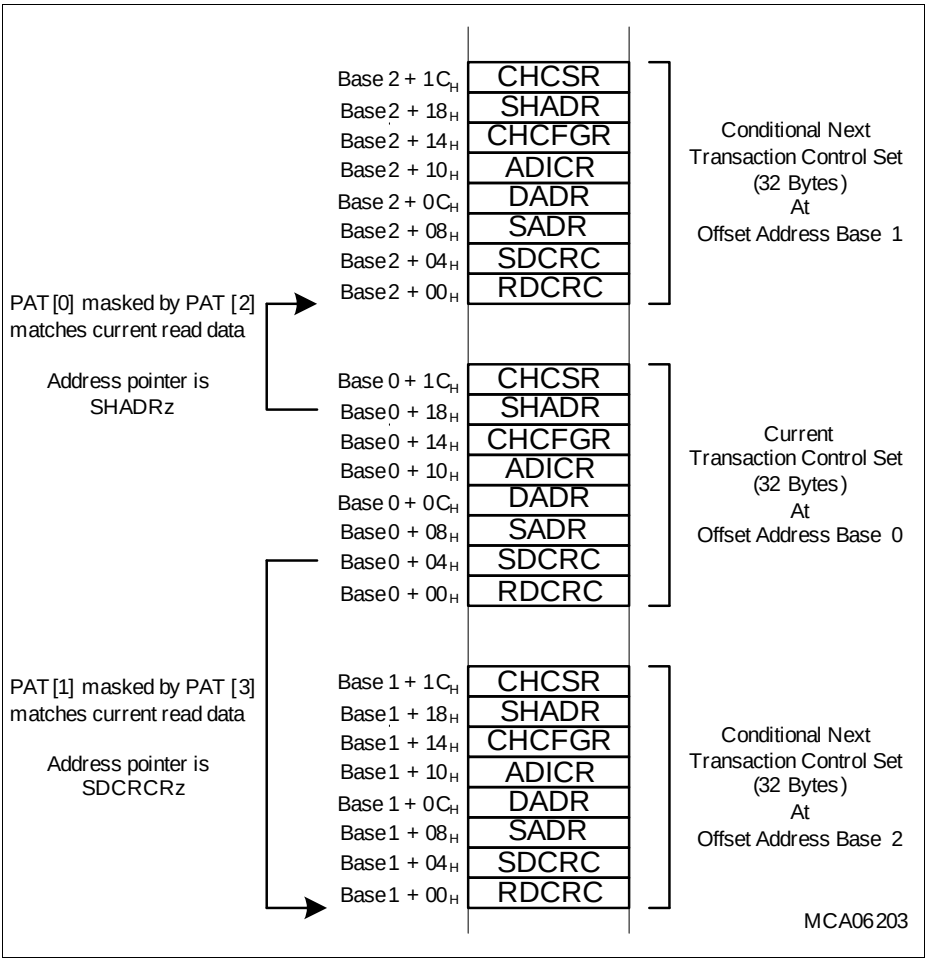

Figure 15-22 Conditional Linked List

In addition to using the shadow address as an address pointer CLL utilizes the source and destination address CRC checksum register SDCRCRz as a second address pointer.

CLL Pattern Detection

The DMA channel must be programmed to select one of the pattern read registers:

- PRR0 is selected if CHCFGRz.PATSEL = 000_B
- PRR1 is selected if CHCFGRz.PATSEL = 100_B

Note: If a DMA channel is configured for CLL then CHCFGRz.PATSEL[1:0] = 00_B

The configuration of the pattern detection logic to support conditional linked lists is shown in **Figure 15-23**.

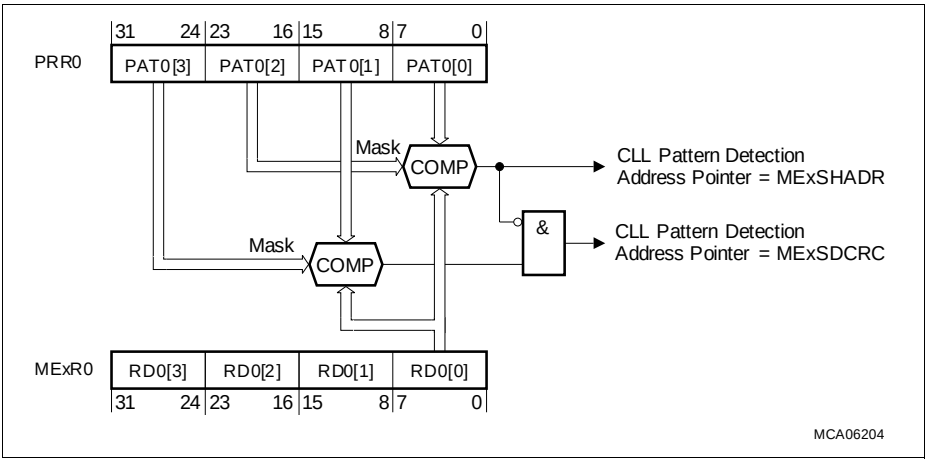

Figure 15-23 Conditional Linked List and Pattern Detection Logic

During each DMA move the pattern detection logic is used to determine the selection of the address pointer:

- If PAT[0] masked by PAT[2] is matching with the current read data MEx0R.RD0[0] then when the current DMA move is completed load a new transaction control set. The shadow address register MExSHADR stores the address pointer to the next transaction control set in the linked list.
- If PAT[1] masked by PAT[3] is matching with the current read data MEx0R.RD0[0] then when the current DMA move is completed load a new transaction control set. The source and destination address CRC checksum register MExSDCRC stores the address pointer to the next transaction control set in the linked list.
- If both PAT[0] masked by PAT[2] and PAT[1] masked by PAT[3] are matching with the current read data MEx0R.RD0[0] then when the current DMA move is completed

load a new transaction control set. The shadow address register MExSHADR stores the address pointer to the next transaction control set in the linked list.

- If there is no match then continue with the DMA transaction.

If a pattern match is detected then:

- The DMA transaction ends with the current DMA move.
- TSRz.CH will clear when the DMA write move has completed.

Completion of Current DMA Transaction

If the current DMA transaction completes when MExCHSR.TCOUNT = 0 and there is no pattern match then the conditional linked list will load a new transaction control set. The shadow address register MExSHADR stores the address pointer to the next transaction control set in the linked list.

Multiple Pattern Detection Conditions

The user may intentionally program PAT[0] masked by PAT[2] not to match with the current read data MEx0R.RD0[0] and transition across a series of DMA transactions in the Conditional Linked List. In each DMA transaction the user may programme a series of different PAT[1] masked by PAT[3] values and test if each value matches with the current read data MEx0R.RD0[0].

If PAT[1] masked by PAT[3] is matching with the current read data MEx0R.RD0[0] then when the current DMA move is completed load a new transaction control set. The source and destination address CRC checksum register MExSDCRC stores the address pointer to the next transaction control set in the linked list.

15.4.4 Transaction Control Engine

Each DMA sub-block has a Transaction Control Unit. The Transaction Control Unit in the DMA sub-block, as shown in the DMA Controller block diagram in **Figure 15-24**, contains the transaction control set stored in the active channel register set and a move engine.

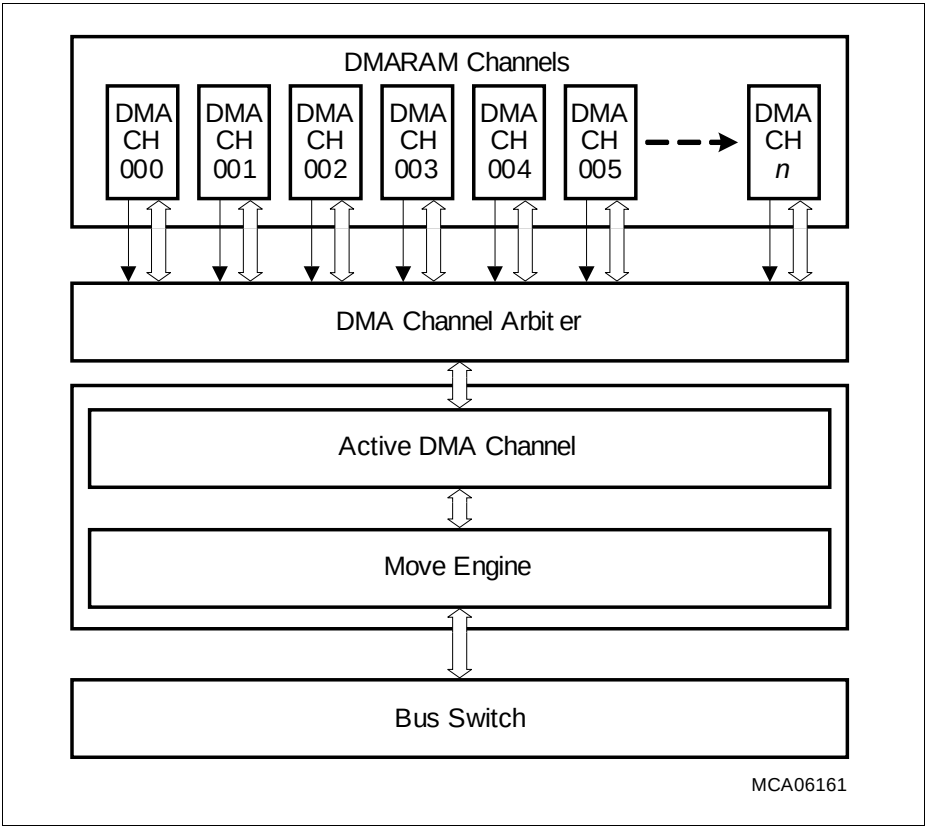

Figure 15-24 Transaction Control Engine

Any move engine can service hardware or software requests from any DMA channel.

DMA Channel Arbitration

The DMA channel arbiter continuously monitors DMA channel transfer access pending requests. The highest number DMA channel with an access pending wins the DMA channel arbitration. On winning arbitration the transaction control set is read from the

DMARAM and written to the DMA sub-block active channel register set. The DMA channel parameters are passed to the move engine and a DMA transfer composed of a number of DMA moves is processed.

On completion of each DMA transfer the move engine re-arbitrates for the highest priority DMA channel and services the next DMA transfer request. If there is a higher priority DMA transfer request then the current lower priority DMA channel transaction control set is copied to the DMARAM and the active channel register set overwritten with the parameters of the higher priority DMA channel.

If the DMA channel is halted, suspended or has finished the DMA transaction then the move engine will also re-arbitrate for the highest priority DMA request.

DMA Read Buffer

Each DMA move engine includes a 256-bit buffer to store read data from DMA read moves. The read buffer supports the reading of four double words (=256-bit) of data.

A read move to a cached area of memory (Segments 8 and 9) will be translated into an SRI-Bus BTR4 transaction. The 256-bit read data will be stored together with the related 64-bit aligned address in the move engine. If the next and subsequent read access to a segment 8 or 9 address is identical (64-bit aligned) to the current read buffer contents, the requested read data will be read from the read buffer instead of from the SRI-Bus.

If the next read from a segment 8 or 9 address is not identical (64-bit alignments) to the current read buffer contents, the content of the read buffer is invalidated. A BTR4 read request is generated, the read buffer will be updated with the new 256-bit data and its related addresses.

The loading of a new DMA transfer into the move engine or a DMA write to a segment 8 or 9 address invalidates the DMA read buffer.

Address range of segments 8 & 9 is $8000\ 0000_H$ - $9FFF\ FFFF_H$.

DMA Move Engine

The move engine requests the required buses and loads or stores data according to the parameters of a DMA transfer. It is able to wait if a targeted bus is not available.

The processing of a DMA transfer (composed of several DMA moves) of a DMA transaction by the move engine cannot be interrupted and is always completed. A DMA channel interrupt, reset, halt request or debug suspend only becomes active when the DMA channel completes the current DMA transfer.

On completion of a DMA transfer the move engine will send back the updated address register information to the active channel register set. If the current DMA channel continues to win arbitration then the move engine will continue processing DMA transfers until the DMA transaction is completed.

Possible source and destination error conditions are also reported.

15.4.4.1 Error Conditions

The DMA move engine reports bus error and source/destination error status. In the case of multiple errors, the error bits are set according to the error conditions. This means that more than one bus error flag and source/destination flag can be set.

The DMA channel should be configured to generate an error interrupt service request.

Bus Errors

The bus error flag ERRSRx.SPBER indicates an SPB Bus error occurred during a move (read or write) of a DMA module transaction.

The bus error flag ERRSRx.SRIER indicates an SRI Bus error that occurred during a move (read or write) of a DMA module transaction.

Source and Destination Errors

The source error flags ERRSRx.SER indicate that an error occurred during a DMA read move from a source address during a DMA transaction of DMA sub-block x.

The destination error flags ERRSRx.DER indicate that an error occurred during a DMA write move to a destination address during a DMA transaction of DMA sub-block x.

If a source or destination error is reported then the DMA transaction completes. If a source error is reported during a DMA read move then the DMA write move is not executed, but the destination address is updated.

Source and destination errors include unsupported types of bus transaction.

Source and Destination Errors in a Linked List

If a DMA channel is configured as a linked list and a source or destination error is reported then the current DMA transaction must complete. In the case of the Conditional Linked List pattern matches will be disabled. The new transaction control set must not be loaded and the linked list stops to allow debug of the current DMA transaction.

Transaction Control Set Load Error in a Linked List

During all linked list operations (DMA, Accumulated, Safe and Conditional) if an error is reported during the loading of a next transaction control set then the error flag ERRSRx.DLLER is set, the last error channel ERRSRx.LEC is recorded and the source of the error is set. The linked list operation will be aborted and the transaction request state bit TSRz.CH bit cleared.

Safe Linked List SDCRC Errors

A Safe Linked List must confirm that the calculated SDCRC checksum matches the expected SDCRC checksum before the next transaction control set is loaded. If the

SDCRC checksum does not match then a Safe Linked List error ERRSRx.SLLER is reported.

RAM Errors

When a DMA channel wins arbitration the transaction control set is copied from the DMARAM to the DMA sub-block active channel register set. If an ECC error is signalled during the DMARAM read then the error flag ERRSRx.RAMER is set and the last error channel ERRSRx.LEC recorded. The DMA transfer will be aborted and the transaction request state bit TSRz.CH bit cleared.

Transaction Request Lost

The transaction request lost error flag TSRz.TRL indicates if a DMA request for DMA channel z has been lost.

15.4.5 Bus Switch, Bus Switch Priorities

The bus switch of the DMA controller provides the connection from the DMA sub-blocks and system peripheral masters to on chip bus master interfaces (see **Figure 15-25**). One access can be buffered in the bus interfaces.

The Bus Switch supports Switch Address Routing to the whole memory range.

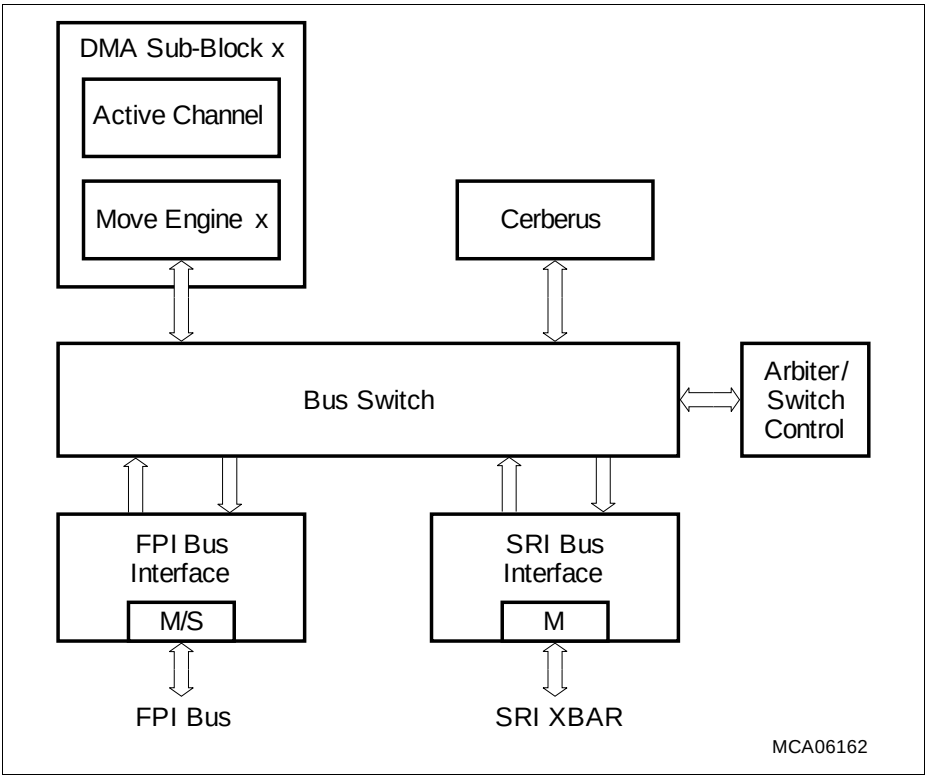

Figure 15-25 Bus Switch

Note: The accesses of the DMA Move Engine's bus interfaces to the On Chip Bus interfaces are always done in Supervisor Mode.

The arbiter/switch control unit arbitrates the requests from the connected active interfaces (DMA move engines and Cerberus) and grants the buses connected to the switch for data transfers. **Table 15-2** and **Table 15-3** defines the Bus Switch priorities for requests to the same on chip bus interface. The arbitration scheme is valid in case of a collision of requests from active peripherals connected to the DMA bus switch (move engines) for the same resource (SPB Bus Interface, SRI Bus Interface). The arbitration is done for each bus switch request.

In case of a collision between DMA move engine requests and a Cerberus request on the DMA bus switch for the same resource, the priorities are as given in **Table 15-2**.

Table 15-2 DMA Bus Switch Priorities

Priority	Agent Requests	Comment
Highest	Cerberus to On Chip Bus High	Priority selection by software in Cerberus.
	DMA move engine write	-The detailed Bus Switch priorities for the two engines with concurrent reads or concurrent writes are listed in **Table 15-3**.
	DMA move engine read	-The detailed Bus Switch priorities for the two engines with concurrent reads or concurrent writes are listed in **Table 15-3**.
Lowest	Cerberus to On Chip Bus Low	Priority selection by software in Cerberus.

Concurrent SRI Accesses

In case of a collision of both move engines with concurrent read requests or concurrent write requests for the SRI resource, the highest channel wins.

Concurrent SPB Accesses

In case of a collision of both move engines with concurrent read requests or concurrent write requests for the SPB resource, the move engine with the highest DMA priority determined by MExCHCR.DMAPRIO determines the winning arbitration on the DMA bus switch (see **Table 15-3**).

Table 15-3 DMA SPB Resource Switch Priorities of DMA Move Engines

Priority	DMA Move Engine Request	Comment
Highest	Move Engine x MExCHCR.DMAPRIO = “11”	Move engine with high DMA priority.
	Move Engine x MExCHCR.DMAPRIO = “10”	Move engine with medium DMA priority.
	Move Engine x MExCHCR.DMAPRIO = “01”	Move engine with medium DMA priority.
Lowest	Move Engine x MExCHCR.DMAPRIO = “00”	Move engine with low DMA priority.

If the move engines are processing DMA moves with concurrent read requests or concurrent write requests of equal DMA priority then the move engine processing the highest DMA channel number wins the arbitration at the DMA bus switch.

15.4.6 DMA Module Priorities on On Chip Busses

Every active peripheral connected to the DMA bus switch that requests for access to SPB Bus or SRI Bus has to go through two arbitration stages before accessing the on chip bus: DMA internal arbitration at the DMA bus switch and DMA module external arbitration at the on chip bus.

The DMA can be connected to the SPB Bus and to the SRI Bus with master interfaces.

- The complete list of SPB master priorities can be found in the SPB Bus Control Unit Chapter.
- The complete list of SRI master priorities can be found in the Shared Resource Interconnect Chapter.

15.4.6.1 On Chip Bus Access Rights, RMW support

All accesses triggered by the DMA Move Engines are always done in SV mode.

The DMA module does not support read/modify write instructions.

15.4.6.2 On Chip Bus Master Interfaces

This chapter describes the features of the DMA on chip bus master interfaces to the SPB Bus and to the SRI Bus.

The DMA SPB master interface supports:

- single data read and write transactions (8-bit, 16-bit, 32-bit)
- generation of interleaved FPI transactions from different sources (move engines)
- de-assertion of request after retry in order to prevent bus blocking.
- out of order transactions from different sources in order to avoid side effects (blocking) between the different sources (move engines)
- three dedicated SPB requests (low, medium, high priority)[1)].

A single move engine supports only one DMA transaction from one DMA channel at a time and generates a sequence of read - write sequences. The DMA sub-block will not generate permanent, pipelined, high priority requests.

The DMA SRI master interface supports:

- single data read and write transactions (8-bit, 16-bit, 32-bit, 64-bit)[2)]
- block transfer read and write transactions (128-bit, 256-bit)[3)]
- generation of interleaved SRI transactions from different sources (move engines)

1) The complete list of SPB master priorities can be found in the SPB Bus Control Unit Chapter.

2) 64-bit DMA move supported for DMA read move from SRI source to DMA write move to SRI destination

3) Block transfer DMA move supported for DMA read move from SRI source to DMA write move to SRI destination

A single move engine supports only one DMA transaction from one DMA channel at a time and generates a sequence of read - write sequences. The DMA sub-block will not generate permanent, pipelined, high priority requests.

15.4.7 Pattern Detection

Pattern detection is only supported for 8-bit, 16-bit and 32-bit channel data width. Only the read data in MEx0R is compared with the value in one of the pattern read registers.

After a DMA read move, read data in the move engine least significant word read register MEx0R can be compared with data stored in one of the pattern read registers. Any move engine can service any DMA channel request. If pattern detection is selected then the DMA channel must be configured to select one of the pattern read registers (PRR0 or PRR1) for the pattern compare.

The result of a pattern compare match is always stored in a bit (MExCHSR.LXO) of the channel status register of the active DMA channel in the move engine x that is currently executing the DMA move. Therefore, the pattern match result LXO of the previous read move can also be combined together with the pattern match result of the actual read move. Move engine x read register MEx0R is overwritten with each read move.

The configuration and capabilities of the pattern detection logic further depends on the settings of MExCHCR.CHDW. CHDW determines the data width for the DMA read and write moves for each individual DMA channel z. The control bits, MExCHCR.PATSEL, selects among the different pattern detection modes for a specific value of CHDW.

If a DMA channel z is configured for pattern detection then the appendage of timestamps is not supported (ADICRz.STAMP = 0_B).

Interrupt Service Request

If MExCHCR.PATSEL[1:0] is not equal to 00_B and a pattern match is detected then:

- The DMA transaction ends with the current DMA move.
- TSRz.HTRE is cleared to stop DMA transfers on the current active channel z.
- TSRz.CH will clear when the DMA write move has completed.
- A pattern detection interrupt service request will be raised corresponding to the current active DMA channel z except in the case that a source error is reported.

The value of MExCHSR.TCOUNT and MEx0R can be read out by the interrupt software.

If MExCHCR.PATSEL=000_B or 100_B then no action will be taken when a pattern match is detected. A wrap interrupt can be used.

The software will have to service the interrupt and to activate the channel again.

15.4.7.1 Pattern Compare Logic

Read move data and compare match patterns are compared on a bit-wise level. The logic as shown in **Figure 15-26** is implemented in each COMP block of **Figure 15-27**, **Figure 15-28**, and **Figure 15-29**. One COMP block controls either 8 bits or 16 bits of data and makes it possible to mask each data bit for the compare operation.

In the compare logic for one bit of the COMP block, a data bit from register MEx0R is compared to the corresponding pattern bit stored in a pattern read register. If both bits

are equal and a pattern mask bit stored in another part of pattern read register is 0, the compare matched condition becomes active. When the pattern mask bit is set to 1, the compare matched condition is always active (set) for the related bit. When the compare matched conditions for each bit within a COMP block are true, the compare match output line of the COMP block becomes active.

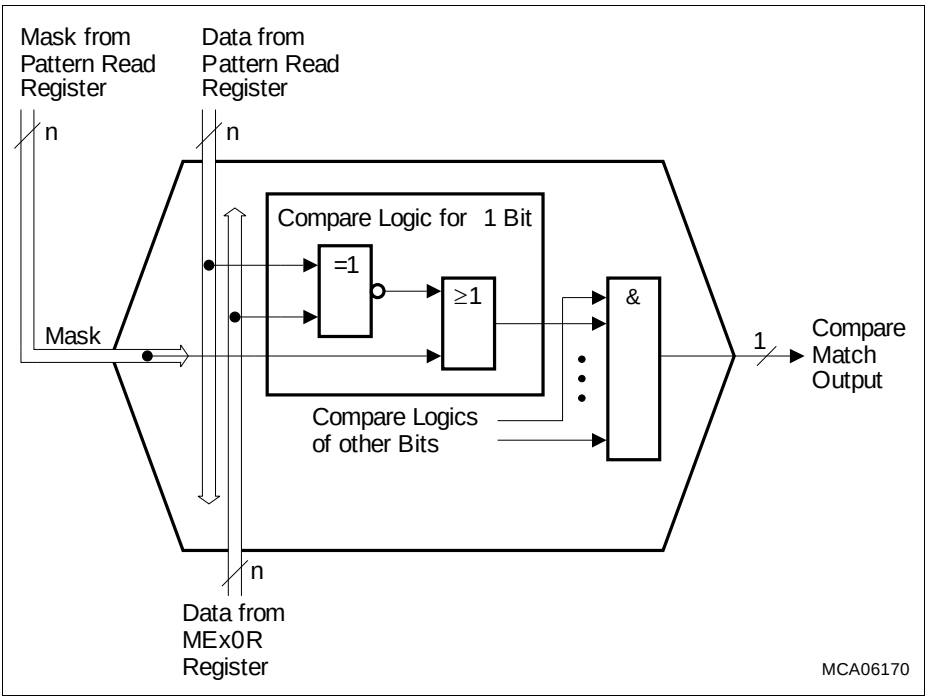

Figure 15-26 Pattern Compare Logic (COMP Block)

15.4.7.2 Pattern Detection for 8-bit Data Width

When 8-bit channel data width is selected (MExCHCR.CHDW = 000_B) and the channel is configured to select PRR0 (MExCHCR.PATSEL[2] = 0_B), the pattern detection logic is configured as shown in **Figure 15-27**.

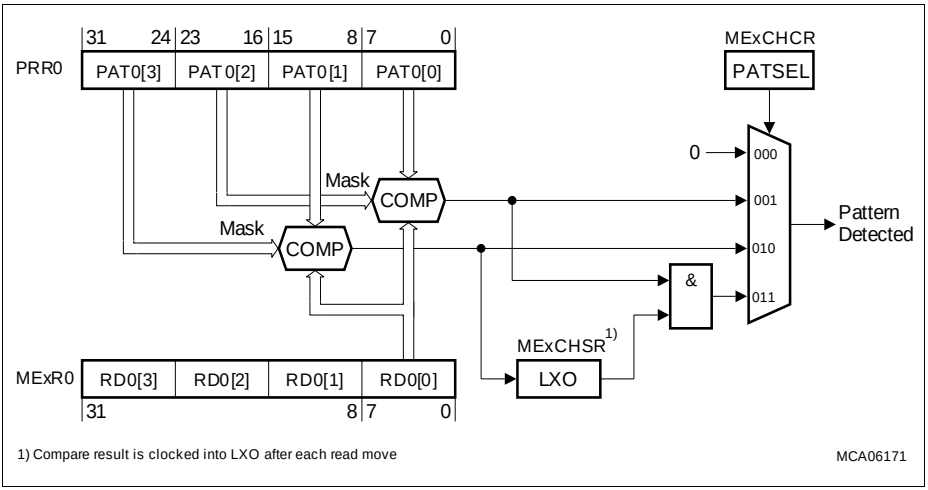

Figure 15-27 Pattern Detection for 8-bit Data Width (MExCHCR.CHDW = 000_B)

When 8-bit channel data width is selected, the pattern detection logic allows the byte of a DMA read move to be compared with two different patterns. Three compare match configurations are possible (see **Table 15-4**). A mask operation of each compared bit is possible.

Table 15-4 Pattern Detection for 8-bit Data Width

MExCHCR. PATSEL	Pattern Detection Operating Modes
000_B	Pattern detection disabled
001_B	Pattern compare of MExR.RD0[0] to PAT0[0], masked by PAT0[2]
010_B	Pattern compare of MExR.RD0[0] to PAT0[1], masked by PAT0[3]
011_B	Pattern compare of MExR.RD0[0] to PAT0[0], masked by PAT0[2] of the actual DMA read move **and** Pattern compare of MExR.RD0[0] to PAT0[1], masked by PAT0[3] of the previous DMA read move of DMA channel z
100_B	Pattern detection disabled
101_B	Pattern compare of MExR.RD0[0] to PAT1[0], masked by PAT1[2]

Table 15-4 Pattern Detection for 8-bit Data Width

MExCHCR. PATSEL	Pattern Detection Operating Modes
110_B	Pattern compare of MExR.RD0[0] to PAT1[1], masked by PAT1[3]
111_B	Pattern compare of MExR.RD0[0] to PAT1[0], masked by PAT1[2] of the actual DMA read move **and** Pattern compare of MExR.RD0[0] to PAT1[1], masked by PAT1[3] of the previous DMA read move of DMA channel z

Two Byte Pattern Detection Sequence

If the DMA channel pattern selection is configured to select a two byte sequence (MExCHCR.PATSEL[1:0] = 11_B) against PRR0 (MExCHCR.PATSEL[2] = 0_B) then after each DMA read move the pattern match result “MEx0R.RD0[0] with PRR0.PAT0[1], masked by PRR0.PAT0[3]” is stored in bit MExCHSR.LXO.

This operating mode allows, for example, two-byte sequences to be detected in an 8-bit data stream coming from a serial peripheral unit with 8-bit data width (e.g.: recognition of carriage-return, line-feed characters).

15.4.7.3 Pattern Detection for 16-bit Data Width

When 16-bit channel data width is selected (MExCHCR.CHDW = 001_B) and the DMA channel is configured to select to PRR0 (MExCHCR.PATSEL[2] = 0_B), the pattern detection logic can be configured as shown in **Figure 15-28**.

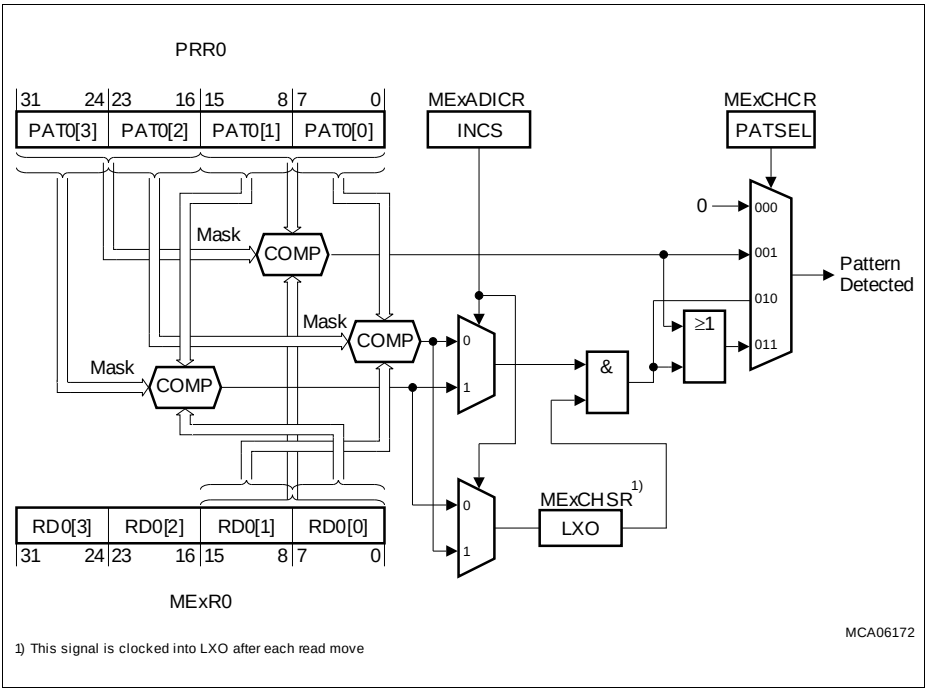

Figure 15-28 Pattern Detection for 16-bit Data Width (CHCFGRz.CHDW = 001_B)

When 16-bit channel data width is selected, the pattern detection logic makes it possible to compare the complete half-word of one read move only (aligned mode) or to compare upper and lower byte of two consecutive read moves (unaligned modes). Both modes can be combined (combined mode) too. Three compare match configurations are possible (see **Table 15-5**). A mask operation of each compared bit is possible.

Table 15-5 Pattern Detection for 16-bit Data Width

MExCHCR.PATSEL	MExADICR.INCS	Pattern Detection Operating Modes
000_B	–	Pattern detection disabled
001_B	–	**Aligned Mode:** Pattern compare of MEx0R.RD0[1:0] to PAT0[1:0], masked by PAT0[3:2]

Table 15-5 Pattern Detection for 16-bit Data Width (cont'd)

MExCHCR. PATSEL	MExADICR. INCS	Pattern Detection Operating Modes
010_B	0	**Unaligned Mode 1 (Source Address Decrement):** Pattern compare of MEx0RMEx1R.RD0[1] to PAT0[0], masked by PAT0[2] of the actual DMA read move **and** Pattern compare of MEx0R.RD0[0] to PAT0[1], masked by PAT0[3] (LXO) of the previous DMA read move of DMA channel z
	1	**Unaligned Mode 2 (Source Address Increment):** Pattern compare of MEx0R.RD0[0] to PAT0[1], masked by PAT0[3] of the actual DMA read move **and** Pattern compare of MEx0R.RD0[1] to PAT0[0], masked by PAT0[2] (LXO) of the previous DMA read move of DMA channel z
011_B	0 or 1	**Combined Mode:** Pattern compare for aligned mode (PATSEL = 001_B) **or** unaligned modes (PATSEL = 010_B)
100_B	–	Pattern detection disabled
101_B	–	**Aligned Mode:** Pattern compare of MEx0R.RD0[1:0] to PAT1[1:0], masked by PAT1[3:2]
110_B	0	**Unaligned Mode 1 (Source Address Decrement):** Pattern compare of MEx0R.RD0[1] to PAT1[0], masked by PAT1[2] of the actual DMA read move **and** Pattern compare of MEx0R.RD0[0] to PAT1[1], masked by PAT1[3] (LXO) of the previous DMA read move of DMA channel z
	1	**Unaligned Mode 2 (Source Address Increment):** Pattern compare of MEx0R.RD0[0] to PAT1[1], masked by PAT1[3] of the actual DMA read move **and** Pattern compare of MEx0R.RD0[1] to PAT1[0], masked by PAT1[2] (LXO) of the previous DMA read move of DMA channel z
111_B	0 or 1	**Combined Mode:** Pattern compare for aligned mode (PATSEL = 101_B) **or** unaligned modes (PATSEL = 110_B)

Unaligned Mode 1

In unaligned mode 1 (source address decremented), the high byte (MEx0R.RD01) of the current and the low byte (MEx0R.RD00) of the previous 16-bit DMA read move are compared.

Unaligned Mode 2

In unaligned mode 2 (source address incremented), the low byte (MEx0R.RD00) of the current and the high byte (MEx0R.RD01) of the previous 16-bit DMA read move are compared.

Combined Mode

If it is not known on which byte boundary (even or odd address) the 16-bit pattern to be detected is located, the combined mode must be used. This mode is the most flexible mode that combines the pattern search capability for aligned and unaligned 16-bit data searches.

15.4.7.4 Pattern Detection for 32-bit Data Width

When 32-bit channel data width is selected (MExCHCR.CHDW = 010_B) the pattern detection logic and the DMA channel is configured to select to PRR0 (MExCHCR.PATSEL[2] = 0_B), is configured as shown in **Figure 15-29**.

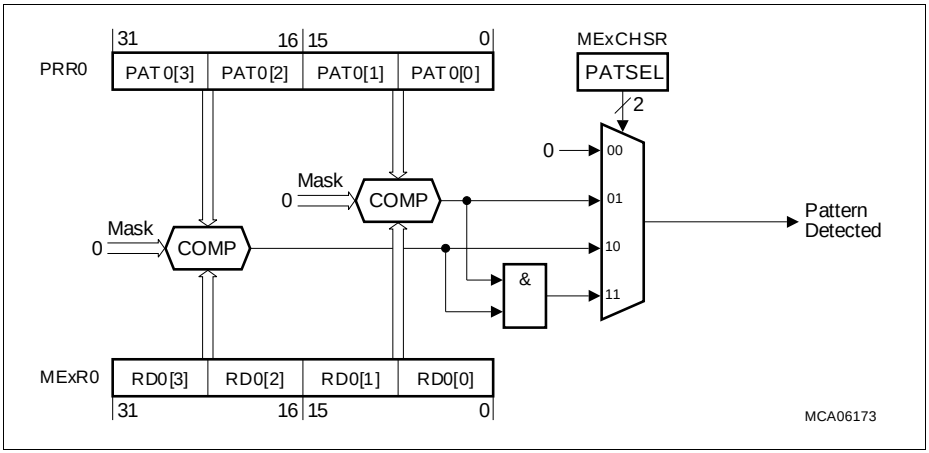

Figure 15-29 Pattern Detection for 32-bit Data Width (MExCHCR.CHDW = 010_B)

In 32-bit channel data width mode, the pattern detection logic makes it possible to compare the lower half-word only, the upper half-word only, or the complete 32-bit word

with a pattern stored in the pattern read register. Three compare match configurations are possible (see **Table 15-6**). A mask operation is not possible.

Table 15-6 Pattern Detection for 32-bit Data Width

MExCHCR.PATSEL	Pattern Detection Operating Modes
000_B	Pattern detection disabled
001_B	Unmasked pattern compare of RD0[1:0] to PAT0[1:0]
010_B	Unmasked pattern compare of RD0[3:2] to PAT0[3:2]
011_B	Unmasked pattern compare of RD0[3:0] to PAT0[3:0]
100_B	Pattern detection disabled
101_B	Unmasked pattern compare of RD0[1:0] to PAT1[1:0]
110_B	Unmasked pattern compare of RD0[3:2] to PAT1[3:2]
111_B	Unmasked pattern compare of RD0[3:0] to PAT1[3:0]

15.4.8 DMA Configuration Interface

The DMA controller implements a standard FPI slave interface compliant with the FPI bus protocol on the SPB bus. The SPB slave interface supports the following functions:

- Control of the DMA general control registers to support clock control, power management, debug, etc.
- Reading and writing DMA registers that manage DMA transactions.
- Reading and writing the transaction control set for each DMARAM channel z.
- Reading the active channel transaction registers in the DMA sub-block.
- Configuring and reading the move engine and error registers.

The DMA controller supports single data transfers and does not support block transfers.

15.4.8.1 DMARAM Channel Control and Status Word

The DMARAM Control and Status Word CHCSRz supports two functions:

- Storing channel status bits including the transfer count status. The status is updated when the active channel is written back on completion of a DMA transaction or on completion of a DMA transfer on losing channel arbitration.
- Write only triggers to set and clear state in the channel configuration and status.

The write only control and clear triggers (CHCSRz.SCH, TSRz.ECH, TSRz.DCH, CHCSRz.SWB, CHCSRz.CICH, CHCSRz.CWRP and CHCSRz.SIT) can be written independently of the channel transaction state (active, pending or idle).

15.4.8.2 DMA Active Channel Write Back

A DMA channel is active when a move engine services a hardware or software request. When a pending DMA channel request wins arbitration the transaction control set is copied from the DMARAM and loaded into the DMA sub-block active channel registers and the active channel field MExSR.CH is updated. The DMA channel is defined to be active.

The point at which transaction control set is written back to the DMARAM is dependent on the MExCHCR.RROAT:

- MExCHCR.RROAT = 0, the transaction control set is written back on completion of each DMA transfer.
- MExCHCR.RROAT = 1, the transaction control set is written back when the DMA channel loses channel arbitration and completes the current DMA transfer.

If a write back has occurred then the transaction control set stored in the DMARAM will not match the transaction control set held in the DMA sub-block active channel registers.

15.4.8.3 DMA Active Channel Shadow Control

An SPB write to a DMARAM channel z addresses other than the CHCSRz word when DMA channel z transaction request state bit TSRz.CH has an access pending will result in a bus error with the following shadow address source or destination address buffering exceptions as defined in **Table 15-7**.

Table 15-7 DMA Active Channel SPB Write Shadow Control Exceptions

SHCT	Description
0001_B	**Source Address Buffering (Read Only)** Active DMA channel z SPB writes to the source address SADRz are permitted. The shadow register MExSHADR in DMA sub-block x stores the SADRz value while DMA channel z is active in move engine x. On write back from DMA sub-block to DMARAM: • The source address SADRz stored in DMARAM is updated to the shadow address SHADRz value. • The shadow address SHADRz stored in DMARAM is set to 00000000_H.
0101_B	**Source Address Buffering (Direct Write)** Active DMA channel z SPB writes to the shadow address SHADRz are permitted and result in a update to the active channel shadow register MExSHADR in DMA sub-block x. On write back from DMA sub-block to DMARAM: • The shadow address SHADRz stored in DMARAM is updated on completion of the DMA transfer. • The source address SADRz is updated to the SHADRz value.
0010_B	**Destination Address Buffering (Read Only)** Active DMA channel z SPB writes to the destination address DADRz are permitted. The shadow register MExSHADR in DMA sub-block x stores the DADRz value while DMA channel z is active in move engine x. On write back from DMA sub-block to DMARAM: • The source address DADRz stored in DMARAM is updated to the shadow address SHADRz value. • The shadow address SHADRz stored in DMARAM is set to 00000000_H.
0110_B	**Destination Address Buffering (Direct Write)** Active DMA channel z SPB writes to the shadow address SHADRz are permitted and result in a update to the active channel shadow register MExSHADR in DMA sub-block x. On write back from DMA sub-block to DMARAM: • The shadow address SHADRz stored in DMARAM is updated on completion of the DMA transfer. • The destination address DADRz is updated to the SHADRz value.

15.4.8.4 DMARAM Write Back During Linked List Execution

When a linked list is executed by move engine x the contents of the move engine read register are selectively written back to the DMARAM transaction control set as defined in **Table 15-8**.

Table 15-8 Linked List Write Backs

SHCT	Description
1100_B	**DMA Linked List** The DMA controller reads a DMA channel transaction control set and overwrites 8 X words in the DMARAM. *Note: The SDCRC and RDCRC checksums are unique for each DMA transaction in the DMA LInked List.*
1101_B	**Accumulated Linked List** The DMA controller reads a DMA channel transaction control set and overwrites 6 X words in the DMA RAM. The SDCRC and RDCRC words are not overwritten. *Note: The SDCRC and RDCRC checksums are accumulated across all DMA transactions of the DMA Linked List.*
1110_B	**Safe Linked List** The DMA controller reads a DMA channel transaction control set. The Linked List only proceeds with the next DMA transaction if the existing SDCRC checksum matches the expected SDCRC checksum in the loaded from the new DMA transaction control set. *Note: The SDCRC and RDCRC checksums are accumulated across all DMA transactions of the DMA LInked List.*
1111_B	**Conditional Linked List** Shadow address register (MExSHADR) and source and destination address CRC register (MExSDCRC) are used as address pointers to a DMA linked lists. The selection of the address pointer is determined by DMA channel pattern detection conditions. *Note: Calculation of SDCRC checksums is not supported.*

15.4.9 Interrupt Service Requests

The interrupt structure of the DMA controller is very flexible. There are five different types of interrupt events. The service control registers are located in the Interrupt Router.

- Each DMA channel has its own interrupt service request that covers DMA channel traffic management events:
  - Channel transfer interrupt service request
  - Channel pattern detection interrupt service request
  - Channel source and destination wrap buffer interrupt service requests
- The DMA controller has one interrupt service request covering all error events:
  - Channel transaction request lost interrupt service request
  - Channel safe linked list SDCRC checksum comparison error
  - Move engine source and destination error interrupt service request
  - Read DMARAM ECC error interrupt service request
  - DMA linked list transaction control set load error interrupt service request

The DMA controller interrupt service requests are shown in **Figure 15-30**. The number of interrupt service requests in the DMA controller is one greater than the number of DMA channels.

The channel interrupt service requests detect normal DMA traffic events and raise an interrupt request via the shared DMA channel interrupt service request output. The interrupt event is internally generated as a request pulse and always stored in the active DMA Channel Status Register MExCHSR.

The move engine interrupt service requests detect error conditions and raise an interrupt request via the shared error interrupt service request output. Source and destination errors are stored in the move engine error status register ERRSRx. The transaction request lost condition is stored in the channel status register TSRz.TRL. A transaction request lost error interrupt service request is generated if ADICRz.ETRL enables the service request when channel z becomes an active DMA channel.

The routing of both channel transaction request lost and move engine source and destination error conditions via the error interrupt service request centralizes the reporting of all errors in each DMA sub-block to one interrupt service request. In the event that a DMA error interrupt request is raised then the error handler will read the contents of the move engine error status register ERRSRx and all the TSRz.TRL bits to identify the source of the error.

Software Activation of Interrupt Service Requests

Each channel interrupt service request can be activated by programming CHCSRz.SIT.

The error interrupt service request can be activated by programming ERRINTR.SIT.

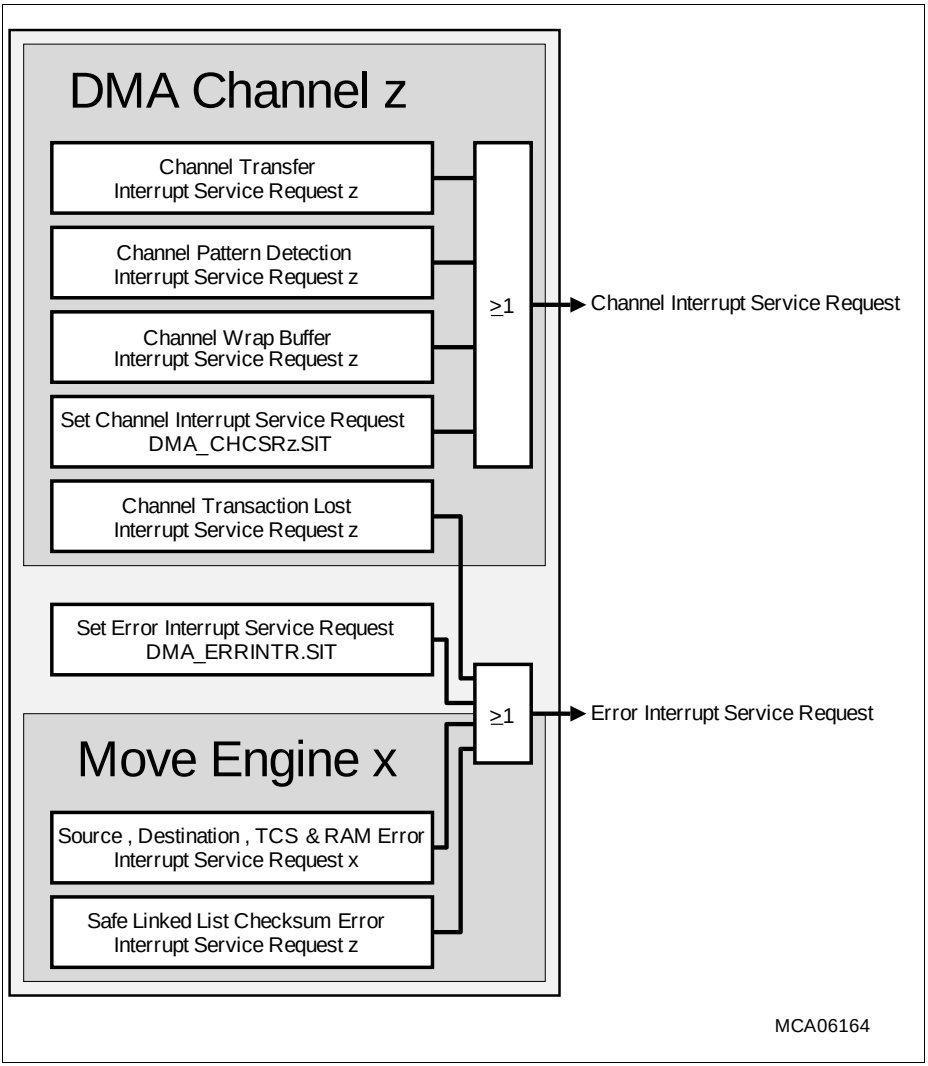

Figure 15-30 DMA Controller Interrupt Service Requests

The following sections describe each of the interrupt service request types in detail.

15.4.9.1 Channel Transfer Interrupt Service Request

The channel transfer interrupt service request is always activated after a DMA transfer, or when MExCHSR.TCOUNT matches with the value of bit field MExADICR.IRDV after it has been decremented after a DMA transfer. A channel transfer interrupt is indicated when status flag MExCHSR.ICH (CHCSRz.ICH) is set. The status flag can be reset together by software when setting bit CHCSRz.CICH (or TSRz.RST). The channel interrupt of DMA channel z is enabled when bit ADICRz.INTCT[1] is set.

Bit MExADICR.INTCT[0] selects one of two types of interrupt source. For the compare operation, bit field MExADICR.IRDV (4-bit) is zero-extended to 14-bit and then compared with the 14-bit TCOUNT value. This means that a TCOUNT match interrupt can be generated after one of the last 16 DMA transfers of a DMA transaction. Note that with IRDV = 0000_B, the match interrupt is generated at the end of a DMA transaction (after the last DMA transfer).

If MExCHCR.PRSEL = 1B for DMA channel z then the channel transfer service request interrupt is masked and the access pending bit is set in the next lower priority DMA channel z-1.

15.4.9.2 Channel Pattern Detection Interrupt Service Request

The channel pattern detection interrupt service request is enabled when MExCHCR.PATSEL[1:0] is not equal 00_B. The pattern detection interrupt is indicated when status flag MExCHSR.IPM is set. The status flag MExCHSR.IPM can be reset together by software when setting bit CHCSRz.CICH (or TSRz.RST).

Further details on the pattern detection are described in **Section 15.4.7**.

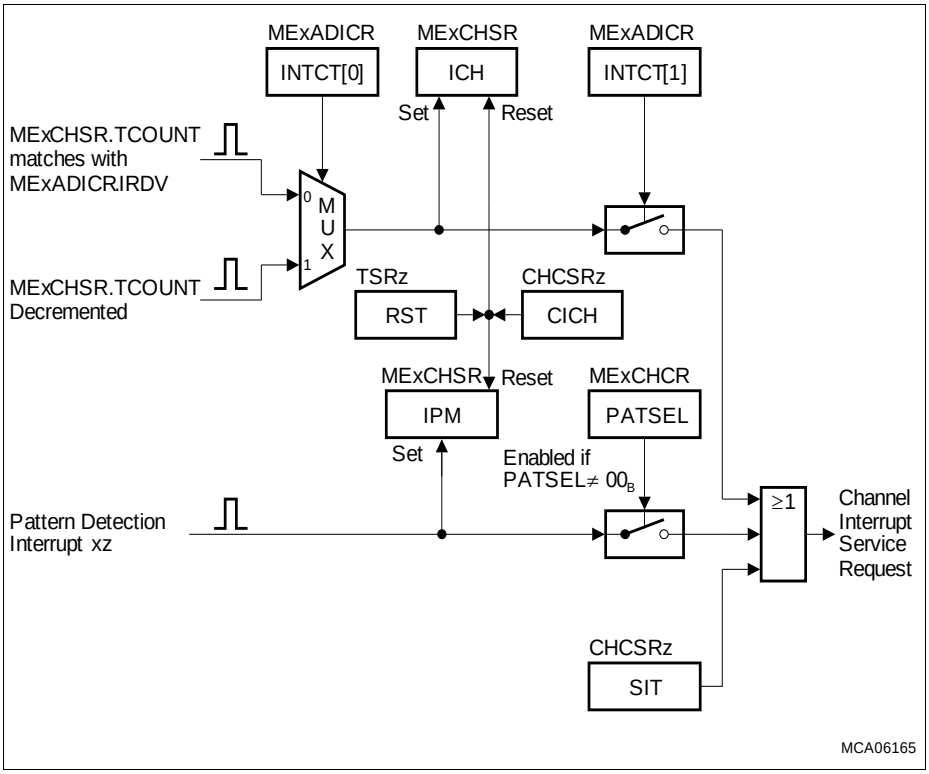

Figure 15-31 Channel Transfer and Pattern Detection Interrupt Service Requests

Figure 15-31 shows the implementation of the channel transfer interrupt service request, the pattern detection interrupt service request and the channel set interrupt service request functions.

15.4.9.3 Channel Wrap Buffer Interrupt Service Request

Each DMA channel z is able to generate a wrap buffer interrupt for source buffer or destination buffer overflow.

A wrap source buffer interrupt of DMA channel z is indicated by status flag MExCHSR.WRPS. A wrap destination buffer interrupt of DMA channel z is indicated by the status flag MExCHSR.WRPD. Both interrupt status flags can be reset by software when bit CHCSRz.CWRP (or TSRz.RST) becomes set. The wrap source buffer interrupt is enabled when bit MExADICR.WRPSE is set. The wrap destination buffer interrupt is enabled when bit MExADICR.WRPDE is set. The two interrupts for wrap source buffer and wrap destination buffer are OR-ed together with other channel interrupt service requests to form one common channel interrupt service request.

The channel pattern match detection must not be enabled while a wrap interrupt is enabled for the same channel.

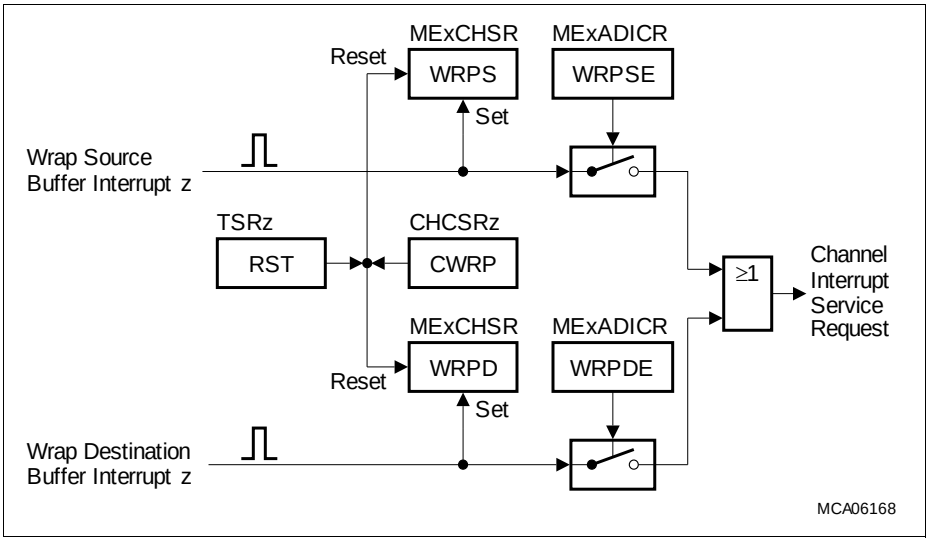

Figure 15-32 Channel Wrap Buffer Interrupt Service Requests

15.4.9.4 Transaction Request Lost Interrupt Service Request

Each DMA channel z is able to detect a transaction request lost condition. This condition becomes true when a new hardware or software DMA request occurs while the previous transaction or transfer on DMA channel z is not finished, indicated by TSRz.CH is still set. If such a transaction request lost condition occurs then bit TSRz.TRL is set.

A transaction request lost condition of DMA channel z is indicated by status flag TSRz.TRL, which can be reset by setting bit TSRz.CTL or TSRz.RST.

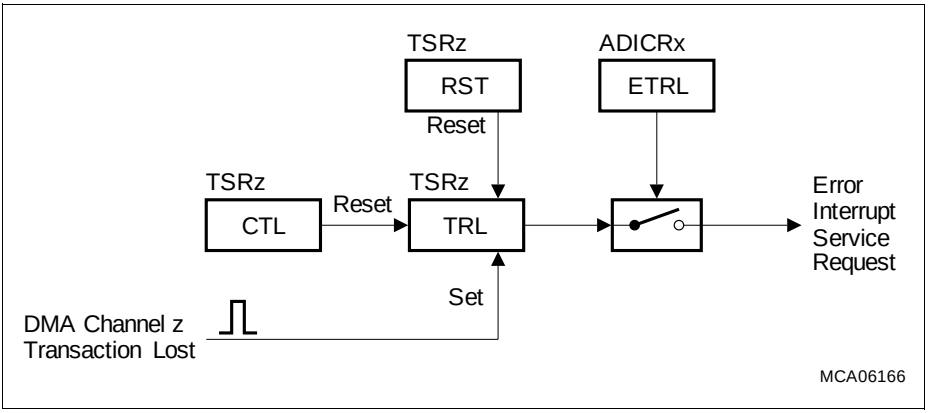

Figure 15-33 Transaction Request Lost Interrupt Service Requests

Interrupt Service Request

The transaction request lost interrupt service request is for DMA channel z is enabled when bit ADICRz.ETRL is set. The interrupt service request is routed via the DMA error service request.

15.4.9.5 Source and Destination Error Interrupt Service Requests

The Move Engine is able to detect error conditions that occur during accesses to the bus interfaces of the Bus Switch (see **Figure 15-25**). Two error conditions can be detected:

- Source error indicates a bus error occurred during a read move from the data source.
- Destination error indicates a bus error that occurred during a write move to the data destination.

A source error of Move Engine x is indicated by the status flag ERRSRx.SER. Status flag ERRSRx.SER can be reset by software when setting bit CLREx.CSER. The source error interrupt of Move Engine x is enabled when bit EERx.ESER is set. Separate reset, status, and enable bits are available in the Move Engines for source error condition, as well as for destination error condition.

Note that in case of a read move error, the write move is not executed but the destination address is updated.

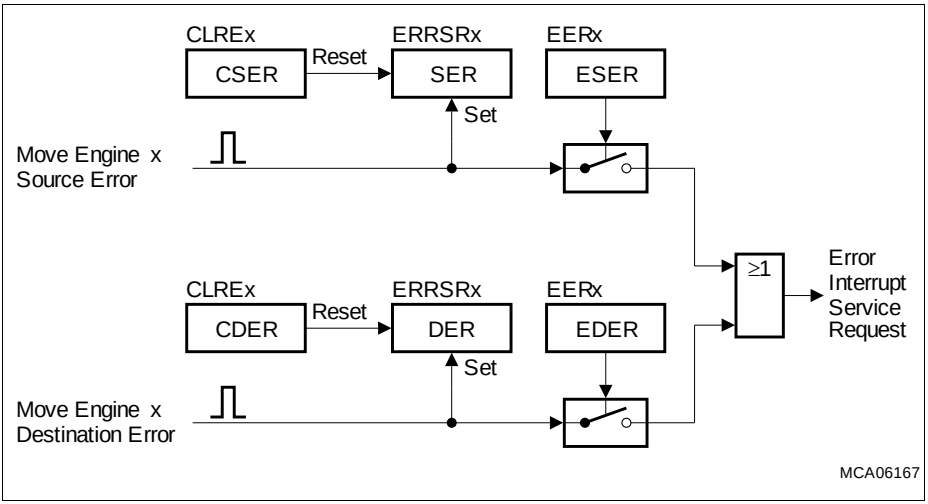

Figure 15-34 Move Engine Interrupt Service Requests

When a move engine source or destination error occurs, additional status bits and bit fields are provided in the error status register ERRSRx to indicate the following two status conditions:

- At which on chip bus interface a move engine error occurred.
- For which DMA channel z a move engine read or write move error was reported (ERRSRx.LEC).

These error status bits and bit fields are required by error handler software to detect in detail at which on chip bus interface and DMA channel z the move engine error has been generated.

- ERRSRx.SPBER is reset when bit CLREx.CSPBER is set.
- ERRSRx.SRIER is reset when bit CLREx.CSRIER is set.

The move engine interrupt service request can be activated by programming ERRINTR.SIT.

15.4.9.6 DMA Linked List Error Interrupt Service Request

During all DMA linked list operations the move engine is able to detect an error if the next transaction control set is not loaded correctly. This condition becomes true when a bus error is reported.

A DMA linked list error is indicated by the error status flag ERRSRx.DLLER. Status flag ERRSRx.DLLER can be reset by software when setting bit CLREx.CDLLER. Additional status bits are provided to indicate the following:

- At which on chip bus interface a move engine error occurred.
- For which DMA channel z the error was reported (ERRSRx.LEC).

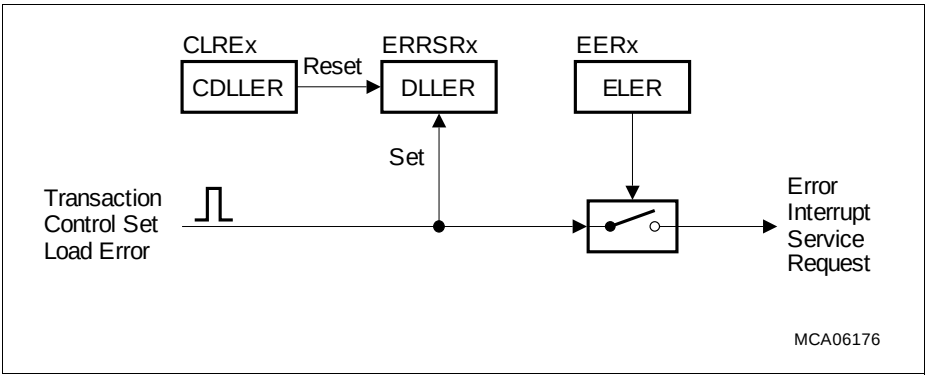

Figure 15-35 DMA Linked List Error Interrupt Service Requests

Interrupt Service Request

The DMA linked list error interrupt service request is enabled when bit EERx.ELER is set. The interrupt service request is routed via the DMA error service request.

15.5 Power Modes

15.5.1 Sleep Mode

Sleep Mode is enabled by the DMA Clock Control Register active low Sleep Mode Enable Control bit DMA_CLC.EDIS. If the enable bit is active when the sleep request input is activated then the DMA clock will be switched off when the move engines have completed any pending DMA transfers.

15.6 Functional Safety Features

15.6.1 Access Protection

A slave destination controls access to its bus peripheral interfaces and kernel address registers. Each on chip resource with bus master capability has a unique master tag identifier that is used to identify the source of an on chip bus transaction. The master tag identifier based access protection is used to enable write accesses to individual slave address ranges. There is no master tag identifier access control associated with read accesses.

Each DMA channel z including its transaction control set stored in DMARAM is assigned to one of y hardware resource partitions (default 0) and is write access control protected. Write accesses to DMA channel z control registers are only possible if the on chip bus master performing the write access has its master tag identifier enabled by the assigned hardware resource partition. Groups of DMA channels can be assigned to a hardware resource and write accesses are limited to individual on chip bus masters.

DMA Master Tag Identifiers

Each hardware resource partition supports a unique master tag identifier as shown in **Table 15-9**. The master tag identifier is driven onto the bus during a read or write access and allows the bus controller to identify the hardware resource requesting the access.

Table 15-9 Bus Master Tag Identifiers

Hardware Partition	Master Tag Identifier
DMA Hardware Resource 0	000110
DMA Hardware Resource 1	000111
DMA Hardware Resource 2	001000
DMA Hardware Resource 3	001001

DMA Supervisor/User Mode

The supervisor or user mode setting for a hardware resource is determined by the control bit MODEy.MODE. All the DMA channels assigned to a hardware resource assume the hardware resource supervisor or user mode setting. If the DMA bus master accesses a supervisor mode protected slave interface in user mode then the slave will reply with ERR acknowledge. The response will be recorded in the Move Engine x Error Status Register.

DMA Write Move

A DMA channel is programmed to read data from a source address and write the data to a destination address. For a DMA write move operation to successfully complete the slave access control logic must enable write accesses to the destination address for the bus master tag identifier of the requesting DMA hardware resource.

15.6.2 Data Integrity

The following data integrity error conditions are detected in the DMA and reported to the SMU:

- Error Correcting Code (ECC) errors generated by the DMARAM.
- Error Correcting Code (ECC) errors generated from SRI data.

15.6.2.1 DMARAM

The DMA controller detects several different classes of ECC error. These errors will set a status flag in the MEMCON register and send a trigger to the SMU for the processing of the error condition. ECC errors are reported for the following error conditions:

Internal ECC Error

The DMARAM is accessed by the internal DMA controller logic during the loading of the transaction control set into the DMA sub-block. If an ECC error occurs then the MEMCON.INTERR is set and a trigger is sent to the SMU. The DMA transaction will not take place and the channel number will be recorded in the move engine last error channel bit field ERRSRx.LEC and the error status bit ERRSRx.RAMER set.

SPB Read Access

If an ECC error is signalled during an SPB read access to the DMARAM then the MEMCON.DATAERR status bit will be set and a trigger sent to the SMU.

SPB Write Access

An SPB write access will require the DMARAM to perform an internal Read Modify Write (iRMW). If an ECC error is reported by the DMARAM during the read phase then the

MEMCON.RMWERR bit will be set and a trigger sent to the SMU. The write phase of the iRMW will not take place.

15.6.2.2 DMA SRI Read and Write Data

The SRI Bus protocol supports the reliable delivery of data between sources and destinations by extending the protocol to include ECC. The ECC word is generated across the address and data words. The DMA read move supports data integrity checking for data sourced from SRI Bus destinations. The ECC word is recoded for a subsequent DMA Write Move to an SRI Bus destination address.

ECC errors can be generated at two locations in the DMA:

- The DMA checks the integrity of read data received across the SRI Bus from SRI sources during a DMA read move.
- Write data to SRI destinations will be sourced from the Move Engine Read Register and is checked for data integrity during a DMA write move.

System Peripheral Bus

The SPB-Bus protocol does not support data integrity checking. ECC extensions will be generated when the read data is stored in the Move Engine Read Register. The integrity of SPB sourced data will be checked when it is written to the SRI Bus.

Data Integrity Testing

The alarm can also be triggered by software. The MBIST is used to generate an ECC error condition in a memory used as a DMA source. When the data is passed through the DMA it will generate an ECC error condition. See MTU chapter for details.

15.7 Debug Features

The DMA controller supports the following debugging capabilities:

- Channel suspend
- OCDS Trigger Bus
- MCDS Trace Interface

15.7.1 Channel Suspend Mode

The on chip debug control unit is able to generate a channel suspend mode request (SUSREQ) for the DMA controller. When this channel suspend request becomes active, the state of a DMA channel becomes frozen regarding hardware changes to ensure that the state of the DMA channels can be analyzed by reading the register contents. Pending transfers in the DMA module on chip Bus master interfaces (SPB master interface, SRI master interface) are completed. The DMA controller signals its channel suspend mode back to the on chip debug control via a suspend acknowledge.

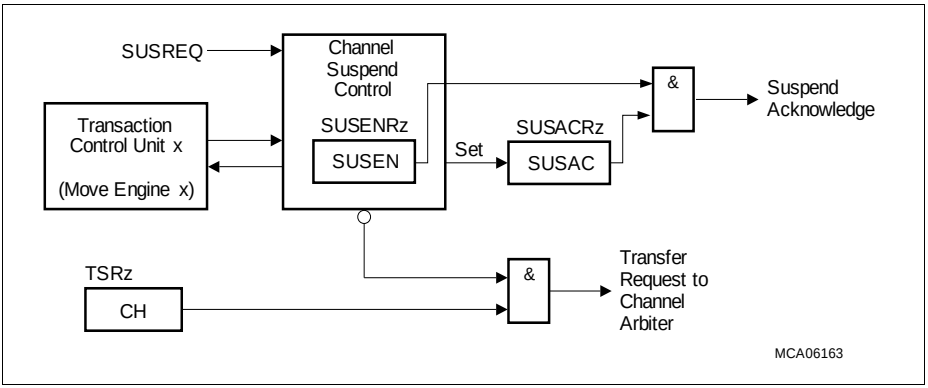

Figure 15-36 Channel Suspend Mode Control

Entering Channel Suspend Mode

Channel suspend mode of DMA channel z is entered if its suspend enable bit in the Suspend Mode Enable Register SUSENRz.SUSEN is set. When SUSREQ becomes active, the operation of all DMA channels enabled for channel suspend mode is stopped automatically after their current DMA transfer has finished in the transaction control unit. Afterwards, the suspend active status flag SUSACRz.SUSAC is set, indicating that DMA channel z is in channel suspend mode.

The DMA suspend acknowledge becomes active when all DMA channels z that are enabled for the Channel Suspend Mode have set their suspend active status flag SUSACRz.SUSAC. In Channel Suspend Mode, register contents can be modified. These modifications are taken into account for further DMA transactions or DMA transfers of the related DMA channel after Suspend Mode has been left again.

DMA channels that are disabled for Suspend Mode (SUSENRz.SUSEN = 0) continue with its normal operation.

Exiting Channel Suspend Mode

Channel suspend mode of DMA channel z is left and its normal operation continues if either the SUSREQ signal becomes inactive, or if the enable bit SUSENRz.SUSEN is reset by software.

15.7.2 OCDS Trigger Bus (OTGB) Interface

A Trigger Set is a collection of signals which supports a specific debug use case. The OCDS Trigger Set Select Register controls which Trigger Set is applied to the bus. The register is cleared by Debug Reset and by each System Reset when OCDS is disabled.

It is not touched by the System Reset when OCDS is enabled. The trigger sets are routed by the OCDS Trigger Mux (OTGM) to the OCDS Trigger Switch (OTGS) and the MCDS.

A DMA Trigger Set is unique to each DMA module dependent on the number of channels and move engines.

15.7.3 MCDS Trace Interface

The DMA module provides two 8 bit vectors for debug and trace signal generation purposes that are used for OCDS Level 3 and for OCDS Level 1:

- One 8 bit vector from SPB master interface via BCU_SPB to BAL_SPB inside MCDS (i.e. spb_clk domain).
- One 8 bit vector from SRI master interface via SRI_XBAR to BAL_SRI inside MCDS (i.e. sri_clk domain).

For each DMA master interface trace is captured to identify the DMA move engine and channel making the request.

Table 15-10 Trace Vector Definition

Bit	Trace
[6:0]	DMA Channel
[7]	DMA Move Engine 0_B Move Engine 0 1_B Move Engine 1

DMA Trace Signal Generation for OCDS Level 3

The trace mechanism allows the identity of the DMA move engine and channel accessing the on chip bus to be determined. The mechanism enables the MCDS system to trace transactions on the on chip bus generated by one or a group of dedicated DMA internal sources.

DMA Trace Signal Generation for OCDS Level 1

For OCDS Level 1 purposes the DMA providestwo 8 bit vectors.

15.8 Register Description

Figure 15-37 and **Table 15-12** show all registers associated with the DMA Controller Kernel. All DMA kernel register names described in this section are also referenced in other parts of the TC21x/TC22x/TC23x User's Manual by the module name prefix "DMA_".

DMA Register Index

The following index numbers are used:

- Index "x" is used to refer to the DMA sub-block (x = 0-1).
- Index "y" is used to refer to the hardware resource partitions (y = 0-3).
- Index "z" is used to refer to the DMA channel (z = 000-015).

DMA Register Classes

The registers fall into the following distinctive classes:

- Control registers that support clock control and the access protection to all registers and the DMARAM.
- Channel control registers are DMA channel control bits directly written into registers:
  - Channel reset
  - Hardware transfer request enable
  - Access pending set by either hardware triggers or software transfer requests
  - Transaction request lost status
  - Suspend enable
  - Suspend acknowledge
  - 2-bit hardware resource to partition channels across DMA partitions
- Active channel control read only registers store DMA channel control and status information for the current DMA move performed by the sub-block move engine.
- Move engine and error registers store control, status and read data for the current DMA transaction.

DMA Registers Overview

1) The absolute register address is calculated as follows:
Module Base Address (**Table 15-11**) + Offset Address (shown in this column)
Further, the following ranges for parameters x, y, and z are valid: x = 0-1, y = 0-3, z = 000-015.

2) Registers (addresses) protected by the default Hardware Resource Partition 0 Access Enable Registers ACCEN00 and ACCEN01 are marked P00 and P01.

3) In shadow address modes write access to DMA_SHADRz is controlled by the register bit DMA_ADICRz.SHCT[2]. If DMA_ADICRz.SHCT =´0001´ or ´0010´ then Access Mode Write for DMA_SHADRz is BE. If DMA_ADICRz.SHCT =´0101´ or ´0110´ then Access Mode Write for DMA_SHADRz is SV.

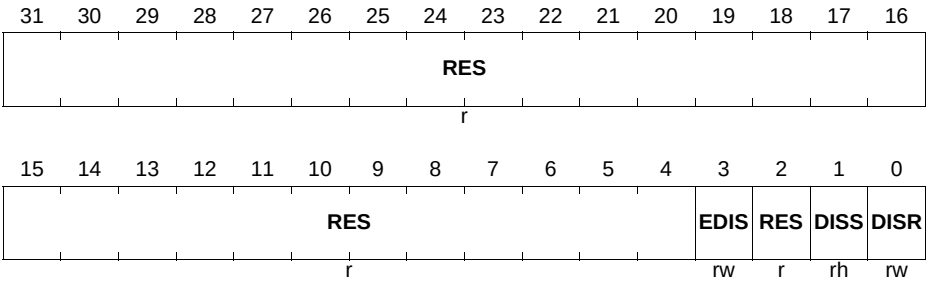
15.8.1 DMA General Module Control Registers

DMA Clock Control Register

The Clock Control Registers DMA_CLC controls the internal f_{DMA} clock signal and sleep mode in order to control the power consumption.

DMA_CLC
DMA Clock Control Register

(0000_H) **Reset Value: $0000\ 0008_H$**



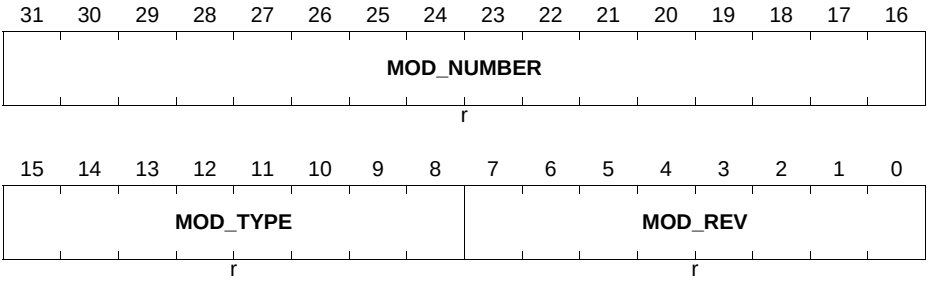
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module
EDIS	3	rw	**Sleep Mode Enable Control** Used for module sleep mode control. 0_B Sleep mode request is regarded. Module is enabled to go into sleep mode. 1_B Sleep mode request is disregarded. Sleep mode cannot be entered on a request.
RES	2, [31:4]	r	**Reserved** Read as 0; must be written with 0.

Note: After a hardware reset operation, the DMA module is enabled.

Note: The sleep mode does not modify any of the registers.

DMA Module Identification Register

DMA_ID
Module Identification Register (0008$_H$) Reset Value: 0087 C003$_H$

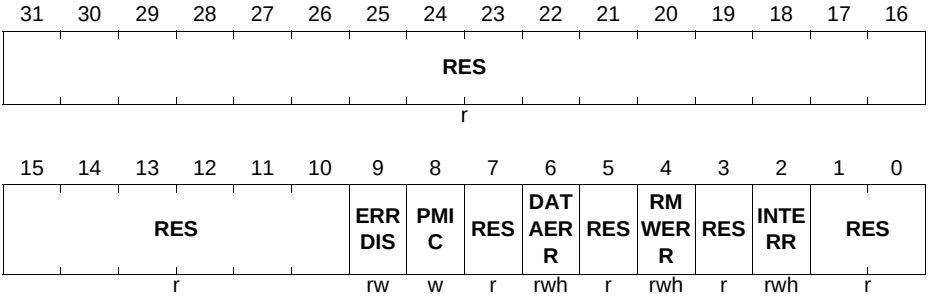


Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number.
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to C0$_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the DMA module is 0087$_H$.

DMA Memory Control Register

Provides control of the memory integrity error checking, error signalling to the SMU and error injection for ECC logic test. The register is cleared by an Application Reset.

DMA_MEMCON
DMA Memory Control Register (0020$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
INTERR	2	rwh	**Internal ECC Error** Flag set by hardware when the DMA logic detects an ECC error while accessing the RAM. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An error has been observed during a RAM access.
RMWERR	4	rwh	**Internal Read Modify Write Error** Flag set by hardware when the DMA logic detects an ECC error on the read phase of an internal RMW operation. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An error has been observed during an internal RMW operation.

Field	Bits	Type	Description
DATAERR	6	rwh	**SPB Data Phase ECC Error** Flag set by hardware when the SPB interface detects an ECC error during the data phase of an incoming read transaction. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An ECC error has been observed on an SPBI transaction addressed to the DMARAM
PMIC	8	w	**Protection Bit for Memory Integrity Control Bit** Will always return 0_B when read 0_B Bit Protection: Bit 9 remains unchanged after DMA_MEMCON write. 1_B Bit 9 will be updated by the current write to DMA_MEMCON
ERRDIS	9	rw	**ECC Error Disable** When set SPB bus errors caused by ECC errors in data read from the SRAM will be disabled 0_B Normal behavior. SPB bus error will occur on SRAM ECC errors. Default after reset 1_B Test Mode. SPB bus errors will not be generated on an SRAM ECC error. This does not affect the generation of interrupts.
RES	[1:0],3,5,7,[31:10]	r	**Reserved** **Read as 0; must be written with 0.**

DMARAM Physical Implementation

If the number of DMA channels is small then the DMARAM may be implemented using logic. A logic implementation shall not generate ECC errors (MEMCON.INTERR = 0_B, MEMCON.RMWERR = 0_B and MEMCON.DATAERR = 0_B).

15.8.2 DMA Access Protection Registers

Write access to each DMA channel z transaction control set is controlled by the respective pair of Access Control Registers for the Hardware Resource assigned to the DMA channel z.

DMA Hardware Resource y Access Enable Register 0

The DMA Access Enable Register 0 controls read / write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B. Each register bit enables one possible 6 bit TAG ID coding.

Mapping of TAG IDs to DMA_ACCEN0.ENn:

- EN0 -> TAG ID 000000_B
- EN1 -> TAG ID 000001_B
- ...
- EN31 -> TAG ID 011111_B

DMA_ACCENy0 (y = 0-3)

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables read / write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

The DMA Hardware Resource y Access Enable Register 0 is safe endinit protected.

DMA Hardware Resource y Access Enable Register 1

The DMA Access Enable Register y1 controls read / write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B. Each register bit enables one possible 6 bit TAG ID coding.

Mapping of TAG IDs to DMA_ACCENx1.ENn:

- EN0 -> TAG ID 100000_B
- EN1 -> TAG ID 100001_B
- ...
- EN31 -> TAG ID111111_B

DMA_ACCENy1 (y = 0-3)
DMA Hardware Resource y Access Enable Register 1

(0044_H + y * 8_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RES	[31:0]	r	**Reserved** Read as 0; must be written with 0.

The DMA Hardware Resource y Access Enable Register 1 is safe endinit protected.

15.8.3 DMA Sub-block Error Registers

DMA Enable Error Register

The Enable Error Register describes how the DMA controller reacts to errors. It enables the interrupts for Move Engine errors.

DMA_EERx (x = 0-1)
DMA Enable Error Register x

(0120_H + x * 1000_H) **Reset Value: $0503\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r					rw	r	rw	r						rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES															
r															

Field	Bits	Type	Description
RES	[15:0]	r	**Reserved** Read as 0; must be written with 0.
ESER	16	rw	**Enable Move Engine x Source Error** This bit enables the generation of a Move Engine x source error interrupt. 0_B Move Engine x source error interrupt is disabled. 1_B Move Engine x source error interrupt is enabled.
EDER	17	rw	**Enable Move Engine x Destination Error** This bit enables the generation of a Move Engine x destination error interrupt. 0_B Move Engine x destination error interrupt is disabled. 1_B Move Engine x destination error interrupt is enabled.
RES	[23:18]	r	**Reserved** Read as 0; must be written with 0.

Field	Bits	Type	Description
ERER	24	rw	**Enable Move Engine x RAM Error** This bit enables the generation of a Move Engine x RAM error interrupt. 0_B Move Engine x RAM error interrupt is disabled. 1_B Move Engine x RAM error interrupt is enabled.
RES	25	r	**Reserved** Read as 0; must be written with 0.
ELER	26	rw	**Enable Move Engine x DMA Linked List Error** This bit enables the generation of a Move Engine x DMA Linked List error interrupt. 0_B Move Engine x DMA Linked List error interrupt is disabled. 1_B Move Engine x DMA Linked List error interrupt is enabled.
RES	[31:27]	r	**Reserved** Read as 0; must be written with 0.

DMA Error Status Register

The Error Status Register indicates if the DMA controller could not answer to a request because the previous request was not terminated (see **Section 15.4.4.1**).

It indicates that an SPB Bus access or an SRI Bus access has terminated with errors.

DMA_ERRSRx (x = 0-1)
DMA Error Status Register x

(0124_H + x * 1000_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RES									LEC						
r									rh						

Field	Bits	Type	Description
LEC	[6:0]	rh	**Move Engine x Last Error Channel** This bit field indicates the channel number of the last channel of Move Engine x leading to an On Chip Bus error that has occurred. *Note: Last Error Channel DMA_ERRSRx.LEC is not set on RAM error DMA_ERRSRx.RAMER or Safe Linked List error DMA_ERRSRx.SLLER*
RES	[15:7]	r	**Reserved** Read as 0; must be written with 0.
SER	16	rh	**Move Engine x Source Error** This bit is set whenever a Move Engine x error occurred during a source (read) move of a DMA transfer, or a request could not been serviced due to the access protection. 0_B No Move Engine x source error has occurred. 1_B A Move Engine x source error has occurred.

Field	Bits	Type	Description
DER	17	rh	**Move Engine x Destination Error** This bit is set whenever a Move Engine x error occurred during a destination (write) move of a DMA transfer, or a request could not been serviced due to the access protection. 0_B No Move Engine x destination error has occurred. 1_B A Move Engine x destination error has occurred.
RES	[19:18]	r	**Reserved** Read as 0; must be written with 0.
SPBER	20	rh	**Move Engine x SPB Bus Error** This bit is set whenever a Move Engine x DMA Move that has been started by the DMA SPB master interface leads to an error on the SPB Bus. 0_B No error occurred. 1_B An error occurred on SPB Bus interface.
SRIER	21	rh	**Move Engine x SRI Bus Error** This bit is set whenever a Move Engine x DMA Move that has been started by the DMA SRI master interface leads to an error on the SRI Bus. 0_B No error occurred. 1_B An error occurred on SRI Bus interface.
RES	[23:22]	r	**Reserved** Read as 0; must be written with 0.
RAMER	24	rh	**Move Engine x RAM Error** This bit is set whenever a Move Engine x error occurred during the loading of a transaction control set from the DMARAM to the DMA sub-block x channel registers. 0_B No error occurred. 1_B An error occurred during the load of a transaction control set.
SLLER	25	rh	**Move Engine x Safe Linked List Error** This bit is set whenever a Move Engine x error occurred during the comparison of a SDCRC checksums during a safe linked list. 0_B No error occurred. 1_B An error occurred during the SDCRC checksum comparison.

Field	Bits	Type	Description
DLLER	26	rh	**Move Engine x DMA Linked List Error** This bit is set whenever a Move Engine x error occurred during the loading of a new transaction control set from anywhere in memory to overwrite the current transaction control set stored in the DMARAM. 0_B No error occurred. 1_B An error occurred during the loading of a new transaction control set. *Note: Error reporting includes all DMA Linked List operations included Accumulated Linked List, Safe Linked List and Conditional Linked List.*
RES	[31:27]	r	**Reserved** Read as 0; must be written with 0.

DMA Clear Error Register

The Clear Error contains bits to clear the corresponding Move Engine error flags.

DMA_CLREx (x = 0-1)
DMA Clear Error Register x

(0128_H + x * 1000_H) **Reset Value: 0000 0000_H**

15.8.4 DMA Sub-block Move Engine Registers

DMA Move Engine Status Register

The Move Engine Status Register is a read-only register that holds status information about the transaction handled by the Move Engines.

DMA_MExSR (x = 0-1)
DMA Move Engine x Status Register

(0130_H + x * 1000_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r									rh						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES											WS	RES			RS
r											rh	r			rh

Field	Bits	Type	Description
RS	0	rh	**Move Engine x Read Status** 0_B Move Engine x is not performing a read. 1_B Move Engine x is performing a read.
RES	[3:1]	r	**Reserved** Read as 0; must be written with 0.
WS	4	rh	**Move Engine x Write Status** 0_B Move Engine x is not performing a write. 1_B Move Engine x is performing a write.
RES	[15:5]	r	**Reserved** Read as 0; must be written with 0.
CH	[22:16]	rh	**Active Channel z in Move Engine x** This bit field indicates the number of the DMA Channel z currently being processed by the Move Engine x.
RES	[31:23]	r	**Reserved** Read as 0; must be written with 0.

DMA Move Engine x Read Register 0

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

The value in the Read Register is compared to the bits in Move Engine Pattern Register depending on the pattern detection configuration and the channel data width.

DMA_MEx0R (x = 0-1)
DMA Move Engine x Read Register 0

(0140_H + x * 1000_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RD01								RD00							
rh								rh							

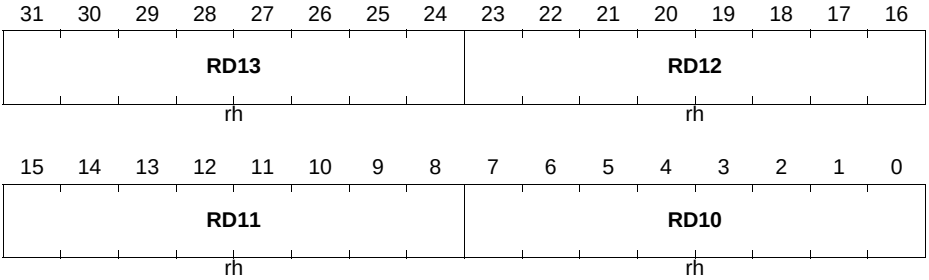
Field	Bits	Type	Description
RD00, RD01, RD02, RD03	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine x** Contains the 32-bit read data (four bytes RD0[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA Sub-block x.

DMA Move Engine x Read Register 1

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx1R (x = 0-1)
DMA Move Engine x Read Register 1

(0144_H + x * 1000_H) **Reset Value: 0000 0000_H**



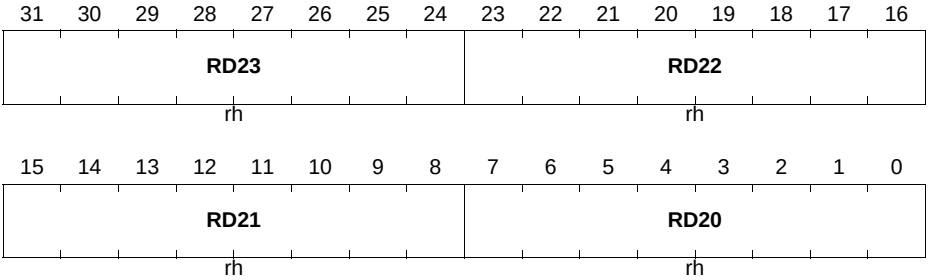
Field	Bits	Type	Description
RD10, RD11, RD12, RD13	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine x** Contains the 32-bit read data (four bytes RD1[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA Sub-block x.

DMA Move Engine x Read Register 2

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx2R (x = 0-1)
DMA Move Engine x Read Register 2

(0148_H + x * 1000_H) **Reset Value: 0000 0000_H**



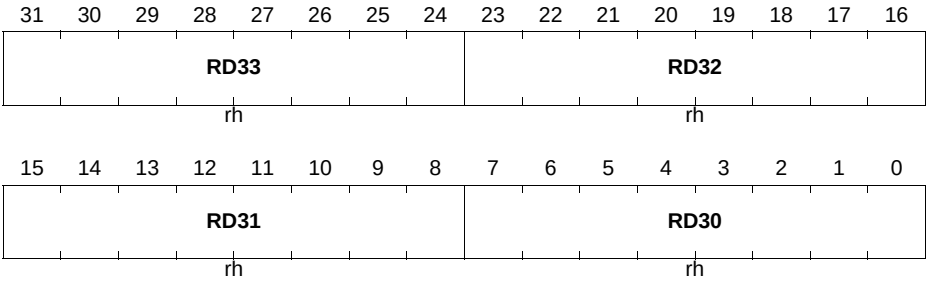
Field	Bits	Type	Description
RD20, RD21, RD22, RD23	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine x** Contains the 32-bit read data (four bytes RD2[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

DMA Move Engine x Read Register 3

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx3R (x = 0-1)
DMA Move Engine x Read Register 3

($014C_H$ + x * 1000_H) **Reset Value: 0000 0000_H**



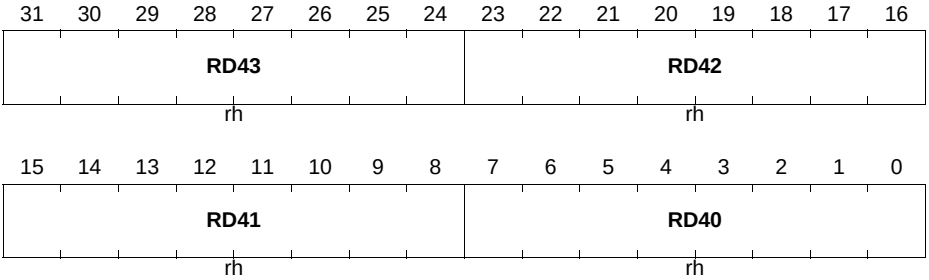
Field	Bits	Type	Description
RD30, RD31, RD32, RD33	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine x** Contains the 32-bit read data (four bytes RD3[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

DMA Move Engine x Read Register 4

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx4R (x = 0-1)
DMA Move Engine x Read Register 4

(0150_H + x * 1000_H) **Reset Value: 0000 0000_H**



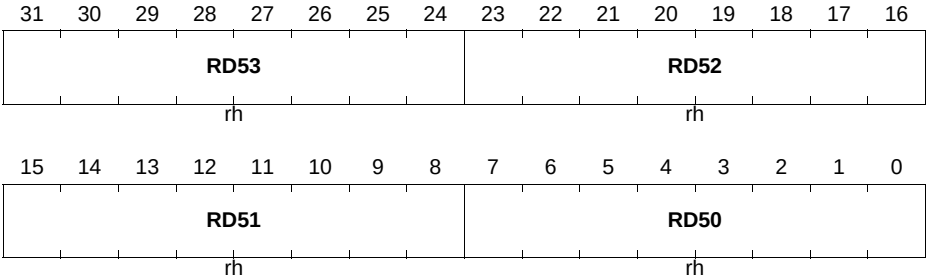
Field	Bits	Type	Description
RD40, RD41, RD42, RD43	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine x** Contains the 32-bit read data (four bytes RD4[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

DMA Move Engine x Read Register 5

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx5R (x = 0-1)
DMA Move Engine x Read Register 5

(0154_H + x * 1000_H) **Reset Value: 0000 0000_H**



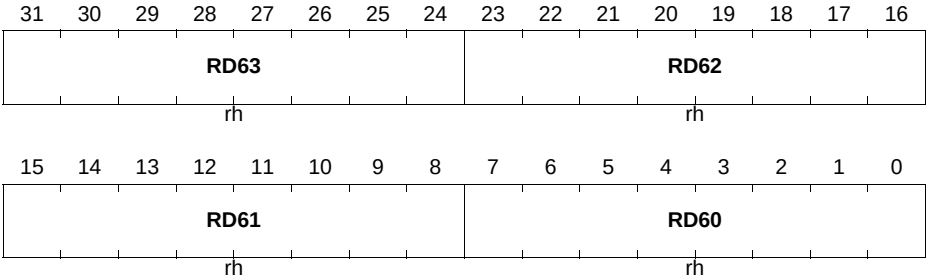
Field	Bits	Type	Description
RD50, RD51, RD52, RD53	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine x** Contains the 32-bit read data (four bytes RD5[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

DMA Move Engine x Read Register 6

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx6R (x = 0-1)
DMA Move Engine x Read Register 6

(0158_H + x * 1000_H) **Reset Value: 0000 0000_H**



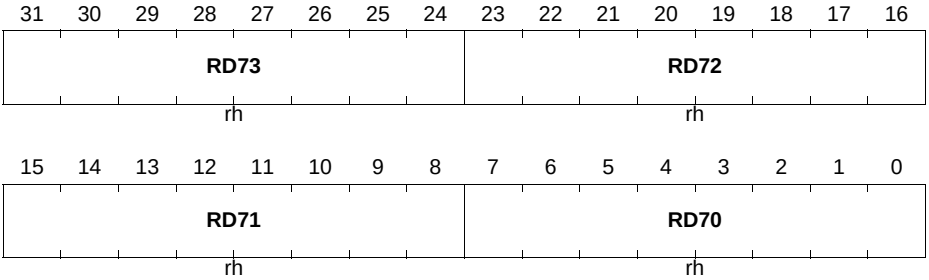
Field	Bits	Type	Description
RD60, RD61, RD62, RD63	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine x** Contains the 32-bit read data (four bytes RD6[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

DMA Move Engine x Read Register 7

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx7R (x = 0-1)
DMA Move Engine x Read Register 7

($015C_H$ + x * 1000_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RD70, RD71, RD72, RD73	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine x** Contains the 32-bit read data (four bytes RD7[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

15.8.5 DMA Move Engine Active Channel Registers

DMA Move Engine Channel Status Register

The read only DMA active channel Channel Status Register contains the current transfer count, pattern detection compare result and the status of traffic management interrupt triggers.

DMA_MExCHSR (x = 0-1)
DMA Move Engine x Channel Status Register
($019C_H$ + x * 1000_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES								FROZEN	BUFFER	RES		IPM	ICH	WRPD	WRPS
r								rh	rh	r		rh	rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LXO	RES	TCOUNT													
rh	r	rh													

Field	Bits	Type	Description
TCOUNT	[13:0]	rh	**Transfer Count Status** TCOUNT holds the actual value of the DMA transfer count for DMA channel z. TCOUNT is loaded with the value of CHCFGRz.TREL when TSRz.CH becomes set (and TCOUNT = 0). After each DMA transfer, TCOUNT is decremented by 1.
RES	14	r	**Reserved** Read as 0; must be written with 0.

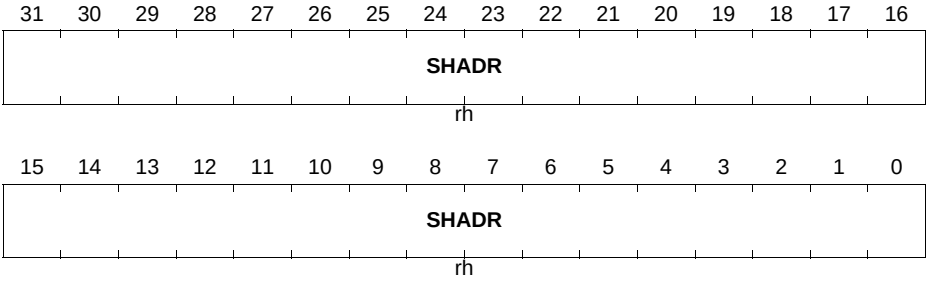
Field	Bits	Type	Description
LXO	15	rh	**Old Value of Pattern Detection** This bit contains the compare result of a pattern compare operation when 8-bit or 16-bit data width is selected. 8-bit data width: see **Table 15-4** and **Figure 15-27** 16-bit data width: see **Table 15-5** and **Figure 15-28** 0_B The corresponding pattern compare operation did not find a pattern match during the previous DMA read move 1_B The corresponding pattern compare operation found a pattern match during the previous DMA read move
WRPS	16	rh	**Wrap Source Buffer** Indicates a wrap-around of source buffer. 0_B No wrap-around occurred for channel z. 1_B A wrap-around occurred for channel z. This bit is reset by software by writing a 1 to CHCSRz.CWRP or TSRz.RST.
WRPD	17	rh	**Wrap Destination Buffer** Indicates a wrap-around of destination buffer. 0_B No wrap-around occurred for channel z. 1_B A wrap-around occurred for channel z. This bit is reset by software by writing a 1 to CHCSRz.CWRP or TSRz.RST.
ICH	18	rh	**Interrupt from Channel** This bit indicates that channel z has raised an interrupt for TCOUNT = IRDV or if TCOUNT has been decremented (depending on ADICRz.INTCT[0]. This bit (and IPM) is reset by software when writing a 1 to ADICRz.CICH or by a channel reset (writing TSRz.RST = 1). 0_B A channel interrupt has not been detected. 1_B A channel interrupt has been detected.

Field	Bits	Type	Description
IPM	19	rh	**Pattern Detection from Channel** This bit indicates that a pattern has been detected for channel z while the pattern detection has been enabled. This bit (and ICH) is reset by software when writing a 1 to ADICRz.CICH or by a channel reset (writing TSRz.RST = 1). 0_B A pattern has not been detected. 1_B A pattern has been detected.
RES	[21:20]	r	**Reserved** Read as 0; must be written with 0.
BUFFER	22	rh	**DMA Double Buffering Active Buffer** This bit is active during DMA double buffering and indicates which buffer is read or filled. 0_B Buffer 0 read or filled by DMA. 1_B Buffer 1 read or filled by DMA.
FROZEN	23	rh	**DMA Double Buffering Frozen Buffer** This bit is active during DMA double buffering and indicates that one of the double buffers is frozen and available for a cyclic software task. 0_B Buffer is not frozen. 1_B Buffer is frozen.
RES	[31:24]	r	**Reserved** Read as 0; must be written with 0.

DMA Move Engine Channel Shadow Address Register

The read only DMA active channel Shadow Address Register holds the 32-bit shadow address.

DMA_MExSHADR (x = 0-1)
DMA Move Engine x Channel Shadow Address Register
(0198_H + x * 1000_H) **Reset Value: 0000 0000_H**

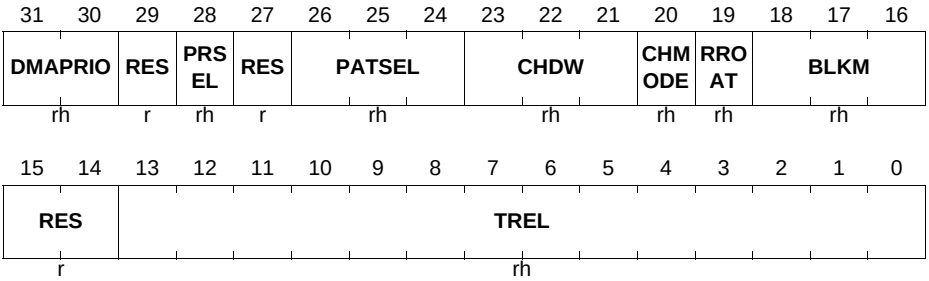


Field	Bits	Type	Description
SHADR	[31:0]	rh	**Shadowed Address** This bit field holds the 32-bit shadow address of the active DMA channel. The function of the shadow address is set by the shadow control settings. See **Table 15-15** for a description.

DMA Move Engine Channel Control Register

The read only DMA active channel Channel Control Register contains the configuration and control bits.

DMA_MExCHCR (x = 0-1)
DMA Move Engine x Channel Control Register
(0194_H + x * 1000_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TREL	[13:0]	rh	**Transfer Reload Value** This bit field contains the number of DMA transfers for a DMA transaction of DMA channel z. This14-bit transfer count value is loaded into MExCHSR.TCOUNT at the start of a DMA transaction (when TSRz.CH becomes set and CHCSRz.TCOUNT = 0). A write to CHCFGz.TREL during a running DMA transaction has no influence to the running DMA transaction. If CHCFGRz.TREL = 0 or if CHCFGRz.TREL = 1 then MExCHSR.TCOUNT will be loaded with 1 when a new transaction is started (at least one DMA transfer must be executed per DMA transaction).

Field	Bits	Type	Description
BLKM	[18:16]	rh	**Block Mode** BLKM determines the number of DMA moves executed during one DMA transfer. 000_B One DMA transfer has 1 DMA move 001_B One DMA transfer has 2 DMA moves 010_B One DMA transfer has 4 DMA moves 011_B One DMA transfer has 8 DMA moves 100_B One DMA transfer has 16 DMA moves 101_B One DMA transfer has 3 DMA moves 110_B One DMA transfer has 5 DMA moves 111_B One DMA transfer has 9 DMA moves See also **Figure 15-12** on **Page 15-23**.
RROAT	19	rh	**Reset Request Only After Transaction** RROAT determines whether or not the TSRz.CH transfer request state flag is reset after each transfer. 0_B TSRz.CH is reset after each transfer. A transfer request is required for each transfer. 1_B TSRz.CH is reset when CHSRz.TCOUNT = 0 after a transfer. One transfer request starts a complete DMA transaction
CHMODE	20	rh	**Channel Operation Mode** CHMODE determines the reset condition for control bit TSRz.HTRE of the DMA channel. 0_B Single Mode operation is selected for DMA channel. After a transaction, DMA channel is disabled for further hardware requests (TSRz.HTRE is reset by hardware) TSRz.HTRE must be set again by software for starting a new transaction. 1_B Continuous Mode operation is selected for DMA channel z. After a transaction, bit TSRz.HTRE remains set

Field	Bits	Type	Description
CHDW	[23:21]	rh	**Channel Data Width** CHDW determines the data width for the read and write moves of DMA channel z. 000_B 8-bit data width for moves selected *Note: Single Data Transfer Byte (SDTB)* 001_B 16-bit data width for moves selected *Note: Single Data Transfer Half-Word (SDTH)* 010_B 32-bit data width for moves selected *Note: Single Data Transfer Word (SDTW)* 011_B 64-bit data width transaction selected *Note: SRI-Bus: Single Data Transfer Double Word (SDTD)* *Note: SPB-Bus: not supported.* 100_B 128-bit data width transaction selected *Note: SRI-Bus: Block Transfer Request - 2 Transfers (BTR2)* *Note: SPB-Bus: not supported.* 101_B 256-bit data width transaction selected *Note: SRI-Bus: Block Transfer Request - 4 Transfers (BTR4)* *Note: SPB-Bus: not supported.* 110_B Reserved 111_B Reserved

Field	Bits	Type	Description
PATSEL	[26:24]	rh	**Pattern Select** This bit field selects the mode of the pattern detection logic. Depending on the channel data width, PATSEL[1:0] selects different pattern detection configurations. If pattern detection is enabled (PATSEL[1:0] not equal 00_B), the pattern detection interrupt line will be activated on the selected pattern match. PATSEL[2] selects the pattern read register. 0_B Pattern Read Register 0 1_B Pattern Read Register 1 **8-bit channel data width (CHDW = 000_B):** Selected pattern detection configuration see **Table 15-4** on **Page 15-55**. **16-bit channel data width (CHDW = 001_B):** Selected pattern detection configuration see **Table 15-5** on **Page 15-57**. **32-bit channel data width (CHDW = 010_B):** Selected pattern detection configuration see **Table 15-6** on **Page 15-60**.
PRSEL	28	rh	**Peripheral Request Select** This bit field controls the hardware request input multiplexer of DMA channel z-1 (see **Figure 15-6** on **Page 15-13**). 0_B Hardware trigger selected 1_B Daisy chain selected
DMAPRIO	[31:30]	rh	**DMA Priority** This bit determines the DMA the request priority that is used when a move operation related to channel z is requesting SPB-Bus. This bit has no effect in channel prioritization inside the Move Engine x in. 00_B Low priority selected 01_B Medium priority selected 10_B Medium priority selected 11_B High priority selected
RES	[15:14], 27, 29	r	**Reserved** Read as 0; must be written with 0.

DMA Move Engine Channel Address and Interrupt Control Register

The read only DMA active channel Address and Interrupt Control Register controls how source and destination addresses are updated after a DMA move. Furthermore, it determines whether or not a source or destination address register update is shadowed.

The interrupt control bits enable the generation of DMA traffic interrupt triggers.

DMA_MExADICR (x = 0-1)
DMA Move Engine x Channel Address and Interrupt Control Register
(0190_H + x * 1000_H) **Reset Value: 0000 0000_H**

CBLD				CBLS				INCD	DMF			INCS	SMF		
rh				rh				rh	rh			rh	rh		

Field	Bits	Type	Description
SMF	[2:0]	rh	**Source Address Modification Factor** This bit field and the data width as defined in MExCHCR.CHDW determine an address offset value by which the source address is modified after each DMA move. See also **Table 15-13**. 000_B Address offset is 1 x MExCHCR.CHDW 001_B Address offset is 2 x MExCHCR.CHDW 010_B Address offset is 4 x MExCHCR.CHDW 011_B Address offset is 8 x MExCHCR.CHDW 100_B Address offset is 16 x MExCHCR.CHDW 101_B Address offset is 32 x MExCHCR.CHDW 110_B Address offset is 64 x MExCHCR.CHDW 111_B Address offset is 128 x MExCHCR.CHDW

Field	Bits	Type	Description
INCS	3	rh	**Increment of Source Address** This bit determines whether the address offset as selected by SMF will be added to or subtracted from the source address after each DMA move. The source address is not modified if CBLS = 0000_B. 0_B Address offset will be subtracted 1_B Address offset will be added.
DMF	[6:4]	rh	**Destination Address Modification Factor** This bit field and the data width as defined in MExCHCR.CHDW determines an address offset value by which the destination address is modified after each DMA move. The destination address is not modified if CBLD = 0000_B. See also **Table 15-13**. 000_B Address offset is 1 x MExCHCR.CHDW 001_B Address offset is 2 x MExCHCR.CHDW 010_B Address offset is 4 x MExCHCR.CHDW 011_B Address offset is 8 x MExCHCR.CHDW 100_B Address offset is 16 x MExCHCR.CHDW 101_B Address offset is 32 x MExCHCR.CHDW 110_B Address offset is 64 x MExCHCR.CHDW 111_B Address offset is 128 x MExCHCR.CHDW
INCD	7	rh	**Increment of Destination Address** This bit determines whether the address offset as selected by DMF will be added to or subtracted from the destination address after each DMA move. The destination address is not modified if CBLD = 0000_B. 0_B Address offset will be subtracted 1_B Address offset will be added

Field	Bits	Type	Description
CBLS	[11:8]	rh	**Circular Buffer Length Source** This bit field determines which part of the 32-bit source address register remains unchanged and is not updated after a DMA move operation (see also **Section 15.4.3.8**). Therefore, CBLS also determines the size of the circular source buffer. 0000_B Source address SADR[31:0] is not updated 0001_B Source address SADR[31:1] is not updated 0010_B Source address SADR[31:2] is not updated 0011_B Source address SADR[31:3] is not updated $\ldots_B$ ... 1110_B Source address SADR[31:14] is not updated 1111_B Source address SADR[31:15] is not updated
CBLD	[15:12]	rh	**Circular Buffer Length Destination** This bit field determines which part of the 32-bit destination address register remains unchanged and is not updated after a DMA move operation (see also **Page 15-25**). Therefore, CBLD also determines the size of the circular destination buffer. 0000_B Destination address DADR[31:0] is not updated 0001_B Destination address DADR[31:1] is not updated 0010_B Destination address DADR[31:2] is not updated 0011_B Destination address DADR[31:3] is not updated $\ldots_B$ ... 1110_B Destination address DADR[31:14] is not updated 1111_B Destination address DADR[31:15] is not updated
SHCT	[19:16]	rh	**Shadow Control** This bit field determines the function of the shadow address register. See **Table 15-15**.
SCBE	20	rh	**Source Circular Buffer Enable** 0_B Source circular buffer disabled 1_B Source circular buffer enabled

Field	Bits	Type	Description
DCBE	21	rh	**Destination Circular Buffer Enable** 0_B Destination circular buffer disabled 1_B Destination circular buffer enabled
STAMP	22	rh	**Time Stamp** This bit enables the appendage of a timestamp after the end of the last DMA Move during a DMA transaction. 0_B No action. 1_B Enable the appendage of a 32-bit timestamp.
ETRL	23	rh	**Enable Transaction Request Lost Interrupt** This bit enables the generation of an interrupt when TSRz.TRLz is set. 0_B The interrupt generation for a request lost event for channel z is disabled. 1_B The interrupt generation for a request lost event for channel z is enabled.
WRPSE	24	rh	**Wrap Source Enable** 0_B Wrap source buffer interrupt trigger disabled 1_B Wrap source buffer interrupt trigger enabled
WRPDE	25	rh	**Wrap Destination Enable** 0_B Wrap destination buffer interrupt trigger disabled 1_B Wrap destination buffer interrupt trigger enabled
INTCT	[27:26]	rh	**Interrupt Control** 00_B No interrupt trigger will be generated on changing the TCOUNT value. The bit CHSRz.ICH is set when TCOUNT equals IRDV. 01_B No interrupt trigger will be generated on changing the TCOUNT value. The bit CHSRz.ICH is set when TCOUNT is decremented 10_B Interrupt trigger is generated and bit CHSRz.ICH is set on changing the TCOUNT value and TCOUNT equals IRDV 11_B Interrupt trigger is generated and bit CHSRz.ICH is set each time TCOUNT is decremented *Note: see **Figure 15-31**.* *Note: If DMA_CHCFGRz.PRSEL = 1_B for the next lower priority channel then the channel transfer trigger interrupt is disabled.*

Field	Bits	Type	Description
IRDV	[31:28]	rh	**Interrupt Raise Detect Value** Defines the Threshold Limit of CHSRz.TCOUNT for which a channel interrupt trigger will be raised.

Address Offset Calculation Tables

Table 15-13 and Table 15-14 show the offset values that are added or subtracted to/from a source or destination address register after a DMA move.

Bit field SMF and bit INCS determine the offset value for the source address.

Bit field DMF and bit INCD determine the offset value for the destination address.

Table 15-13 Address Offset Calculation Table (8-bit, 16-bit and 32-bit)

CHCFGRz.CHDW = 000_B (8-bit Data Width)			CHCFGRz.CHDW = 001_B (16-bit Data Width)			CHCFGRz.CHDW = 010_B (32-bit Data Width)

Shadow Control Table

Table 15-15 defines the functionality of the shadow address register control bits.

Table 15-15 Shadow Control Table

SHCT	Description
0000_B	Source and destination registers written directly. *Note: Shadow address register is not used and set to 00000000_H.*
0001_B	**Source Address Buffering (Read Only)** Shadow address used for source buffering. When writing to SADRz, the address is buffered in SHADRz and transferred to SADRz with the start of the next DMA transaction. *Note: Shadow address register is read only and is automatically set to 00000000_H when the shadow transfer takes place (equal to AudoNG).*
0010_B	**Destination Address Buffering (Read Only)** Shadow address used for destination buffering. When writing to DADRz, the address is buffered in SHADRz and transferred to DADRz with the start of the next DMA transaction. *Note: Shadow address register is read only and is automatically set to 00000000_H when the shadow transfer takes place (equal to AudoNG).*
0011_B	Reserved. *Note: Shadow address register is not used and set to 00000000_H.*
0100_B	Reserved. *Note: Shadow address register is not used and set to 00000000_H.*
0101_B	**Source Address Buffering (Direct Write)** Shadow address used for source buffering. Shadow address register can be read and can be directly written. The value stored in SHADRz is not automatically modified when the shadow transfer takes place.
0110_B	**Destination Address Buffering (Direct Write)** Shadow address used for destination buffering. Shadow address register can be read and can be directly written. The value stored in SHADRz is not automatically modified when the shadow transfer takes place.
0111_B	Reserved. *Note: Shadow address register is not used and set to 00000000_H.*
1000_B	**Double Source Buffering** **Software Switch Only** Shadow address used for double buffering

Table 15-15 Shadow Control Table (cont'd)

SHCT	Description
1001_B	**Double Source Buffering** **Automatic Hardware and Software Switch** Shadow address used for double buffering
1010_B	**Destination Double Destination Buffering** **Software Switch Only** Shadow address used for double buffering
1011_B	**Destination Double Destination Buffering** **Automatic Hardware and Software Switch** Shadow address used for double buffering
1100_B	**DMA Linked List** The DMA controller reads a DMA channel transaction control set and overwrites 8 X words in the corresponding DMARAM channel z. *Note: The SDCRC and RDCRC checksums are unique for each DMA transaction in the DMA Linked List. RDCRCRz and SDCRCRz are overwritten after each DMA transaction in the DMA Linked List.*
1101_B	**Accumulated Linked List** The DMA controller reads a DMA channel transaction control set and overwrites 6 X words in the corresponding DMARAM channel z. *Note: The SDCRC and RDCRC checksums are accumulated across all DMA transactions of the Accumulated Linked List. RDCRCRz and SDCRCRz are not overwritten*
1110_B	**Safe Linked List** The DMA controller reads a DMA channel transaction control set. The Linked List only proceeds with the next DMA transaction if the existing SDCRC checksum matches the expected SDCRC checksum in the loaded from the new DMA transaction control set. *Note: The SDCRC and RDCRC checksums are accumulated across all DMA transactions of the Safe Linked List. RDCRCRz is not overwritten.*
1111_B	**Conditional Linked List** Shadow address register (MExSHADR) and source and destination address CRC register (MExSDCRC) are used as address pointers to a Linked List. The selection of the address pointer is determined by DMA channel pattern detection conditions. *Note: Calculation of SDCRC checksums is not supported.*

Shadow Address used for Source or Destination Buffering

The Shadow Address Register holds the shadowed source or destination address before it is written into the source or destination address register.

Shadow Address used for DMA Double Buffering

The Shadow Address Register holds a second source or destination address used to store data in a second source or destination location.

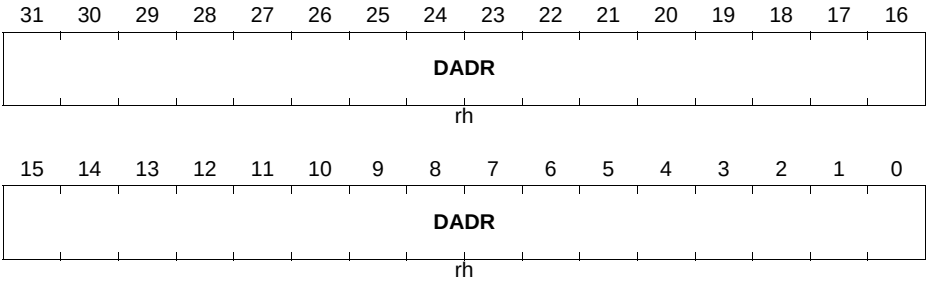
Shadow Address used for DMA Linked Lists

The Shadow Address Register holds an address pointer to the next DMA transaction control set.

DMA Move Engine Channel Destination Address Register

The read only DMA active channel Destination Address Register holds the 32-bit destination address. If a DMA channel is active, MExDADR is updated continuously (if programmed) and shows the actual destination address that is used for write moves within DMA transfers.

DMA_MExDADR (x = 0-1)
DMA Move Engine x Channel Destination Address Register x
($018C_H$ + x * 1000_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DADR	[31:0]	rh	**Destination Address** This bit field holds the actual 32-bit destination address of the active DMA channel that is used for write moves.

DMA Move Engine x Channel Source Address Register

The read only DMA active channel Source Address Register holds the 32-bit source address. If a DMA channel is active, MExSADR is updated continuously (if programmed) and shows the actual source address that is used for read moves within DMA transfers.

DMA_MExSADR (x = 0-1)
DMA Move Engine x Channel Source Address Register
(0188_H + x * 1000_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SADR															
rh															

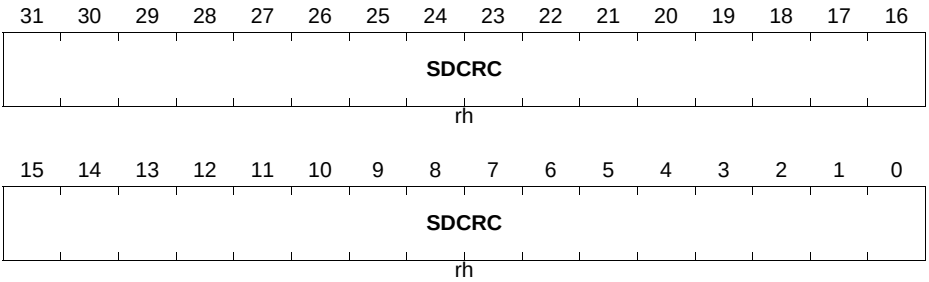
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SADR															
rh															

Field	Bits	Type	Description
SADR	[31:0]	rh	**Source Start Address** This bit field holds the actual 32-bit source address of the active DMA channel that is used for read moves.

DMA Channel Source and Destination Address CRC Register

The read only DMA active channel Source and Destination Address CRC Register will store one polynomial calculation during each DMA read and each DMA write move provided there is no retry or error condition flagged.

DMA_MExSDCRC (x = 0-1)
DMA Move Engine x Channel Source and Destination Address CRC Register
(0184_H + x * 1000_H) **Reset Value: 0000 0000_H**

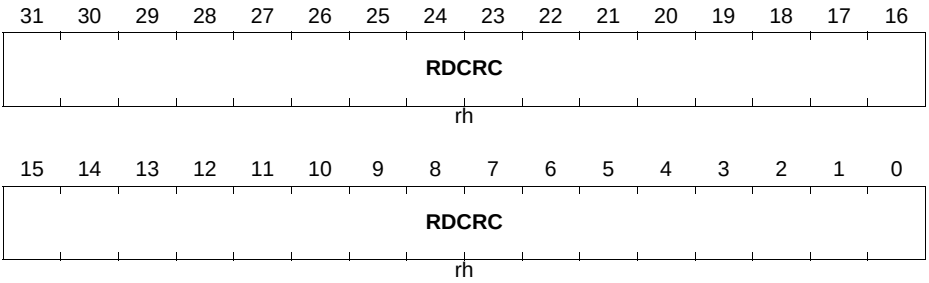


Field	Bits	Type	Description
SDCRC	[31:0]	rh	**Source and Destination Address CRC** This bit field contains the working CRC32 ethernet polynomial checksum for the source and destination address.

DMA Move Engine Channel Read Data CRC Register

The read only DMA active channel Read Data CRC Register will store one polynomial calculation during each DMA read move provided that there is no retry or error condition flagged. In order to start a CRC32 sequence the MExRDCRC must be initialized (e.g. written with 00000000_H or with a desired start value) and an DMA transaction must be set up (start address, length, etc.).

DMA_MExRDCRC (x = 0-1)
DMA Move Engine x Channel Read Data CRC Register
(0180_H + x * 1000_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RDCRC	[31:0]	rh	**Read Data CRC** This bit field contains the working CRC32 ethernet polynomial checksum for read data.

15.8.6 DMA OCDS Registers

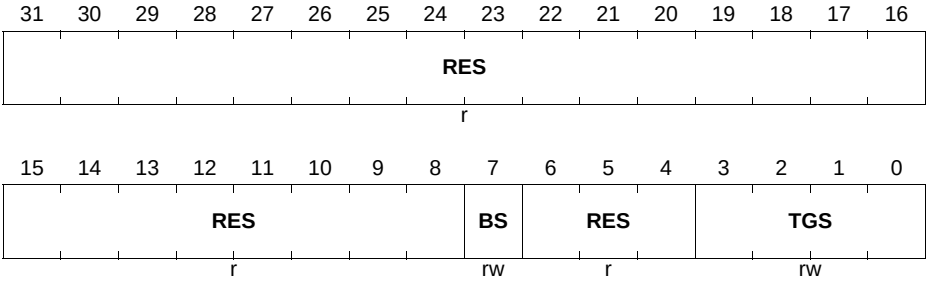
DMA OCDS Trigger Set Select Register

The selection of the OCDS Trigger Bus (OTGB) is controlled by the OTSS register.

The OTSS register is cleared by Debug Reset and it is cleared by each System Reset when OCDS is disabled. The OTSS Register is not touched by the System Reset when OCDS is enabled.

Write access requires OCDS to be enabled and Supervisor mode.

DMA_OTSS
DMA OCDS Trigger Set Select (1200$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TGS	[3:0]	rw	**Trigger Set (Table 15-16) for OTGB0/1** 0_D No Trigger Set selected 1_D Trigger Set 1 2_D Trigger Set 2 8_D Trigger Set 8 others reserved
BS	7	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
RES	[6:4], [31:8]	r	**Reserved** Read as 0; must be written with 0.

OCDS Trigger Bus Interface

Table 15-16 lists the Trigger Sets, which are selected with the DMA_OTSS register for the 16 bit OCDS Trigger Bus (OTGB0/1) interface. Only one Trigger Set can be output at a time either on OTGB0 or on OTGB1.

The OCDS Trigger Bus has no dependency on the OCDS enabled state.

Table 15-16 DMA Trigger Sets

Index	Description	Details
0	No Trigger Set selected	
1	**Channels (TS16_PF)** Active channels	Table 15-17
2	**Channels (TS16_ERR)** Error channel number and flags	Table 15-18
8	**Transaction Request State (TS16_C15)** Transaction Request State Channel [15:0]	
Other	Reserved. No Trigger Set selected	

Performance Trigger Set

Table 15-17 TS16_PF Trigger Set Channels

Bits	Name	Description
[6:0]	CH0	Channel number active in move engine 0
7	ME0	Move engine 0 idle/active 0_B Move engine 0 is idle 1_B Move engine 0 is active
[14:8]	CH1	Channel number active in move engine 1
15	ME1	Move engine 1 active 0_B Move engine 1 is idle 1_B Move engine 1 is active

The performance trigger set continuously monitors the activity in the move engines. While the move engine is servicing a DMA request from DMA channel z the move engine idle/active bit TS16_PF.MEx is set and the TS16_PF.CHx bit field is set to the DMA channel number z. When the move engine is idle the idle/active bit TS16_PF.MEx goes low. The TS16_PF.CHx bit field retains the value of the last active DMA channel.

Error Trigger Set

Table 15-18 TS16_ERR Trigger Set Channels

Bits	Name	Description
[6:0]	LEC	Last error channel number
[11:7]		Reserved
12	ME0SE	Source Error
13	ME0DE	Destination Error
14	ME1SE	Source Error
15	ME1DE	Destination Error

If a move engine x source or destination error occurs then the respective CH.MExSE or TS16_CH.MExDE gets set. The TS16_CH.LEC returns the last error channel. If both move engines generate an error condition in the same clock cycle then the TS16_CH.LEC will record the last error channel for move engine 0.

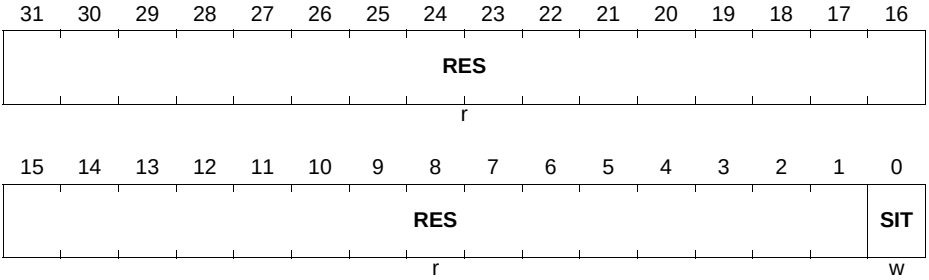
The TS16_ERR trigger set retains its value until there is a new move engine source or destination error. The MCDS must be able to sample the source or destination occurrence and the DMA error channel.

DMA Error Interrupt Set Register

The Error Interrupt Set Register allows the DMA error interrupt service request to be activated by software.

DMA_ERRINTR
DMA Error Interrupt Set Register

(1204_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SIT	0	w	**Set Error Interrupt Service Request** 0_B No action 1_B DMA error interrupt service request will be activated. Reading this bit returns a 0
RES	[31:1]	r	**Reserved** Read as 0; must be written with 0.

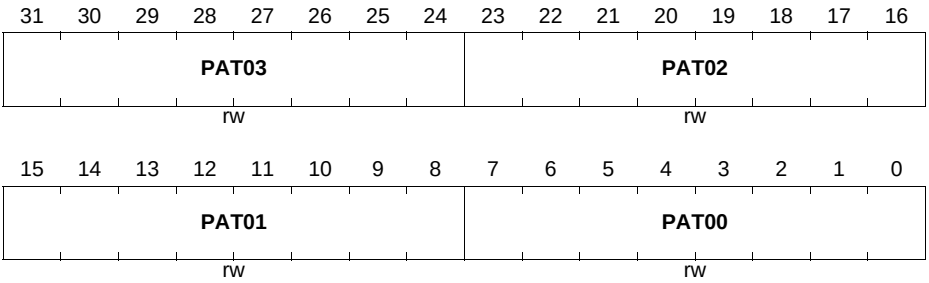
15.8.7 DMA Pattern Detection Registers

Pattern Read Register 0

The Pattern Read Register 0 contains the patterns (mask and/or compare bits) to be processed by the Move Engine pattern detection logic.

DMA_PRR0
Pattern Read Register 0

(1208_H) **Reset Value: 0000 0000_H**



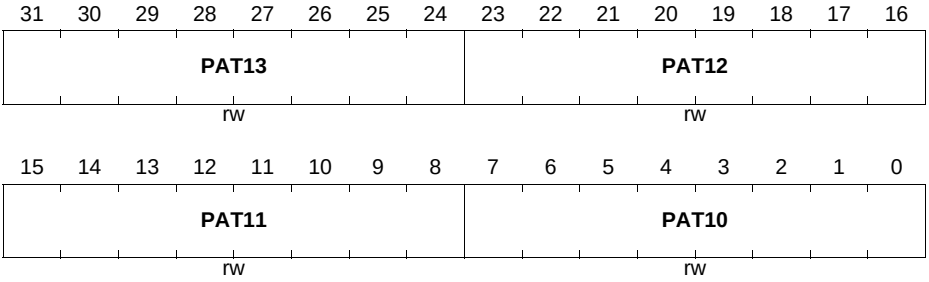
Field	Bits	Type	Description
PAT00, PAT01, PAT02, PAT03	[7:0], [15:8], [23:16], [31:24]	rw	**Pattern for Move Engine** Determines up to four 8-bit compare patterns/mask patterns to be processed by the pattern detection logic in the Move Engine. Depending on the pattern detection configuration (MExCHCR.PATSEL) and channel data width (MExCHCR.CHDW), the patterns are processed as bytes or half-words.

Pattern Read Register 1

The Pattern Read Register 1 contains the patterns (mask and/or compare bits) to be processed by the Move Engine pattern detection logic.

DMA_PRR1
Pattern Read Register 1

($120C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PAT10, PAT11, PAT12, PAT13	[7:0], [15:8], [23:16], [31:24]	rw	**Pattern for Move Engine** Determines up to four 8-bit compare patterns/mask patterns to be processed by the pattern detection logic in the Move Engine. Depending on the pattern detection configuration (MExCHCR.PATSEL) and channel data width (MExCHCR.CHDW), the patterns are processed as bytes or half-words.

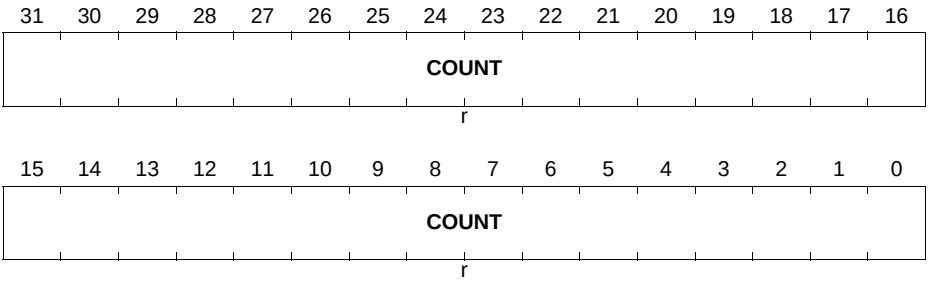
15.8.8 DMA Flow Control Registers

Time Register

The Time Register contains the 32-bit count value used for the appendage of DMA timestamps.

DMA_TIME
Time Register

(1210_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
COUNT	[31:0]	r	**Timestamp Count** This bit field provides the count value used for the appendage of DMA timestamps.

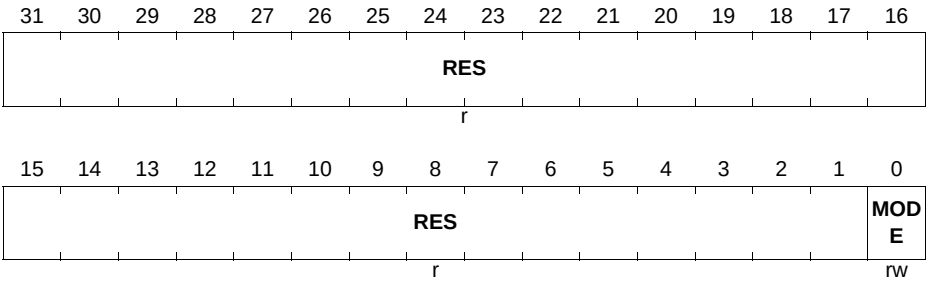
15.8.9 DMA Channel Hardware Resource Registers

DMA Mode Registers

The DMA Mode Registers control whether hardware resources access the on chip buses in supervisor mode or user mode.

DMA_MODEy (y = 0-3)
DMA Mode Register y

(1300_H + y * 4_H) **Reset Value: 0000 0001_H**



Field	Bits	Type	Description
MODE	0	rw	**Hardware Resource Supervisor Mode** Bit determines if a hardware resource 0 makes bus accesses in supervisor mode or user mode. 0_B Bus master is in user mode. 1_B Bus master is in supervisor mode.
RES	[31:1]	r	**Reserved** Read as 0; must be written with 0.

DMA Channel Hardware Resource Register z

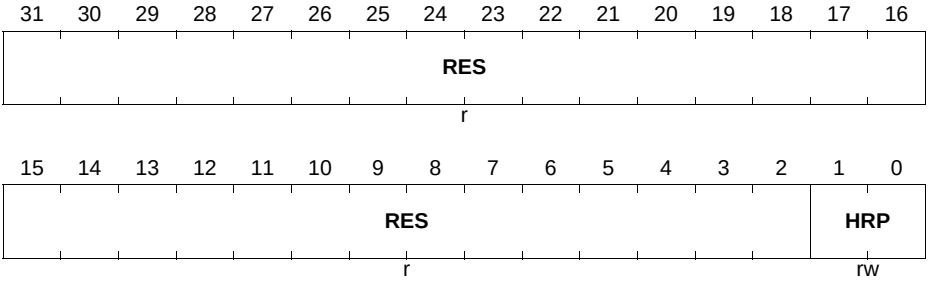
The Hardware Resource Register assigns DMA channels to one of the four hardware resource partitions.

Initially all DMA channels are assigned to Hardware Resource 0 and read/write accesses are controlled by the ACCEN00 and ACCEN01 registers. If a DMA channel z is assigned to one of the other Hardware Resource Partitions then access control will change to the corresponding pair of access enable registers.

Each hardware resource partition supports a unique bus Master Tag Identifier (TAGID).

DMA_HRRz (z = 000-015)
DMA Channel Hardware Resource Register z

(1800_H + z * 0004_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
HRP	[1:0]	rw	**Hardware Resource Partition y** 00_B Hardware Resource Partition 0. 01_B Hardware Resource Partition 1. 10_B Hardware Resource Partition 2. 11_B Hardware Resource Partition 3.
RES	[31:2]	r	**Reserved** Read as 0; must be written with 0.

15.8.10 DMA Channel Suspend Registers

DMA Channel Suspend Enable Register z

The Suspend Enable Register enables/disables soft suspend mode capability.

DMA_SUSENRz (z = 000-015)
DMA Suspend Enable Register z

($1A00_H$ + z * 0004_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES															SUS EN
r															rw

Field	Bits	Type	Description
SUSEN	0	rw	**Channel Suspend Enable for DMA Channel z** This bit enables the channel suspend capability individually for each DMA channel z. 0_B DMA channel z is disabled for channel suspend mode. The DMA channel z does not react on an active suspend request signal SUSREQ 1_B DMA channel z is enabled for Soft-suspend Mode. If the suspend request signal SUSREQ becomes active, a DMA transaction of DMA channel z is stopped after the current DMA transfer has been finished Channel suspend mode can be terminated when SUSENz is written with 0.
RES	[31:1]	r	**Reserved** Read as 0; must be written with 0.

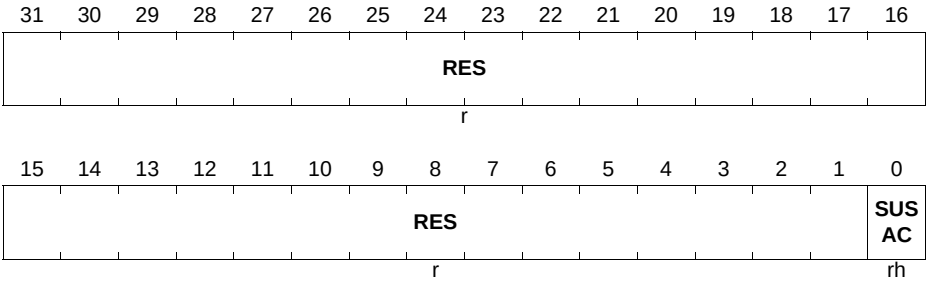
Note: Register is only reset by the Debug Reset.

DMA Suspend Acknowledge Register z

The Suspend Acknowledge Register indicates the DMA Channel soft suspend status.

DMA_SUSACRz (z = 000-015)
DMA Suspend Acknowledge Register z

($1C00_H$ + z * 0004_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SUSAC	0	rh	**Channel Suspend Mode or Frozen State Active for DMA Channel z** This status bit indicates whether or not DMA channel z is in channel suspend mode or in the frozen state. 0_B DMA channel z is not in channel suspend mode, frozen state or internal actions are not yet finished after the channel suspend mode or frozen state was requested. 1_B DMA channel z is in channel suspend mode or frozen state.
RES	[31:1]	r	**Reserved** Read as 0; must be written with 0.

Note: This register is only reset by the Debug Reset.

15.8.11 DMA Transaction State Registers

DMA Channel Transaction State Register z

The Transaction State Register supports:

- The enabling and assertion of DMA channel hardware requests.
- The recording of a transaction request lost event for the channel.
- The setting, reporting and clearing of a DMA channel halt.
- The assertion of a DMA channel reset.

DMA_TSRz (z = 000-015)
DMA Transaction State Register z

($1E00_H$ + z * 0004_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES							HLT CLR	RES					CTL	DCH	ECH
r							w	r					w	w	w

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES						HLT ACK	HLT REQ	RES				CH	TRL	HTRE	RST
r						rh	rwh	r				rh	rh	rh	rwh

Field	Bits	Type	Description
RST	0	rwh	**DMA Channel Reset** These bits force the DMA channel z to stop its current DMA transaction. Once set by software, this bit will be automatically cleared when the channel has been reset. Writing a 0 to RST has no effect. 0_B No action (write) or the requested channel reset has been reset (read). 1_B DMA channel z is stopped. More details see **Page 15-20**.

Field	Bits	Type	Description
HTRE	1	rh	**Hardware Transaction Request Enable State** 0_B Hardware transaction request for DMA Channel is disabled. An input DMA request will not trigger the channel. 1_B Hardware transaction request for DMA Channel is enabled. The transfers of a DMA transaction are controlled by the corresponding channel request line of the DMA requesting source. *Note: HTRE Operation* *4. Single Mode: HTRE is set to 0 when MExCHSR.TCOUNT is decremented and MExCHSR.TCOUNT = 0.* *5. HTRE can be enabled and disabled with TSRz.ECH and TSRz.DCH.* *6. HTRE is reset when a pattern match is detected.*
TRL	2	rh	**Transaction/Transfer Request Lost of DMA Channel** 0_B No request lost event has been detected for channel z. 1_B A new DMA request was detected while TSRz.CH=1 (request lost event). This bit is reset by software when writing a 1 to TSRz.CTL or by a channel reset (writing TSRz.RST = 1).
CH	3	rh	**Transaction Request State** 0_B No DMA request is pending for channel. 1_B A DMA request is pending for channel. CH is reset when a pattern match is detected.
HLTREQ	8	rwh	**Halt Request** The halt request is a status bit that remains active until it is cleared by TSRz.HALTCLR 0_B No action. 1_B Halt request.
HLTACK	9	rh	**Halt Acknowledge** Halt acknowledge status from DMA channel.
ECH	16	w	**Enable Hardware Transfer Request** see table below

Field	Bits	Type	Description
DCH	17	w	**Disable Hardware Transfer Request** see table below
CTL	18	w	**Clear Transaction Request Lost for DMA Channel z** Software clear of the DMA channel transaction request lost interrupt flag TSRz.TRL 0_B No action 1_B Clear DMA channel transaction request lost flag TSRz.TRL Reading this bit returns a 0.
HLTCLR	24	w	**Clear Halt Request and Acknowledge** Software write only active high clear of halt request TSRz.HALTREQ and halt acknowledge status bit TSRz.HALTACK 0_B No action. 1_B Halt clear. Reading this bit returns a 0.
RES	[7:4], [15:10], [23:19], [31:25]	r	**Reserved** Read as 0; must be written with 0.

Note: The DMA channel transaction/transfer request lost of a DMA channel is permanently available state that detects the loss of a DMA service request. If a transaction/transfer request lost is detected then an error interrupt trigger will be generated when the DMA channel z becomes active in a DMA sub-block x and if DMARAM bit ADICRz.ETRL enable bit is high.

DMA Channel Hardware Transaction/Transfer Request Conditions

Table 15-19 Conditions to Set/Reset the Bits TSRz.HTRE

TSRz.ECH	TSRz.DCH	Transaction Finishes[1)] for Channel z	Modification of TSRz.HTRE
0	0	0	unchanged
1	0	0	set
X	1	X	reset
X	X	1	reset

1) In Single Mode only. In Continuous Mode, the end of a transaction has no impact.

15.8.12 DMA Transaction Control Set

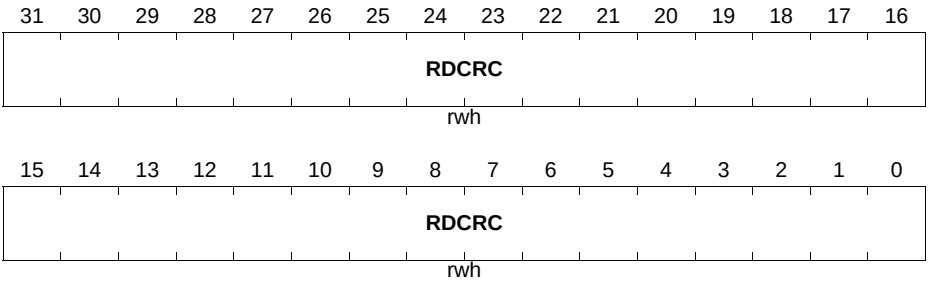
The composition of a DMA transaction for each DMA channel is defined the transaction control set stored in the DMARAM. Each transaction control set consists of 8 X 32-bit words:

- DMA_RDCRCRz, DMA_SDCRCRz[1)], DMA_SADRz, DMA_DADRz and DMA_SHADRz store 32-bit CRC or address values.
- DMA_ADICRz and DMA_CHCFGRz store DMA channel configuration control bits.
- DMA_CHCSRz stores active channel status and write only active triggers.

DMA Channel Read Data CRC Register

DMA_RDCRCRz (z = 000-015)
DMA Channel Read Data CRC Register z

(2000_H + z * 20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RDCRC	[31:0]	rwh	**Read Data CRC** This bit field stores the CRC32 ethernet polynomial checksum for read data of an inactive DMA channel.

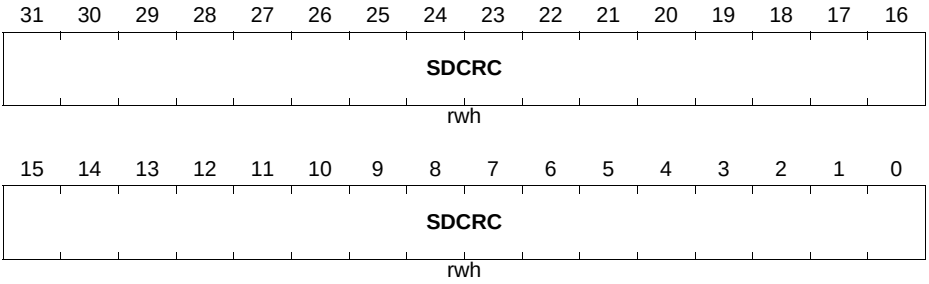
1) The Source and Destination Address CRC can detect failures in the DMA fetch configuration information and updates to the dynamic channel information.

DMA Channel Source and Destination Address CRC Register

DMA_SDCRCRz (z = 000-015)

DMA Channel Source and Destination Address CRC Register z

(2004_H + z * 20_H) **Reset Value: 0000 0000_H**

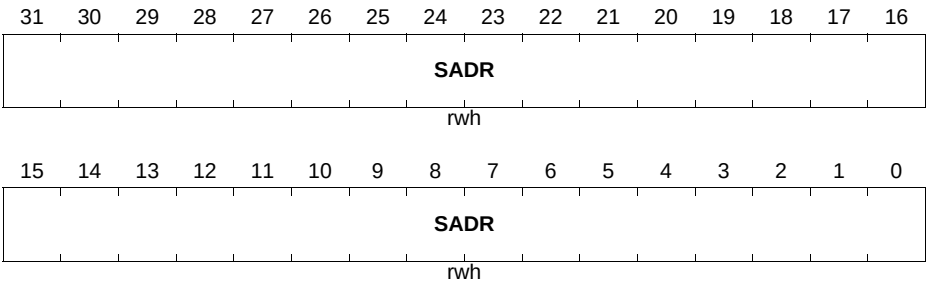


Field	Bits	Type	Description
SDCRC	[31:0]	rwh	**Source and Destination Address CRC** This bit field stores the CRC32 ethernet polynomial checksum for the source and destination address of an inactive DMA channel.

DMA Channel Source Address Register

The Source Address Register stores the source address of an inactive DMA channel.

DMA_SADRz (z = 000-015)
DMA Channel Source Address Register z
(2008_H + z * 20_H) **Reset Value: 0000 0000_H**



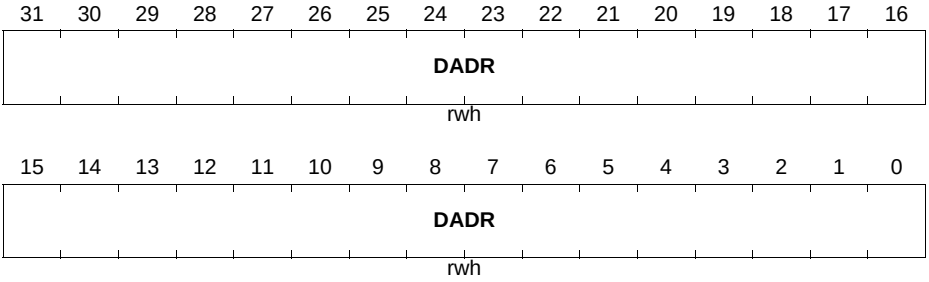
Field	Bits	Type	Description
SADR	[31:0]	rwh	**Source Address** This bit field holds the actual 32-bit source address of an inactive DMA channel.

Note: If a DMA channel is configured to execute 16-bit DMA moves then the source address register should be aligned to a 16-bit start source address.

DMA Channel Destination Address Register

The Destination Address Register stores the destination address of an inactive DMA channel.

DMA_DADRz (z = 000-015)
DMA Channel Destination Address Register x
($200C_H$ + z * 20_H) **Reset Value: 0000 0000_H**



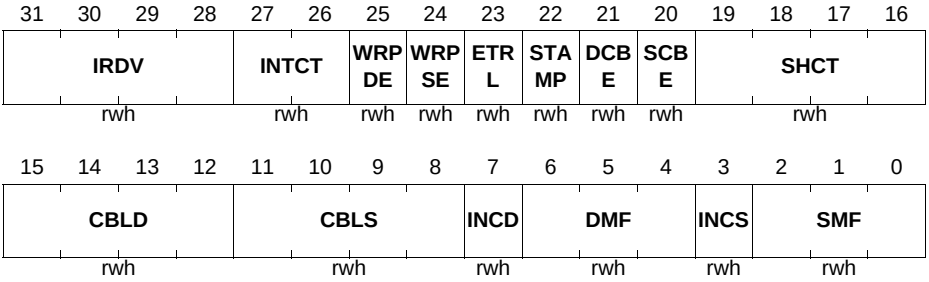
Field	Bits	Type	Description
DADR	[31:0]	rwh	**Destination Address** This bit field holds the actual 32-bit destination address of an inactive DMA channel.

Note: If a DMA channel is configured to execute 16-bit DMA moves then the destination address register should be aligned to a 16-bit start destination address.

DMA Channel Address and Interrupt Control Register

The Address and Interrupt Control Register stores bits to update source and destination addresses and the generation of DMA channel traffic management interrupt triggers.

DMA_ADICRz (z = 000-015)
DMA Channel Address and Interrupt Control Register x
(2010_H + z * 20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SMF	[2:0]	rwh	**Source Address Modification Factor** This bit field stores the Source Address Modification Factor of an inactive DMA channel.
INCS	3	rwh	**Increment of Source Address** This inactive DMA channel control bit determines if the source address is decremented or incremented.
DMF	[6:4]	rwh	**Destination Address Modification Factor** This bit field stores the Destination Address Modification Factor of an inactive DMA channel.
INCD	7	rwh	**Increment of Destination Address** This bit field stores the Destination Address Modification Factor for an inactive DMA channel.
CBLS	[11:8]	rwh	**Circular Buffer Length Source** This bit field stores circular buffer address update control of an inactive DMA channel.
CBLD	[15:12]	rwh	**Circular Buffer Length Destination** This bit field stores circular buffer address update control of an inactive DMA channel.
SHCT	[19:16]	rwh	**Shadow Control** Inactive DMA channel shadow control.

Field	Bits	Type	Description
SCBE	20	rwh	**Source Circular Buffer Enable** Inactive DMA channel source circular buffer enable.
DCBE	21	rwh	**Destination Circular Buffer Enable** Inactive DMA channel destination circular buffer enable.
STAMP	22	rwh	**Time Stamp** Enable appendage of time stamp.
ETRL	23	rwh	**Enable Transaction Request Lost Interrupt** Inactive DMA channel bit to enable the generation of an error interrupt service request.
WRPSE	24	rwh	**Wrap Source Enable** Inactive DMA channel source buffer interrupt trigger enable/disable.
WRPDE	25	rwh	**Wrap Destination Enable** Inactive DMA channel destination buffer interrupt trigger enable/disable.
INTCT	[27:26]	rwh	**Interrupt Control** Inactive DMA channel interrupt control.
IRDV	[31:28]	rwh	**Interrupt Raise Detect Value** Inactive DMA channel interrupt threshold value.

Shadow Address Register Read Only Mode

If ADICRz.SHCT = 0001_B or ADICRz.SHCT = 0010_B then source or destination address buffering is selected and SHADRz is written when a transaction is running. The SHADRz is automatically set to 0000 0000_H when the shadow transfer takes place. The user can read the shadow register in order to detect if the shadow transfer has already taken place. If the value in SHADRz is 0000 0000_H, no shadow transfer can take place and the corresponding address register is modified according to the circular buffer rules.

Shadow Address Register Write Enable Mode

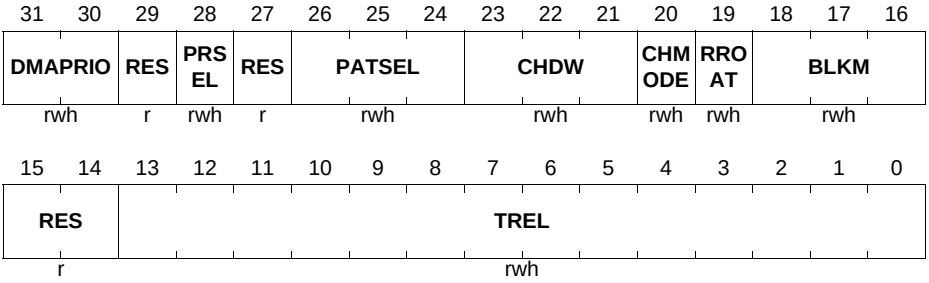
If ADICRz.SHCT = 0101_B or ADICRz.SHCT = 0110_B then the shadow register SHADRz can be directly written. The value stored in the MExSHADR is not modified when the shadow transfer takes place, the shadow mechanism remains active and the shadow transfer will be repeated until Channel z is reset or until the value in SHADRz is 0000 0000_H, is written into the shadow register.

DMA Channel Configuration Register

The Channel Configuration Register stores control and configuration data.

DMA_CHCFGRz (z = 000-015)
DMA Channel Configuration Register z

(2014_H + z * 20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TREL	[13:0]	rwh	**Transfer Reload Value** Inactive DMA channel transfer reload value.
BLKM	[18:16]	rwh	**Block Mode** Inactive DMA channel block mode control bit field.
RROAT	19	rwh	**Reset Request Only After Transaction** Inactive DMA channel control bit to reset the request state flag.
CHMODE	20	rwh	**Channel Operation Mode** Inactive DMA channel control bit to reset condition of the hardware transaction request enable bit.
CHDW	[23:21]	rwh	**Channel Data Width** Inactive DMA channel data width bit field.
PATSEL	[26:24]	rwh	**Pattern Select** Inactive DMA channel pattern select bit field.
PRSEL	28	rwh	**Peripheral Request Select** Inactive DMA channel hardware request trigger control.
DMAPRIO	[31:30]	rwh	**DMA Priority** Inactive DMA channel priority bit field.

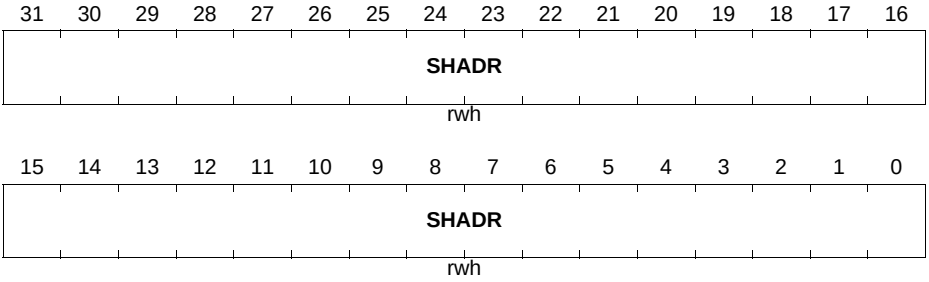
Field	Bits	Type	Description
RES	[15:14], 27, 29	r	**Reserved** Read as 0; must be written with 0.

DMA Channel Shadow Address Register

The Shadow Address Register stores the 32-bit shadow address of an inactive DMA channel.

DMA_SHADRz (z = 000-015)
DMA Channel Shadow Address Register z

(2018_H + z * 20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SHADR	[31:0]	rwh	**Shadowed Address** This bit field stores the 32-bit shadow address of an inactive DMA channel.

DMA Channel Control and Status Register

The Channel Control and Status Register contains the current transfer count, channel reset, pattern detection compare result and the status of traffic management interrupt triggers.

DMA_CHCSRz (z = 000-015)
DMARAM Channel Control and Status Register z
($201C_H$ + z * 20_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
TCOUNT	[13:0]	rh	**Transfer Count Status** DMA transfer count for an inactive DMA channel.
LXO	15	rh	**Old Value of Pattern Detection** Inactive DMA channel compare result.
WRPS	16	rh	**Wrap Source Buffer** Inactive DMA channel wrap-around of source buffer interrupt trigger flag.
WRPD	17	rh	**Wrap Destination Buffer** Inactive DMA channel wrap-around of destination buffer interrupt trigger flag.
ICH	18	rh	**Interrupt from Channel** Inactive DMA channel interrupt trigger flag.
IPM	19	rh	**Pattern Detection from Channel** Inactive DMA channel pattern detection flag.
BUFFER	22	rh	**DMA Double Buffering Active Buffer** This bit is active during DMA double buffering and indicates which buffer is read or filled. 0_B Buffer 0 read or filled by DMA. 1_B Buffer 1 read or filled by DMA.

Field	Bits	Type	Description
FROZEN	23	rwh	**DMA Double Buffering Frozen Buffer** This bit is active during DMA double buffering and indicates that one of the double buffers is frozen and available for a cyclic software task. 0_B Buffer is not frozen. 1_B Buffer is frozen. *Note: FROZEN bit must only be cleared by software.*
SWB	24	w	**DMA Double Buffering Switch Buffer** When double buffering is selected by programming ADICRz.SHCT then the control bit is used to re-direct data from one buffer to the other buffer. 0_B No action. 1_B Switch from buffer. *Note: If a Linked List mode (ADICRz.SHCT[3:2] = 11) is configured then SWB must be 0.*
CWRP	25	w	**Clear Wrap Buffer Interrupt z** Software clear of both the DMA channel source and destination wrap buffer interrupts stored in DMARAM at locations CHSRz.WRPS and CHSRz.WRPD 0_B No action. 1_B Bits CHSRz.WRPS and CHSRz.WRPD are reset. *Note: If DMA channel z is active in Move Engine x then clear bit fields MExCHSR.WRPS and MExCHSR.WRPD* Reading this bit returns a 0.
CICH	26	w	**Clear Interrupt for DMA Channel z** Software clear of the DMA channel interrupt flags stored in DMARAM locations CHSRz.ICH and CHSRz.IPM 0_B No action. 1_B Bits MExCHSR.ICH and MExCHSR.IPM are reset. *Note: If DMA channel z is active in Move Engine x then clear bit fields MExCHSR.ICH and MExCHSR.IPM* Reading this bit returns a 0.

Field	Bits	Type	Description
SIT	27	w	**Set Interrupt Trigger for DMA Channel z** 0_B No action. 1_B Channel z interrupt trigger will be activated. Reading this bit returns a 0. *Note: If a Linked List mode (ADICRz.SHCT[3:2] = 11) is configured then SIT must be 0.*
SCH	31	w	**Set Transaction Request for DMA Channel** 0_B No action. 1_B A transaction for DMA channel z is requested. When setting SCH, TSRz.CH becomes set to indicate that a DMA request is pending for DMA channel z.
RES	14, [21:20], [30:28]	r	**Reserved** Read as 0; must be written with 0.

15.9 Use Cases

This section provides a code example for the DMA module to give an overview about the core functionality. The example realizes a one word (32 bit-length) single data transfer from a data source location to a data destination location without intervention of the CPU. The transfer gets triggered by software in this example. The module also supports hardware triggering, please see **Chapter 15.4.3.3** for more details.

There will be no interrupt or further functions created in this example, please see the respective registers for more details on that. The examples uses DMA channel 000 (z=000).

Step description to initialize and trigger a data transfer via DMA:

(Line 1) The 32-bit data source address (DMA_SADR000_ADD) gets stored in the source address register SADR000 (see register definition **DMA_SADR**).

(Line 2) The 32-bit data destination address (DMA_DADR000_ADD) gets stored in the destination address register DADR000 (see register definition **DMA_DADR**).

(Line 3) The channel data width is defined in the channel configuration register CHCR000 (see register definition **DMA_CHCFGR**). Setting DMA_CHCFGR000.[23:21] = 010_B sets the channel data width to 32 bit.

(Line 4) DMA hardware transfer requests are disabled in the transaction state register TSR000 (see register definition **DMA_TSR**). Writing DMA_TSR000.[17] = 1 disables the hardware transfer requests.

(Line 5) This line starts the data transfer between the source and destination memory address.

Note: the declaration of DMA_SADR000_ADD and DMA_DADR000_ADD must be done by the user.

Initialization Code for 1 ms timer interrupt

```
(1)  DMA_SADR000 = DMA_SADR000_ADD; //data source add
(2)  DMA_DADR000 = DMA_DADR000_ADD; //data destination add
(3)  DMA_CHCFGR000.U |= (010 << 21);
(4)  DMA_TSR000.U |= (1 << 17); //disable hardware requests
(5)  DMA_CHCSR000.U |= (1 << 31); //start transfer
```

Note: The transfer can be started everywhere in the program.

16 Interrupt Router (IR)

The chapter describes the Interrupt Router (IR) module that schedules on TC21x/TC22x/TC23x Interrupts (here called service requests) from external resources, internal resources and SW to the CPU and the DMA module (here called service provider).

Topics covered include the architecture of the interrupt system, interrupt system configuration, and the interrupt operations of the TC21x/TC22x/TC23x peripherals.

16.1 Overview

An interrupt request can be serviced either by the CPUs or by the DMA module. Interrupt requests are called “service requests” rather than “interrupt requests” in this document because they can be serviced by either one of the service providers.

The interrupt system in the TC21x/TC22x/TC23x is realized in the Interrupt Router module which includes the Service Request Nodes (SRNs), the Interrupt Control Units (ICUs) and additional functionality for SW development support.

As shown in **Figure 16-1**, each TC21x/TC22x/TC23x module that can generate service requests is connected to one or more Service Request Nodes (SRNs) in the central Interrupt Router module. The Interrupt Router module includes also several general purpose Service Request Nodes (SRNs) that can be used for software (SW) triggered service requests.

Each SRN contains a Service Request Control Register (SRC) to configure the service request regarding e.g. priority, mapping to one of the available service providers.

Each SRN is connected to all ICUs in the interrupt router module where the SRNs control register setting defines the target service provider and the priority of the service request.

Each ICU handles the interrupt arbitration among competing service requests from SRNs that are mapped to the ICU.

Each ICU is connected to one service provider (CPU or DMA module) where the ICU offers the valid winning service request/SRN of an arbitration round and the service provider signals back to the ICU when and which service request it is processing.

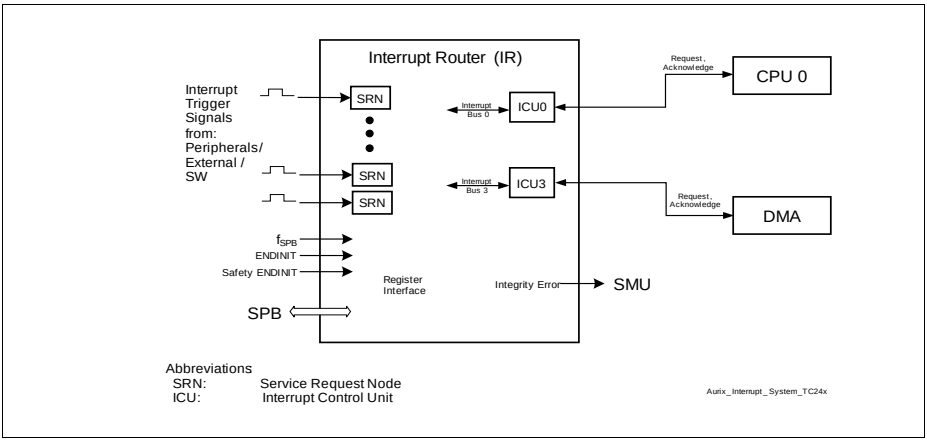

Figure 16-1 Block Diagram of the TC21x/TC22x/TC23x Interrupt System

16.2 Features

- Interrupt System with support of up to 512 / 1024 service requests
- Support of up to 255 service request priority levels per ICU[1)] / Service Provider
- Support of up to 16 ICU / service provider
- Each CPU and the DMA module with dedicated ICU
- Low latency arbitration - three / four clocks[2)] from receipt of an service request to sending it to the service provider
- Each Service Request with a dedicated Service Request Node (SRN)
- Each SRN with a programmable 8-bit priority vector[1)]
- Each SRN can be mapped to one of the implemented ICUs / Service Providers
- SRNs are cleared automatically by hardware on interrupt acknowledge by the configured service provider
- Interrupt System Integrity support
- Four General Purpose Service Requests (GPSR) per CPU that can be used as Software Interrupts (not assigned to peripherals or external interrupts)
- Mechanism to signal General Purpose Service Requests (Software Interrupts) simultaneously to multiple Service Providers (Service Request Broadcast Registers, SRB)

1) Max. 255 of the implemented service requests can be mapped to one CPU

2) Depends on the complexity and the clock frequency of the Interrupt Router. Details for the implementation are described in the chapter Module Implementation

- Priority dependent masking of service requests (for CPUs, related control registers included in the CPUs)
- External Interrupts with filter modes and trigger modes (to e.g. falling edge, rising edge, high or low level). Modes can be configured during runtime[1)]

16.3 Service Request Nodes (SRN)

Each Service Request node (SRN) inside the Interrupt Router module contains a Service Request Control (SRC) Register and interface logic that connects it to the triggering unit outside the Interrupt Router module and to the interrupt arbitration buses inside the Interrupt Router (see also: **Figure 16-1**).

16.3.1 Service Request Control Registers

All Service Request Control Registers in the Interrupt Router module have the same format. In general, these registers contain:

- Enable/disable information
- Service Request Set bit and Service Request Clear bit
- Service Request Priority Level vector (8-bit)
- Service provider destination
- Service request status bit
- Software-initiated service request set and reset bits
- Integrity errors signalled to the Safety Monitor Unit (SMU)
- Interrupt Sticky and Overflow bits

Besides being activated by the associated triggering unit through hardware, each SRN can also be set or reset by software via two software-initiated service request control bits.

The description given in this chapter characterizes all Service Request Control Registers of the TC21x/TC22x/TC23x. Information on peripheral module interrupt functions such as enable or request flags is provided in the corresponding sections of the module chapters.

16.3.1.1 General Service Request Control Register Format

Service Request Control Register (SRC)

The description given in this chapter characterizes all Service Request Control Registers of the TC21x/TC22x/TC23x. Information on peripheral module interrupt functions such as enable or request flags is provided in the corresponding sections of the module chapters.

1) External Interrupt logic and related control registers are described in the System Control Unit (SCU) chapter, External Request Unit (ERU)

SRC

Service Request Control Register (xx_H) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number** 00_H Service request is on lowest priority 01_H Service request is one before lowest priority … … FF_H Service request is on highest priority *Note: For a CPU 01H is the lowest priority as 00H is never serviced. For the DMA 00H triggers channel 0* *Note: For DMA, SRPN must be =< the highest implemented DMA channel number*
SRE	10	rw	**Service Request Enable** 0_B Service request is disabled 1_B Service request is enabled
TOS	11	rw	**Type of Service Control** 0_H CPU0 service is initiated 1_H DMA service is initiated

Field	Bits	Type	Description
ECC	[20:16]	rwh	**ECC** The SRC.ECC bit field will be updated by the SRN under the following conditions: • write or Read-Modify-Write to SRC[31:0] • write to SRC[15:0] (16-bit write) • write to SRC[15:8] or write to SRC[7:0] (byte write) In case of a 32 bit write to SRC, the ECC bit field will be updated with the calculated ECC, the data written to ECC bit field will be ignored. ECC encoding covers new SRPN, TOS, SRE values and the internal index number of the written SRN. There is no permanent ECC check. ECC check will be done whenever the SRN with a pending interrupt was accepted by the selected (TOS) service provider as next service request to be processed. For a check of the error detection mechanisms ECC errors can be inserted (ECC bit field modified) by: writing directly to the ECC bit field. • writing to SRC[23:16] (8-bit write) • writing to SRC[31:16] (16-bit write) *Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*
SRR	24	rh	**Service Request Flag** 0_B No service request is pending 1_B A service request is pending
CLRR	25	w	**Request Clear Bit** CLRR is required to reset SRR. 0_B No action 1_B Clear SRR; bit value is not stored; read always returns 0; no action if SETR is set in parallel.
SETR	26	w	**Request Set Bit** SETR is required to set SRR. 0_B No action 1_B Set SRR and SWS; SRR bit value is not stored; read always returns 0; no action if CLRR is set in parallel.

Field	Bits	Type	Description
IOV	27	rh	**Interrupt Trigger Overflow Bit** The IOV bit is set by HW if a new service request was triggered via interrupt trigger or SETR bit while the SRN has still an pending service request 0_B No Interrupt Trigger Overflow detected 1_B Interrupt Overflow Detected.
IOVCLR	28	w	**Interrupt Trigger Overflow Clear Bit** IOVCLR is required to reset IOV. 0_B No action 1_B Clear IOV; bit value is not stored; read always returns 0.
SWS	29	rh	**SW Sticky Bit** The Software Sticky Bit is set when the SRR bit has been set via the SETR (Request Set Bit). 0_B No interrupt was initiated via SETR 1_B Interrupt was initiated via SETR This bit can be cleared by writing with 1. Writing with 0 has no effect.
SWSCLR	30	w	**SW Sticky Clear Bit** SWSCLR is required to reset SWS. 0_B No action 1_B Clear SWS; bit value is not stored; read always returns 0.
0	31, [23:21], [15:12], [9:8]	r	**Reserved** Read as 0; should be written with 0.

16.3.1.2 Changing the SRN configuration

All Service Request Nodes are disabled per default. To use a Service Request Node, it has to be configured and enabled by setting the SRC.SRE bit=´1´.

The Service Request Nodes can be configured regarding the interrupt service provider target (SRC.TOS) and regarding the service request priority number (SRC.SRPN).

Once an SRN is enabled, the TOS and/or SRPN bit fields can be changed by using the following sequence:

- disable the SRN (SRC.SRE=´0´) (write to SRC.SRE)
- check that the SRN is disabled (read back SRC.SRE and check for SRE=´0)
- check the register LWSRx (read/poll LWSRx, see note below):
- if LWSRx.STAT=´1´ and LWSRx.SRPN and LWSRx.ECC are equal to the (old) SRC value check again
- if LWSRx.STAT=´0´ or LWSRx.SRPN or LWSRx.ECC are not equal to the old SRC values anymore go on with the next step (change SRC value)
- change the SRC.TOS and/or SRC.SRPN bit field
- enable the SRN (SRC.SRE=´1´) (write to SRC.SRE)

The read/poll of LWSRx is mandatory before changing SRC.TOS and/or SRC.SRPN. Otherwise the last interrupt before the SRN disabling could still be taken (enter) for execution in the CPU. It could be acknowledged later by the CPU with the side effect that the first interrupt of the just re-configured SRN can get lost. The time between enter and acknowledge is not deterministic if the ISP is a TriCore. If the ISP is the DMA module, enter and acknowledge are signalled in the same cycle. The ´x´ in LWSRx means that the LWSR register related to the TOS setting has to be checked (TOS=0 -> LWSR0, TOS=1 -> LWSR1, ...).

16.3.1.3 Protection of the SRC Registers

The SRC register is write protected via an On Chip Bus Master TAG-ID protection (see **Chapter 16.6.1**). This protection is controlled via the Interrupt Router control registers ACCEN10 and ACCEN00.

- SRC[31:16] is write protected by ACCEN00
- SRC[15:0] is write protected by ACCEN10

This implementation allows to define a first group of TAG ID(s) that are allowed to modify the configuration of the Service Request Nodes (TOS, SRPN, SRE), and a second group of TAG IDs that are allowed to modify the Service Request Nodes control bits (set/clear of SW Interrupts, clear of Sticky and Overflow bits)

Write access to SRC[31:16] with access protection violation

When an SRC register is written with a 32 bit data access, only the SRC register parts without ACCEN protection violation will be updated:

- Violation for SRC[31:16] (ACCEN00) and SRC[15:0] (ACCEN10)
- no update of the SRC register, Alarm send to SMU
- Violation for SRC[31:16] (ACCEN00)
- no update of SRC[31:16], SRC[15:0] updated, Alarm send to SMU
- Violation for SRC[31:16] (ACCEN10)
- SRC[31:16] updated, no updated of SRC[15:0], Alarm send to SMU

16.3.1.4 Request Set and Clear Bits (SETR, CLRR)

The SETR and CLRR bits allow software to set or clear the service request bit SRR.

- Writing a 1 to SETR causes bit SRR to be set to 1
- Writing a 1 to CLRR causes bit SRR to be cleared to 0
- Writing a 1 to SETR and CLRR at the same time, SRR is not changed
- The value written to SETR or CLRR is not stored
- Writing a 0 to these bits has no effect
- These bits always return 0 when read

16.3.1.5 Enable Bit (SRE)

The SRE bit enables an interrupt to take part in the arbitration for the selected service provider. It does not enable or disable the setting of the request flag SRR; the request flag can be set by hardware or by software (via SETR) independent of the state of the SRE bit. This allows service requests to be handled automatically by hardware or through software polling.

If SRE = 1, pending service requests are passed on to the designated service provider for interrupt arbitration. The SRR bit is automatically set to 0 by hardware when the service request is acknowledged by the Interrupt Service Provider. It is recommended that in this case, software should not modify the SRR bit to avoid unexpected behavior due to the hardware controlling this bit.

If SRE = 0, pending service requests are not passed on to service providers. Software can poll the SRR bit to check whether a service request is pending. To acknowledge the service request, the SRR bit must then be reset by software by writing a 1 to CLRR.

Note: In this document, ‘active source’ means an SRN whose Service Request Control Register has its request enable bit SRE set to 1 to allow its service requests to participate in interrupt arbitration.

16.3.1.6 Service Request Flag (SRR)

When set, the SRR flag indicates that a service request is pending. It can be set or reset directly by hardware or indirectly through software using the SETR and CLRR bits. Writing directly to this bit via software has no effect.

SRR can be set or cleared either by hardware or by software regardless of the state of the enable bit SRE. However, the request is only forwarded for service if the enable bit is set. If SRE = 1, a pending service request takes part in the interrupt arbitration of the service provider selected by the device's TOS bit field. If SRE = 0, a pending service request is excluded from interrupt arbitrations.

SRR is automatically reset by hardware when the service request is acknowledged and serviced. Software can poll SRR to check for a pending service request. SRR must be reset by software in this case by writing a 1 to CLRR.

Note: Clearing a pending service request flag SRR and enabling the corresponding service request node (SRN) should be done in two steps / two writes: first clear the SRR flag (SRC.CLRR), than enable the (SRC.SRE).

16.3.1.7 Type-Of-Service Control (TOS)

There are two service providers for service requests in the TC21x/TC22x/TC23x, the CPU and the DMA module. The TOS bit is used to select to which of the available interrupt service provider an service request has to be forwarded.

Note: Before modifying an TOS or an SRPN bit field, the corresponding SRN must be disabled (SRE = 0).

16.3.1.8 Service Request Priority Number (SRPN)

The 8-bit Service Request Priority Number (SRPN) indicates the priority of a service request with respect to other sources requesting service from the same service provider, and with respect to the priority of the service provider itself.

SRPN Rules:

- Each active source selecting the same service provider must have a unique SRPN value to differentiate its priority
- Active sources selecting different service provider could use same SRPN values
- If a source is not active – meaning its SRE bit is 0 – no restrictions are applied to the service request priority number
- The SRPN is used by service providers to select an Interrupt Service Routine (ISR)) or DMA channel to service the request

Service Provider is a CPU:

ISRs are associated with Service Request Priority Numbers by an Interrupt Vector Table located in each CPU. This means that the CPU Interrupt Vector Table is ordered by priority number. This is unlike traditional interrupt CPU architectures in which their interrupt vector tables are ordered by the source of the interrupt. The CPU Interrupt Vector Tables allow a single peripheral to have multiple priorities for different purposes.

Note: For a CPU, the SRPN value of 0000_H is a special value and must not be used for service requests mapped to a CPU.

Note: TC1.6E and TC1.6P CPUs are providing a flexible interrupt table alignment with a configurable vector spacing of 8 byte or 32 byte. Pls. see also CPU chapter.

Service Provider is the DMA:

The complete SRPN number is used for the arbitration of service requests the DMA module. Within the module, the DMA channels are associated with the Service Request Priority Number by the SRPN LSBs of the SRPN.

Only the SRPN numbers 0 ... max_channel_number will result in a trigger of the related DMA channel. SRPN numbers > max_channel number do not result in a DMA channel trigger nor any other signalling.

Examples:

- In case of an 16 channel DMA module the SRPN number 00H will trigger the channel 0, 07H will trigger the channel 7. All SRPN > 0FH will not result in a channel trigger.
- In case of an 64 channel DMA module the SRPN number 00H will trigger the channel 0, 17H will trigger the channel 23 an 3FH. will trigger channel 64. All SRPN > 3FH will not result in a channel trigger.

16.3.1.9 ECC Encoding (ECC)

The SRC.ECC bit field will be updated by the SRN under the following conditions:

- write or Read-Modify-Write to SRC[31:0]
- write to SRC[15:0] (16-bit write)
- write to SRC[15:8] or write to SRC[7:0] (byte write)

In case of a 32-bit write or a Read-Modify-Write to the SRC, the ECC bit field will be updated with the calculated ECC, the data written to ECC bit field will be ignored.

ECC encoding covers the new values of SRC.SRPN, SRC.TOS, SRC.SRE and the internal 10 bit index number of the written SRN.

There is no permanent ECC check. ECC check will be checked whenever the SRN with an pending service request was accepted by the selected (TOS) service provider as next service request to be processed.

For a check of the error detection mechanisms ECC errors can be inserted (ECC bit field modified) by:

- writing to SRC[23:16] (byte write)
- writing to SRC[31:16] (16-bit write)

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

ECC Code

The ECC code used for the IR Error Detection mechanism is a Hsiao 22_5 code with DED (double error detection) capability:

```
GEN_ENC22_5 : if (word_width_g/(nb_mems_g*ecc_granularity_g)) =
22 and (nb_check_bits_g = 5) generate
    cmr22_5: for i in 0 to nb_check_bits_g - 1 generate
      CODE_MATRIX_ROWS(i)     <= code_rows_22_5(i);
    end generate;
  end generate;

type rows_22_5_t is array (4 downto 0) of std_ulogic_vector(21
downto 0);
  constant code_rows_22_5 : rows_22_5_t :=
("0001001011001011011011",
"0010010101010101101101",
"0100100110100110110110",
"1000111000111000111111",
"1111000000111111000111");
```

16.3.1.10 Interrupt Trigger Overflow Bit (IOV)

The IOV bit is set by HW if both conditions are true:

- service request is pending
- a new service request is triggered via interrupt trigger or SETR bit

16.3.1.11 Interrupt Trigger Overflow Clear Bit (IOVCLR)

The Interrupt Trigger Overflow Clear Bit can be used to clear the IOV bit. The IOV bit is cleared by writing a ´1´ to the IOVCLR bit.

16.3.1.12 SW Sticky Bit (SWS)

The Software Sticky Bit is set when the SETR (Request Set Bit) is written with 1.

16.3.1.13 SW Sticky Clear Bit (SWSCLR)

The Software Sticky Clear Bit can be used to clear the SWS bit. The SWS bit is cleared by writing a ´1´ to the SWSCLR bit.

16.4 Interrupt Control Unit (ICU)

The Interrupt Router module includes one ICU per service provider (CPUs and DMA module) where each ICU is related to one service provider. SRNs can be mapped to one of the ICUs via the SRNs SRCx.TOS register bit field (see also: **Figure 16-1**).

The Interrupt Control Units (ICU):

- Manages the arbitration among competing service requests from SRNs that are mapped to the ICU
- Provides the winner of the arbitration round to the service provider
- Receives the information from the service provider which service request was accepted
- Checks the accepted service request information (ECC check)
- Signals integrity errors to the Safety Monitor Unit (SMU)
- Manages the clearing of acknowledged service requests in the related SRNs

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

16.4.1 ICU Control Registers

This section describes the Interrupt Control Unit (ICU) registers. Each ICU includes two control registers:

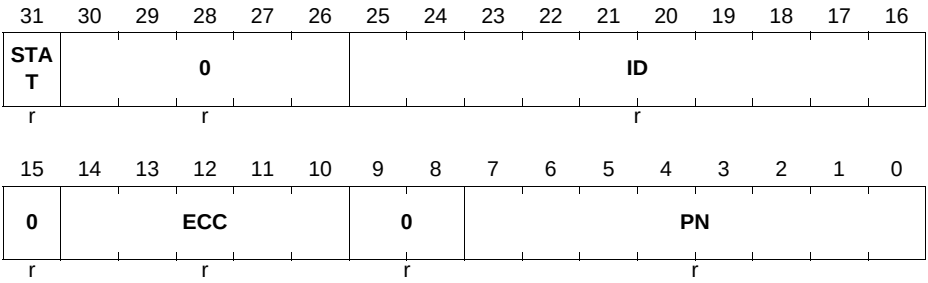
- Latest Winning Service Request register (LWSR) provides information about the winner of the last service request arbitration round
- Last Acknowledged Service Request register (LASR) provides information about the last service request that was accepted by the service provider

16.4.1.1 Latest Winning Service Request Register (LWSR)

Latest Winning Service Request (LWSR)

The Latest Winning Service Request register provides information about the winner of the last arbitration round. The register bit fields are representing what is provided by the ICU to the Interrupt Service Provider.

LWSR
Latest Winning Service Request (xx_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
PN	[7:0]	r	**Latest Winner Priority Number** This bit field shows the Priority Number of the service request that won the last arbitration round. This bit field is only valid if STAT is set to 1
ECC	[14:10]	r	**Latest Winner ECC** This bit field shows the ECC field (SRN.ECC) that was transferred from the last winning SRN to the ICU. This bit field is only valid if STAT is set to 1. *Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*
ID	[25:16]	r	**Latest Winner ID** This bit field shows the ID number of the last winning SRN. This bit field is only valid if STAT is set to 1

Field	Bits	Type	Description
STAT	31	r	**LWSR Register Status** The STAT register indicates if the PN, ECC and ID bit fields are still valid. They are still valid if the interrupt from the SRN identified by ID is still pending. If the ICU does not have an winner because no interrupt is pending or not yet arbitrated than it clears the STAT bit. 0_B LWSR bit fields are not valid 1_B LWSR bit fields are valid
0	[30:26], 15, [9:8]	r	**Reserved** Read as 0; should be written with 0.

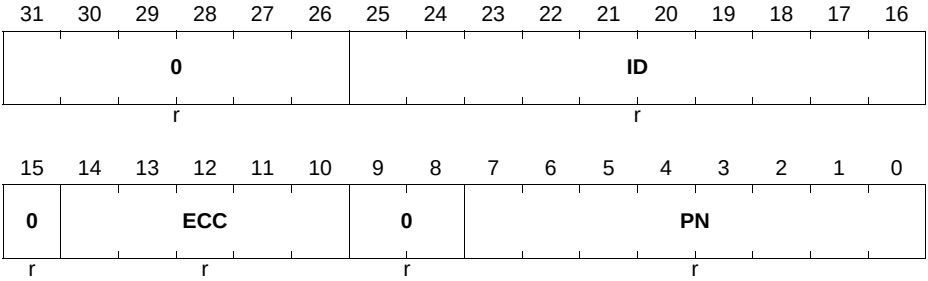
16.4.1.2 Last Acknowledged Service Request Register (LASR)

Last Acknowledged Service Request (LASR)

The Last Acknowledged Service Request register is representing the information that was sent by the Interrupt Service Provider together with the last acknowledge.

LASR

Last Acknowledged Service Request (xx_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
PN	[7:0]	r	**Last Acknowledged Service Request Priority Number** This bit field shows the Priority Number of the last acknowledged service request
ECC	[14:10]	r	**Last Acknowledged Interrupt ECC** This bit field shows the ECC value of the last acknowledged service request, as send by the service provider with acknowledge *Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*
ID	[25:16]	r	**Last Acknowledged Interrupt SRN ID** This bit field shows the ID number of the last acknowledged service request,, as send by the service provider with acknowledge
0	[31:26], 15, [9:8]	r	**Reserved** Read as 0; should be written with 0.

16.4.1.3 Error Capture Register (ECR)

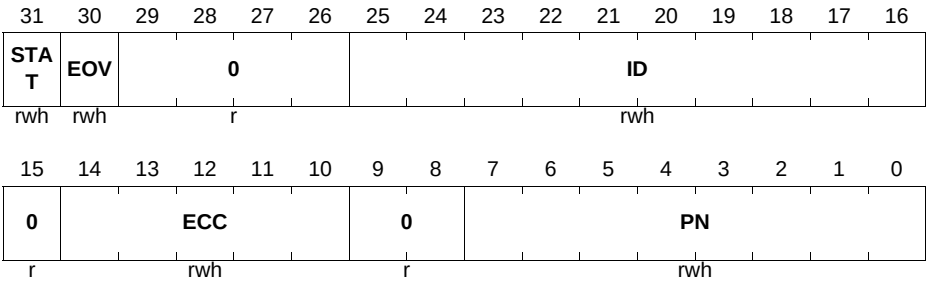
Error Capture Register (ECR)

The Error Capture Register captures the Last Acknowledged Service Request (LASR) register contents when an ECC error was detected by the ICU. The ECR shows always the last ECR contents where an ECC error was detected. Software can clear the ECR contents by writing to the ECR. Error Status (STAT) and Error Overflow (EOV) bits can be used as error handling mechanism and indication that error information where lost.

If ECR.EOV is cleared by SW, ECR.EOV must be cleared together with ECR.STAT. If a new error is detected in parallel to the ECR.EOV clear than ECR.EOV is set again by hardware while ECR.STAT is cleared.

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

ECR
Error Capture Register **(xx_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
PN	[7:0]	rwh	**Service Request Priority Number** This bit field shows the priority number of the last service request where an error was detected. Bit field can be modified by writing to it.
ECC	[14:10]	rwh	**Service Request ECC** This bit field shows the ECC of the last service request where an error was detected. Bit field can be modified by writing to it. This bit field can be modified by. • writing to SRC[23:16] (byte write) • writing to SRC[31:16] (16-bit write)

Field	Bits	Type	Description
ID	[25:16]	rwh	**Service Request Node ID** This bit field shows the ID of the last service request where an error was detected. Bit field can be modified by writing to it
EOV	30	rwh	**Error Overflow Bit** The bit is set if an ECC error was detected by the ICU while ECR.STAT=´1´ (Error Overflow situation). 0_B No Error Overflow situation detected 1_B Error Overflow situation detected This bit can be cleared by writing with 1. Writing with 0 has no effect. If this bit is cleared, it must be cleared together with the STAT bit.
STAT	31	rwh	**Error Status Bit** The Error Status Bit is set whenever an ECC was detected by the ICU. 0_B No ECC error detected 1_B ECC error detected This bit can be cleared by writing with 1. Writing with 0 has no effect.
0	[29:26], 15, [9:8]	r	**Reserved** Read as 0; should be written with 0.

16.5 General Purpose Service Requests, Service Request Broadcast

The Interrupt Router module provides multiple groups of General Purpose Service Requests (GPSR) and a mechanism to trigger multiple Service Requests of a GPSR group in parallel, by software. The GPSR can be used as Software Interrupt.

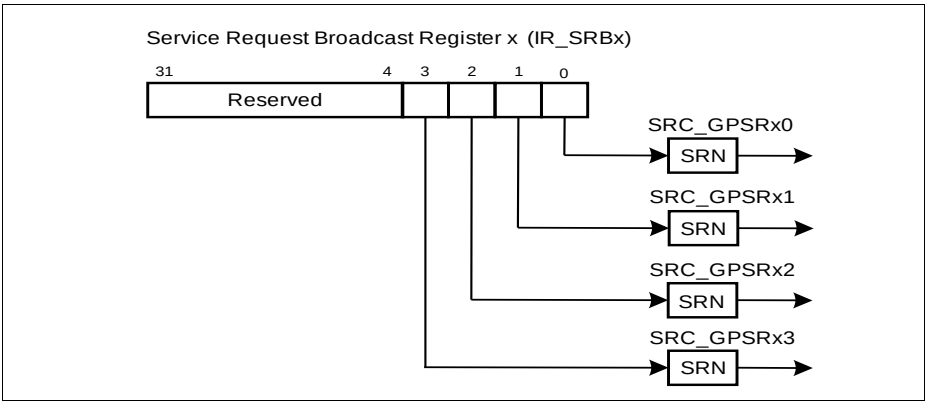


Figure 16-2 Structure of a General Purpose Service Request Group and the related Broadcast register (Example for SRC_GPSR0x, SRB0)

16.5.1 General Purpose Service Requests (GPSRxy)

The Interrupt Router module provides multiple groups of General Purpose Service Requests:

- Each General Purpose Service Request Group consists of four Service Request Nodes. Nodes that can be used as Software Interrupt
- The General Purpose Service Requests can be configured and controlled via the related Service Request Control registers SRC_GPSRxy[1)]
- The GPSR are not mapped to module service request triggers so they can only be used a SW trigger
- A General Purpose Service Request xy can only be triggered by writing ´1´ to the related SRC_GPSRxy.SETR[1)] bit or by writing a ´1´to the related Service Request Broadcast register bit SRBx[y]

16.5.2 Service Request Broadcast Registers (SRBx)

There is one Service Request Broadcast register (SRBx) implemented for each General Purpose Service Request Group (GPSRxy[1)]).

The Service Request Broadcast register x can be used to trigger multiple Service Requests within the SRC_GPSRx[1)] group in parallel.

- SRBx is always read as 0
- Writing ´1´ to SRBx[y] triggers the service request GPXRxy (y=3:0)
- Writing ´1´ to SRBx[31:4] has no effect.

1) SRC_GPSRxy: x = group number; y= number of interrupt within the group, y=0:3

16.6 System Registers

The Interrupt Router module includes the standard set of TC21x/TC22x/TC23xsystem registers. **Figure 16-3** shows these system registers which include registers for:

- Register access protection
- Module Clock Control[1)]
- Module Kernel Reset[1)]
- OCDS Control and Status Register

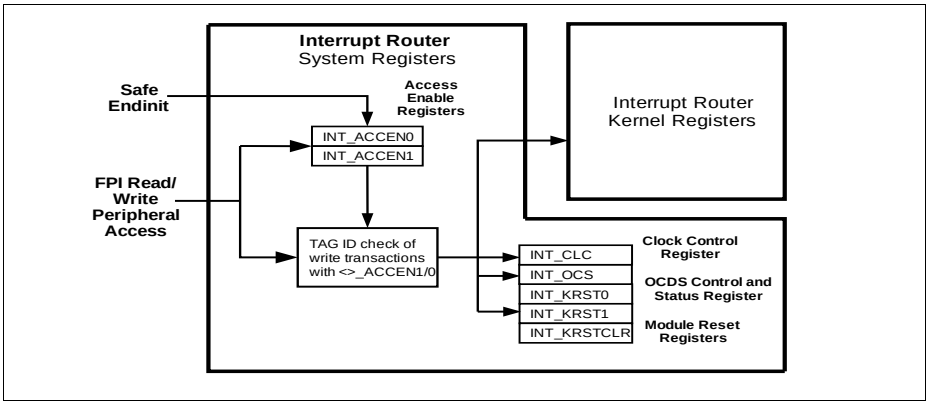

Figure 16-3 Interrupt Router System Registers

16.6.1 Register Access Protection (ACCEN1/0)

The Interrupt Router module provides a master TAG ID based write access protection as part of the AURIX safety concept. Each on chip resource with direct or indirect bus master capability has a unique master TAG ID that can be use to identify the master of an on chip bus transaction (see also chapter On Chip Bus Systems).

The SRC register is write protected via an On Chip Bus Master TAG-ID protection (see **Chapter 16.6.1**). This protection is controlled via the Interrupt Router control registers ACCEN10 and ACCEN00.

TAG ID based protection means that the support of write tansactions to the Interrupt Router control registers can be enabled / disabled for each master TAG ID individually. For a disabled master TAG ID, write access will be disconnected with error acknowledge, read access will be processed (see also **Figure 16-3**).

1) The Interrupt Router module does not support the features of this system register

The register access protection is controlled via the registers INT_ACCEN1 and INT_ACCEN0 where each bit is related to one encoding of the 6 bit On Chip Master TAG ID.

The INT_ACCEN1/0 access protection controls the write access to all Interrupt Router control and system registers with the exception of INT_ACCEN1/0. INT_ACCEN1/0 are only Safety Endinit protected.

After reset, all access enable bits and access control bits are enabled. INT_ACCEN1/0 have to be configured and checked to bring the system into a safe state.

16.6.2 Kernel Reset Registers (KRST1/0, KRSTCLR)

The Interrupt Router module does not include the kernel reset registers (KRST1, KRST0, KRSTCLR).

Note: The Interrupt Router module does not support a module kernel reset.

16.6.3 Clock Control Register (CLC)

The Interrupt Router module does not include the module clock control (CLC).

Note: The Interrupt Router module does not support the Clock Control register functionality which means that the Interrupt Router module clock can not be disabled by the CLC register.

16.6.4 OCDS Control and Status Register (OCS)

The Interrupt Router module does not include OCDS Control and Status (OCS) register.

Note: The Interrupt Router module does not support the OCS register functionality.

16.7 Arbitration Process

Each ICU in the interrupt module is related to one Interrupt Service Provider (ISP). Each ICU is related to one Interrupt Router internal arbitration bus. An arbitration bus can be related to a single ICU or it can be shared between two ICUs. This is an implementation configuration of the Interrupt Router module. If an interrupt bus is shared, the interrupt bus is arbitrating for the related ICUs in a round robin manner. Each Service Request Node (SRN) can be directed to one ISP (CPU or DMA) by mapping it via the SRC.TOS bit field setting to the related ICU.

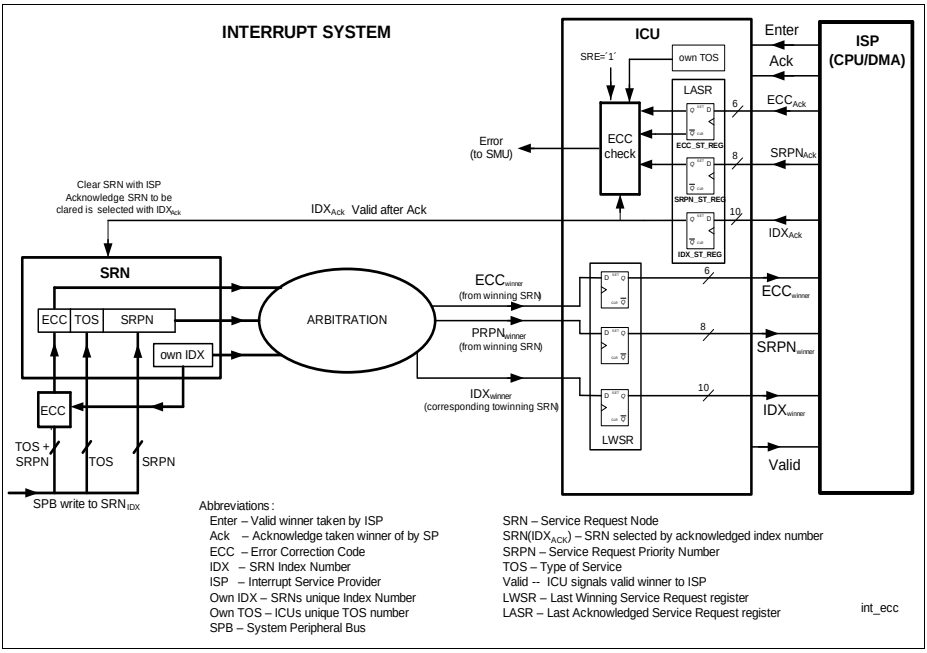

Figure 16-4 Interrupt System Arbitration Scheme Overview

With a first pending service request to an ICU, the related interrupt bus is starting an arbitration process. The arbitration process on one interrupt bus is repeated as long at least one service request mapped to the related ICUs is pending. An Interrupt Control Unit provides the service request that won the last arbitration process to its Interrupt Service Provider.

The arbitration process implemented in the TC21x/TC22x/TC23x uses 3 to 4 system peripheral bus clock cycles to determine the pending service request with the highest priority number (SRPN):

- 3 cycles as long all pending service requests are all related to one ISP. This means that the ICU can offer every 3 clock cycles a new service request to the CPU0 or to the DMA
- 4 cycles if service requests are pending for both ISPs (CPU0 and DMA). This means that the ICU can offer every 4 clock cycles a new service request to the CPU0 and every 4 clock cycles a new service request to the DMA.

During the arbitration process, the interrupt bus compares the SRC.SRPN bit fields of all pending Service Request Nodes (mapped via the SRC.TOS setting). At the end of the arbitration process, the pending service request with the highest priority number is identified as winner and the related SRN Service Request Control register bit field values SRPN, ECC and the Index of the SRN are provided to the ICU. The ICU provides these (SRPN, ECC, SRN Index) to the service provider. The ICU does an ECC check when it gets these information back from the service provider with an acknowledge. The ECC check is done with the received values: ECC, SRPN, SRN Index Number, SRE bit assumed to be´1´ (SRN enabled) and the TOS number of the ICU.

The Interrupt Router module signals detected errors to the Safety Management Unit (one bit in the SMU, covers errors from all SRN and ICUs).

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

16.7.1 Number of Clock Cycles per Arbitration Process

The Interrupt Router implementation is can be configured regarding the number of:

- supported service requests (Service Request Nodes, SRN, up to 1024)
- supported service providers (Interrupt Control Units, ICUs)
- dedicated or shared interrupt bus
- clock cycles per service request arbitration (3-4 for a shared interrupt bus, 3 SPB clock cycles for a dedicated interrupt bus)

The characteristics of the Interrupt Router module implemented in an AURIX product is described in the Module Implementation sub-chapter.

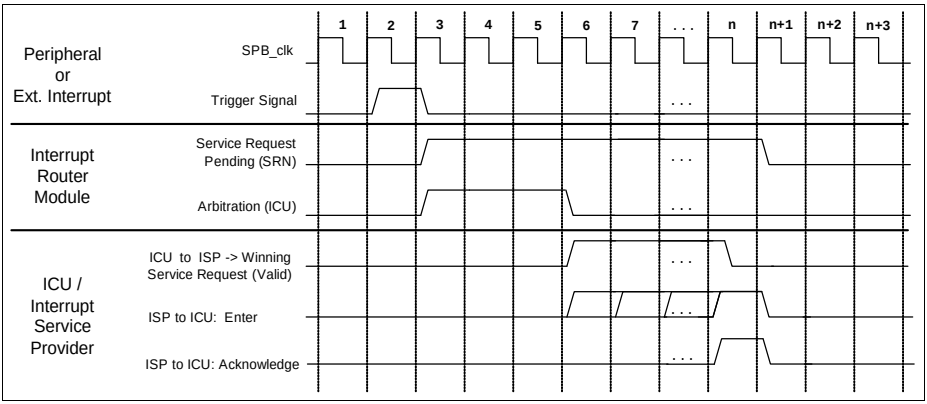

Figure 16-5 Interrupt System Timing (Schematic Overview, 3 Cycle Arbitration)

Figure 16-5 shows the interrupt timing of an Interrupt Router implementation with 2 cycle arbitration.

Cycle 1: No service request for the ICU is pending (therefore no arbitration round)

Cycle 2: One module is triggering a service request by sending a pulse to the related SRN in the Interrupt Router module.

Cycle 3-5: Arbitration among all pending service requests to the ICU

Cycle 6: ICU provides winning service request to the service provider (SRPN, ECC, SRN Index)

Cycle 7 - n-1: ICU re-arbitrates whenever a new service request from another SRN is pending, provides new winning service request to ICU if there is a new pending one with a higher SRPN number (higher priority)

Cycle 6- n-1: Interrupt Service Provider takes the information of the latest winning SRN (Enter)

Cycle n: Service provider acknowledges service request (provides SRPN, ECC, SRN Index informations of the acknowledged service request). ICU changes signals to ICU to ´no valid service request available´ in the same clock cycle.

Cycle n+1: ICU does an ECC check of the acknowledge information (SRPN, ECC, SRN Index, SRE=´1´, TOS number of the ICU. If mismatch -> Integrity Error signalled to SMU/ SRPN, ECC and Index are captured in the ECR)

Cycle n+2: ICU selects the acknowledged SRN (selected by SRN Index). Selected SRN checks acknowledged SRPN and ECC with own SRC SRPN/ECC values (if mismatch -> Integrity Error signalled to SMU)

Cycle n+3: If at least one service request to the ICU is pending: new arbitration among all pending service request to the ICU

16.7.2 Service Request Acknowledge

When a Service Provider starts with the execution of a service request that was provided by the ICU, the Service Provider sends an acknowledge to the ICU. In parallel to the acknowledge, the Service Provider sends the informations about the executed service request back to the ICU (SRPN, ECC, SRN Index Number).

In the same clock cycle, the Service Provider sends an acknowledge, the ICU changes to ´no service request available´: the ICU does not provide an arbitration winner to the service provider. This behavior of the ICU ensures that a just acknowledged service request is not provided again before the SRN was re-set (see **Figure 16-5**).

16.7.3 Handling of detected ECC Errors

The ICU does an ECC check of the informations it receives with the acknowledge from the Service Provider and the TOS number of the ICU itself. Assumption for the SRE bit is ´1´ (SRN was enabled). ECC in the SRN is covering the SRC bit field values: SRC.SRPN, SRC.SRN Index, SRC.SRE and SRC.TOS. (see **Figure 16-5**)

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

If the ICUx detects an ECC error:

- ICUx captures the ECC, SRPN and the Index that showed an ECC error in the Error capture registers (ECRx), sets the ECRx.STAT bit and the ECRx.EOV bit if the STAT bit is still set.
- ICU signals the error via the IR error signal to the TC21x/TC22x/TC23x Safety Management Unit (SMU). SMU forwards this information to a CPU (if enabled).
- ICUx clears the service request in the SRN (selected by the Index)
- The CPU that received the ´ECC error detected in Interrupt Router´ information via SMU can identify the ICU via the Error Status bits (ECRx.STAT=´1´), read out the related service request information and clear the ECRx.STAT bit by writing with ´1´. The CPU can also identify if one or multiple ECC errors where detected by this ICU via the Error Overflow bit (ECRx.EOV=´1´).

16.8 Usage of the TC21x/TC22x/TC23x Interrupt System

The following sections provide a short description of the Service Provider interfaces to the Interrupt Router ICUs.

Note: All ICU sub-modules in the Interrupt Router have the same functionality.

16.8.1 CPU to ICU Interface

Each CPU has one Interface is connected to one ICU of the Interrupt Router module. The CPU ICU interface consists of a register set where it takes over the informations of a service request provided by the ICU (SRPN, SRN Index, ECC). The informations will be send back to the ICU when the CPU acknowledges the provided service request.

The CPU ICU interface contains an Interrupt Control Register (ICR) that holds the current CPU priority number (CCPN), the global interrupt enable/disable bit (IE) and the pending interrupt priority number (PIPN). Further details of the CPU ICU interface and the CPU handling of interrupts can be found in the CPU chapter.

16.8.2 DMA to ICU Interface

The DMA module has one interface where it is connected to one ICU of the Interrupt Router module.

The DMA takes over the service request informations for the ICU, triggers internally the addressed channel and acknowledge it immediately to the ICU where the related SRN is cleared.

The DMA to ICU interface consists of a register set where it takes over the information of a service request provided by the ICU (SRPN, SRN Index, ECC), The DMA sends them back to the ICU in the next clock cycle with an acknowledge.

The DMA channel priority scheme is identical to the scheme of the interrupt system: higher SRPN number -> higher service request priority, higher DMA channel number -> higher priority of the DMA channels where channel 0 has the lowest priority within the DMA.

16.8.3 Software-Initiated Interrupts

Software can set the service request bit (SRR) in any SRN by writing to its Service Request Control Register. Thus, software can initiate service requests that are handled by the same mechanism as hardware initiated service requests.

After the SRR bit is set in an SRN, there is no way to distinguish between a software initiated service request and a hardware initiated service request. For this reason, software should only use SRNs and interrupt priority numbers that are not being used for hardware initiated service requests.

The TC21x/TC22x/TC23x contains groups of General Purpose Service Request SRNs per CPU that support software-initiated interrupts. One group per implemented TriCore CPU, each group including four SRNs. These SRNs are not connected to internal or external hardware trigger signals and can only be used as software interrupts / software initiated service requests. These SRNs are called General Purpose Service Requests Nodes (SRC_GPSRxy, x=group number, y=0-3).

Additionally, any otherwise unused SRN can be employed to generate software interrupts.

16.8.4 External Interrupts

Four SRNs (Int_SCUSRC[3:0]) are reserved to handle external interrupts. The setup for external GPIO port input signals (edge/level triggering, gating etc.) that are able to generate an interrupt request is controlled in the External Request Unit (ERU). The ERU functionality is described in detail in the SCU chapter.

16.9 Use Case Examples

This section shows a use case for the interrupt system and a use case for the OTGS.

16.9.1 Use Case Example Interrupt Handler

This section explains how to organize the TriCore interrupt vector table. When an interrupt is accepted by the TriCore, the entry address into the interrupt vector table is calculated by the base interrupt vector table pointer TriCore register BIV and the priority number of that interrupt (PIPN). The TriCore TC1.6P and TC1.6E architecture offers the possibility to configure the vector spacing per entry to either 32 Byte (see Figure below a (**Figure 16-6**) or 8 Byte (see Figure below b (**Figure 16-6**)). As a third option the vector table can be reduced to a single entry by masking the PIPN (see Figure below c (**Figure 16-6**)).

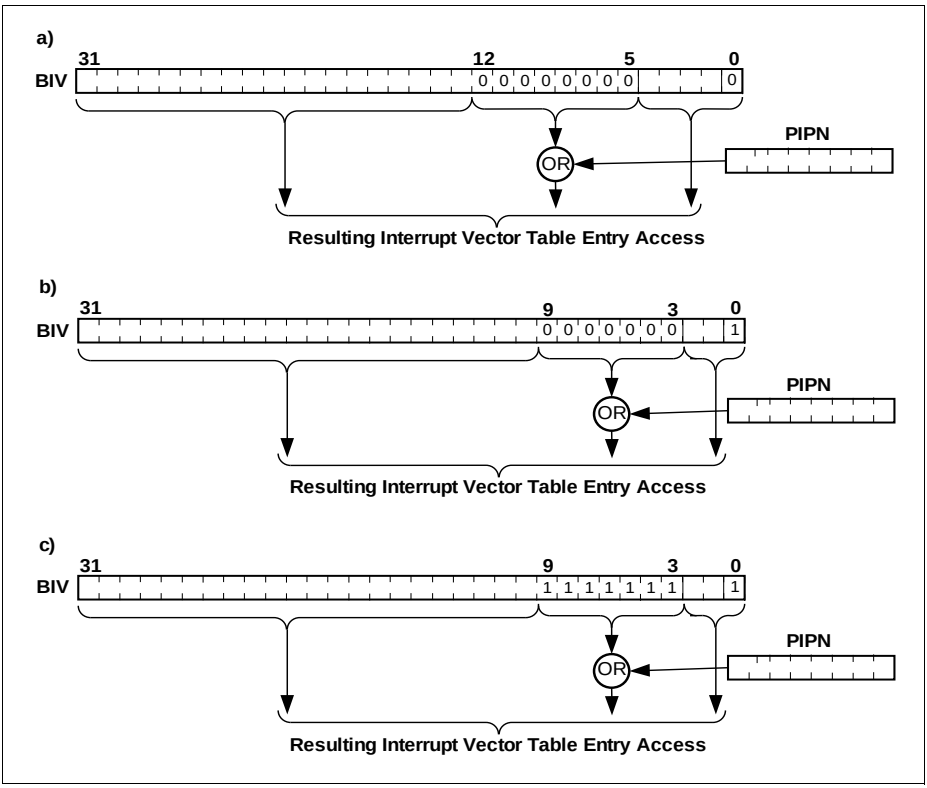

Figure 16-6 Interrupt Vector Table Address Calculation for a) 32 Byte b) 8 Byte vector entry or c) single entry

By using the 32 Byte configuration small interrupt routines can the implemented directly into the vector table. They can even span multiple vector entries (see also TriCore Architecture Manual). This type of fast interrupt handling is useful, if the vector table can

be located into the TriCore program side memory. The 8 Byte configuration reduces the vector table size. Each vector entry contains only a jump instruction or a call and return as 16-bit opcode instruction. The TriCore compiler supports this kind of interrupt vector table generation by keywords or functions. A minimum vector table can be configured if the BIV mask the PIPN so that any interrupt address calculation results in the same address. E.g.

```
__mtcr(BIV,0x80000001 | 0xFF<<3); // move to core register BIV
```

This configures the BIV register to use a common, single entry where a function interruptHandler is located to branch to the specific interrupt routine by using an array of function pointers. If a pointer to the array is used the array could be switched quickly.

Step description to initialize and install interrupts:

(Line 1) define ISR pointer array. Max. 255 interrupts possible.

(Line 2) define pointer which points to the start of the isr_pointer_array.

(Line 3) start of function interruptHandlerInstall. This function installs the interrupts in the array. Necessary information are the interrupt priority and ISR entry address.

(Line 4) This line stores the ISR entry address in the array.

(Line 5 and 6) This function branches to the specific interrupt routine and gets called immediately after an interrupt occurs.

(Line 7) This line gives the return command, after the ISR has been processed.

C Code Example to initialize and install interrupts:

```
(1) void (*isr_pointer_array[256])(void);
(2) void (**isr)(void) = isr_pointer_array;
(3) void interruptHandlerInstall(long int SRprio, long int addr){
(4) *isr_pointer_array[SRprio]=addr;
}
(5) void interruptHandler(void){
(6) isr[__mfcr(ICR) & 0xFF]();
(7) asm (" rfe");              // return from event
}
```

The interrupt entry addresses are stored in a data array instead of encoding the values into the instructions. The function interruptHandlerInstall organizes the installation of the interrupts in that array (see the application of this interrupt handler in a module e.g. use case example in STM chapter). This kind of vector table generation offers sometimes more flexibly than the 8 Byte configuration and does not require any specific compiler support for interrupts.

Note: Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit

(ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):
__enable();
to set this bit. (See also Architecture Manual for more details)

16.10 Module Implementation

16.10.1 Characteristics of TC21x/TC22x/TC23x Interrupt Router Module

The Interrupt Router module is implemented with the following characteristics:

- Number of clock cycles per arbitration process: 3
- Number of Interrupt Control Units (ICU): 1
- Number of General Purpose Service Request groups: 3

16.10.2 Mapping of TC21x/TC22x/TC23x Module Service Request Triggers to SRNs

All TC21x/TC22x/TC23x module service requests are mapped to one Service Request Node in the Interrupt Router.

Each SRN has one unique SRN Index Number within the Interrupt Router module.

The Interrupt Router module has one 511 interrupt trigger input vector where the interrupt trigger input vector bit [x] is related to the SRN with the SRN Index Number x[1)]. This means that a trigger pulse on interrupt trigger input vector bit [x] will trigger the SRN [x].

1) The Interrupt Router register overview table shows for all TC21x/TC22x/TC23x module service requests the SRC registers with its address offset and the related SRN Index number

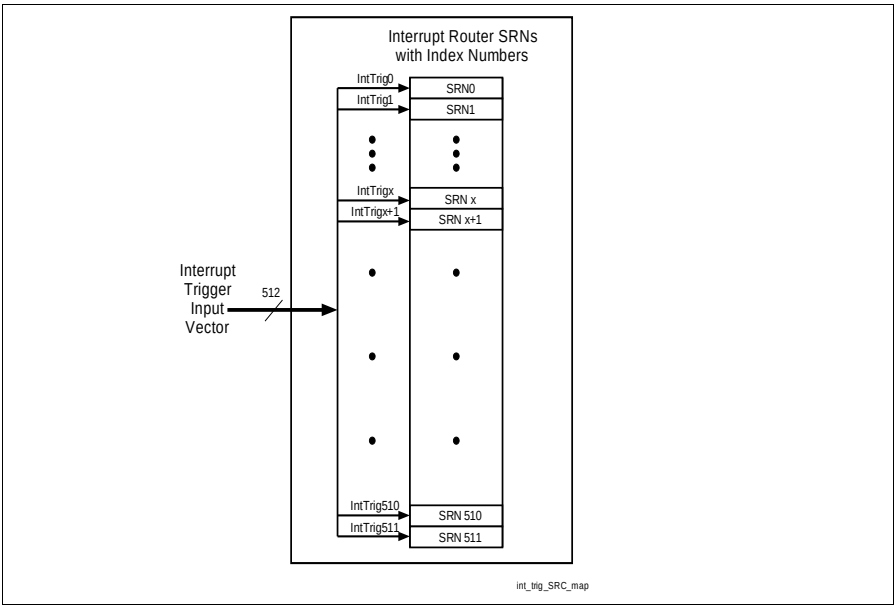

Figure 16-7 Mapping of Module Interrupt Trigger to SRN (Index Numbers)

16.10.2.1 Mapping of Service Request Control Registers

The address of SRC registers related to one module instance is identical over the whole AURIX family (e.g. interrupts of SPI0).

Each SRN has one unique SRN Index Number within the Interrupt Router module.

The number of the implemented SRNs for each AURIX device is adapted the devices feature set. All SRNs in an Interrupt Router module have consecutive Index Numbers (e.g.: if 256 SRNs are implemented, Index Numbers are 0 - 255). Each SRN has one unique SRN Index Number within the Interrupt Router module.

Example:

In a high end device with many modules/module instances SPI0 interrupts might be mapped to the SRNs with Index Numbers 180 to 185, related SRC can be accessed with address offset 0x2F0 to 0x2F5

In order to fulfill both requirements (same address for SPI0 related SRCs in all AURIX devices but reduced number of SRNs in smaller family devices with consecutive Index Numbers, the Interrupt Router module includes an address mapping shell (**Figure 16-8**). This address mapping shell re-maps the fixed SRC addresses of e.g. SPI0 of the above example to the SRN in the Interrupt Router module[1)].

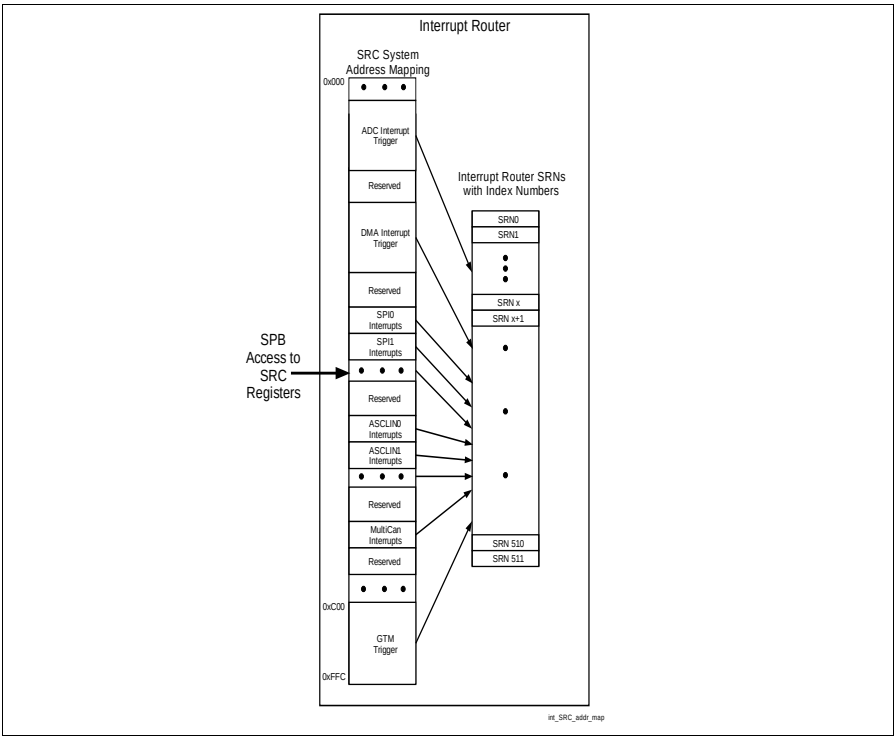

Figure 16-8 Mapping of SRC System Address to SRNs

16.10.2.2 Interrupts related to the Debug Reset

For software debug purposes the AURIX devices require some service request nodes related only to the Debug Reset. These SRNs keep its SRC register contents and the pending service request status in case of a non Debug Reset (e.g. an Application Reset). In combination with other debug reset related debug logic (e.g. breakpoint logic) this allows customer SW to debug situations that result in an application reset and after an application reset.

16.10.2.3 Timing characteristics of Service Request Trigger Signals

The Interrupt Router is clocked with the System Peripheral Bus (SPB) clock

Rules for the TC21x/TC22x/TC23x module interrupt / Service Request trigger signals to the IR:

- Trigger signals must be synchronous to SPB clock

- IR trigger inputs are edge sensitive (positive clock edge)
- Trigger signal pulse with min. high length of one SPB clock cycle, high pulse length can be > 1 SPB clock cycle
- Debug related trigger signal pulse should be kept high by the related TC21x/TC22x/TC23x module until the trigger was processed

16.11 Interrupt Router System and Module Registers

Figure 16-9 shows all registers associated with the Interrupt Router module in the TC21x/TC22x/TC23x device. The Interrupt Router allocates two address ranges:

- 2 * 256 byte address range covering the Interrupt Router system registers, ICU control registers and OTGM registers (**Table 16-1**)
- 8 KByte address range covering the Service Request Control registers (**Table 16-3**)

List of used Reset Class abbreviations

- Reset Class 1 -> Debug Reset (see description in the chapter SCU / Reset Types)
- Reset Class 3 -> Application Reset (see description in the chapter SCU / Reset Types)

List of used Access Protection Register abbreviations

- P0 -> ACCEN01/00, write protects bits [31:16] of all implemented SRC registers (SRC_xxx[31:16]).
- P1 -> ACCEN11/10, write protects bits [15:0] of all implemented SRC registers (SRC_xxx[15:0]) and the implemented ICUx Error Capture registers (INT_ECRx)

Note: A violation of the access protection will not be executed (e.g. a write to a ´Px´/ACCEN protected register from a disabled master). In this case an access protection error is signaled to the SMU. Beside this signaling to the SMU, no other error, interrupt or trap is generated.

Interrupt Router Module Registers

-	Reserved	$13C_{H-FFFH}$	U, SV	BE	-	-

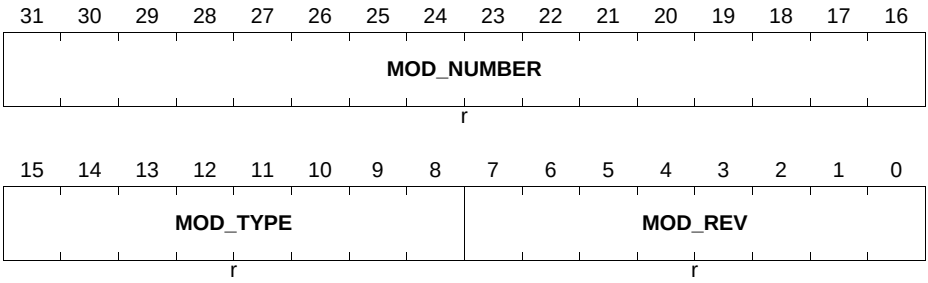
Note: Register bits marked “r” in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

16.11.1 System and ICU Control Registers

Module Identification Register (ID)

Interrupt Router Module Identification Register.

INT_ID
Module Identification Register **(008_H)** **Reset Value: 00B9 C0XX$_H$**



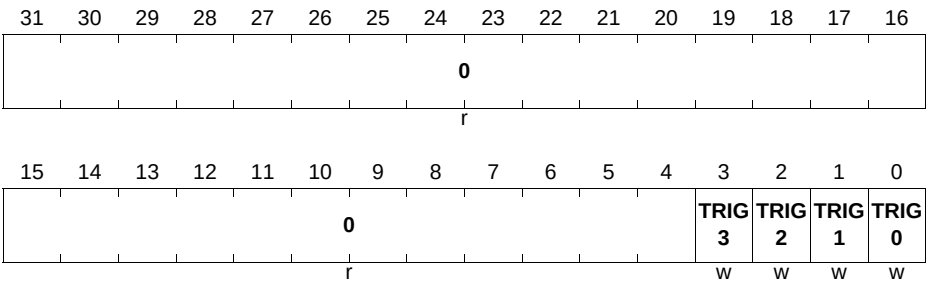
Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to C0H which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the Interrupt Router module is 0087H.

Service Request Broadcast Register (SRB0)

Interrupt Service Request Broadcast Register can be used to trigger multiple Service Requests of a General Purpose Service Request Group in parallel.

INT_SRB0

Service Request Broadcast Register 0(010_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TRIG0	0	w	**General Purpose Service Request Trigger 0** Writing with ´1´ SRBx.TRIG0 triggers the General Purpose Service Request 0 in group x (GPSRx0). Writing with 0 has no effect. This bit is always read as 0.
TRIG1	1	w	**General Purpose Service Request Trigger 1** Writing with ´1´ SRBx.TRIG1 triggers the General Purpose Service Request 0 in group x (GPSRx1). Writing with 0 has no effect. This bit is always read as 0.
TRIG2	2	w	**General Purpose Service Request Trigger 2** Writing with ´1´ SRBx.TRIG2 triggers the General Purpose Service Request 0 in group x (GPSRx2). Writing with 0 has no effect. This bit is always read as 0.
TRIG3	3	w	**General Purpose Service Request Trigger 3** Writing with ´1´ SRBx.TRIG3 triggers the General Purpose Service Request 0 in group x (GPSRx3). Writing with 0 has no effect. This bit is always read as 0.
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.

Access Enable Register 0 (ACCEN00/10)

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The registers ACCEN00 / ACCEN01 are providing one enable bit for each 6-bit On Chip Bus Master TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... ,EN31 -> TAG ID 011111B.

INT_ACCEN00
Access Enable Register 0 ($0F4_H$) Reset Value: FFFF FFFF$_H$
INT_ACCEN10
Kernel 1 Access Enable Register 0 ($0FC_H$) Reset Value: FFFF FFFF$_H$

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

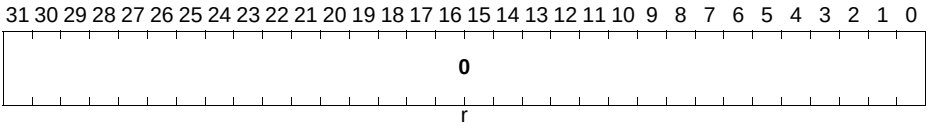
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1 (ACCEN11/01)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). ACCEN11/01 are not implemented with register bits as the related On Chip Bus Master TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... ,EN31 -> TAG ID 111111B.

INT_ACCEN01
Kernel 0 Access Enable Register 1 ($0F0_H$) Reset Value: $0000\ 0000_H$
INT_ACCEN11
Kernel 1 Access Enable Register 1 ($0F8_H$) Reset Value: $0000\ 0000_H$

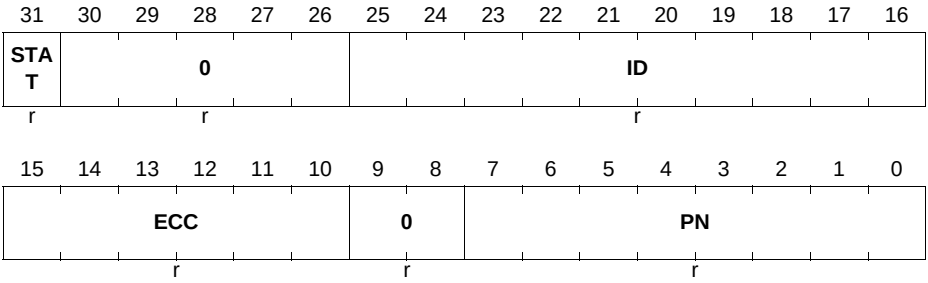


Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Latest Winning Service Request (LWSR)

The Latest Winning Service Request register provides informations about the winner of the last arbitration round. The register bit fields are representing what is provided by the ICU to the Interrupt Service Provider.

INT_LWSRx (x = 0-1)
Latest Winning Service Request Register x (100_H+x*10_H) Reset Value: $0000\ 0000_H$



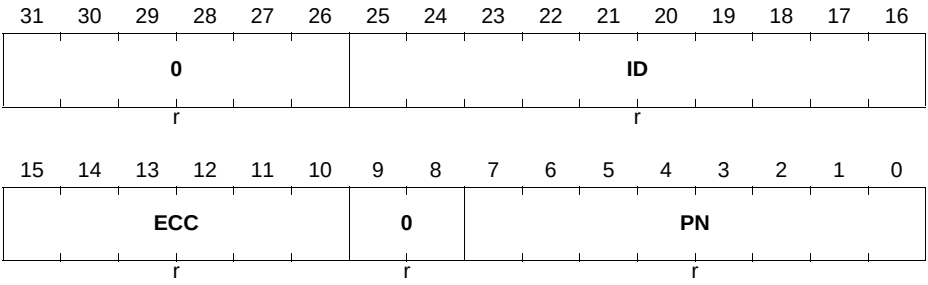
Field	Bits	Type	Description
PN	[7:0]	r	**Latest Winner Priority Number** This bit field shows the Priority Number of a pending service request that won the last arbitration round. This bit field is only valid if STAT is set to 1

Field	Bits	Type	Description
ECC	[15:10]	r	**Latest Winner ECC** This bit field shows the ECC field (SRN.ECC) that was transferred from the last winning SRN to the ICU. This bit field is only valid if STAT is set to 1.
ID	[25:16]	r	**Latest Winner Index Number** This bit field shows the index number of the last winning SRN. This bit field is only valid if STAT is set to 1
STAT	31	r	**LWSR Register Status** The STAT register indicates if the PN, ECC and ID bit fields are still valid. They are still valid if the interrupt from the SRN identified by ID is still pending. If the ICU does not have an winner because no interrupt is pending or not yet arbitrated than it clears the STAT bit. 0_B LWSR bit fields are not valid 1_B LWSR bit fields are valid
0	[30:26], [9:8]	r	**Reserved** Read as 0; should be written with 0.

Last Acknowledged Service Request (LASR)

The Last Acknowledged Service Request register provides informations about the last service request that was acknowledged by the Interrupt Service Provider. The register bit fields are representing what was sent by the Interrupt Service Provider together with the latest acknowledge.

INT_LASRx (x = 0-1)
Last Acknowledged Service Request Register x (104_H+x*10_H) **Reset Value: 0000 0000_H**

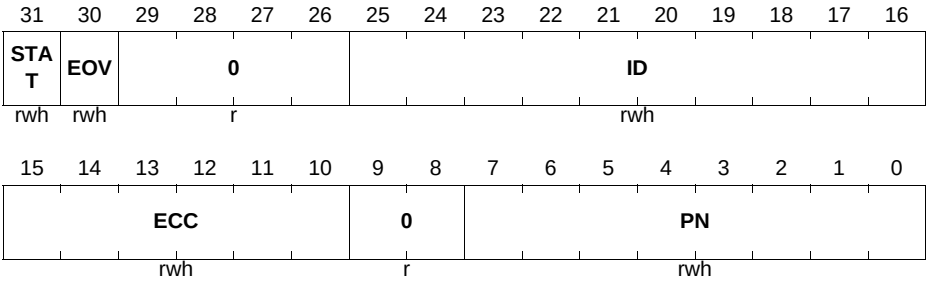


Field	Bits	Type	Description
PN	[7:0]	r	**Last Acknowledged Service Request Priority Number** This bit field shows the Priority Number of the last acknowledged service request
ECC	[15:10]	r	**Last Acknowledged Interrupt ECC** This bit field shows the ECC value of the last acknowledged service request, as send by the service provider with acknowledge
ID	[25:16]	r	**Last Acknowledged Interrupt SRN Index Number** This bit field shows the index number of the SRN, related to the last acknowledged service request, as send by the service provider with acknowledge
0	[31:26], [9:8]	r	**Reserved** Read as 0; should be written with 0.

Error Capture Register (ECR)

The Error Capture Register captures the Last Acknowledged Service Request (LASR) register contents when an ECC error was detected by the ICU. The ECR shows always the last ECR contents where an ECC error was detected. Software can clear the ECR contents by writing to the ECR.

INT_ECRx (x = 0-1)
Error Capture Register x **(108_H+x*10_H)** **Reset Value: 0000 0000_H**



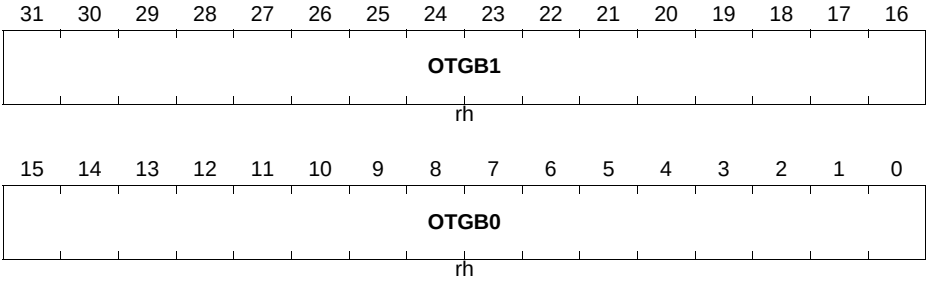
Field	Bits	Type	Description
PN	[7:0]	rwh	**Service Request Priority Number** This bit field shows the priority number of the last service request where an error was detected. Bit field can be modified by writing to it.
ECC	[15:10]	rwh	**Service Request ECC** This bit field shows the ECC of the last service request where an error was detected. Bit field can be modified by writing to it.
ID	[25:16]	rwh	**Service Request Node Index Number** This bit field shows the index number of the last service request where an error was detected. Bit field can be modified by writing to it
EOV	30	rwh	**Error Overflow Bit** The bit is set if an ECC error was detected by the ICU while ECR.STAT=´1´ (Error Overflow situation). 0_B No Error Overflow situation detected 1_B Error Overflow situation detected This bit can be cleared by writing with 1. Writing with 0 has no effect. If this bit is cleared, it must be cleared together with the STAT bit.
STAT	31	rwh	**Error Status Bit** The Error Status Bit is set whenever an ECC was detected by the ICU. 0_B No ECC error detected 1_B ECC error detected This bit can be cleared by writing with 1. Writing with 0 has no effect.
0	[29:26], [9:8]	r	**Reserved** Read as 0; should be written with 0.

16.12 OTGM Registers

All OTGM registers are cleared by Debug Reset and by each System Reset when OCDS is disabled. They are not touched by System Reset when OCDS is enabled.
Write access is 32 bit wide only and requires Supervisor Mode and OCDS enabled.

16.12.1 Status and Control

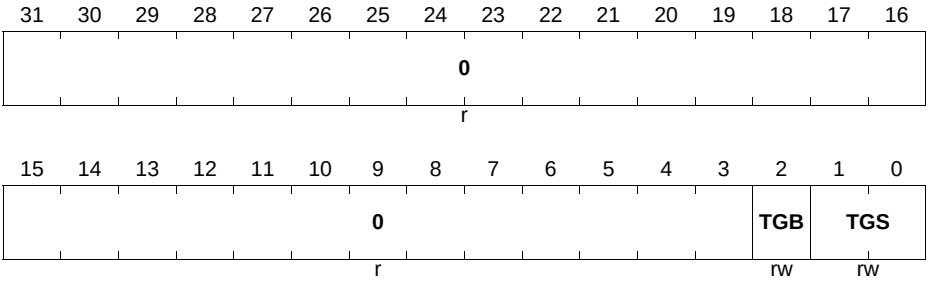
INT_OOBS
OTGM OTGB0/1 Status **(80_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
OTGB0	[15:0]	rh	**Status of OTGB0**
OTGB1	[31:16]	rh	**Status of OTGB1**

Note: OTGB0/1 value is sampled not captured. A capture register is available in OTGS.

INT_OSSIC
OTGM SSI Control **(84_H)** **Reset Value: 0000 0000$_H$**



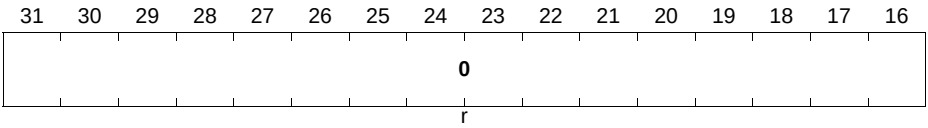
Field	Bits	Type	Description
TGS	[1:0]	rw	**Trigger Set for OTGB0/1** 0_H No Trigger Set output 1_H Trigger Set TS16_SSI (**Table 1-1**) **others**, reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1

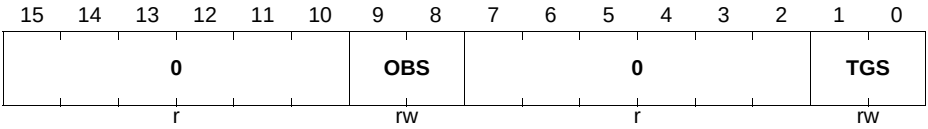
Field	Bits	Type	Description
0	[31:3]	r	**Reserved** Read as 0; must be written with 0.

16.12.2 IRQ MUX Control

INT_OIXTS

OTGM IRQ MUX Trigger Set Select (88_H) Reset Value: 0000 0000$_H$

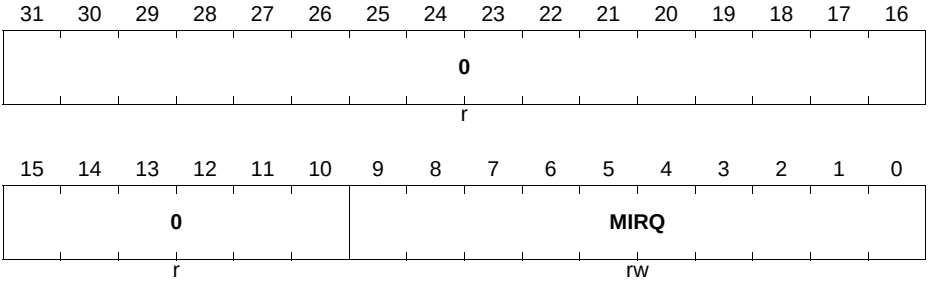




Field	Bits	Type	Description
TGS	[1:0]	rw	**Trigger Set Select for OTGB0/1 Overlay** 0_D No overlay 1_D Trigger Set TS8_IS (**Table 1-2**) 2_D Trigger Set TS8_SPA (**Table 1-3**) 3_D reserved
OBS	[9:8]	rw	**Overlay Byte Select** 0_D OTGB0 [7:0] 1_D OTGB0 [15:8] 2_D OTGB1 [7:0] 3_D OTGB1 [15:8]
0	[7:2], [31:10]	r	**Reserved** Read as 0; must be written with 0.

INT_OIXMS

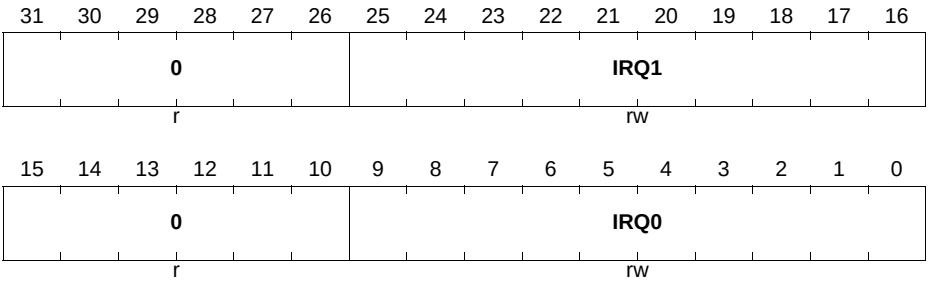
OTGM IRQ MUX Missed IRQ Select ($8C_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
MIRQ	[9:0]	rw	**SRN Index for Missed Interrupt Trigger**
0	[31:10]	r	**Reserved** Read as 0; must be written with 0.

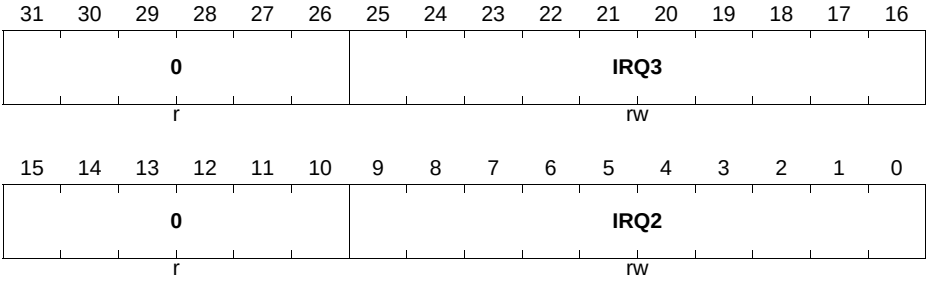
INT_OIXS0

OTGM IRQ MUX Select 0 (90_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
IRQ0	[9:0]	rw	**SRN Index for Interrupt Trigger 0**
IRQ1	[25:16]	rw	**SRN Index for Interrupt Trigger 1**
0	[31:26], [15:10]	r	**Reserved** Read as 0; must be written with 0.

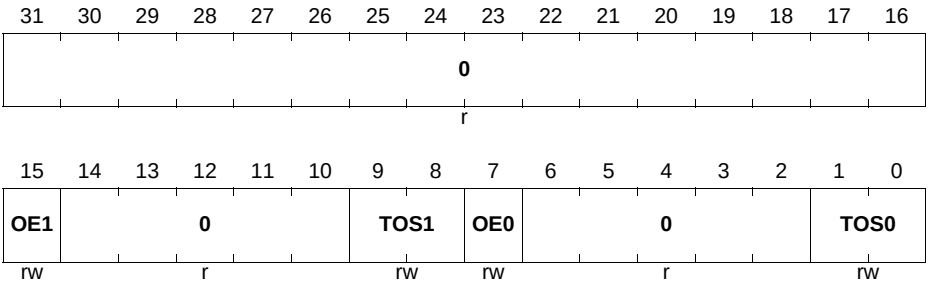
INT_OIXS1
OTGM IRQ MUX Select 1 **(94_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
IRQ2	[9:0]	rw	**SRN Index for Interrupt Trigger 2**
IRQ3	[25:16]	rw	**SRN Index for Interrupt Trigger 3**
0	[31:26], [15:10]	r	**Reserved** Read as 0; must be written with 0.

16.12.3 Interrupt System Trace

INT_OIT
OTGM IRQ Trace **($A0_H$)** **Reset Value: 0000 0000$_H$**

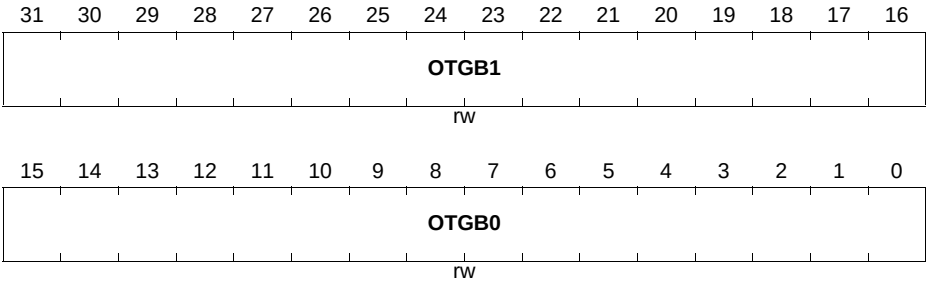


Field	Bits	Type	Description
TOS0	[1:0]	rw	**Type of Service for Observation on OTGB0** Trigger Set TS16_SP (**Table 1-4**) 0_D CPU0 service is observed 1_D DMA service is observed 2_D CPU0 service is observed 3_D DMA service is observed Compatible with SRC.TOS and with TC26/7/9x devices
OE0	7	rw	**Output Enable for OTGB0** 0_B Disabled 1_B Enabled
TOS1	[9:8]	rw	**Type of Service for Observation on OTGB1** Trigger Set TS16_SP (**Table 1-4**) 0_D CPU0 service is observed 1_D DMA service is observed 2_D CPU0 service is observed 3_D DMA service is observed Compatible with SRC.TOS and with TC26/7/9x devices
OE1	15	rw	**Output Enable for OTGB1** 0_B Disabled 1_B Enabled
0	[6:2], [14:10], [31:16]	r	**Reserved** Read as 0; must be written with 0.

16.12.4 MCDS Interface

INT_OMISP

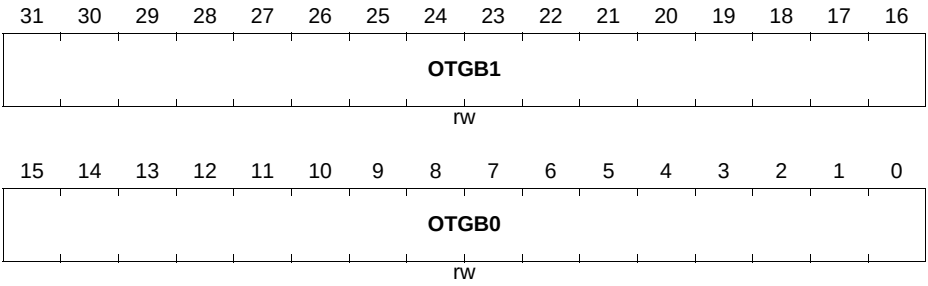
OTGM MCDS I/F Sensitivity Posedge ($A4_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
OTGB0	[15:0]	rw	**Bitwise Posedge Sensitivity for OTGB0** If a bit is set an OTGB value will be written to MCDS on a rising edge of the associated OTGB0 bit.
OTGB1	[31:16]	rw	**Bitwise Posedge Sensitivity for OTGB1** If a bit is set an OTGB value will be written to MCDS on a rising edge of the associated OTGB1 bit.

INT_OMISN

OTGM MCDS I/F Sensitivity Negedge (A8$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
OTGB0	[15:0]	rw	**Bitwise Negedge Sensitivity for OTGB0** If a bit is set an OTGB value will be written to MCDS on a falling edge of the associated OTGB0 bit.
OTGB1	[31:16]	rw	**Bitwise Negedge Sensitivity for OTGB1** If a bit is set an OTGB value will be written to MCDS on a falling edge of the associated OTGB1 bit.

16.13 Interrupt Router SRC Registers

Figure 16-9 shows all registers associated with the Interrupt Router module in the TC21x/TC22x/TC23x device. This chapter describes the Service Request Control registers including:

- Mapping of AURIX module interrupt triggers to SRC
- SRC offsets
- SRN Index numbers

List of used Reset Class abbreviations

- Reset Class 1 -> Debug Reset (see description in the chapter SCU / Reset Types)
- Reset Class 3 -> Application Reset (see description in the chapter SCU / Reset Types)

List of used Access Protection Register abbreviations

- P0 -> ACCEN01/00, write protects bits [31:16] of all implemented SRC registers (SRC_xxx[31:16]).
- P1 -> ACCEN11/10, write protects bits [15:0] of all implemented SRC registers (SRC_xxx[15:0]) and the implemented ICUx Error Capture registers (INT_ECRx)

Note: A violation of the access protection will not be executed (e.g. a write to a ´Px´/ACCEN protected register from a disabled master). In this case an access protection error is signaled to the SMU. Beside this signaling to the SMU, no other error, interrupt or trap is generated.

17 System Timer (STM)

This chapter describes the System Timer (STM). The TC21x/TC22x/TC23x's STM is designed for global system timing applications requiring both high precision and long period.

17.1 Overview

The STM has the following features:

- Free-running 64-bit counter
- All 64 bits can be read synchronously
- Different 32-bit portions of the 64-bit counter can be read synchronously
- Flexible service request generation based on compare match with partial STM content
- Counting starts automatically after an Application Reset
- STM registers are reset by an Application Reset if bit ARSTDIS.STMxDIS is cleared. If bit ARSTDIS.STMxDIS is set, the STM registers are not reset.

Special STM register semantics provide synchronous views of the entire 64-bit counter, or 32-bit subsets at different levels of resolution.

17.2 Operation

The STM is an upward counter, running at frequency f_{STM}. In case of an Application Reset, the STM is reset if bit SCU_ARSTDIS.STMxDIS is cleared. After reset, the STM is enabled and immediately starts counting up. It is not possible to affect the content of the timer during normal operation. The timer registers can only be read but not written to.

The STM can be optionally disabled for power-saving purposes, or suspended for debugging purposes. In suspend mode, the STM clock is stopped but all registers are still readable.

Due to the 64-bit width of the STM, it is not possible to read its entire content with one instruction. It needs to be read with two load instructions. Since the timer would continue to count between the two load operations, there is a chance that the two values read are not consistent (due to possible overflow from the low part of the timer to the high part between the two read operations). To enable a synchronous and consistent reading of the STM content, a capture register (CAP) is implemented. It latches the content of the high part of the STM each time when one of the registers TIM0 to TIM5 is read. Thus, CAP holds the upper value of the timer at exactly the same time when the lower part is read. The second read operation would then read the content of the CAP to get the complete timer value.

The STM can also be read in sections from seven registers, TIM0 through TIM6, that select increasingly higher-order 32-bit ranges of the STM. These can be viewed as individual 32-bit timers, each with a different resolution and timing range.

The content of the 64-bit System Timer can be compared against the content of two compare values stored in the CMP0 and CMP1 registers. Service requests can be generated on a compare match of the STM with the CMP0 or CMP1 registers.

Figure 17-1 provides an overview on the STM module. It shows the options for reading parts of the STM content.

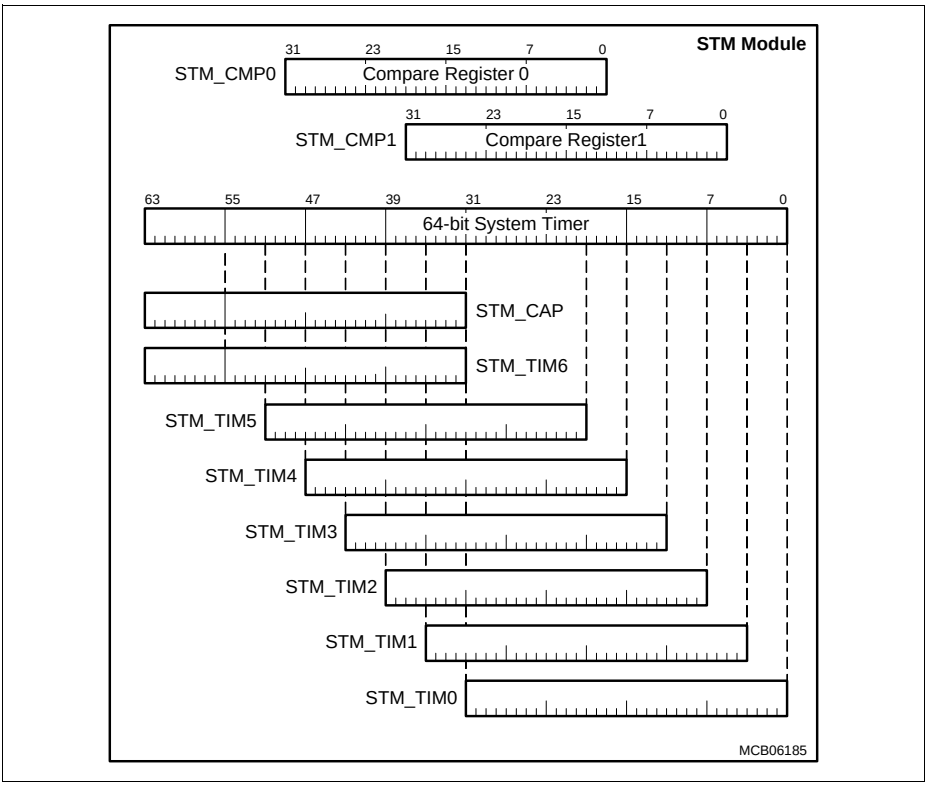

Figure 17-1 General Block Diagram of the STM Module

17.2.1 Compare Register Operation

The content of the 64-bit STM can be compared against the content of two compare values stored in the CMP0 and CMP1 registers. Service requests can be generated on a compare match of the STM with the CMP0 or CMP1 registers.

Two parameters are programmable for the compare operation:

1. The width of the relevant bits in registers CMP0/CMP1 (compare width MSIZEx) that is taken for the compare operation can be programmed from 0 to 31.
2. The first bit location in the 64-bit STM that is taken for the compare operation can be programmed from 0 to 31.

These programming capabilities make compare functionality very flexible. It even makes it possible to detect bit transitions of a single bit n (n = 0 to 31) within the 64-bit STM by setting MSIZE = 0 and MSTART = n.

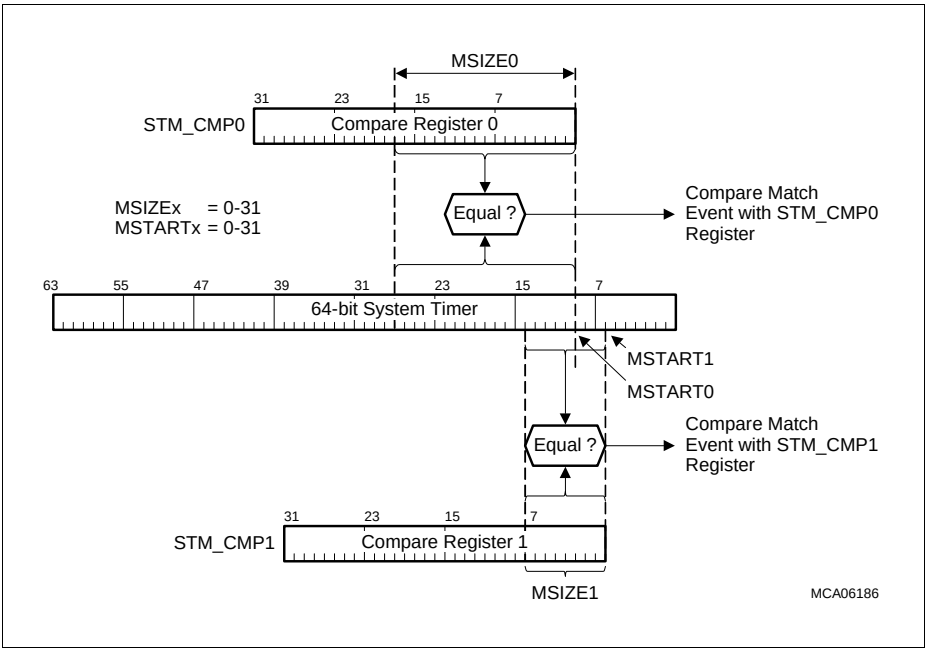

Figure 17-2 Compare Mode Operation

Figure 17-2 shows an example of the compare operation. In this example the following parameters are programmed:

- MSIZE0 = 10001_B = 17_D; MSTART0 = 01010_B = 10_D
- MSIZE1 = 00111_B = 7_D; MSTART1 = 00111_B = 7_D

A compare operation with MSIZE not equal 11111_B always implies that the compared value as stored in the CMP register is right-extended with zeros. This means that in the example of **Figure 17-2**, the compare register content CMP0[17:0] plus ten zero bits right-extended is compared with STM[27:0] with STM[9:0] = 000_H. In case of register CMP1, STM[14:0] with STM[6:0] = 00_H are compared with CMP1[9:0] plus seven zero bits right-extended.

17.2.2 Compare Match Interrupt Control

The compare match interrupt control logic is shown in **Figure 17-3**. Each CMPx register has its compare match interrupt request flag (ICR.CMPxIR) that is set by hardware on a compare match event. The interrupt request flags can be set (ISSR.CMPxIRS) or cleared (ISSR.CMPxIRR) by software. Note that setting ICR.CMPxIR by writing a 1 into ISSR.CMPxIRS does not generate an interrupt at STMIRx. The compare match interrupts from CMP0 and CMP1 can be further directed by ICR.CMPxOS to either output signal STMIR0 or STMIR1.

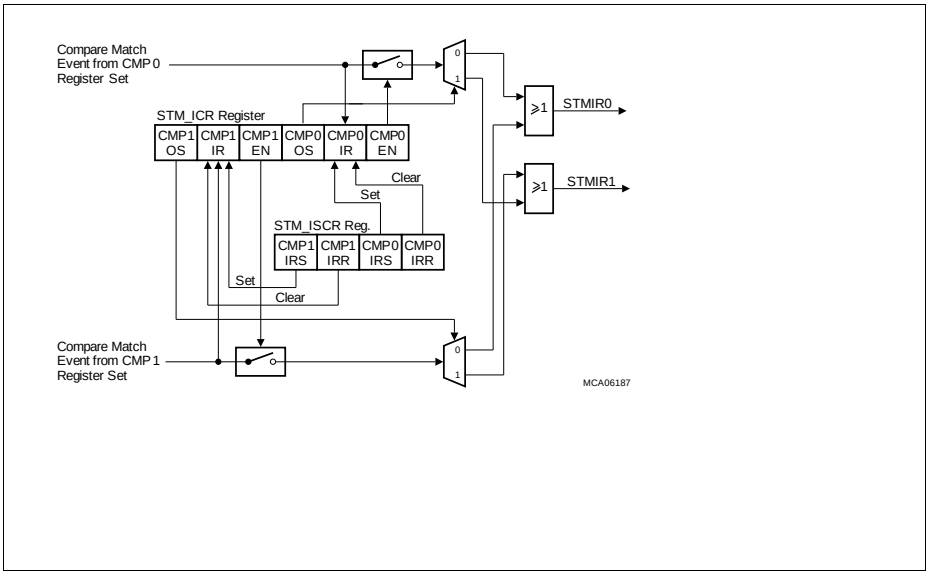

Figure 17-3 STM Interrupt Control

The compare match interrupt flags ICR.CMPxIR are immediately set after an STM reset operation, caused by a compare match event with the reset values of the STM and the compare registers CMPx. This setting of the CMPxIR flags does not directly generate compare match interrupts because the compare match interrupts are automatically disabled after a STM reset operation (CMPxEN = 0). Therefore, before enabling a

compare match interrupt after a STM Application Reset, the CMPxIR flags should be cleared by software (writing register ISSR with CMPxIRR set). Otherwise, undesired compare match interrupt events are triggered.

17.2.3 STM as Reset Trigger

A compare match triggered by an CMP0 event can generate a reset in the system. The reset has to be enable for each STM module individually in register SCU_RSTCON.

17.3 STM Registers

This section describes the STM registers of the STM.

Table 17-1 Registers Address Space

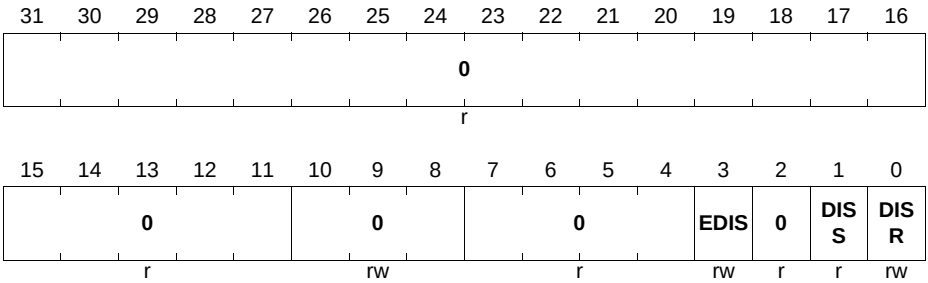
1) These registers are reset by an application reset if bit ARSTDIS.STMxDIS is cleared.

17.3.1 Clock Control Register

The STM clock control register is used to switch the STM on or off and to control its input clock rate. After reset, the STM is always enabled and starts counting. The STM can be disabled by setting bit DISR to 1.

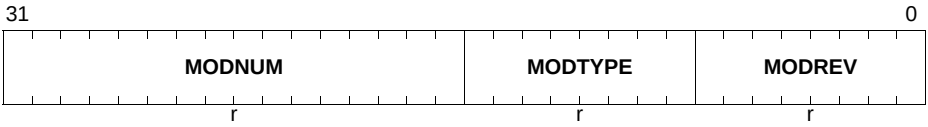
CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the STM module. 0_B No disable requested 1_B Disable requested *Note: f_{STM} is generated by the CCU.*
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the STM module. 0_B STM module is enabled 1_B STM module is disabled
EDIS	3	rw	**Sleep Mode Enable Control** Used for module sleep mode control.
0	[10:8]	rw	**Reserved** Should be written with 0.
0	2, [7:4], [31:11]	r	**Reserved** Read as 0; should be written with 0.

The STM Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(08_H)** **Reset Value: 0000 C0XX$_H$**



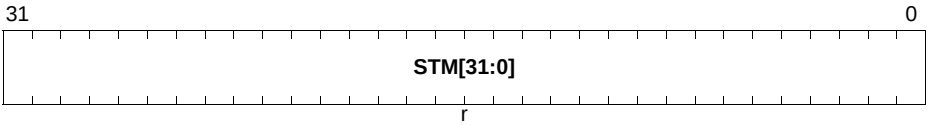
Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the STM: 0000_H

17.3.2 Timer/Capture Registers

Registers TIM0 to TIM6 provide 32-bit views at varying resolutions of the underlying STM counter.

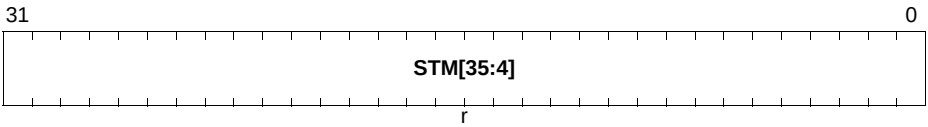
Register TIM0SV address the STM[31:0] bits at a second optional address as TIM0.

TIM0
Timer Register 0 **(10_H)** **Reset Value: $0000\ 0000_H$**
TIM0SV
Timer Register 0 Second View **(50_H)** **Reset Value: $0000\ 0000_H$**



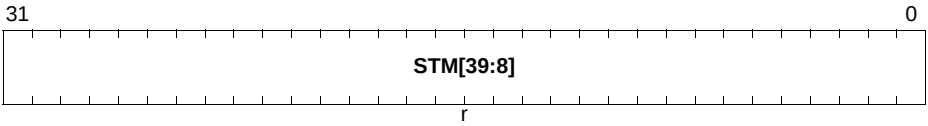
Field	Bits	Type	Description
STM[31:0]	[31:0]	r	**System Timer Bits [31:0]** This bit field contains bits [31:0] of the 64-bit STM.

TIM1
Timer Register 1 **(14_H)** **Reset Value: $0000\ 0000_H$**



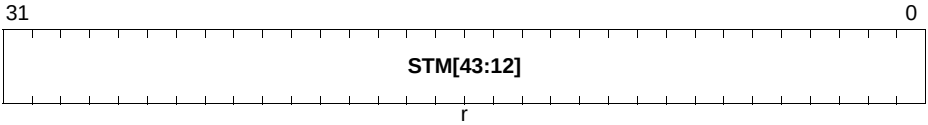
Field	Bits	Type	Description
STM[35:4]	[31:0]	r	**System Timer Bits [35:4]** This bit field contains bits [35:4] of the 64-bit STM.

TIM2
Timer Register 2 **(18_H)** **Reset Value: 0000 0000$_H$**



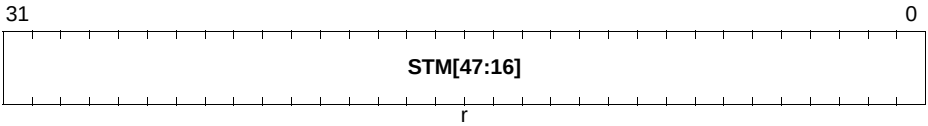
Field	Bits	Type	Description
STM[39:8]	[31:0]	r	**System Timer Bits [39:8]** This bit field contains bits [39:8] of the 64-bit STM.

TIM3
Timer Register 3 **($1C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
STM[43:12]	[31:0]	r	**System Timer Bits [43:12]** This bit field contains bits [43:12] of the 64-bit STM.

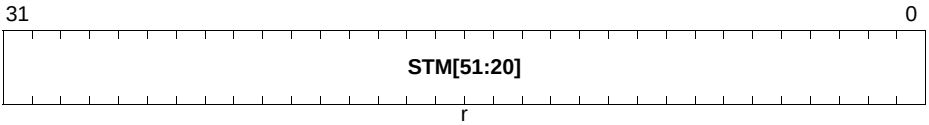
TIM4
Timer Register 4 **(20_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
STM[47:16]	[31:0]	r	**System Timer Bits [47:16]** This bit field contains bits [47:16] of the 64-bit STM.

TIM5

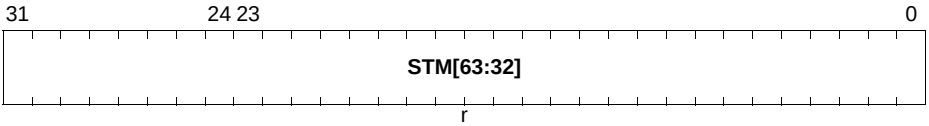
Timer Register 5 **(24_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
STM[51:20]	[31:0]	r	**System Timer Bits [51:20]** This bit field contains bits [51:20] of the 64-bit STM.

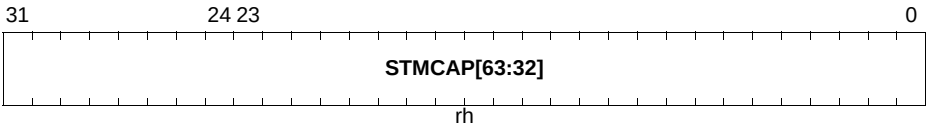
TIM6

Timer Register 6 **(28_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
STM[63:32]	[31:0]	r	**System Timer Bits [63:32]** This bit field contains bits [63:32] of the 64-bit STM.

CAP
Timer Capture Register ($2C_H$) Reset Value: 0000 0000$_H$
CAPSV
Timer Capture Register Second View (54_H) Reset Value: 0000 0000$_H$

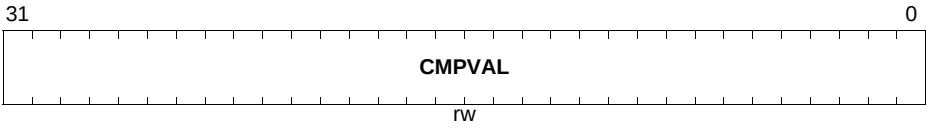


Field	Bits	Type	Description
STMCAP[63:32]	[31:0]	rh	**Captured System Timer Bits [63:32]** The capture register STMCAP always captures the STM bits [63:32] when one of the registers TIM0 to TIM5 and TIM0SV is read. This capture operation is performed in order to enable software to operate with a coherent value of all the 64 STM bits at one time stamp.This bit field contains bits [63:32] of the 64-bit STM. *Note: Reading register TIM0SV capture also the read value for register TIM6. In this way reading TIM0SV followed by CAP6SV delivers the timer values for the first read request.*

17.3.3 Compare Registers

The compare register CMPx holds up to 32-bits; its value is compared to the value of the STM.

CMPx (x = 0-1)
Compare Register x (30_H+x*4_H) Reset Value: 0000 0000$_H$

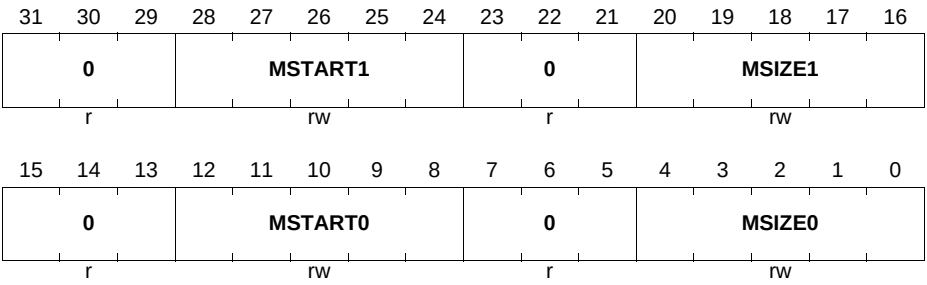


Field	Bits	Type	Description
CMPVAL	[31:0]	rw	**Compare Value of Compare Register x** This bit field holds up to 32 bits of the compare value (right-adjusted).

The STM Compare Match Control Register controls the parameters of the compare logic.

CMCON
Compare Match Control Register

(38_H) **Reset Value: $0000\ 0000_H$**



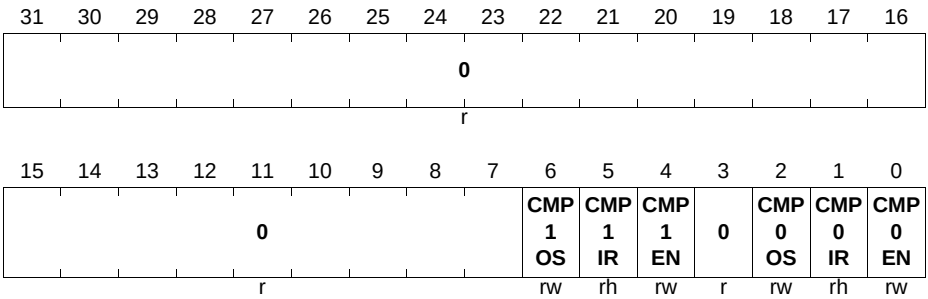
Field	Bits	Type	Description
MSIZE0	[4:0]	rw	**Compare Register Size for CMP0** This bit field determines the number of bits in register CMP0 (starting from bit 0) that are used for the compare operation with the System Timer. 00000_B CMP0[0] used for compare operation 00001_B CMP0[1:0] used for compare operation ... 11110_B CMP0[30:0] used for compare operation 11111_B CMP0[31:0] used for compare operation
MSTART0	[12:8]	rw	**Start Bit Location for CMP0** This bit field determines the lowest bit number of the 64-bit STM that is compared with the content of register CMP0 bit 0. The number of bits to be compared is defined by bit field MSIZE0. 00000_B STM[0] is the lowest bit number 00001_B STM[1] is the lowest bit number ... 11110_B STM[30] is the lowest bit number 11111_B STM[31] is the lowest bit number

Field	Bits	Type	Description
MSIZE1	[20:16]	rw	**Compare Register Size for CMP1** This bit field determines the number of bits in register CMP1 (starting from bit 0) that are used for the compare operation with the System Timer. 00000_B CMP1[0] used for compare operation 00001_B CMP1[1:0] used for compare operation ... 11110_B CMP1[30:0] used for compare operation 11111_B CMP1[31:0] used for compare operation
MSTART1	[28:24]	rw	**Start Bit Location for CMP1** This bit field determines the lowest bit number of the 64-bit STM that is compared with the content of register CMP1 bit 0. The number of bits to be compared is defined by bit field MSIZE1. 00000_B STM[0] is the lowest bit number 00001_B STM[1] is the lowest bit number ... 11110_B STM[30] is the lowest bit number 11111_B STM[31] is the lowest bit number
0	[7:5], [15:13], [23:21], [31:29]	r	**Reserved** Read as 0; should be written with 0.

17.3.4 Interrupt Registers

The two compare match interrupts of the STM are controlled by the STM Interrupt Control Register.

ICR
Interrupt Control Register **($3C_H$)** **Reset Value: 0000 0000$_H$**

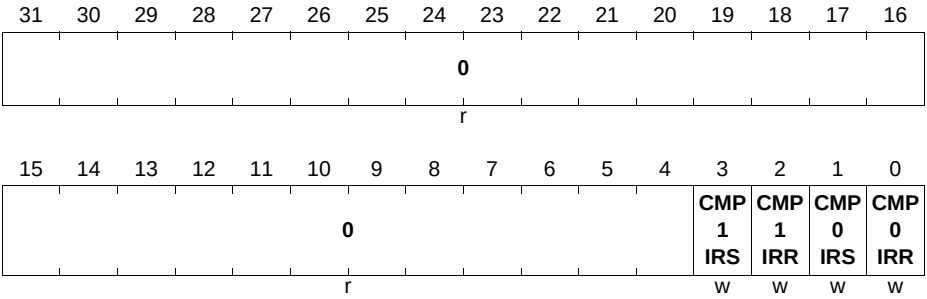


Field	Bits	Type	Description
CMP0EN	0	rw	**Compare Register CMP0 Interrupt Enable Control** This bit enables the compare match interrupt with compare register CMP0. 0_B Interrupt on compare match with CMP0 disabled 1_B Interrupt on compare match with CMP0 enabled
CMP0IR	1	rh	**Compare Register CMP0 Interrupt Request Flag** This bit indicates whether or not a compare match interrupt request of compare register CMP0 is pending. CMP0IR must be cleared by software. 0_B A compare match interrupt has not been detected since the bit has been cleared for the last time. 1_B A compare match interrupt has been detected. CMPIR0 must be cleared by software and can be set by software, too (see CMPISCR register). After a STM reset operation, CMP0IR is immediately set as a result of a compare match event with the reset values of the STM and the compare registers CMP0.

Field	Bits	Type	Description
CMP0OS	2	rw	**Compare Register CMP0 Interrupt Output Selection** This bit determines the interrupt output that is activated on a compare match event of compare register CMP0. 0_B Interrupt output STMIR0 selected 1_B Interrupt output STMIR1 selected
CMP1EN	4	rw	**Compare Register CMP1 Interrupt Enable Control** This bit enables the compare match interrupt with compare register CMP1. 0_B Interrupt on compare match with CMP1 disabled 1_B Interrupt on compare match with CMP1 enabled
CMP1IR	5	rh	**Compare Register CMP1 Interrupt Request Flag** This bit indicates whether or not a compare match interrupt request of compare register CMP1 is pending. CMP1IR must be cleared by software. 0_B A compare match interrupt has not been detected since the bit has been cleared for the last time. 1_B A compare match interrupt has been detected. CMPIR1 must be cleared by software and can be set by software, too (see CMPISCR register). After a STM reset, CMP1IR is immediately set as a result of a compare match event with the reset values of the STM and the compare register CMP1.
CMP1OS	6	rw	**Compare Register CMP1 Interrupt Output Selection** This bit determines the interrupt output that is activated on a compare match event of compare register CMP1. 0_B Interrupt output STMIR0 selected 1_B Interrupt output STMIR1 selected
0	3, [31:7]	r	**Reserved** Read as 0; should be written with 0.

The bits in the STM Interrupt Set/Clear Register make it possible to set or cleared the compare match interrupt request status flags of register ICR.

ISCR
Interrupt Set/Clear Register **(40_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CMP0IRR	0	w	**Reset Compare Register CMP0 Interrupt Flag** 0_B Bit ICR.CMP0IR is not changed. 1_B Bit ICR.CMP0IR is cleared.
CMP0IRS	1	w	**Set Compare Register CMP0 Interrupt Flag** 0_B Bit ICR.CMP0IR is not changed. 1_B Bit ICR.CMP0IR is set. The state of bit CMP0IRR is “don’t care” in this case.
CMP1IRR	2	w	**Reset Compare Register CMP1 Interrupt Flag** 0_B Bit ICR.CMP1IR is not changed. 1_B Bit ICR.CMP1IR is cleared.
CMP1IRS	3	w	**Set Compare Register CMP1 Interrupt Flag** 0_B Bit ICR.CMP1IR is not changed. 1_B Bit ICR.CMP1IR is set. The state of bit CMP1IRR is “don’t care” in this case.
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.

Note: Reading register ISCR always returns $0000\ 0000_H$.

17.3.5 Interface Registers

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

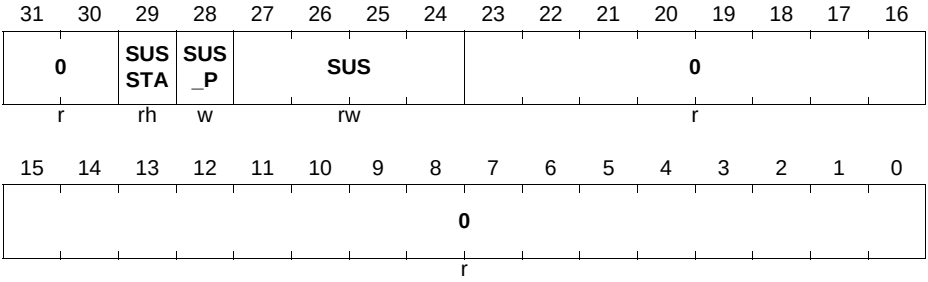
The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change.

When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status **($E8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Reserved, do not use this combination 2_H 64-bit counter will be stopped **others**, Reserved, do not use this combination *Note:* For details see the OCDS chapter.
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B , ... ,EN31 -> TAG ID 011111_B.

ACCEN0

Access Enable Register 0 **(FC_H)** **Reset Value: FFFF FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

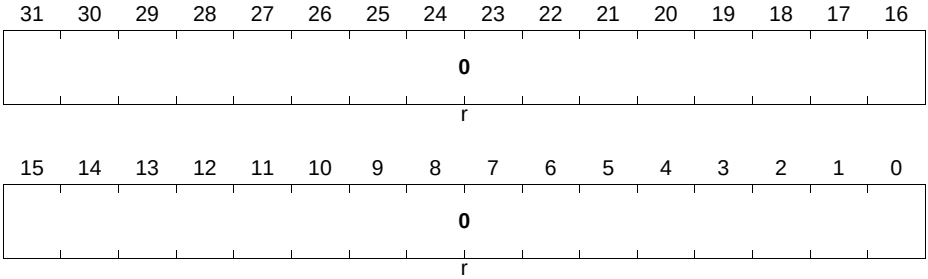
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID master peripheral mapping).

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: 0000 0000$_H$**

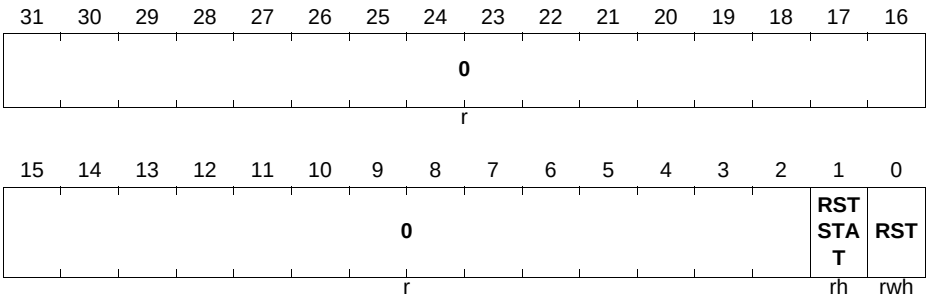


Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

The Kernel Reset Register 0 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). In order support modules with two kernel the BPI_FPI provides two set of kernel reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing to it with ´1´.

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**

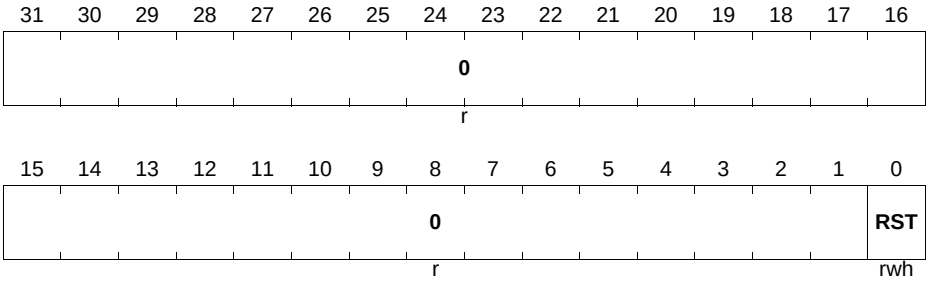


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rw	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the STM kernel. STM kernel registers related to the Debug Reset (Class 1) are not influenced. To reset the STM kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be cleared with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: $0000\ 0000_H$**

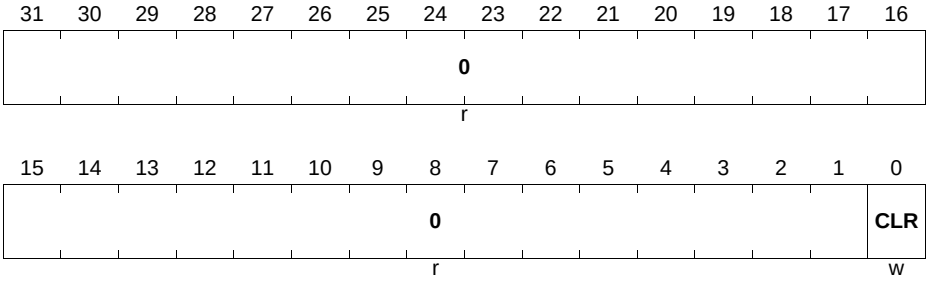


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (<>_KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

18 On-Chip Debug Support (OCDS)

AURIX devices contain powerful resources for debugging and performance optimization. They provide high visibility and controllability of software, hardware and system, especially also under hard real-time constraints. The resources are either embedded in specific modules (e.g. breakpoint logic of CPUs) or part of the central CERBERUS module.

Figure 18-1 shows the AURIX family concept of the OCDS with all potentially usable pins. The same OCDS function is always on the same port pin including full DAP/JTAG functionality but the number of $\overline{\text{TGI}}$/$\overline{\text{TGO}}$ trigger pins depends on the device type.

Trace functionality is available for TC29x with miniMCDS, for all other AURIX devices only with the associated Emulation Device (ED) with MCDS.

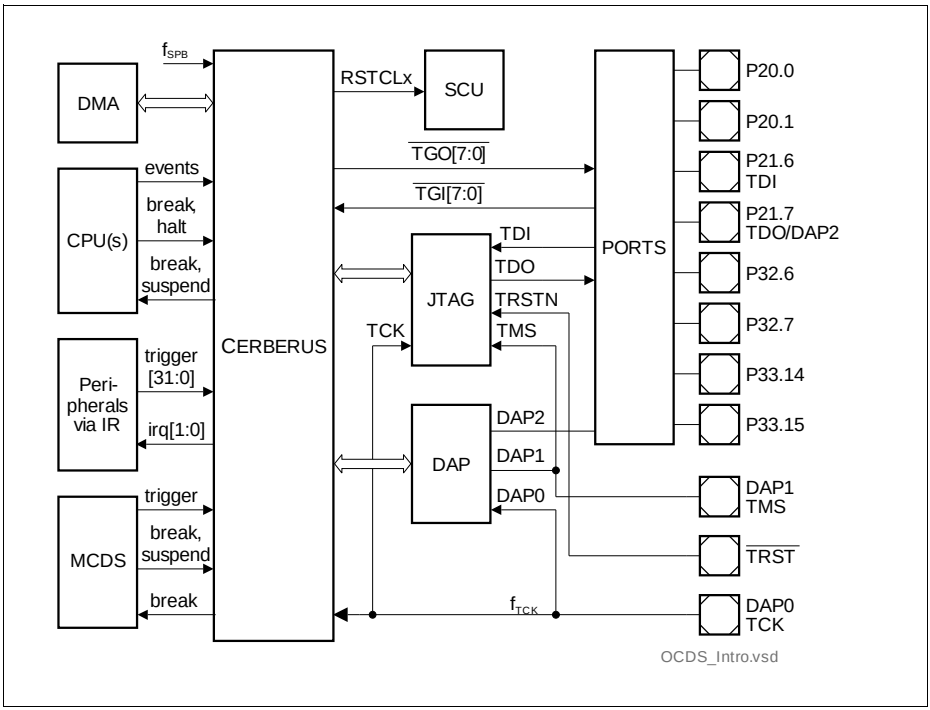


Figure 18-1 OCDS Block Diagram (Family Concept)

When acting as bus master CERBERUS shares the master interfaces of the DMA (using a different master tag) to access memories and SFRs attached to the SPB or SRI via the shortest possible path.

18.1 Feature List

Please also refer to debug specific features in other modules, e.g.

- Eight hardware breakpoints for TriCore, based on instruction or data address.
- Unlimited number of software breakpoints (DEBUG instruction).
- Trigger generated by the access to a specific bus address by any bus master
- Peripheral trigger and trace with OCDS Trigger Bus (OTGB)
  - Peripherals provide vectors (Trigger Sets) of their most interesting signals
  - Signals can be routed to trigger pins
  - Flexible tracing of signal vectors from one or two peripherals in parallel (ED)
- Dedicated interrupt resources to handle debug events, both local inside the CPUs (breakpoint trap, software interrupt) and global (triggered by CERBERUS), e.g. for implementing monitor programs

Central functions implemented by CERBERUS

- Run/stop and single-step execution independently for each CPU.
- Run/stop and time-step execution of the complete device using the Trigger Switch.
- Automatic suspension of the SCU watchdogs when the device is halted by the tool.
- All kinds of reset can be requested using only the tool interface.
- Halt-after-Reset for repeatable debug sessions.
- Tool access to all SFRs and internal memories independent of the CPUs.
- Bus priority of CERBERUS can be chosen dynamically to minimize real-time impact.
- Up to 8 package pins can be used optional as with Trigger In/Out ($\overline{\text{TGI}}$/$\overline{\text{TGO}}$).
- Central OCDS Trigger Switch (OTGS) with 7 independent Trigger Lines to collect debug events from various sources (all CPUs, all interrupt requesters, bus controllers, several complex peripherals, MCDS, trigger input pins) and distribute them selectively to all CPUs and trigger output pins (extension of the former Break Switch concept).
- Central Suspend Switch using up to three Lines of the Trigger Switch infrastructure. This allows to selectively suspend all or only part of the CPUs and peripherals instead of halting them as reaction to any debug event.
- Access to all OCDS resources also for the CPUs themselves for debug tools integrated into the application code.
- Triggered Transfer of data for simple variable tracing.
- A dedicated trigger bank (TRIG) with 96/512 independent status bits is provided to post requests at a central location from application code to the tool.
- The tool is notified automatically when the trigger bank is updated by any processor. No polling via a system bus is required.

Tool Interfaces

Several options exist for the communication channel between tools and TC21x/TC22x/TC23x:

- DAP and JTAG are clocked by the tool.
- Two pin DAP (Device Access Port) protocol for long connections or noisy environments.
- Three unidirectional pin DAP mode for off-chip transceiver integration (e.g. LVDS).
- Three pin DAP Wide Mode for high bandwidth needs.
- DAP bit clock can have any frequency up to 160 MHz.
- 15 MByte/s for block read or write, 30 MByte/s in Wide Mode
- Optimized random memory accesses (read word within 0.5 µs at 160 MHz).
- CAN (plus software linked into the application code) for embedded purposes with lower bandwidth requirements.
- Four pin JTAG (IEEE 1149.1) for standard manufacturing tests.
- Hot attach (i.e. physical disconnect/reconnect of the host connection without reset) for all interfaces.
- Infineon standard DAS (Device Access Server) implementation for seamless, transparent and parallel tool access over any supported interface.
- Lock mechanism to prevent unauthorized tool access to application code.
- DAP over CAN Messages (DXCM) u, TC23x/22x only)

FAR Support

To efficiently locate and identify faults after integration of an AURIX device into a system special functions are available:

- Boundary Scan (IEEE 1149.1) via JTAG or DAP.
- SSCM (Single Scan Chain Mode) for structural scan testing of the chip itself.
- DXCPL (DAP over CAN Physical Layer) via CAN pins (AP32264)

18.2 Family Overview

The OCDS architecture and features are very consistent over the whole AURIX family. This makes it easy for tool partners and users to switch between different devices. **Table 18-1** lists all OCDS and the main Emulation Device differences of the devices, and **Table 18-2** the JTAG IDs. The associated ED step has the same JTAG ID.

Table 18-1 OCDS Differences of AURIX Devices

Feature	TC29x	TC27x	TC26x	TC24x	TC23x	TC22x/1x
TRIG triggers	512	512	512	512	96	96
DAP Over CAN Msg. (DXCM)	-	-	-	-	yes	yes
miniMCDS	yes	-	-	-	-	-
Emulation Device (ED)	9xED	7xED	6xED	(6xED)	3xED	(3xED)
ED packages B=BGA, Q=QFP	B 292 B 416 B 516	B 292 Q 176	Q 176 Q 144	Q 144	Q 144	Q 144
ED's TDI pin replaced by VDDPSB	-	Q 176	Q 176 Q 144	Q 144	-	-

Table 18-2 JTAG IDs of AURIX Devices

	A-Step	B-Step	C-Step	D-Step
TC29x	$101E9083_H$	$201E9083_H$		
TC27x	$201DA083_H$	$301DA083_H$	$401DA083_H$	$501DA083_H$
TC26x	$101E8083_H$	$201E8083_H$		
TC24x	$101EA083_H$			
TC23x	10200083_H			
TC22x	10201083_H			
TC21x	10202083_H			

18.3 Tool Interface Recommendations

AURIX devices are well supported by many tool partners for different types of tools. Standard tool interface for debug, measurement and calibration is DAP due to its reduced pin-count, higher performance (3-6x) and higher robustness (CRC) than JTAG. Please note that the full "JTAG" boundary scan functionality is also available with DAP, it is supported however only by specific tool providers. Please refer to application note AP24003 for more information about the standard DAP connector and board design for high speed DAP. **Table 18-3** lists all pins and considerations for connecting tools.

Table 18-3 Tool Relevant Device Pins of AURIX Family

Pins	Remark
TRST	DAP: Has to be high at PORST pin release. Can be statically connected to VDDP3 (e.g. in the development phase only) with these effects: • Causes a static current due to pull-down element on chip • VDDSB and VDDPSB supplies need to be ensured • DXCPL is disabled JTAG: Needs to be controlled by the tool via the tool connector.
DAP0/TCK	DAP: Please consider AP24003 for high speed DAP
DAP1/TMS	
DAP2/TDO TGI3/TGO3	DAP: Needed for three pin modes like high bandwidth Wide Mode. The standard DAP connector (AP24003) allows to use this pin on demand either for Wide Mode e.g. for measurement or as trigger pin for system debugging.
TDI/(VDDPSB) TGI2/TGO2	For certain EDs in QFP packages (**Table 18-1**) this pin is the VDDPSB supply pin and needs to be supplied with 3.3 V (e.g. VDDP3). Please note for the “TDI is VDDPSB” case: • JTAG is not available for such EDs • VDDP3 connection can be hardwired. This is compatible for PD and ED, however TGI2/TGO2 is then also unavailable for the PD.
VDDSB	1.3 V supply of the ED memory. This supply can be separate of VDD if standby functionality is needed. Please consider the additional VDDSB current for your supply.
VDDPSB	3.3 V supply for the DAP pins of EDs. Can be connected to VDDP3 or supplied by the tool.
TGIx/TGOx	Optional trigger pins, overlaid to port pins. Availability depends on device and package type.
AGBT_xyz	AGBT high-speed serial pins in the center ball matrix of EDs in BGA packages. Please connect to VSS if no AGBT is needed.

Note: Please ensure that VDDSB and VDDPSB are always supplied in regular operation (VDD supplied, TRST/PORST inactive) to avoid internal cross currents which can damage the ED device. For instance connect VDDSB to VDD and VDDPSB to VDDP3.

For more information please contact your Infineon support.

18.4 Debug Access Server (DAS)

The DAS API provides an abstraction of the physical device interface for tool access. The key paradigm of DAS is to read or write data in one or several address spaces of the target device.

DAS Features

- Standard interface for all types of tools
- Efficient and robust methods for data transfer
- Standardized system security support (authorization)
- Several independent tools can share the same physical interface
- Product chip address space is represented with DAS address map 0, EEC with 1
- Infineon's miniWiggler supports DAP, JTAG, SWD and SPD

DAS is not device specific. It can be used for all Infineon 8-, 16- and 32-bit microcontrollers with DAP, JTAG, SWD, or SPD interface. For more information please refer to **www.infineon.com/DAS**.

19 Asynchronous/Synchronous Interface (ASCLIN)

The main purpose of the ASCLIN module is to provide asynchronous serial communication with external devices using only data-in, data-out signals.

The focus of the module is set to fast and flexible communication: either fast point-to-point or master-to-many slaves communication using the LIN protocol.

Additionally, the module supports the synchronous SPI communication.

Figure 19-1 shows an overview of the ASCLIN module.

Note: The RX, TX, RTS, CTS, SCLKO, SLSO signal names are prefixed with "A" in order to achieve unique names on chip level, distinct from signal names of other communication modules.

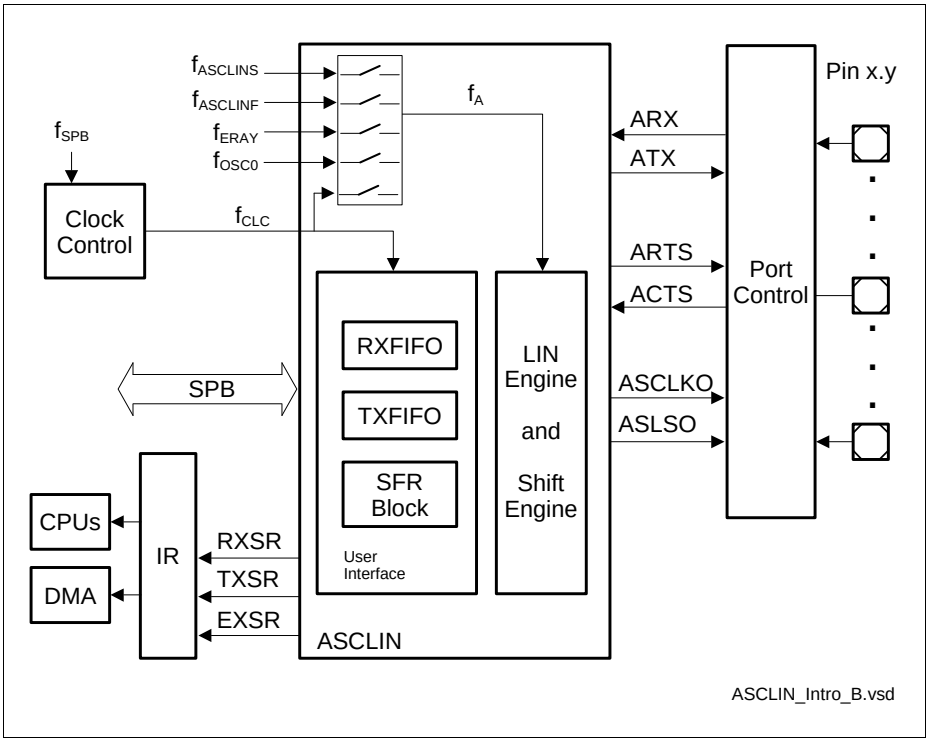

Figure 19-1 Block Diagram of the ASCLIN module.

>> **Registers Overview**

>> **BPI_FPI Module Registers**

19.1 Feature List

This section describes the features of the ASCLIN module.

General Features

- 16 bytes TxFIFO
- 16 bytes RxFIFO
- Pack / unpack capabilities of the Tx and Rx FIFO
- Interrupt generation
  - On a configurable transmit FIFO level
  - On a configurable receive FIFO level
  - On an error condition (frame, parity, overrun error)
  - On various module internal events (end of ASC/SPI frame, LIN events)
- Interrrupt signals capable of triggering either a CPU or a DMA
- Programmable oversampling of 4 to 16 times per bit
- Programmable sampling point position
- Programmable digital glitch filter and median filter for incoming bit stream
- Shift direction LSB first
- Internal loop-back mode

Standard ASC Features

- Full-duplex asynchronous operating modes
  - 7-bit, 8-bit or 9-bit (or up to 16-bit) data frames, LSB first
  - Parity-bit generation/checking
  - One or two stop bits
  - Max baud rate f_A / 16 (6.25 MBaud @ 100 MHz f_A module clock)
  - Min. baud rate f_A / 268 435 456 (0.37 Baud @ 100 MHz f_A module clock)
- Optional RTS / CTS handshaking
- Support of
  - JASO D 903

Extended ASC Features

- Programmable oversampling of 4 to 16 times per bit
  - module capability of up to 4 times higher baud rates (f_A / 4) then the standard ASC
  - system considerations like pad type, incoming signal quality and accumulated PLL jitter can lead to constraints regarding the usable oversampling ratios (for example f_A / 8 = 200MHz / 8 = 25 MBaud)
- Programmable sampling point position

LIN Features

- Support of

  - LIN version 1.3
  - LIN version 2.0
  - LIN version 2.1 and
  - J2602
- Break detection
- Break injection
- Sync field generation
- Auto baud detection based on Sync Field measurement
- Optional Collision detection, required for LIN version 2.1
- LIN Watchdogs
  - Header time-out
  - Frame or Response time-out
- Stuck at zero/one monitoring
- Bus idle time monitoring
- Wake-Up
- Minimum CPU load in master mode
  - Single interrupt indicating the end of the frame
- Minimum CPU load in slave mode
  - Single interrupt at the end of the header reception
  - Single interrupt at the end of the response or end of frame
- Standard operation with one interrupt per transmitted or received byte supported

SPI Features

- SPI master modes (slave mode not supported):
  - Four-wire or three-wire (with / without slave select output signal)
- Up to 16-bit data width
- Full-duplex and half-duplex
  - Min. baud rate f_A / 268 435 456 MBaud (= 0.37 Baud @ 100 MHz f_A module clock)
  - Max. baud rate f_A / 4 MBaud (= 25 MBaud @ 100 MHz f_A module clock)
- Programmable leading and trailing delays

19.2 Overview

This section shows the essential sub blocks of the module when used as standard ASC, as LIN or as SPI master.

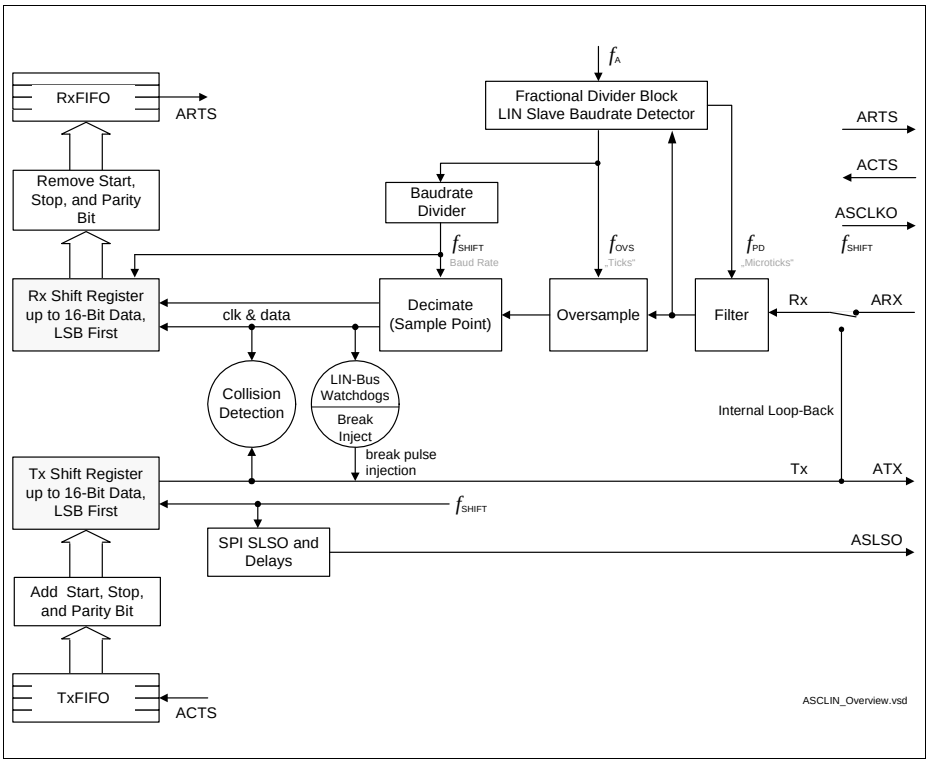

Figure 19-2 Architecture Overview

Note: Collision detection is mandatory only in the LIN specification V2.1.

Note: In LIN mode, both ARX and ATX signal must be connected to the LIN bus in order ASCLIN module to work properly.

19.3 External Signals

The ASCLIN module provides the following external signals:

- Serial clock output ASCLK
- Receive data input ARX (Master Receive MR input in SPI mode)
- Transmit data output ATX (Master Transmit MT output in SPI mode)
- Slave select signal output ASLSO
- Request to send handshake output ARTS
- Clear to send handshake input ACTS

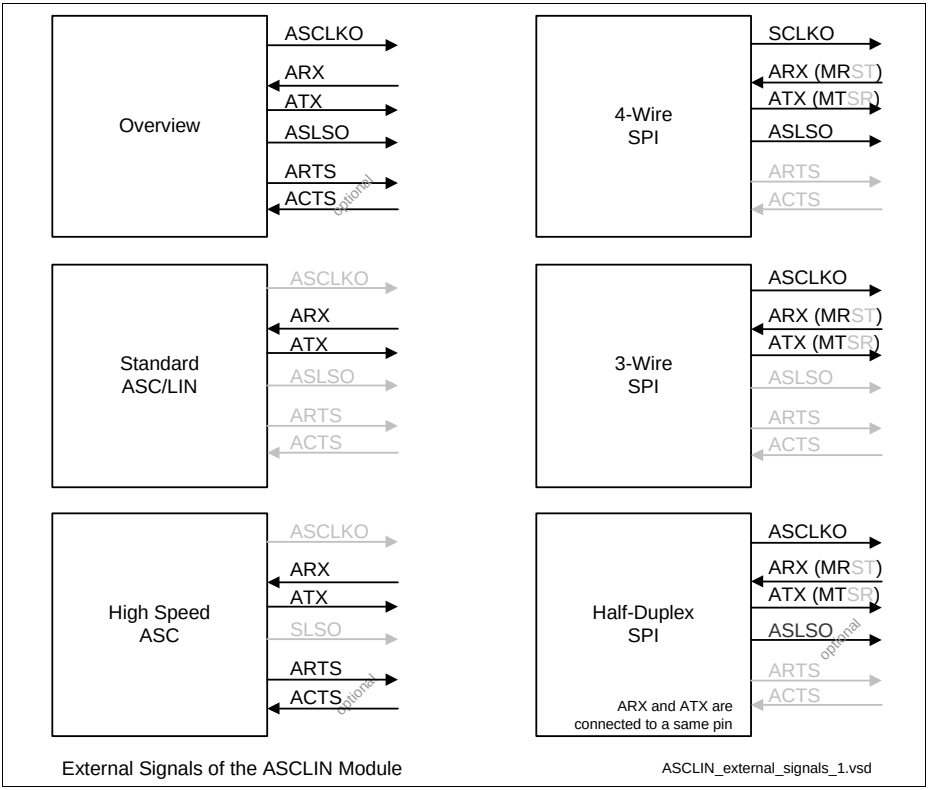

Figure 19-3 External Signals of the ASCLIN Module in Different Modes

19.4 User Interface

The user interface contains a Tx FIFO and an Rx FIFO.

They provide the following services: takes data packets with width optimal for the FPI[1)] bus and packs them to serial frames, buffers the FPI bus data, manages handshaking. These features are designed to optimize the use of the module in LIN, high-speed ASC and SPI mode. They also optimize the use of the module in standard ASC mode.

19.4.1 TxFIFO Overview

The Tx FIFO has the ability to pack 16-bit writes from the FPI bus to two up-to-8-bit frames or one up-to-16-bit frame. It also has the ability to pack 32-bit writes from the FPI bus to four up-to-8-bit or two up-to-16-bit frames.

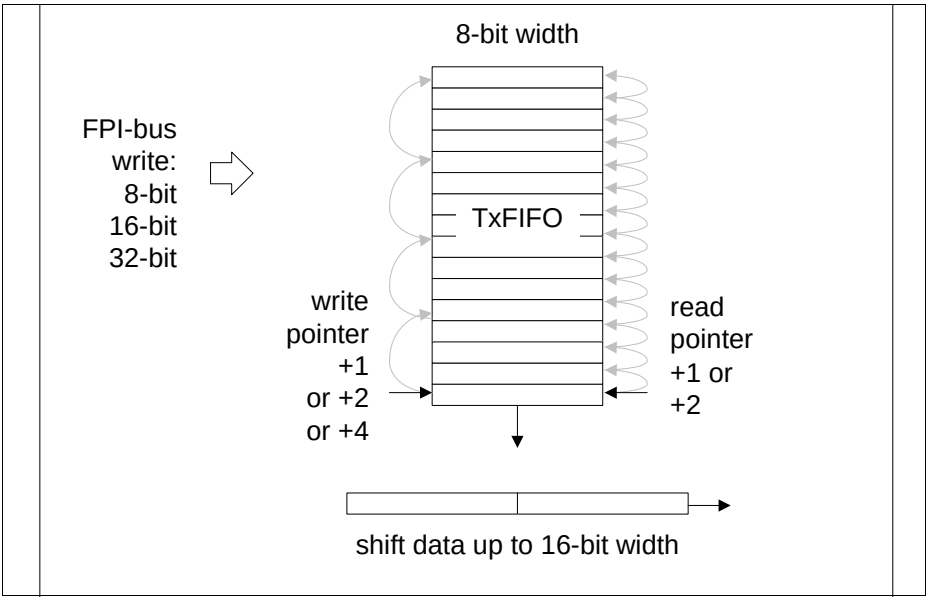

Figure 19-4 TXFIFO Overview

The number of bytes written to the TxFIFO is always defined with the **TXFIFOCON**.INW, does not depend on the SPB write width, and should be equal to it.

If the SPB write width is shorter than INW, then the missing part is padded with zeros.

If the SPB write width is longer then INW, then the excessive part is lost.

1) FPI is the protocol used on the System Peripheral Bus (SPB).

On the shift register side, the TxFIFO is always emptied by a number of bytes as needed for the data width field **DATCON**.DATLEN.

The **Table 19-1** describes all the possible write (fill) combinations. The bytes which will be filled into the TXFIFO are labeled as A, B, C, D and 0.

Table 19-1 Inlet Width versus SPB Write Width

TxFIFO Contents		SPB Bus Write Width		
		8-Bit A	**16-Bit BA**	**32-Bit DCBA**
Inlet Width INW	**8-Bit**	A	A	A
	16-Bit	0A	BA	BA
	32-Bit	000A	00BA	DCBA

19.4.2 Using the TxFIFO

The Tx FIFO has the ability to pack 16-bit writes from the FPI bus to two up-to-8-bit frames or one up-to-16-bit frame.

Note: Some (but not all) use-cases are described in the sections below. The software can always access the TXFIFO 8, 16 or 32 bit wide, according to its requirements.

19.4.2.1 Standard ASC Mode

The most standard usage of the ASC module is to transmit 7 or 8-bit values, and to fill the FIFO with 8-bit wide FPI-bus accesses. The FPI bus access is 8-bit wide, and there is only BS0 (Byte Select 0) signal active.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is 8-bit, and the Tx_Outlet_Width is 8-bit.

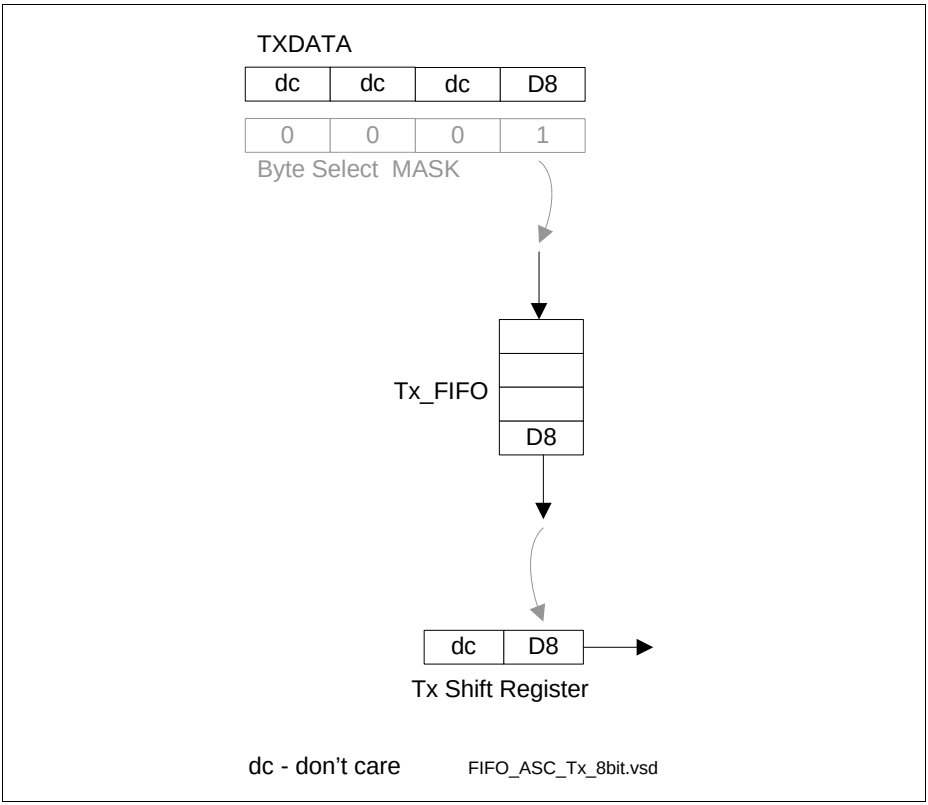

Figure 19-5 FIFO Operation in 7- or 8-Bit ASC Mode, with or without Parity

A less common mode of operation of the ASC module is to transmit 9-bit values, containing either 9-bit data or 8-bit data. The FPI bus access should be 16-bit wide, and there are BS0 and BS1 (Byte Select 0 and 1) signals active. The shift register is filled with two 8-bit values at the location read pointer and read pointer + 1.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is 16-bit, and the Tx_Outlet_Width is 16-bit.

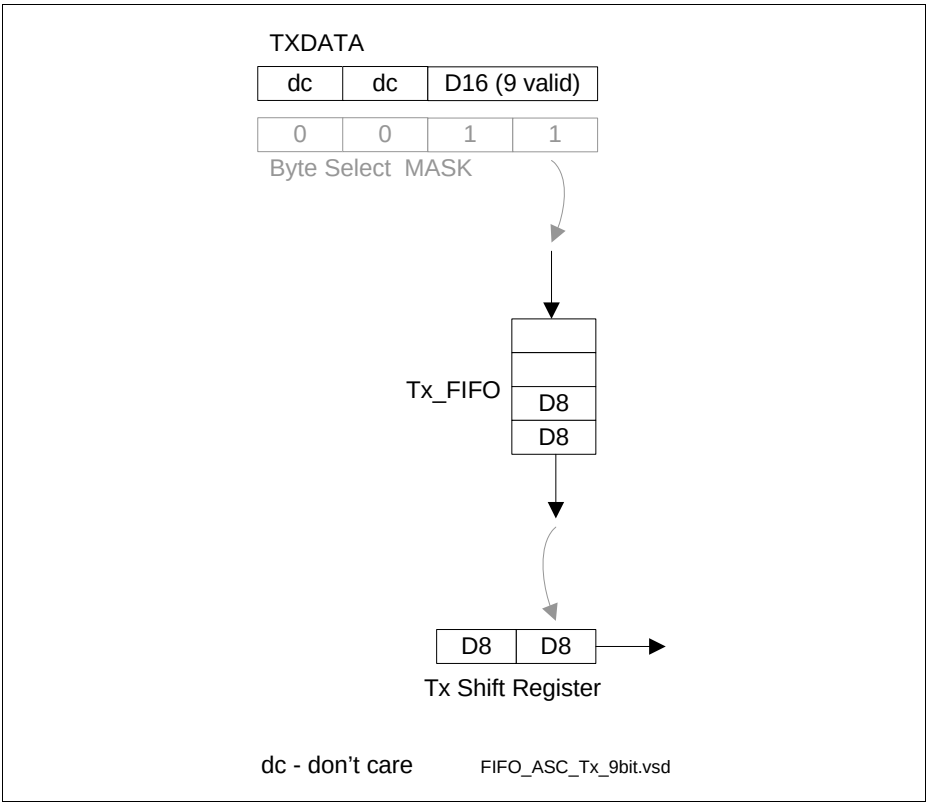

Figure 19-6 FIFO Operation in 9-Bit ASC Mode

19.4.2.2 High Speed ASC Mode

In order to reduce the FPI bus load by not using a 32-bit move for 7 or 8-bit values, one option is to fill the FIFO with 32-bit wide accesses containing four 8-bit wide values. All Byte Select signals BS[3:0] are active, and all four bytes are written in the TX FIFO in one cycle. At the same time, the write pointer of the TXFIFO jumps by the amount of four.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is 32-bit, and the Tx_Outlet_Width is 8-bit.

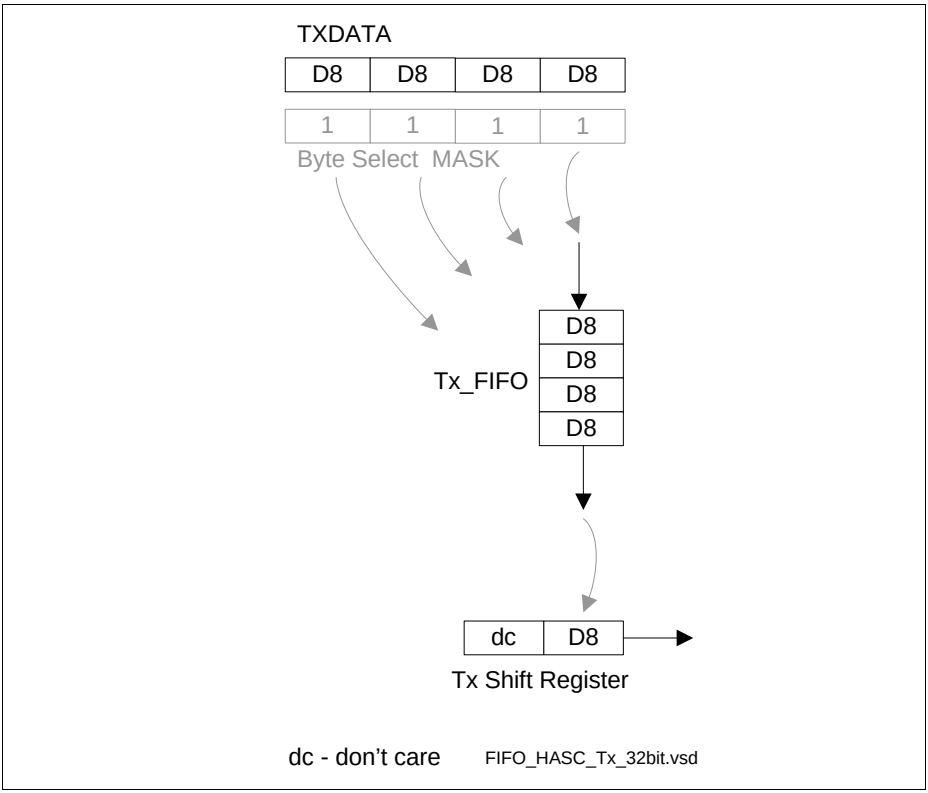

Figure 19-7 High-Speed Communication Scenario

19.4.2.3 LIN Mode

In LIN mode, several 8-bit frames are preceded by a low break pulse.

The generation of the break pulse is programmable with an 8 bit timer in units of bits, where the wide range of break pulses can be generated, for example in a range between 13 and 26 bits and beyond (up to 256 bits, but these lengths would violate the maximum LIN header length). The detection of the break pulse is programmable with an 8 bit timer in units of bits. Among others , the standard thresholds of 10 and 11 bit times can be set. .

The pulse is generated by an module internal timer. The transmit sequence consists of filling the stopped TXFIFO with the appropriate bytes, and then starting the break pulse, which activates the TxFIFO.

The transmit data is written to the address TXDDATA. The Tx_Inlet_Width can be 8-bit (or 16-bit, or 32-bit), and the Tx_Outlet_Width is 8-bit.

19.4.2.4 SPI Mode

SPI mode is used most often to send or receive data of 8 or 16-bits length, or some length in between. Therefore the reading out of the Tx FIFO must be 8 or 16-bit wide, and write could be 16-bit wide, or even 32-bit wide if two frames are packed in one FPI bus access.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is up to 32-bit, and the Tx_Outlet_Width is up to 16-bit.

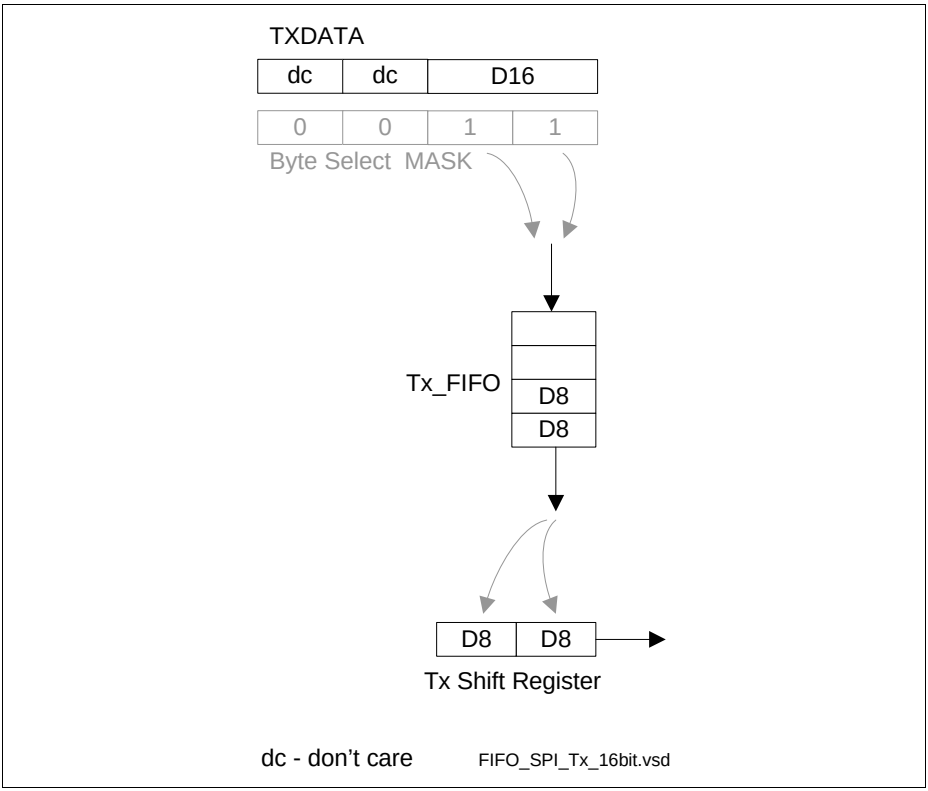

Figure 19-8 TXFIFO Operation in SPI Mode

19.4.3 RxFIFO Overview

The Rx FIFO has the ability to pack two up-to-8-bit frames or one up-to-16-bit frame to one 16-bit write to the FPI bus. It also has the ability to pack four up-to-8-bit 2-up-to-16-bit frames to one 32-bit write to the FPI bus.

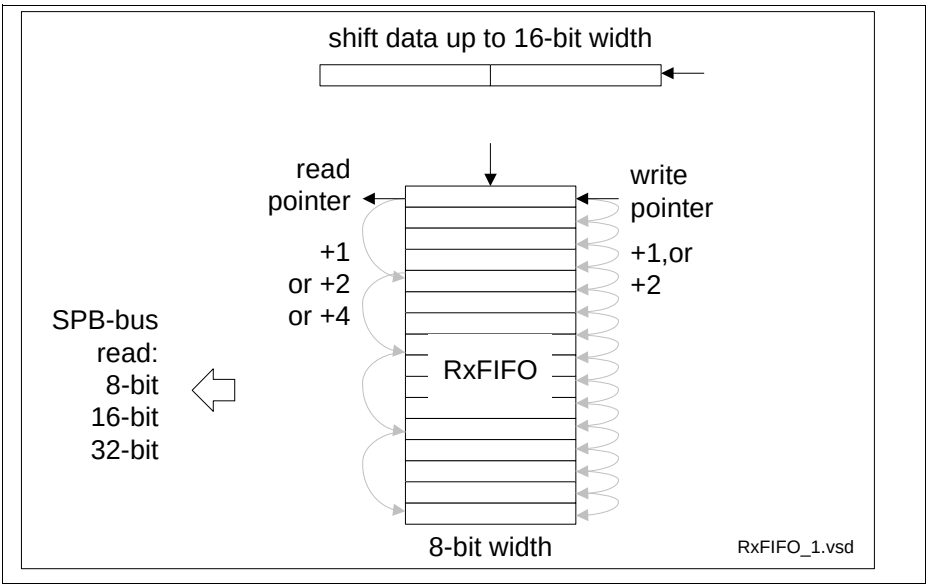

Figure 19-9 RXFIFO Overview

The number of bytes taken out of the RxFIFO is always **RXFIFOCON**.OUTW, does not depend on the SPB bus read width, which should be normally equal to OUTW.

If the SPB read width is shorter than the OUTW, then the missing part is filled with zeros.

If the SPB read width is longer then OUTW width, then the excessive part is lost.

On the shift register side, the RxFIFO is always filled with a number of bytes as needed for the data width field **DATCON**.DATLEN.

The **Table 19-2** describes all the possible combinations. The bytes in the RxFIFO are named A, B, C and D, A being the first one to take out. The padding byte is 0.

*Note: In case of an underflow, i.e. when a read access is performed to RXDATA and the number of bytes to be taken out of the FIFO as given by the setting of **RXFIFOCON**.OUTW exceeds the number of bytes that are actually stored in the FIFO, as indicated by **RXFIFOCON**.FILL, then the RXFIFO delivers the available data padded with zeros up to the read access width. However, the data remain in the FIFO and the filling level **RXFIFOCON**.FILL is not changed. To remove the data, the user software must flush the RXFIFO. The bit **FLAGS**.RFU is set.*

Table 19-2 Outlet Width versus SPB Read Width

SPB-Read Data, taken from the RxFIFO		SPB Bus Read Width		
		8-Bit	**16-Bit**	**32-Bit**
Outlet Width OUTW	**8-Bit**	A	A	A
	16-Bit	0A	BA	BA
	32-Bit	000A	00BA	DCBA

19.4.4 Using the RxFIFO

The Rx FIFO has the ability to pack two up-to-8-bit frames or one up-to-16-bit frame to one 16-bit write to the FPI bus.

19.4.4.1 Standard ASC Mode

The received data is read from the address RXDATA.

In case of data width of 7 or 8 bits, one read on this address delivers one byte and empties the FIFO for one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit.

In case of data width of 9 bits, one read on this address delivers two byte and empties the FIFO for two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit.

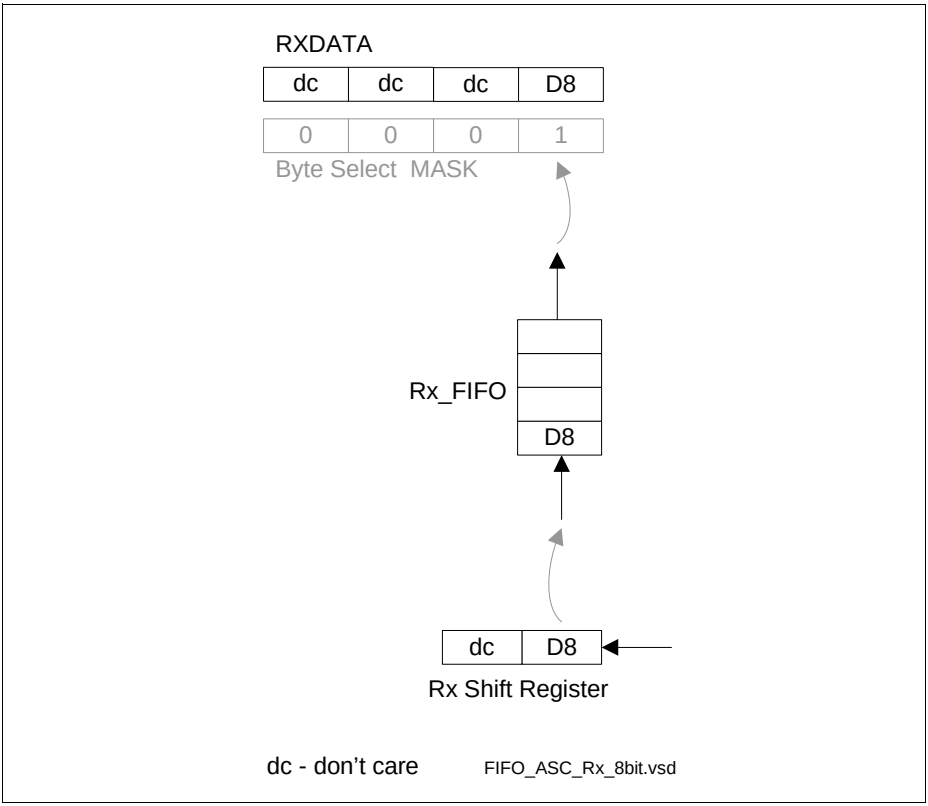

Figure 19-10 8-Bit ASC Reception

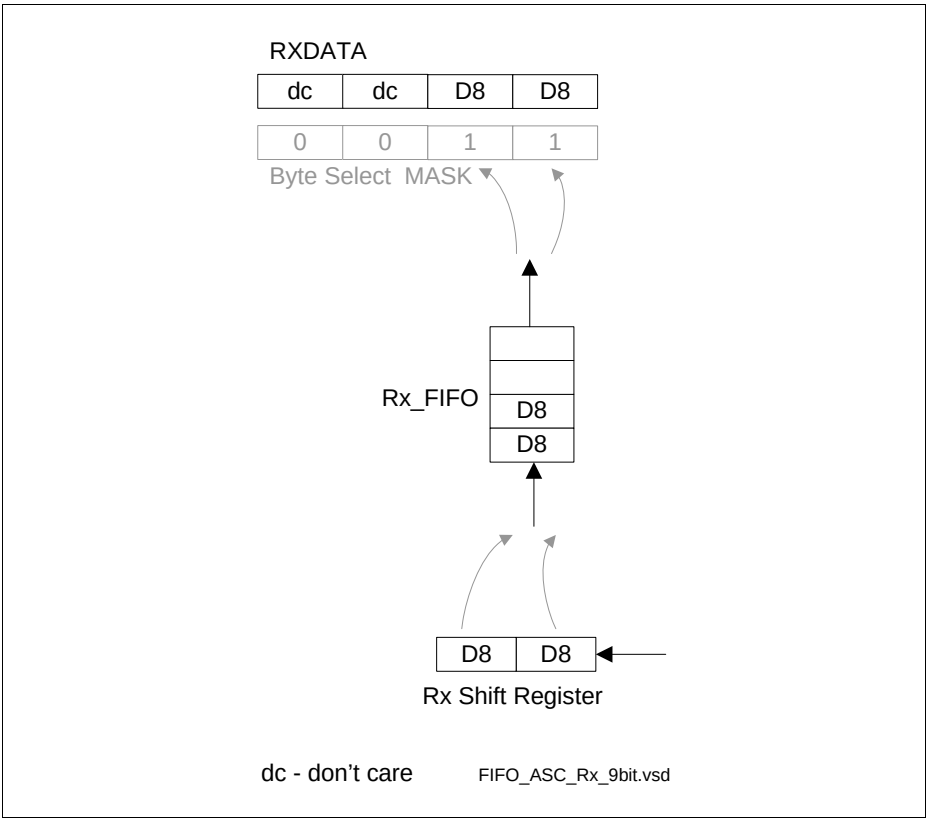

Figure 19-11 9-Bit ASC Reception

19.4.4.2 High Speed ASC Mode

The received data is read from the address RXDATA.

In case of data width of 7 or 8 bits, one read on this address can deliver (one or two or) four bytes and empties the FIFO by four elements, if the Rx_Outlet_Width is 32-bit. The Rx_Inlet_Width is 8-bit.

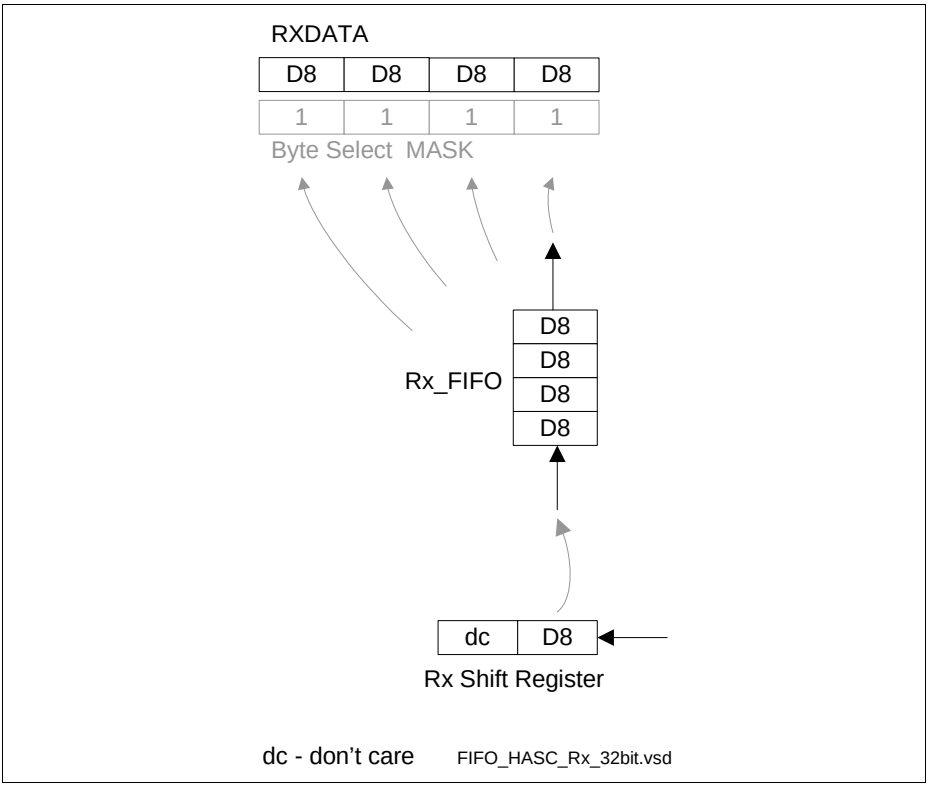

Figure 19-12 High Speed ASC Communication

19.4.4.3 LIN Mode

The received data is read from the address RXDATA.

The read data width is 8 bits (or 16 bit or 32 bit), one read on this address delivers one byte and empties the FIFO by one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit

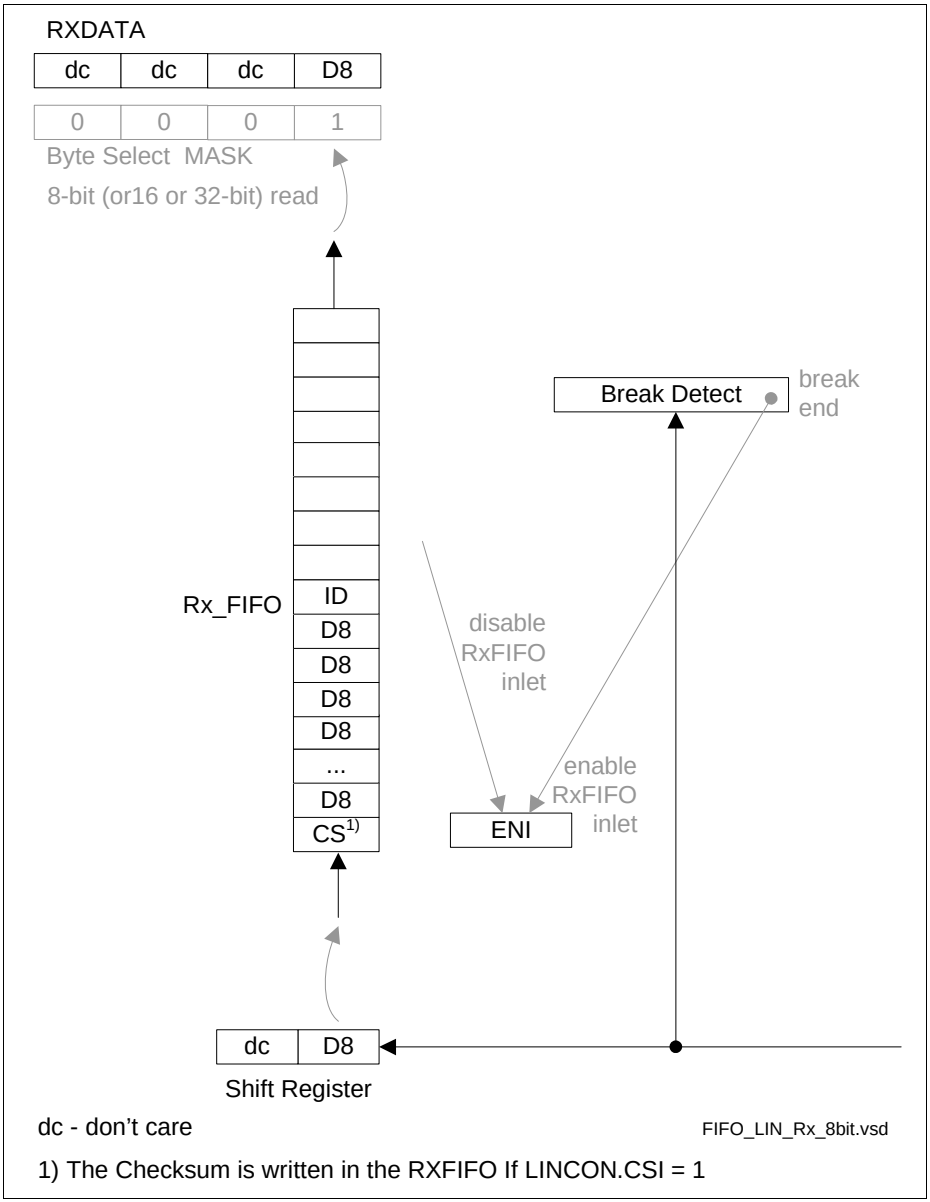

Figure 19-13 RXFIFO Operation in LIN Mode

19.4.4.4 SPI Mode

The received data is read from the address RXDATA.

In case of data width of 16 bits, one read on this address delivers two bytes and empties the FIFO by two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit

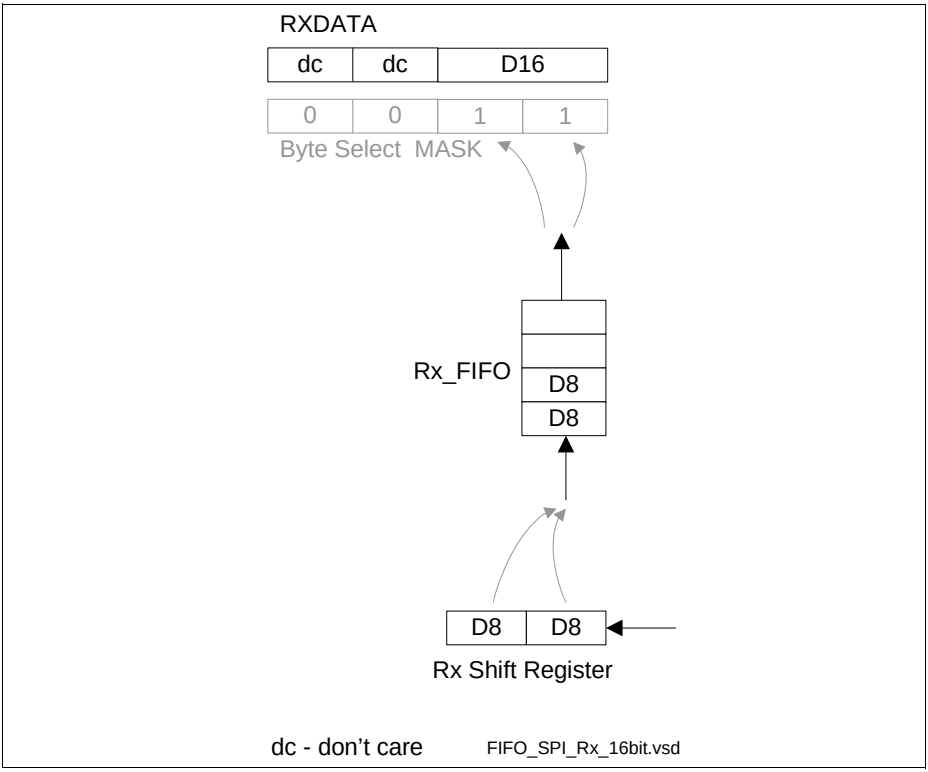

Figure 19-14 RXFIFO Operation in SPI Mode

19.4.5 RTS / CTS Handshaking

A receiver deactivates the RTS (Request to Send) output signal when the RXFIFO is almost full, in order to avoid its overload. When the the emptying of the RXFIFO starts, for example by a DMA, and the filling level falls below the threshold level, the RTS output is activated again. The threshold level is fixed to RXFIFO size minus four, in order to support byte, two bytes and four bytes DMA transfers.

The transmitter receives the RTS output of the receiver on its CTS input and accordingly pauses and resumes the transmission.

19.5 Clock System

The clock system generates all the clocks needed for the proper operation of the ASCLIN module: digital filter clock, oversampling clock, bit time and serial SPI clock.

The clock used for the clock system f_A is independent from the SPB bus clock and remains constant if the SPB bus clock changes, for example in power saving scenarios. The bit field **CSR**.CLKSEL selects the clock source for the f_A frequency, which can be synchronous or asynchronous, higher or lower than the SPB bus frequency.

19.5.1 Baud Rate Generation

Fractional Divider, n-divider and oversampling divider with configurable sample point.

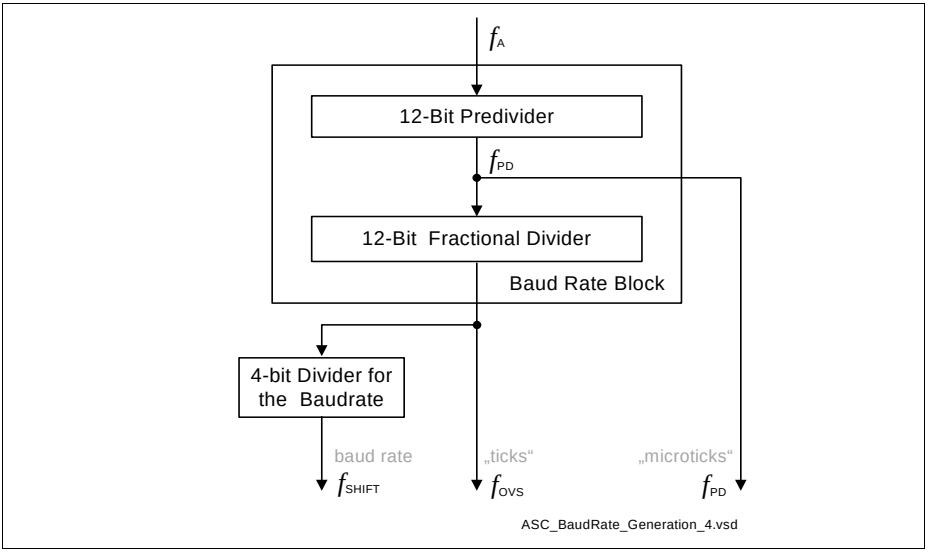

Figure 19-15 Baud Rate Generation

The following bit fields are available for configuring of the 28-bit baud rate divider chain:

- **BITCON**.PRESCALER - the division ratio of the predivider
- **BRG**.NUMERATOR - the nominator of the fractional divider
- **BRG**.DENOMINATOR - the denominator of the fractional divider
- **BITCON**.OVERSAMPLING - the division ratio of the baudrate post divider

The chain of the generated frequencies from f_A down to the f_{SHIFT} (the baudrate) is calculated as follows:

$f_{PD} = f_A$ / (**BITCON**.PRESCALER + 1)

$f_{OVS} = f_{PD}$ * **BRG**.NUMERATOR / **BRG**.DENOMINATOR,

$f_{SHIFT} = f_{OVS}$ / (**BITCON**.OVERSAMPLING + 1)

*Note: Fractional division requires that **BRG**.NUMERATOR is less or equal than the **BRG**.DENOMINATOR.*

The overall formula is given as follows:

(19.1)

$$BAUDRATE = \frac{f_A \times NUMERATOR}{(PRESCALER + 1) \times DENOMINATOR \times (OVERSAMPLING + 1)}$$

19.5.2 Bit Timing Properties

The ASCLIN module provides flexible programming of the bit oversampling, sampling point and input signal filtering properties.

The oversampling factor for the incoming bit-stream is configurable from 4 to 16 ticks (or time quanta) per bit.

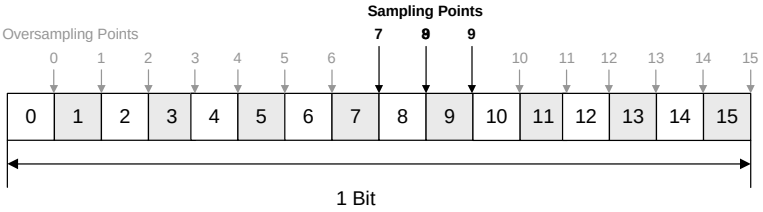
At the same time, using the oversampling frequency, a digital median filter can be enabled to filter the incoming bit stream. The filtering uses the standard majority out of three procedure. If the filter is disabled, then each bit is sampled only once.

The sampling point is also configurable and should be used in conjunction with the oversampling factor. One standard setting is 16x oversampling and using the samples 7, 8 and 9 for the data. Another possible setting could be 8x oversampling and using the samples 3, 4, and 5 for data.

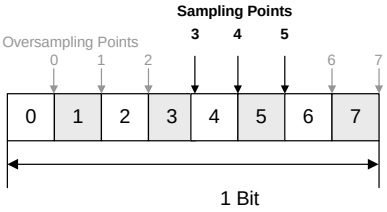
The following bitfields are available for configuring the bit properties:

- **BITCON**.PRESCALER - the twelve bit integer divider defining the microtick used by the fractional divider to generate the baud rate, and by the digital filter for the deglitching of the RX input signal.
- **BITCON**.SAMPLEPOINT - the bit field defining the sampling point position, and the duty cycle in the SPI mode.
- **BITCON**.SM - the bit enables the digital median filter (majority out of three): 1 or 3 samples per bit.
- **IOCR**.DEPTH - the bitfield defining the floating average filter depth: off or 1 to 63 microticks
- **BITCON**.OVERSAMPLING - the bitfield defining the number of ticks per bit, in the range of 4 to 16. This is a post-divider located after the fractional divider.

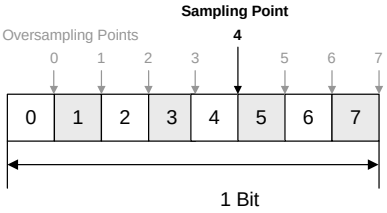
16x Oversampling, 3 sample points, relevant sample position 8



8x Oversampling, 3 sample points, relevant sample position 4



8x Oversampling, 1 sample point, relevant sample position 4



16x Oversampling, 1 sample point, relevant sample position 12

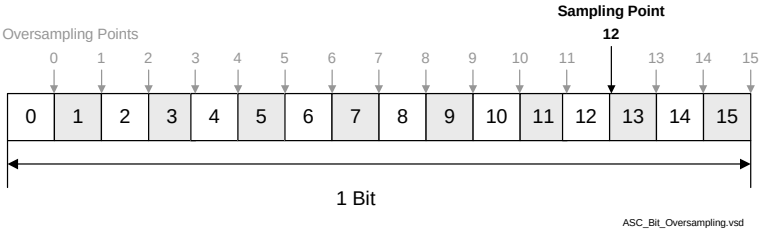


Figure 19-16 ASCLIN Bit Structure

Generally, the sampling point should be placed in the middle of the bit. This position is optimal in case the baud rate (the oscillator frequency) is not very precise and stable.

If the oscillator precision is very high, which is usually the case when two microcontrollers driven by quartz oscillators communicate, but the signal edges are very unsymmetrical, which is the case if open drain half-duplex connection is used, it can be of advantage to move the sample point somewhere in the second half of the bit. Open drain connection usually causes the “0” bits to be longer than the “1” bits. In such a case, optimizing the sampling point would mean placing it in the middle of the shorter “1” bit.

At the end, different combinations of oscillator precision, asymmetry of the edges, and loop-delays for collision detection result in different optimal positions of the sampling point.

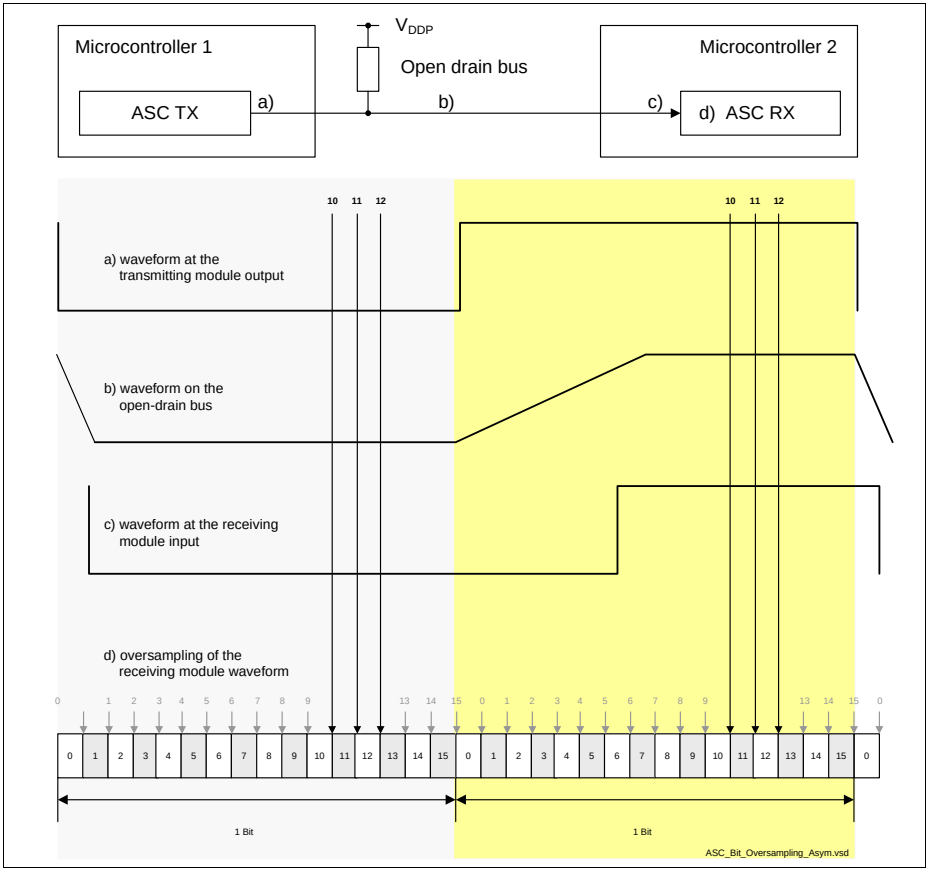

Figure 19-17 Bit Length Asymmetry and the Sampling Point

19.6 Data Frame Configuration

Applicable as transmitter and receiver, the parity scheme is configured in the bit fields **FRAMECON**.ODD, the data length in the bit fields **DATCON**.DATLEN and the stop bits in the bit fields **FRAMECON**.STOP.

19.7 Miscellaneous Configuration

Loop - back

19.8 Synchronous Mode

In synchronous mode the module supports the SPI setting of shift edge first, than the latch edge, see **Figure 19-18**. The module is set in synchronous mode by using the bit field **FRAMECON**.MODE.

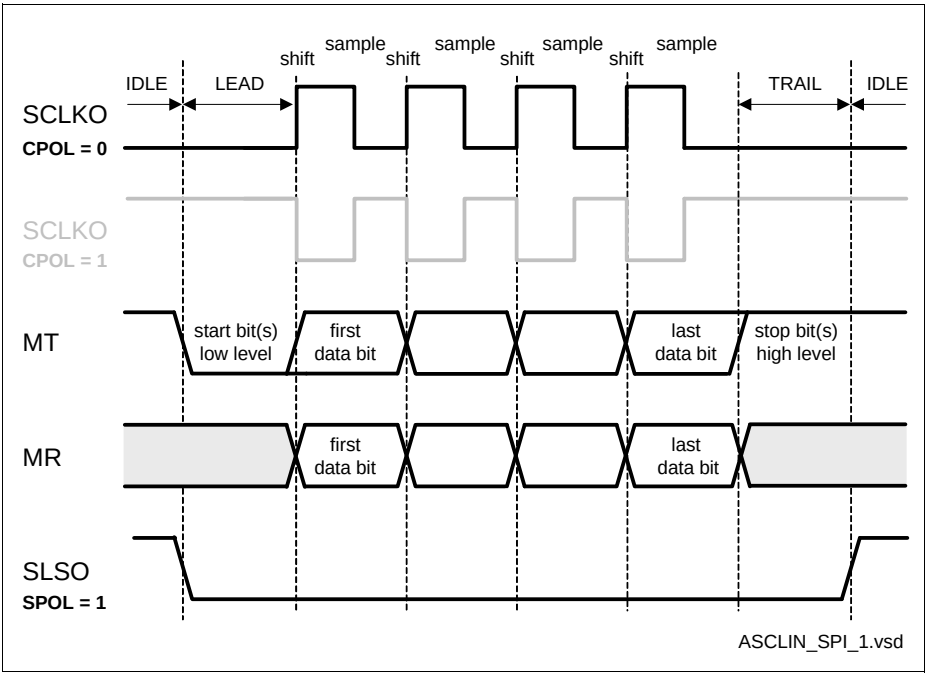

Figure 19-18 SPI Timing

19.8.1 Baud Rate and Clock Generation

The baud rate and clock generation in the synchronous mode uses generally the same counters and principles as in the asynchronous mode. It uses the same prescaler, fractional divider, and oversampling divider with configurable sample point. The only difference is that the shift clock is driven as output signal at the pin SCLKO. If a symmetrical shift clock is required, the oversampling ratio should be an even number, and the sampling point should be set to one half of the oversampling ratio (see the **BITCON** register).

The clock polarity is configured in the bit **IOCR**.CPOL.

19.8.2 Data Frame Configuration

The leading and trailing delays are configured in the bit fields **FRAMECON**.LEAD and **FRAMECON**.STOP. The IDLE phase duration is configured using the bit field **FRAMECON**.IDLE. The data length of 2 to 16 bit is defined in the bit field **DATCON**.DATLEN.

19.8.3 Slave Selects Configuration

The SPI master activates automatically the slave select output signal for each data word. The polarity of the slave select can be configured by using **IOCR**.SPOL

19.8.4 Miscellaneous Configuration

Loop - back

19.9 LIN Support

The ASCLIN module provides hardware support for the LIN protocol.

It supports all four elementary LIN transactions:

- TxH - Transmission of Header
- TxR - Transmission of Response
- RxH - Reception of Header
- RxR - Reception of Response

By supporting additionally the combinations of these elementary transactions, the module actually supports all LIN use cases: sending and receiving headers and responses as

- LIN master or
- LIN slave

A LIN master is engaged in three elementary transactions: TxH, TxR, RxR. It never engages in RxH, because a master never receives a header, it only transmits a header.

A LIN slave engages also in three elementary transactions: RxH, TxR, RxR. It never engages in TxH, because a slave never transmits a header, it only receives a header.

Each elementary transaction needs some hardware resources in order to be completed with minimum CPU intervention. Here is a list of tasks per transaction, supported by hardware, and the required hardware resources:

- TxH - Transmission of Header - master mode only
  - break generation: 8-bit bit-field defining the break length in units of bits
  - sync-field generation: hard coded 55H byte
  - ID transmission with interrupt generation
- TxR - Transmission of Response - master and slave mode
  - number of bytes parameter: bit-field of length 4
  - checksum generation: hardware engine, supporting classic and enhanced checksum, which can be enabled or disabled
- RxH - Reception of Header - slave mode only
  - optional auto-baud detection: fractional divider with programmable nominator and denominator
  - number of bytes parameter: bit-field of length 4
  - checksum detection: hardware that supports classic and enhanced checksum, which can be enabled or disabled; a checksum error is flagged, and an error interrupt can be triggered, if enabled
  - interrupt at end of header (necessary to set the number of bytes for the RxR phase)
  - timeout on overflow: 8-bit timer
  - break detection:8 bit timer with programmable threshold in units of bits
- RxR - Reception of Response - master and slave mode
  - number of bytes parameter: bit-field of length 4

– checksum: the received checksum is optionally delivered in the RXFIFO
– timeout on overflow: 8-bit timer

The break detection feature is always active.

Wake-up signal generation in both slave and master mode

For many LIN configuration parameters, the hardware of the ASCLIN module provides wider ranges than the LIN standard parameters. Therefore the application software shall take care that appropriate LIN standard values are used to configure the module. Such configuration parameters are:

- break length
- data width
- break threshold
- wake-up length
- header, frame and response timeout
- idle time

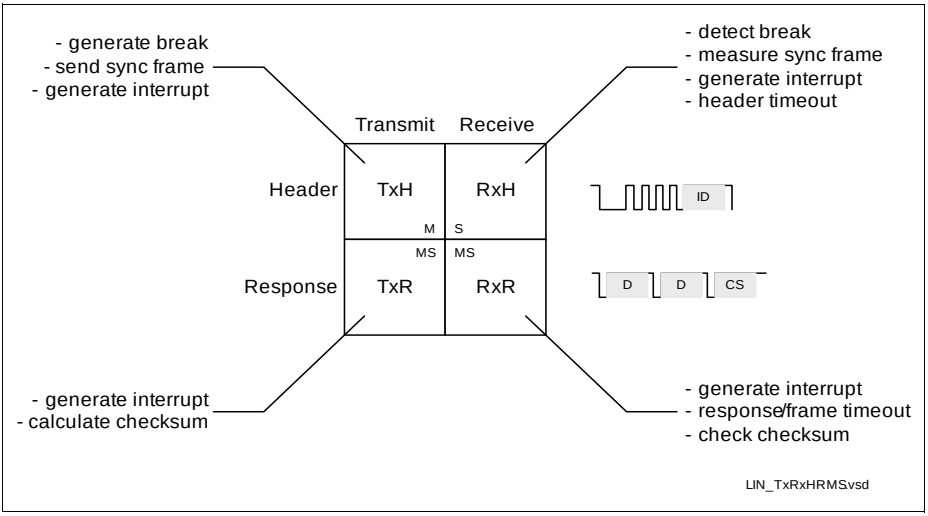

Figure 19-19 Overview of the elementary LIN transactions

19.9.1 LIN Watchdog

The LIN watchdog monitors the duration of the header, the frame or the response, and appearance of break pulses. It checks against the pre-defined time limits.
If the limits are violated, timeout interrupts are generated.

The LIN watchdog is necessary in slave mode.

The wake pulse generation is performed using the shift register and an appropriate data byte containing several consecutive zero bits. The wake pulse detection is done using falling edge detection.

For monitoring the bus for long idle or zero states flags for rising and falling edge are available. These flags can be polled with some appropriate time raster (in microseconds or miliseconds range).

The header timeout value is known at module initialization time and remains constant for all frames.

The frame or response timeout value depends on the length of the response (1 to 8 bytes) and must be set by software depending on the received ID, after the header has been received. The initial value of this timeout should be set by software to the maximum allowed by the timer, that is 256.

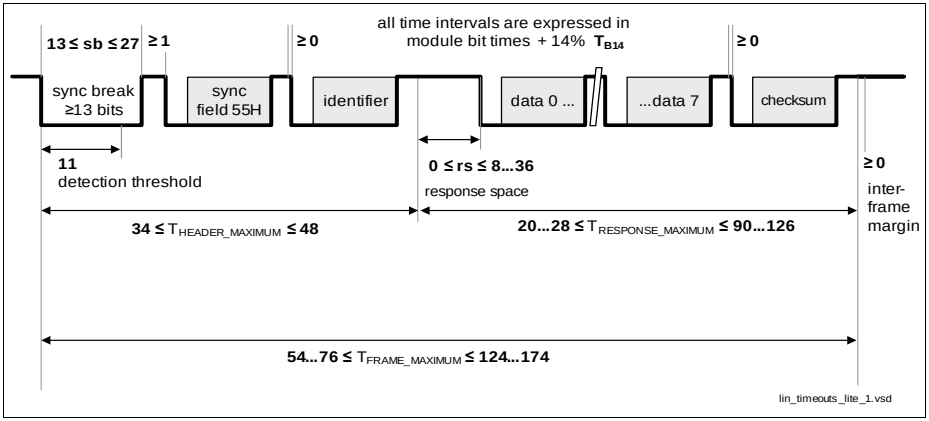

Figure 19-20 Duration of the Elements of a LIN Frame

The module provides timer blocks running in parallel, performing watchdog functions on specific timing requirements of the LIN protocol.

19.9.1.1 LIN Break, Wake, Stuck Handling

This subsection describes:

- the monitoring of the LIN Bus
- Break Pulse detection and generation and
- Wake Pulse detection and generation.

Monitoring the Bus

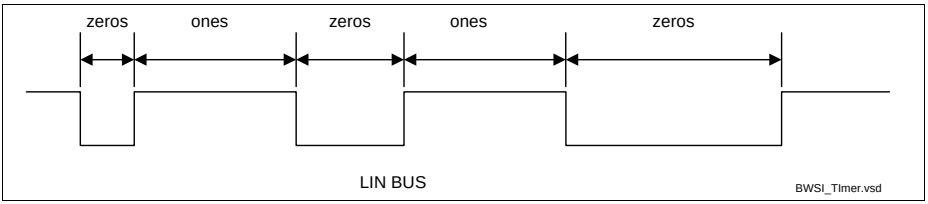

Figure 19-21 LIN Bus View as Sequence of Sequences of Zeros and Ones

Monitoring the bus for long idle periods (or stuck periods) is supported by providing the bit fields **FLAGS**.RED and **FLAGS**.FED. Polling these fields periodically within some time raster defined by the operating system or timer for example each 1ms or each 10 ms can be used for detecting very long inactive periods in the range, for example, of 150 ms to 10s. Additionally, an interrupt on edge can be enabled by using the corresponding enable bits in the **FLAGSENABLE** registers. Setting and clearing the flags can be done by software by using the **FLAGSSET** and **FLAGSCLEAR** register.

Note: The low break or wake up pulses do not cause a dummy byte to be transferred to the receive FIFO and do not cause a frame violation error interrupt. After the pulse the shift register goes into initial state and waits for the falling edge of the start bit of the next frame.

Break and Wake Pulse Detection

The detection of the break pulse, which is defined as low pulse with a minimum duration of 13 bit times, is performed using a threshold of either 10 or 11 bit times. The break detection threshold is set using the bitfield **LINBTIMER**.BREAK.

Detecting a break pulse anywhere in the frame resets the LIN state machine to the “Break Delimiter Detected” state BDD and the whole sequence inclusive the watchdog timeout counting starts from the beginning .

Note: Detecting a break pulse anywhere in the frame could result in setting the Frame Error Flag (FE)

Wake low-pulse detection is done by monitoring the bus for a falling edge in sleep mode. If an early wake-up shall be suppressed, the parameter **IOCR**.DEPTH (glich filter) may be used.

Break and Wake Pulse Generation

The generated break low-pulse duration is defined by the bit field **LINBTIMER**.BREAK in the range of 1 to 64 bits.

Wake low-pulse is nominal 5 bit times long, but can be set to any value between 1 and 9, by writing the appropriate character in the TXFIFO and requesting its transmission as the wake pulse by setting **FLAGS**.TWRQ.

Note: Injecting the low pulse disables the reception with the shift register, so that this low pulse is not detected or treated as a normal ASC frame.

19.9.1.2 LIN Header and Response Timers

The LIN header and response times can be monitored separately.

(>>**LINHTIMER**, **DATCON** description)

- Header duration measurement
  - In master mode starting point of the time measurement is falling edge of the break pulse.
  - In slave mode starting point of the time measurement is the moment of detecting that there is a break pulse going on, that is the moment of detection of a low pulse longer than either 10 or 11 bit times, as configured in the **LINBTIMER** register.
- Response duration measurement
  - In both master and slave modes the response duration measurement starts with the end of the header and ends with the end of the response. “End” means end of the last bit of the last byte (of the checksum byte).

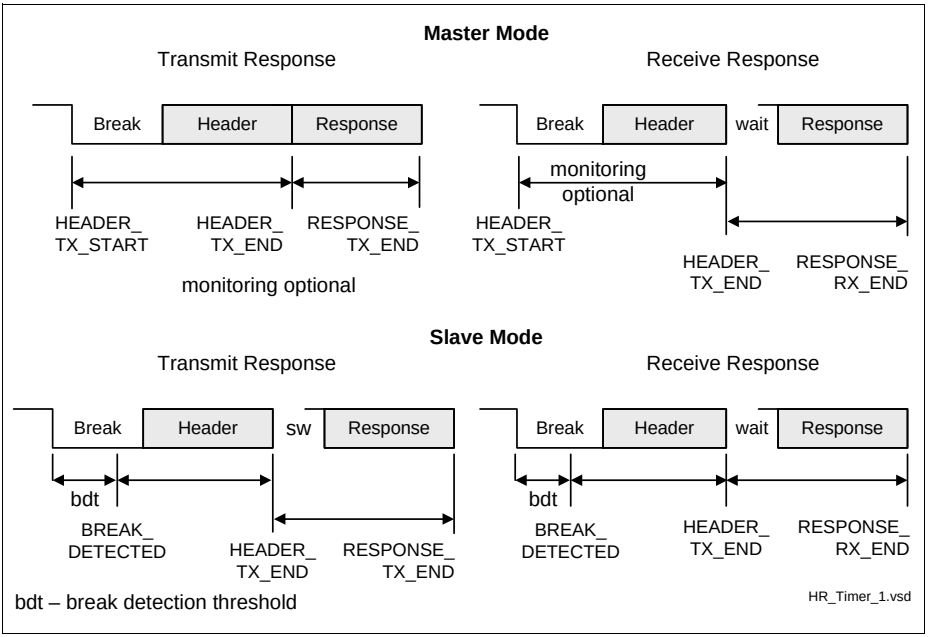

Figure 19-22 Duration Measurement of the Header and Response

Note: Transmitting master node can optionally monitor its own header or response timouts, in order to detect some error conditions, like TXFIFO not containing the ID or data to be transmitted. However, these error conditions can be detected also in other ways.

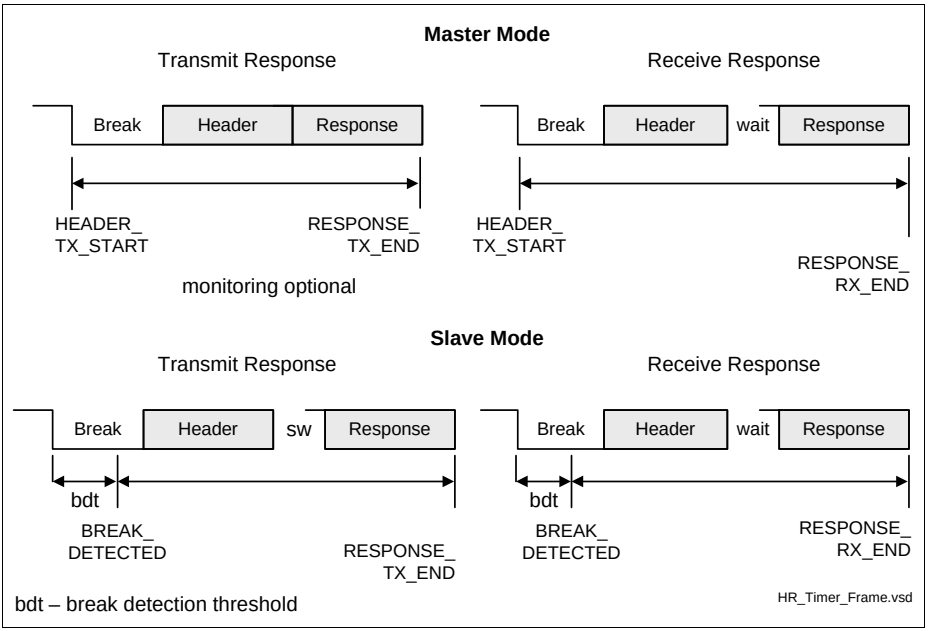

Figure 19-23 Duration Measurement of the Response or Frame

Acording to the setting of the bit **DATCON**.RM, the **DATCON**.RESPONSE bit field defines response or frame duration threshold.

19.9.2 LIN Master Sequences

The sequences described below are examples how the elementary LIN transactions can be executed. There exist other ways to do them, for example by using other events to control the protocol flow: fifo level events instead of end of header / response events. Some alternatives are indicated in the lists below with brackets.

Initialize the module in LIN master mode:

- deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- wait or poll for **CSR**.CON = 0 (see also **Clock Reconfiguration**)
- enter the INIT mode : **FRAMECON**.MODE = INIT
- activate the clock source : set **CSR**.CLKSEL
- wait or poll for **CSR**.CON = 1
- deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- wait or poll for **CSR**.CON = 0
- select the operation mode : **FRAMECON**.MODE = 3 (LIN)
- configure the master mode : **LINCON**.MS = 1
- configure the baud rate : **BRG**
- configure the bit timing : **BITCON**.PRESCALER and OVERSAMPLING
- configure the bit sampling : **IOCR**.DEPTH, **BITCON**.SM, SAMPLEPOINT
- configure the frame parameter : **FRAMECON**.PEN=0 (no parity), STOP = 1
- configure the break length : **LINBTIMER**.BREAK = 13 (typ)
- configure the delay parameter : **FRAMECON**.LEAD, **FRAMECON**.IDLE
- configure the checksum mode : **LINCON**.CSEN, **LINCON**.CSI
- activate the clock source : set **CSR**.CLKSEL
- wait or poll for **CSR**.CON = 1

Send only a header [master task]:

- configure the watchdog timer : **DATCON**.RESPONSE =256 (max)
- configure the RXFIFO : **RXFIFOCON**.ENI = 0 (or 1), OUTW, BUF=0, flush
- configure the TXFIFO : **TXFIFOCON**.ENO = 0, INW, flush
- clear the event flags : **FLAGSCLEAR**.THC, TRC, RRC, CEC, FEC, HTC, RTC, LPC, LC, TFOC/LC, RFOC/UC/LC
- enable the TX interrupt event : **FLAGSENABLE**.THE
- enable the EX interrupt events : **FLAGSENABLE**.HTE, CEE, (FEE, LPE)
- write into the TXFIFO : **TXDATA** = ID byte
- start the header transmission : **FLAGSSET**.THRQS = 1
- configure the TXFIFO : **TXFIFOCON**.ENO = 1

Note: If the software needs the sent ID in the RXFIFO, it should add the setting of ENI=1 to the sequence above - before triggering the header transmission. In such a case

after the header has been transmitted the ID byte will be available in the RXFIFO, but not the sync byte.

React to the interrupt(s) indicating the end of transmission (and reception) of the ID byte:

- check the error flags : **FLAGS**.HT, CE (FE, LP)
- read from the RXFIFO : **RXDATA**=received ID, if no error has been detected

Check the transmitted / received ID to determine with which response sequence: transmit, receive or ignore to continue (same procedure as in the slave mode).

Send a response to the latest header [slave task]:

- configure the response count : **DATCON**.DATLEN
- configure the watchdog timer : **DATCON**.RESPONSE
- configure the checksum mode: **DATCON**.CSM
- configure the RXFIFO : **RXFIFOCON**.ENI =0
- configure the TXFIFO : **TXFIFOCON**.ENO = 1
- clear the event flags : **FLAGSCLEAR**.TRC, TFOC/UC, CEC, RTC, BDC
- enable the TX interrupt event : **FLAGSENABLE**.TRE
- enable the EX interrupt events: **FLAGSENABLE**.TFOE, CEE (RTE), BDE
- write into the TXFIFO : **TXDATA** = data bytes D0, D1, ... (and optionally the checksum byte if the hardware checksum generation is disabled)
- start response transmission : **FLAGSSET**.TRRQS = 1
- the corresponding interrupts signal an error or the end of the response transmission

Receive a response to the latest header [slave task]:

- configure the response count : **DATCON**.DATLEN
- configure the watchdog timer : **DATCON**.RESPONSE
- configure the checksum mode: **DATCON**.CSM
- configure the RXFIFO : **RXFIFOCON**.ENI = 1
- clear the event flags : **FLAGSCLEAR**.RRC, RFOC/UC, FEC, LCC, RTC, FEDC, REDC, BDC
- enable the RX interrupt event : **FLAGSENABLE**.RRE
- enable the EX interrupt events: **FLAGSENABLE**.RFOE/UE, FEE, (LCE), RTE, BDE
- The corresponding interrupts signal that the whole response has been received (= end of the frame) or an error has occured.

Note: If checksum injection has been enabled, the received (custom) checksum is also written into the RXFIFO and should be taken into account.

- Fetch from the RXFIFO : **RXDATA** = received data, if no error occured

*Note: The hardware checksum check can be enabled using the bit **LINCON**.CSEN. The received checksum write to the RXFIFO can be enabled using the **LINCON**.CSI.*

Ignore the latest header [slave task]:

- configure the RXFIFO : **RXFIFOCON**.ENI = 0
- set the header only mode : **DATCON**.HO = 1
- clear the event flags : **FLAGSCLEAR**.FEDC, REDC, BDC

The LIN master always knows if the header is followed by a response transmission (by himself) or a response reception (by a slave) or the response transmission is from slave to slave, except in case of a slave that does not respond always, but driven by internal events.

In case of addresing an always responding slave, it is recommended first to configure the header and response (transmission or reception), and afterwards to start the header transmission and optionally, at the same time, the response transmission.

To start a transaction consisting of sending a header and sending or receiving a response, which makes one whole LIN frame [master node]:

- configure the response count : **DATCON**.DATLEN
- configure the watchdog timer : **DATCON**.RESPONSE
- configure the checksum mode : **DATCON**.CSM
- configure the RXFIFO : **RXFIFOCON**.BUF = 0, flush, ENI = 0
- configure the TXFIFO : **TXFIFOCON** flush, ENO = 0
- clear the interrupt event flags : **FLAGSCLEAR**.THC, TRC, RRC, CEC, FEC, HTC, RTC, LPC, LCC, TFOC/UC/LC, RFOC/UC/LC, FEDC, REDC, BDC
- send case
  - enable the TX interrupt event : **FLAGSENABLE**.TRE, (THE, HTE)
  - enable the EX interrupt events: **FLAGSENABLE**.TFOE, CEE, (FEE, RTE, LPE, BDE)
- receive case
  - enable the RX interrupt event: **FLAGSENABLE**.RRE. (THE, HTE)
  - enable the EX interrupt events: **FLAGSENABLE**.RFOE/UEE, CEE, FEE, RTE, (LCE, BDE)
- write into the TXFIFO : **TXDATA** = ID byte
- send case
  - write to TXFIFO : **TXDATA** = data bytes (and optionally checksum byte if the hardware checksum is disabled)
- start the header transmission : **FLAGSSET**.THRQS = 1
- configure the TXFIFO : **TXFIFOCON**.ENO = 1

Note: If the software needs the sent ID in the RXFIFO, it should add the setting of ENI=1 to the sequence above - before triggering the header transmission. In such a case after the header has been transmitted the ID byte will be available in the RXFIFO, but not the sync byte.

- send case
  - start transmit response : also set **FLAGSSET**.TRRQS = 1

- the corresponding interrupt signals an error or the end of the response transmission
- read from the RXFIFO : if no error detected, **RXDATA** = received ID
- receive case
  - fetch from the RXFIFO : if no error has been detected, **RXDATA** = received data bytes and optionally the checksum byte

19.9.3 LIN Slave Sequences

The sequences described below are examples how the elementary LIN transactions can be executed. There exist other ways to do them, for example by using other events to control the protocol flow: fifo level events instead of end of header / response events. Some alternatives are indicated in the lists below with brackets.

Initialize the module in slave mode:

- deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- wait or poll for **CSR**.CON = 0 (see also **Clock Reconfiguration**)
- enter the INIT mode : **FRAMECON**.MODE = INIT
- activate the clock source : set **CSR**.CLKSEL
- wait or poll for **CSR**.CON = 1
- deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- wait or poll for **CSR**.CON = 0
- select the operation mode : **FRAMECON**.MODE = 3 (LIN)
- configure the slave mode : **LINCON**.MS = 0
- configure the baud rate : **BRG**, autobaud detection enable, **BRD**.UPPER / LOWERLIMIT
- configure the bit timing : **BITCON**.PRESCALER and OVERSAMPLING
- configure the bit sampling : **IOCR**.DEPTH, **BITCON**.SM, SAMPLEPOINT
- configure the frame parameter : **FRAMECON**.PEN = 0 (no parity), STOP= 1
- configure the break length : **LINBTIMER**.BREAK = 11 (typ)
- configure the header timeout : **LINHTIMER**.HEADER
- configure the delay parameter : **FRAMECON**.IDLE
- configure the checksum mode : **LINCON**.CSEN, **LINCON**.CSI
- activate the clock source : set **CSR**.CLKSEL
- wait or poll for **CSR**.CON = 1

In slave mode, the module waits for a header from the master, that is, it waits for a break pulse followed by the sync byte and the ID.

Configure for header reception [slave task]:

- configure the watchdog timer : **DATCON**.RESPONSE =256 (max)
- configure the RXFIFO : **RXFIFOCON** bufmode = 0, flush, ENI = 0
- clear the interrupt flags : **FLAGSCLEAR**.RHC, TRC, RRC, FEC, HTC, RTC, BDC, LPC, LAC, LCC, TFOC/UC/LC, RFOC/UC/LC
- enable the RX interrupt event : **FLAGSENABLE**.RHE
- enable the EX interrupt event : **FLAGSENABLE**.HTE, CEE, FEE, LAE, LPE

React to the interrupt(s) generated after receiving the ID byte:

- check error flags : **FLAGS**.HT, FE, LA, LP
- read from the RXFIFO : if no error detected, **RXDATA** = received ID

Check the received ID to determine which response sequence (send, receive or ignore header) to use next.

The LIN slave does not know in advance if it will respond to the header with a transmission himself or it will receive a response by another slave. It looks up the received ID and decides if this ID is associated with a transmit or receive response or if it is don't care (it is for some other slave). This look-up and the subsequent configuration of the module must be performed by software within the allowed response time.

Send a response to the latest header [slave task]:

(same sequence as in master mode)

Receive a response to the latest header [slave task]:

(same sequence as in master mode)

Ignore the latest header (if the received ID contains an error or is not for this slave) [slave task]:

(same sequence as in master mode)

19.9.4 Using the ENI and HO Bits

Both the ENI (Enable Input) and HO (Header Only) bits affect the reception of the various byte types in the LIN frame.

The HO bit is normally used in cases where the response part of a frame should be ignored; the module waits for the next break signal. The ENI bit can be set by the user software, but is also set by the hardware in slave mode after the sync byte reception, in order to enable the transfer of the ID byte of the header in the RXFIFO.

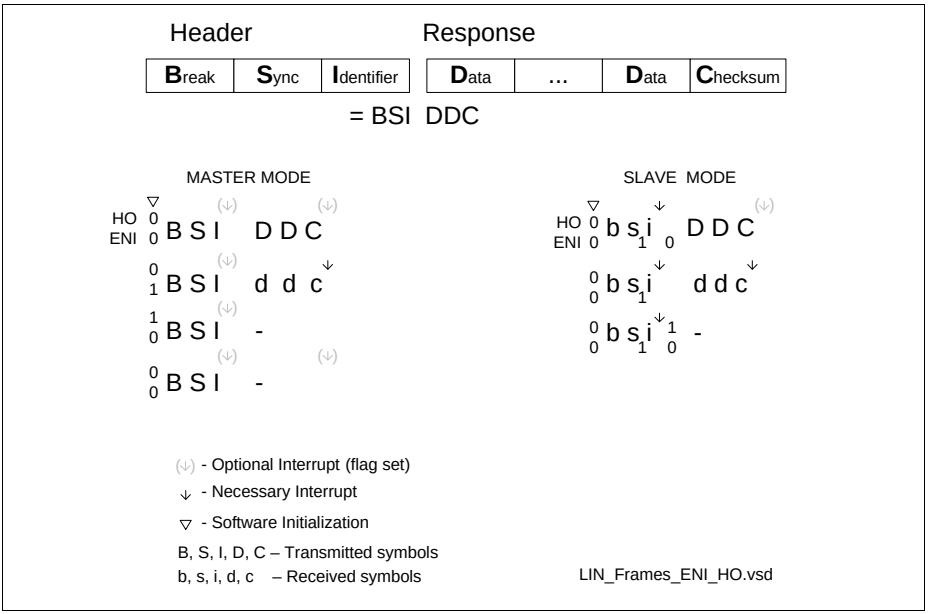

Figure 19-24 ENI and HO bits

19.9.5 LIN Error Recovery

This section describes the behavior of the module in case of errors detected during reception and during transmission of a LIN frame.

Recepton Related Errors

In case of an reception error, the receive state machine goes into the state for waiting for break, and the corresponding interrupt is triggered.

ID Parity error

Checksum error

Timeout error

Framing error

Baud Rate error

Transmission Related Errors

Collision error (LIN2.1 mandatory). If the collision detection mechanism is enabled **FLAGSENABLE**.CEN, the frame will be aborted and the transmiter state machine goes to the idle state.

19.9.6 LIN Sleep and LIN Wake-Up

Wake up low pulse in duration of 250us to 5ms can be generated by the module.

Wake up low pulse in duration longer than 150us wakes up a sleeping module.

A master node which has received a wake up pulse can start polling the slaves, that is it can start sending break pulses and headers, and sending or receiving corresponding responses.

A slave which has been woken up shall be capable of receiving LIN headers after a wake-up time of maximum 100ms. A slave issuing a wake-up pulse expects to receive a header within 150ms to 250ms after the end of the wake-up pulse. If the header does not come, the slave issues a wake up pulse again.

19.10 Auto Baud Rate Detection

Auto baud rate detection is active in slave mode during the reception of the sync field in the LIN header. It measures the longest time interval between two falling edges in the 55H sync field. The measured value is loaded in the denominator of the fractional divider and used afterwards for generating the baudrate for the reminder of this frame if the auto baud rate usage is enabled (**LINCON**.ABD = 1).

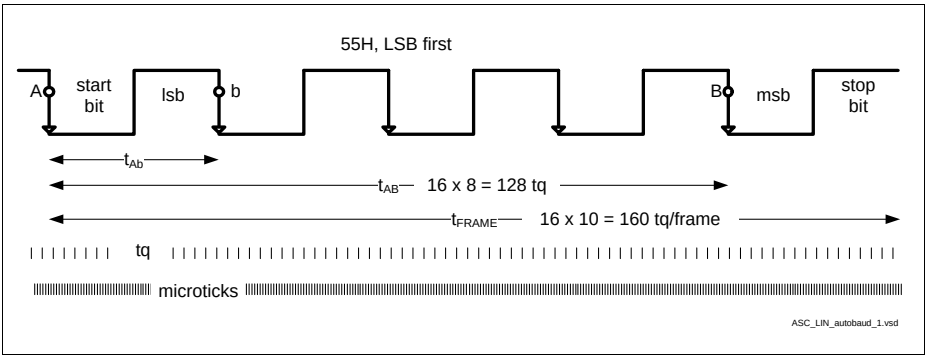

Figure 19-25 Measurement of the Sync field

The following bitfields are available for monitoring the autobaud detection:

- **BRD**.MEASURED - the measured time interval between the first and the fifth falling edge of the sync byte
- **BRD**.UPPERLIMIT - In case the LIN autobaud detection measures a baud rate 14% lower than the nominal one, that is measures a time interval longer than the UPPERLIMIT, a baud rate error event is triggered that, if enabled, generates an interrupt.
- **BRD**.LOWERLIMIT - In case the LIN autobaud detection measures a baud rate 14% higher than the nominal one, that is measures a time interval shorter than the LOWERLIMIT, a baud rate error event is triggered that, if enabled, generates an interrupt.

Auto Baud Rate Operation

The **BRD**.UPPERLIMIT defines the maximum allowed duration for 8 bits in microticks, and therefore the minimum allowed baud rate. In order to define 14% lower baud rate, 8-bit duration 16% longer than the nominal must be entered in the UPPERLIMIT bit field. This is due to the fact that BaudRate = 1 / BitTime, and UPPERLIMIT defines the time.

The **BRD**.LOWERLIMIT defines the minimum allowed duration for 8 bits in microticks, and therefore the maximum allowed baud rate. In order to define 14% higher baud rate, 8-bit duration 12% shorter than the nominal must be entered in the LOWERLIMIT bit

field. This is due to the fact that BaudRate = 1 / BitTime, and LOWERLIMIT defines the time.

If the autobaud is activated, the fractional divider uses a numerator value of 8 x (**BITCON**.OVERSAMPLING + 1) and ignores the bit field **BRG**.NUMERATOR. For the standard LIN protocol oversampling of 16 (**BITCON**.OVERSAMPLING = 15), the numerator value used internally is 128, ignoring the bit field **BRG**.NUMERATOR. Nevertheless, programming 128, or 8 x (OVERSAMPLING + 1) in **BRG**.NUMERATOR may increase the clarity of the software.

Regarding the denominator of the fractionial divider, defined in **BRG**.DENOMINATOR, its initial value is the nominal value and is set by the application software. During the operation of the module, the **BRD**.MEASURED value is automatically loaded into the **BRG**.DENOMINATOR, as long as it is within the limits.

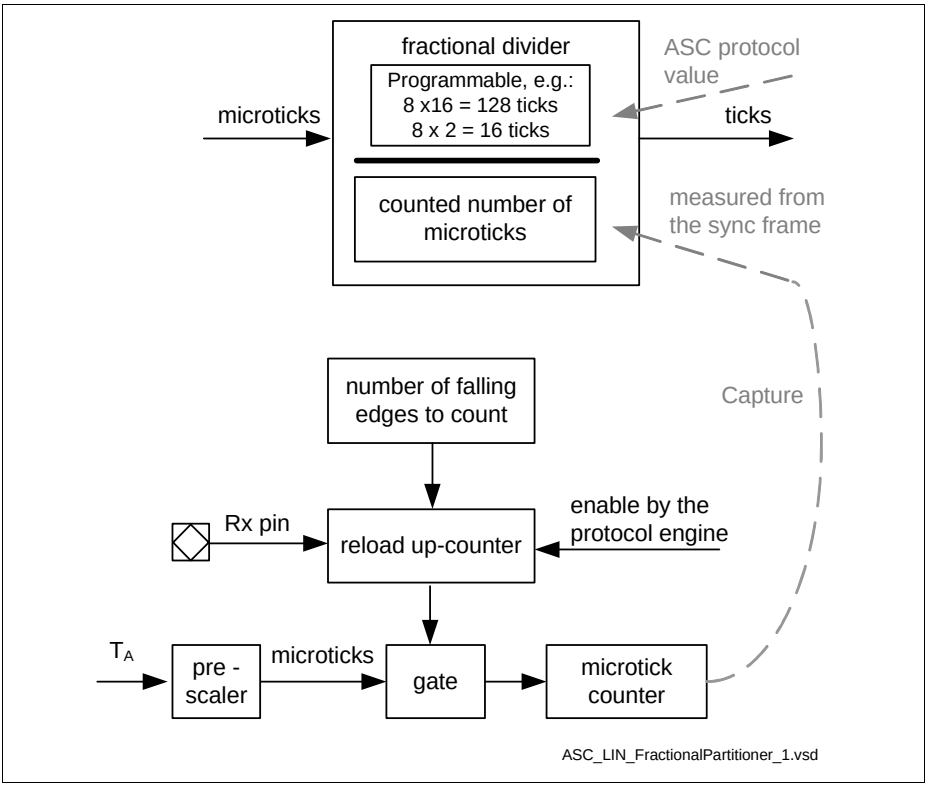

Figure 19-26 Overview of the LIN Auto Baud Detection Principle

Auto baud rate detection measures the time between the first and the fifth falling edge of the sync field in T_{SYS} units and loads this number in the denominator. The LIN protocol uses baud rates in a range between 2400 Baud to 19200 Baud.The expected time at 19.2 KBaud is 8 * 52.1 us = 416.8 us abd the expected denominaror value at T_{SYS} = 10ns is in the range of 417us / 10ns = 41 700.

The numerator operates internally with the quantums for 8 bits, 16 times oversampling for LIN protocol: 8*16=128. The bit field **BRG**.NUMERATOR is ignored.

19.11 Collision Detection

Collison detection monitors the consistency of transmitted and the echoed received bytes in LIN mode and half duplex SPI mode.

19.12 LIN Protocol Control

There is a central LIN protocol state machine. It is connected to the receiver and the transmitter shift registers, the Tx and Rx FIFOs, the checksum logic and the watchdog timers. The machine takes care of generating the sync byte of 55_H and the automatic handling of the checksum. Both the classic LIN V1.3 and the enhanced LIN V2.0 / V2.1 checksum are supported (>> **LINCON** register). The hardware checksum feature is switchable on and off, and the choice between using the classical and the enhanced checksum is done by software with the **DATCON**.CSM bit on a frame by frame basis. As can be seen in the **Figure 19-28**, for the LIN version 2.0 and 2.1, the enhanced checksum is calculated for the identifiers 0...59, and the classical checksum for the identifiers 60...63.

Additionally, the parity of the ID field is generated in master mode, and checked in slave mode. In slave mode, in case of a mismatch between the received and the calculated parity, an error interrupt is raised.

In receive case, if **LINCON**.CSI = 1, the received checksum byte is written to the RXFIFO after the last data byte.

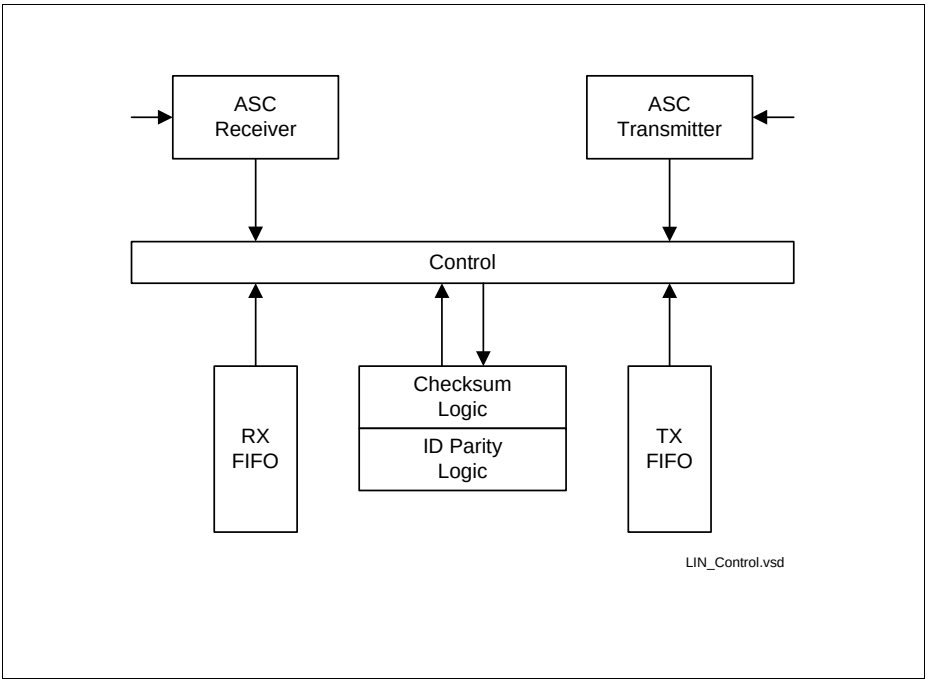

Figure 19-27 Block Diagram of the LIN Control Subsystem

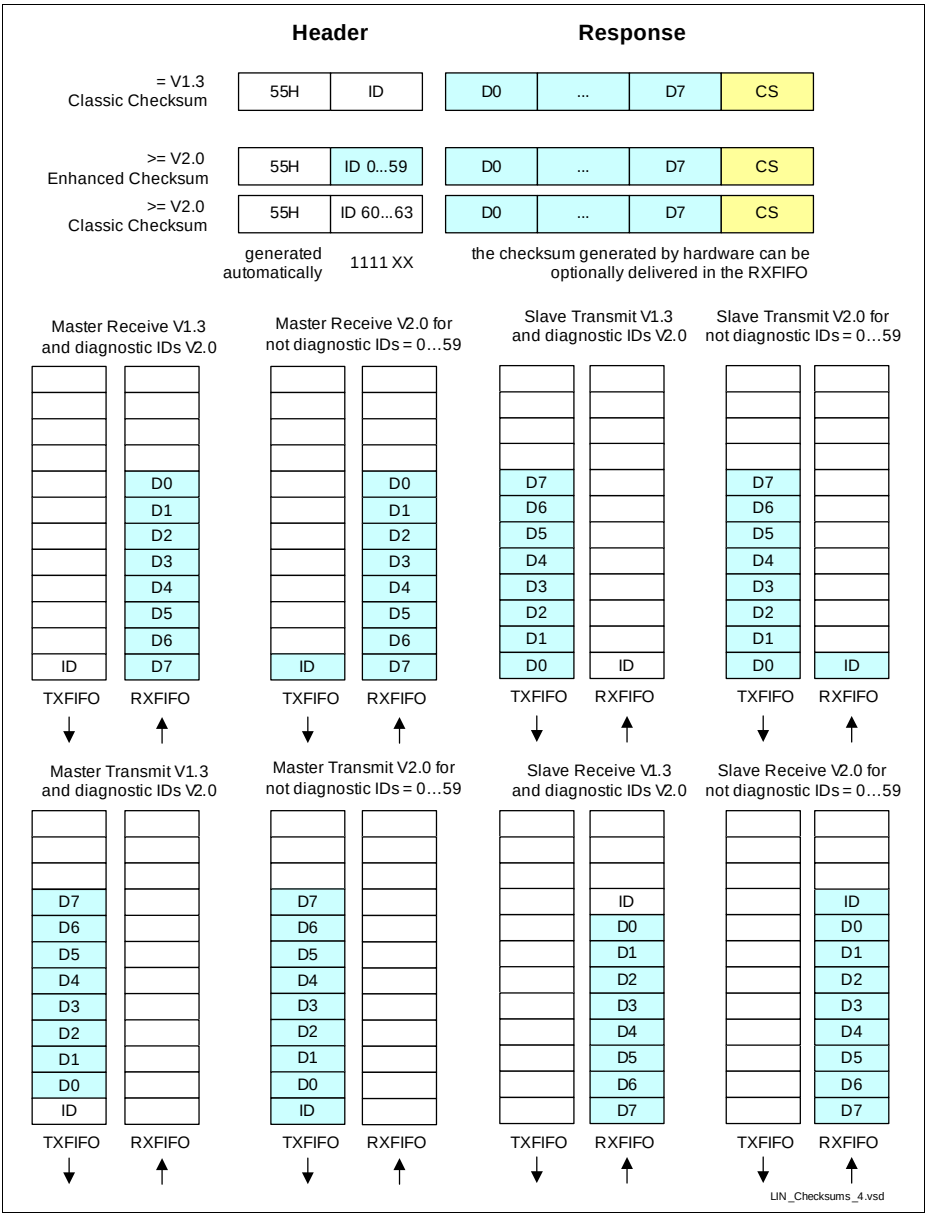

Figure 19-28 Coverage of the Checksum in Different Use Cases

19.13 Interrupts

The ASCLIN module generates three interrupts:

- TX - Transmit Interrupt
  - signals the TxFIFO level event (**FLAGS**.TFL)
- RX - Receive Interrupt
  - signals the RxFIFO level event (**FLAGS**.RFL)
- EX - Extended Error Interrupt
  - signals every error (**FLAGS**.PE, FE, CE, RFO, RFU, TFO) and
  - some additional events (**FLAGS**.FED, RED)

The LIN events related to transmission and reception of header and response are mapped to the corresponding transmit, receive and extended error interrupts

- TX:
  - transmission of the header in master mode completed (**FLAGS**.TH)
  - transmission of a response completed (**FLAGS**.TR)
- RX:
  - reception of the header in a slave mode completed (**FLAGS**.RH)
  - reception of the response completed (**FLAGS**.RR)
- EX:
  - LIN protocol (**FLAGS**. BD, TC) and
  - LIN error events (**FLAGS**.HT, RT, LP, LA, LC)

In order to determine which event is the source of a LIN interrupt, the **FLAGS** register must be polled.

Triggering a DMA

The interrupt signals are used also as DMA trigger signals. The interrupt signals are connected to the Interrupt Router Module, which routes the interrupts either to a CPU or to a DMA. There are no separate DMA triger signals.

Relationship between the Service Request Nodes and the Event Nodes

There are several events mapped to each service request node.

Each service request (interrupt) node contains an SRC (Service Request Control) register containing a sticky flag bit and the associated set, clear and enable bits. The SRC registers are located in the IR (Interrupt Router) module.

The service request flags in the SRC registers are set by hardware, and if the enable bit is set, will be cleared by hardware when the interrupt servicing starts.

One interrupt node may be triggered by more than one events. Each event which causes an interrupt also has a sticky flag bit and associated set, clear and enable bits. These bits are distributed in four registers: **FLAGS**, **FLAGSSET**, **FLAGSCLEAR**, and **FLAGSENABLE** located in the ASCLIN module. Each set of four bits associated to one event builds a virtual “event node”, see **Figure 19-29**.

The event flags are set by hardware and if enabled, trigger an interrupt. They are not cleared by hardware. They are cleared only by software in the corresponding interrupt service routine, which usually polls the flags to find the cause for the interrupts. The event flags can be also set by software for test purposes.

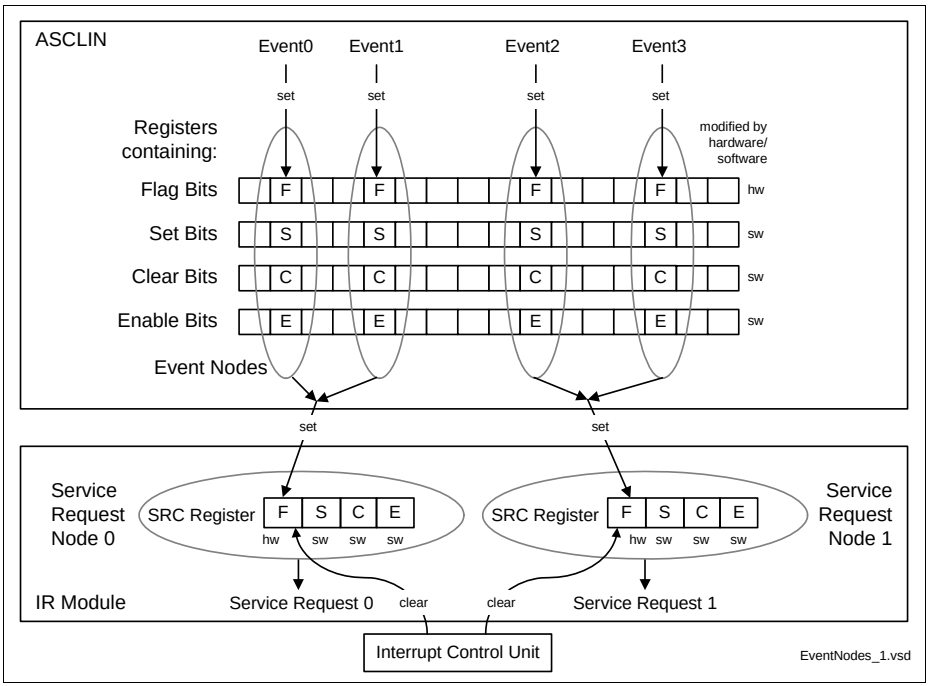

Figure 19-29 Relationship between Event Nodes and Service Request Nodes

Some flags do not generate interrupts and do not have enable bits. They are used either for issueing requests, which are subsequently acknowledged by hardware, or only for polling by software, see **Figure 19-30**.

Clearing an request / acknowledge flag by software is ignored (for example **FLAGS**.TRRQ, THRQ, TWRQ).

There are no pure polled only flags in the ASCLIN module, although by letting the enable bits disabled, all interrupt event flags can be used as polled only (for example idle and stuck monitoring by using **FLAGS**.FED, RED). Setting such bits per software in such a case is meaningless, except for test purposes.

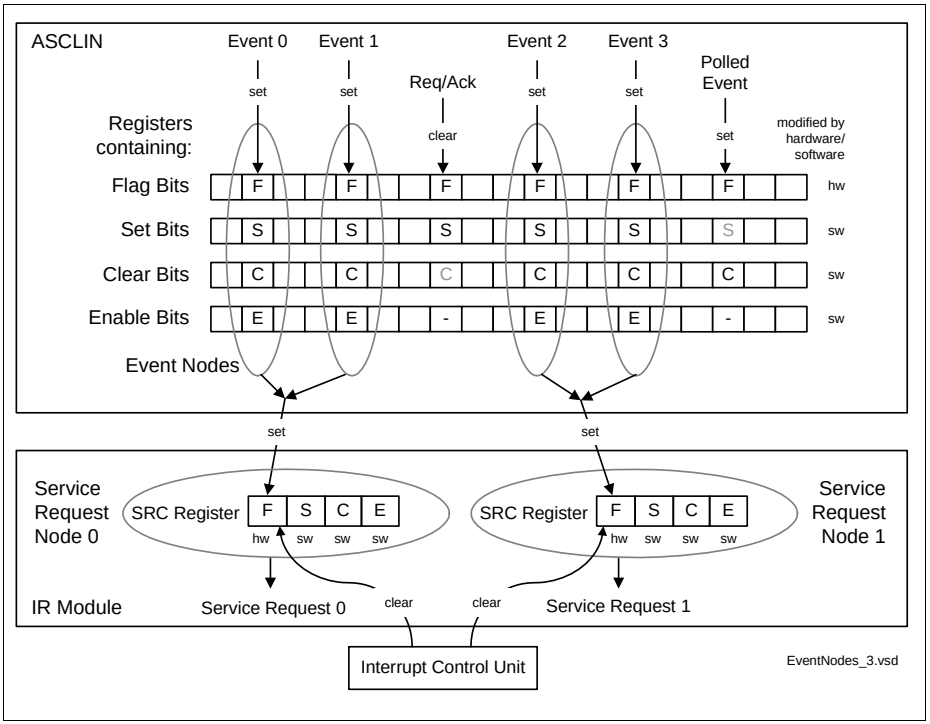

Figure 19-30 Acknowledge Flags and Polled Flags

19.14 Digital Glitch Filter

The digital glitch filter removes short glitches from the input data signal by using an increment / decrement counter with programmable threshold. On the other hand, the filter introduces a delay into the signal path, depending on the digital filter sampling frequency f_{PD} and the threshold programmed in the bit field **IOCR**.DEPTH.

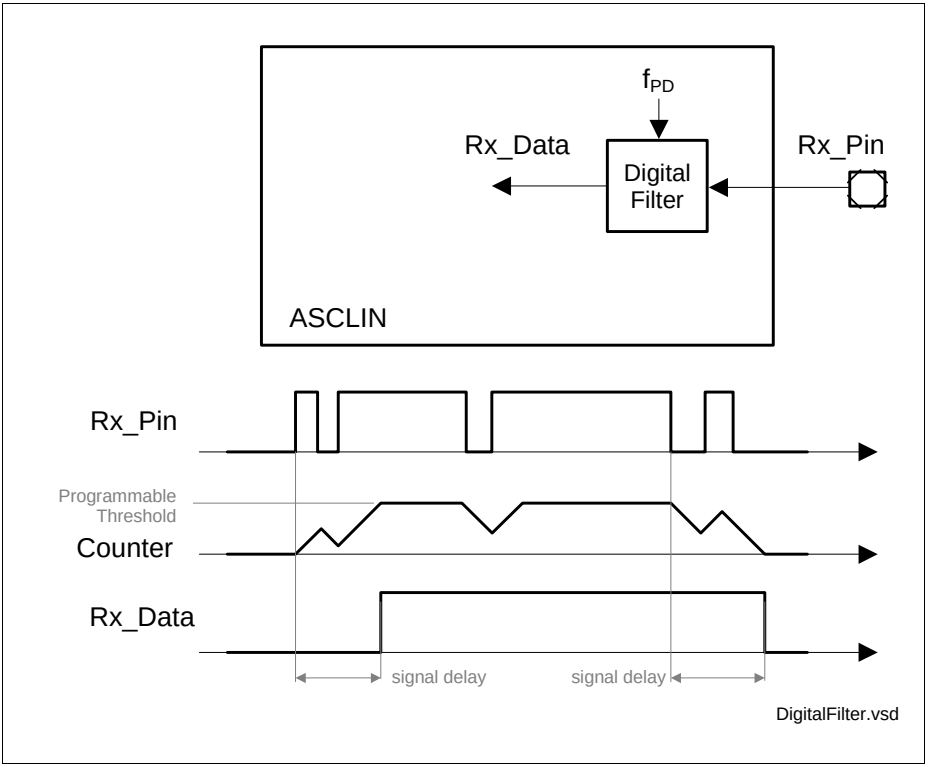

Figure 19-31 Digital Filter

19.15 Suspend, Sleep and Power-Off Behavior

Generally, the ASCLIN module transmits short data frames, not longer than 16 bits, mostly 8 bit long, sometimes with very low baud rates, down to few KBaud. In LIN mode, the data frames build LIN frames.

Simply freezing the module in the middle of an asynchronous ASC frame mostly results in an erroneous data at the receiver side, depending on the data content.

Freezing the module inside the LIN frame transmission, but between the transmission of single bytes results in a timeout error at the receiver side.

If the ASCLIN module gets a request for switching off the clock, it disables immediately all request lines towards the DMA in order to stop further DMA transfers.

In order to power down the module in a well defined way, the user software must take care that the power down request is issued when there is no ongoing single frame or LIN frame transfer and that both FIFOs are empty.

19.15.1 OCDS Suspend

OCDS soft suspend request suspends the module activity at the end of the current transaction. In ASC and SPI cases, this is the end of the current frame. In LIN case, this is the end of the current LIN frame (regular end of response, header timout, or response timeout).

OCDS hard suspend request, for debugging purposes, immediately freezes the ASCLIN module in the current state. The SPB clock feeding the kernel clock f_{CLC} is immediatly switched off. If f_{CLC} is selected for f_A (by using the **CSR**.CLKSEL bit field), the asynchronous clock f_A is also immediately switched off.

*Note: The asynchronous clock f_A remains switched on if a clock source other than f_{CLC} is selected for f_A (by using the **CSR**.CLKSEL bit field).*

Note: Reading and writing of registers is possible but will enable the kernel clock f_{CLC} for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a ASCLIN kernel reset might not be sufficient to bring the system into a defined state.

19.15.2 Sleep Mode

Going into sleep mode implies that the ASCLIN module has finished all activities and that the TX and RX FIFOs are empty. It is the responsibility of the user software to issue a sleep request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur.

The ASCLIN module behaves in the same way as in case of disable request..

19.15.3 Disable Request (Power-Off)

Going into power off implies that the ASCLIN module has finished all activities and that the TX and RX FIFOs are empty. It is the responsibility of the user software to issue a power-off request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur. This is no issue if the power-off procedure is one-way, that is no continuation of operation without reinitialization of the module is expected.

The ASCLIN module sets immediately all outputs to inactive, stops reacting to inputs, the internal state machines go to initial state, the registers remain unchanged, and then the module acknowledges the request. All clocks to the module are switched off.

19.16 Reset Behavior

There are two sources of reset:

- BPI (Bus Peripheral Interface)
- Reset bit in the kernel register KRSTx0.RST and KRSTx1.RST.

Both sources reset the ASCLIN module. They execute an Application Reset, which resets all the registers except the OCS register. All output signals get the reset value.

The **OCS** register is reset by the Debug Reset.

19.17 Use Case Example ASC Interface

This section explains the core functionality of the ASCLIN interface with a code example. The example uses the ASC feature of the module to transmit and receive a data set via loop back mode (see also figure 21-2 (LINK!)). The following settings are used:

- Data length: 8 bit
- Baud rate: 9600 Bd
- One stop bit, parity bit checking, oversampling factor 16, sampling points 7,8 and 9
- Rx and Tx interrupt

Step description to initialize the ASC module with the settings from above:

(Line 1) reset ENDINIT to get access to ENDINIT protected register, here ASCLIN0_CLC. (see also ENDINIT protection chapter 8.9.3(LINK))

(Line 2) enable the control of the module in the clock control register CLC (LINK)

(Line 3) store CLC register in a dummy variable (has to be defined before). Read back to avoid pipeline effects.

(Line 4) set ENDINIT to lock the protected register again.

(Line 5) The clk source gets set in the clock selection register CSR (LINK). Before setting a source, no clk supply ([3:0]=0) must be set. Final clk selection in Line 20.

(Line 6) This line sets the loop back mode in the input and output control register IOCR (LINK). (see also figure 21-2 (LINK))

(Line 7) This line clears and enables the Tx FIFO and also defines the writing size of 1 byte per clk. The Tx FIFO filling level to trigger an interrupt gets set to 0 ([11:8] =0). The Tx FIFO triggers a Tx interrupt, if the Tx FIFO filling level falls to or below that defined level. The Tx interrupt get enabled in Line 14. (see also chapter 21.4.1 TxFIFO Overview (LINK) and TXFIFOCON (LINK) register)

(Line 8) This line installs the Rx FIFO identically like the Tx FIFO from the line above. (see also RXFIFOCON (LINK) and chapter 21.4.2 RxFIFO Overview (LINK))

(Line 9) The oversampling factor (here 16), the sample points (here 7,8 and 9) and the prescalar for the baudrate (here 10) gets configured in the bit configuration register BITCON (LINK). (see also section 21.5. Clock System (LINK))

(Line 10) One stop bit and initialize mode as basic operation mode (necessary before switching to another mode) are getting configured in the FRAMECON (LINK) register. The parity bit feature with parity type even gets also enabled.

(Line 11) The data length of 8 bits gets set in the DATCON (LINK) register.

(Line 12) the clk divider for the baud rate gets set to 48/3125 in the baud rate generation register BRG (LINK) (see also 21.5. Clock System (LINK))

*Note: assuming f_{clc} = 100 MHz and (defined in line 8) prescalar = 10, oversampling = 16: f_{shift} = (f_{clc}/prescalar * 48/3125) / oversampling =* ***9600 Bd***

(Line 13) Clear all interrupt flags in the FLAGSCLEAR (LINK) register. Before setting the respective interrupt flags in Line 14

(Line 14) enable the Tx and Rx interrupts in the FLAGSENABLE (LINK) register. The interrupts getting triggered by the FIFO's (see Line 6/7).

(Line 15) This line enables the Tx interrupt in the service request control register SRC_ASCLIN0TX (LINK) and sets the interrupt priority to ASC0TX_PRIO (1...255).

(Line 16) This line enables the Rx interrupt in the service request control register SRC_ASCLIN0RX (LINK) and sets the interrupt priority to ASC0RX_PRIO (1...255).

(Line 17 and 18) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example (LINK) for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority ASC0TX_PRIO respectively ASC0RX_PRIO.

(Line 19) setting operating mode finally to ASC (see also Line 9).

(Line 20) setting clk source finally to f_{clc} (see also Line 4).

Note: your Tx ISR function prototype would be: void ASC0_TX_ irq (void); here could be your ISR code;

Initialization of the ASC interface:

```
(1)  SCU_vResetENDINIT (0);     // enable ENDINIT register
(2)  ASCLIN0_CLC = 0x000;       // disable module control
(3)  dummy = ASCLIN0_CLC;       //read back
(4)  SCU_vSetENDINIT (0);       // lock ENDINIT register
(5)  ASCLIN0_CSR = 0;           // clk source, no clk
(6)  ASCLIN0_IOCR = 0x10000001;           // Loopback
(7)  ASCLIN0_TXFIFOCON = 0x00000043;      // init TXFIFO
(8)  ASCLIN0_RXFIFOCON = 0x00000043;      // init RXFIFO
(9)  ASCLIN0_BITCON = 0x830F0009;    // OS 16, SP 7,8,9, PS 10
(10) ASCLIN0_FRAMECON = 0x40000200;       // 1 Stop, Init Mode, P
(11) ASCLIN0_DATCON = 0x7;      //8 Data Bits
(12) ASCLIN0_BRG = 0x00300C35;       // divider for Baudrate
(13) ASCLIN0_FLAGSCLEAR = 0xFFFFFFFFF;    // Clear all Flags
(14) ASCLIN0_FLAGSENABLE = 0xF0000000;    // Enable TX/RX Int.

(15) SRC_ASCLIN0TX = (1 << 10) | ASC0TX_PRIO;

(16) SRC_ASCLIN0RX = (1 << 10) | ASC0RX_PRIO;
```

```
(17) interruptHandlerInstall (ASC0TX_PRIO, & ASC0_TX_irq);
(18) interruptHandlerInstall (ASC0RX_PRIO, & ASC0_RX_irq);

(19) ASCLIN0_FRAMECON |= 0x00010000;// Mode ASC
(20) ASCLIN0_CSR = 1;            //clk source CLC
```

Note: Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):
__enable();
to set this bit. (See also Architecture Manual for more details)

19.18 Kernel Registers

This section describes the kernel registers of the ASCLIN module. All ASCLIN kernel register names described in this section will be referenced in other parts of the TC21x/TC22x/TC23x User's Manual by the module name prefix "ASCLIN0_" for the ASCLIN0 interface and "ASCLIN1_" for the ASCLIN1 interface.

All registers in the ASCLIN address spaces are reset with the application reset (definition see SCU section "Reset Operation").

ASCLIN Kernel Register Overview

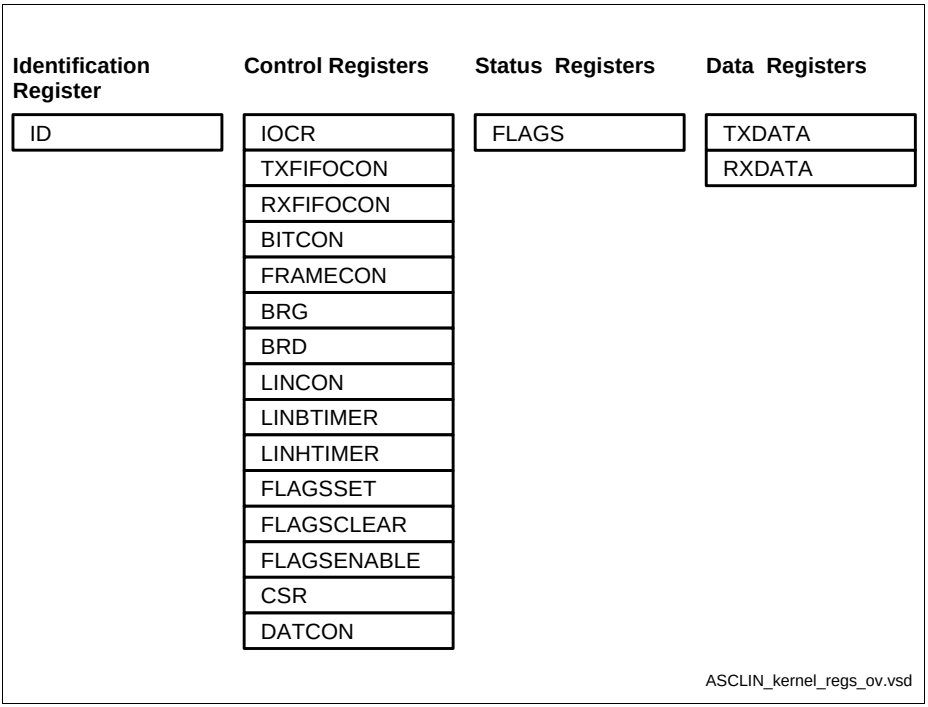

Figure 19-32 ASCLIN Kernel Registers

*Note: Absolute Register Address = Module Base Address (**Table 19-3**) + Offset Address (**Table 19-4**).*

Table 19-3 Registers Address Space

Module	Base Address	End Address	Note
ASCLIN0	$F0000600_H$	$F00006FF_H$	–
ASCLIN1	$F0000700_H$	$F00007FF_H$	–

Table 19-4 Registers Overview

Register Short Name	Register Long Name	Offset Address	Write [1] Access	Reset Value
IOCR	Input Output Control Register [2]	04_H	U, SV,P	X000 0000
ID	Module Identification Register	08_H	BE	00C1 C0XX
TXFIFOCON	TX FIFO Configuration Register	$0C_H$	U, SV,P	0000 0000
RXFIFOCON	RX FIFO Configuration Register	10_H	U, SV,P	0000 0000
BITCON	Bit Timing Configuration Reg. [2]	14_H	U, SV,P	0000 0000
FRAMECON	Frame Configuration Register [2]	18_H	U, SV,P	0000 0000
DATCON	Data Configuration Register	$1C_H$	U, SV,P	0000 0000
BRG	Baud Rate Generation Register [2]	20_H	U, SV,P	0000 0000
BRD	Baud Rate Detection Register [2]	24_H	U, SV,P	0000 0000

RXDATA	Receive Data Register	48_H	BE	0000 0000
CSR	Clock Selection Register	$4C_H$	U, SV,P	0000 0000
RXDATAD	Receive Data Debug Register	50_H	BE	0000 0000
BPI Registers				
CLC	Clock Control Register	00_H	SV, E, P	0000 0003
OCS	OCDS Control and Status Reg.	$E8_H$	SV, P	0000 0000
KRSTCLR	Reset Status Clear Register	EC_H	SV, E, P	0000 0000
KRST1	Reset Control Register 1	$F0_H$	SV, E, P	0000 0000
KRST0	Reset Control Register 0	$F4_H$	SV, E, P	0000 0000
ACCEN1	Access Enable Register 1	$F8_H$	SV, SE	0000 0000
ACCEN0	Access Enable Register 0	FC_H	SV, SE	FFFF FFFF

1) All registers have read access mode U, SV. Read access from reserved addresses delivers bus error (BE). All registers belong to application (class 3) reset except OCS, which belongs to debug (class 1) reset.
2) This register is writable only if **CSR**.CLKSEL=0.

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - Safety ENDINIT

19.18.1 Kernel Registers

IOCR

The Input and Output Control Register IOCRx determines several properties of the RX and TX signal path:

for the RX signal:

- the alternate input
- the filter depth

for the TX signal

- the trigger source

(>> **Table 19-4** register overview)

(>> **Baud Rate Generation**)

(>> **Bit Timing Properties**)

IOCR

Input and Output Control Register (04) **Reset Value: X000 0000$_H$**

0						**DEPTH**						**0**		**ALTI**	
r						rw						r		rw	

Field	Bits	Type	Description
ALTI	[2:0]	rw	**Alternate Input Select** Selects the alternate input for the RX signal: 000_B Alternate Input 0 selected 001_B Alternate Input 1 selected $\cdots_B$ … 111_B Alternate Input 7 selected

Field	Bits	Type	Description
DEPTH	[9:4]	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with microticks that are taken into account for the calculation of the floating average. The higher the DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 000000_B off, default 000001_B 1 000010_B 2 000011_B 3 $\ldots_B$ … 111111_B 63
CTS	[17:16]	rw	**CTS Select** Selects the CTS input pin out of maximum four possible. 00_B 0 01_B 1 10_B 2 11_B 3
RCPOL	25	rw	**RTS CTS Polarity** RCPOL defines the active level or the RTS and CTS signals. Active means ready/clear to send. 0_B active high 1_B active low
CPOL	26	rw	**Clock Polarity in Synchronous Mode** CPOL defines the idle level of the clock signal if the module is set in the SPI mode. The idle level is the level outside the data transmission time intervals. Default is low level. 0_B Idle low 1_B Idle high
SPOL	27	rw	**Slave Polarity in Synchronous Mode** Defines the idle level of the SLSO signal, which is the level outside the data transmission, leading and trailing time intervals. 0_B Idle low 1_B Idle high

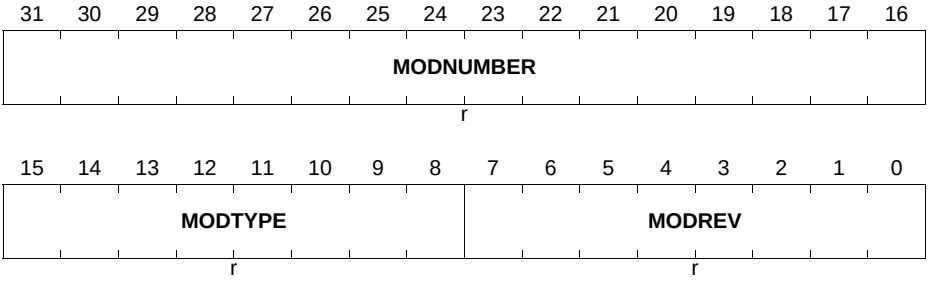
Field	Bits	Type	Description
LB	28	rw	**Loop Back Mode** Enables the in module connection of the transmit signal to receive signal. If Loop-back is enabled, the module can be run and tested without an external connection, in ASC and SPI modes. In LIN mode, loopback should not be used, because the module can be either master or slave. 0_B Disabled 1_B Enabled
CTSEN	29	rw	**Input Signal CTS Enable** Enables the sensitivity of the module to the external CTS signal. If disabled, the CTS signal is considered being permanently active. 0_B Disabled 1_B Enabled
RXM	30	rh	**Receive Monitor** Shows the status of the receive signal. 0_B Current signal is low. 1_B Current signal is high.
TXM	31	rh	**Transmit Monitor** Shows the status of the transmit signal. 0_B Current signal is low. 1_B Current signal is high.
0	3, [15:10], [24:18]	r	**Reserved** Read as 0; should be written with 0.

ID

The Module Identification Register ID contains read-only information about the module version.

(>> **Table 19-4** register overview)

ID
Module Identification Register (08$_H$) Reset Value: 00C1 C0XX$_H$



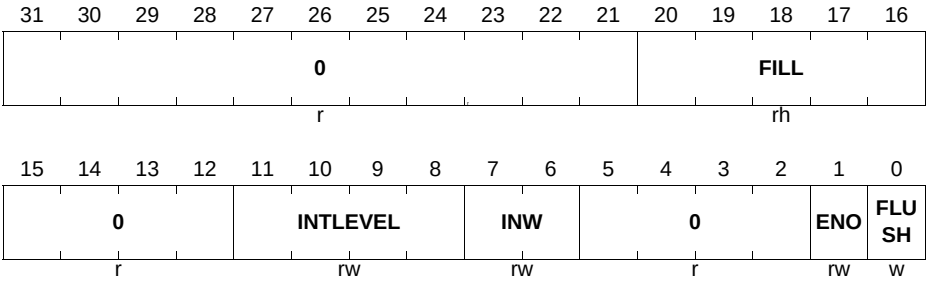
Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field is C0$_H$. It defines a 32-bit module.
MOD NUMBER	[31:16]	r	**Module Number Value** This bit field together with MODTYPE uniquely identifies a module.

TXFIFOCON

(>> **Table 19-4** register overview)

TXFIFOCON

TX FIFO Configuration Register (0C$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
FLUSH	0	w	**Flush the transmit FIFO** Write of 1 brings the Tx FIFO in empty state. Write of 0 has no effect. 0_B No effect 1_B Empty the Tx FIFO
ENO	1	rw	**Transmit FIFO Outlet Enable** Enables the TxFIFO outlet. In SPI and ASC modes, data transmission starts immediately when the data is available, whereas in LIN case the transmission start is controlled by the protocol engine. 0_B Disabled. In LIN case, if the protocol engine tries to fetch data. 1_B Enabled. In LIN case, no data is moved to the shift register until it is fetched by the protocol engine.
INW	[7:6]	rw	**Transmit FIFO Inlet Width** Defines the number of bytes written to the Tx FIFO with one FPI bus write. 00_B 0 01_B 1 10_B 2 11_B 4

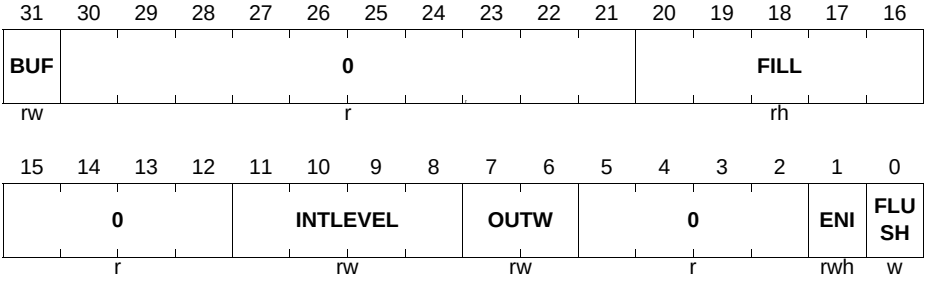
Field	Bits	Type	Description
INTLEVEL	[11:8]	rw	**FIFO Interrupt Level** Defines the filling level that triggers an re-fill interrupt or DMA access. An interrupt is generated when the filling level falls to INTLEVEL or below, each time when a data byte is taken out of the FIFO 0000_B 0 0001_B 1 0010_B 2 $...B$ ... 1111_B 15
FILL	[20:16]	rh	**FIFO Filling Level** Read only bit-field containing the current filling level of the FIFO. 00000_B 0 00001_B 1 $...B$ ... 10000_B 16 10001_B reserved 10010_B reserved 10011_B reserved 10100_B reserved 10101_B reserved 10110_B reserved 10111_B reserved 11000_B reserved 11001_B reserved 11010_B reserved 11011_B reserved 11100_B reserved 11101_B reserved 11110_B reserved 11111_B reserved
0	[5:2], [15:12], [31:21]	r	**Reserved**

RXFIFOCON

(>> **Table 19-4** register overview)

RXFIFOCON

RX FIFO Configuration Register (10_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
FLUSH	0	w	**Flush the receive FIFO** Write of 1 brings the Rx FIFO in empty state. Write of 0 has no effect. 0_B No effect 1_B Empty the Rx FIFO
ENI	1	rwh	**Receive FIFO Inlet Enable** Enables the receiver and the filling of the Rx FIFO through the shift register. In LIN slave mode, this bit is set by hardware after the correct reception of the sync byte. The software can clear this bit after reception of an foreign ID in order to suppress the reception of the following response. 0_B Disabled 1_B Enabled
OUTW	[7:6]	rw	**Receive FIFO Outlet Width** Defines the number of bytes read to the Rx FIFO with one FPI bus read. 00_B 0 01_B 1 10_B 2 11_B 4

Field	Bits	Type	Description
INTLEVEL	[11:8]	rw	**FIFO Interrupt Level** Defines the filling level that triggers a drain interrupt or DMA access. An interrupt is generated when the filling level rises to INTLEVEL or beyond, each time when a data byte is delivered to the FIFO. 0000_B 1 0001_B 2 $...B$ ... 1111_B 16
FILL	[20:16]	rh	**FIFO Filling Level** Read only bit-field containing the current filling level of the FIFO. 00000_B 0 00001_B 1 $...B$ ... 10000_B 16 10001_B reserved 10010_B reserved 10011_B reserved 10100_B reserved 10101_B reserved 10110_B reserved 10111_B reserved 11000_B reserved 11001_B reserved 11010_B reserved 11011_B reserved 11100_B reserved 11101_B reserved 11110_B reserved 11111_B reserved

Field	Bits	Type	Description
BUF	31	rw	**Receive Buffer Mode** If this bit is zero, then the RXFIFO behaves normally as described in the ITS If this bit is set, the RXFIFO behaves as simple 32-bit one stage RX buffer, which is overwritten with each new received data. The received bits appear in the RXDATA register on the lowest bit locations. The upper locations are padded with zeros. 0_B RXFIFO 1_B Single Stage RX Buffer
0	[5:2], [15:12], [30:21]	r	**Reserved**

BITCON

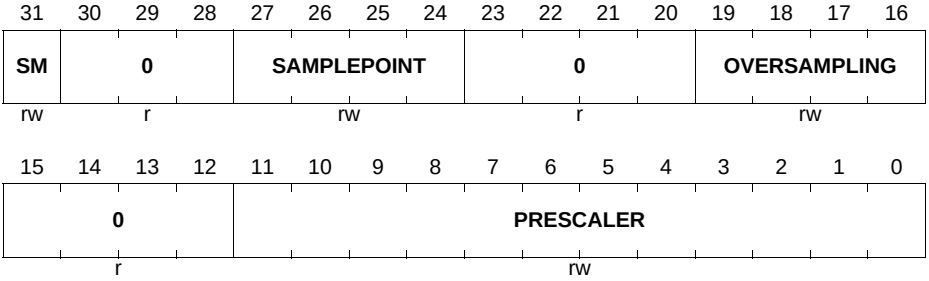
The BITCON Register defines the integer timer parameters in the baud rate generation block.

(>> **Table 19-4** register overview)

(>> **Baud Rate Generation**)

(>> **Bit Timing Properties**)

BITCON
Bit Configuration Register **(14_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
PRE SCALER	[11:0]	rw	**Prescaling of the Fractional Divider** Prescaler in the range of 1 to 4096. Used also as a microtick generator for the input digital filter.
OVER SAMPLING	[19:16]	rw	**Oversampling Factor** Defines the bit length in ticks in the range of 1 to 16. The lengths of 1 to 3 are not allowed. The position of the sampling points is shown in **Figure 19-16**. 0000_B 1 (not allowed) 0001_B 2 (not allowed) 0010_B 3 (not allowed) 0011_B 4 $\cdots_B$ ... 1111_B 16

Field	Bits	Type	Description
SAMPLE POINT	[27:24]	rw	**Sample Point Position** Programmable in the range of 0 to 15 according to the Figure 19-16. For example, if three sample points at position 7, 8, 9 are required, this bit field would contain 9. 0000_B 0 (not allowed) 0001_B 1 $...{}_B$ ... 1111_B 15 In SPI mode, this bit field + 1 defines the length of the first SCLK half period in ticks. Values equal or higher then the OVERSAMPLING value are forbidden.
SM	31	rw	**Sample Mode** Number of samples per bit. 0_B 1 1_B 3
0	[15:12], [23:20], [30:28]	r	**Reserved**

FRAMECON

The parameters regarding the properties of the message frame of the ASC communication are controlled by the Frame Control Register FRAMECON.

(>> **Table 19-4** register overview)

FRAMECON
Frame Control Register **(18_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	**LEAD**			**STOP**			**IDLE**			**0**					
r	rw			rw			rw			r					

Field	Bits	Type	Description
IDLE	[8:6]	rw	**Duration of the IDLE delay** Defines the duration of the IDLE delay in bit times. If more characters are available in the TXFIFO, this is the pause inserted between the characters. In the SPI mode, this is the idle time between the frames. In the ASC and LIN mode, this is the pause inserted between transmission of bytes. Idle also applies to the pause between the header and the response (response space). *Note: The collision detection runs in parallel to the idle delay and in LIN mode may extend the time between two bytes for one bit length. This effect may occure if the the round trip delay including the digital filter delay is longer than the idle delay.* 000_B 0 001_B 1 ...B ... 111_B 7
STOP	[11:9]	rw	**Number of Stop Bits** Defines the number of stop bits in ASC and LIN mode, or the trailing delay in SPI mode. In ASC mode, standard values are 1 and 2. In LIN mode, standard value is 1. In SPI mode there is no standard value. Nevertheless, all settings are possible in all modes. 000_B 0 (not allowed in ASC and LIN modes) 001_B 1 ...B ... 111_B 7
LEAD	[14:12]	rw	**Duration of the Leading Delay** Defines the leading delay in bit times in SPI mode. Has no meaning in the ASC mode. In LIN mode, this is a delay inserted between the end of the break and the start of the sync character. 000_B 0 (not allowed in LIN mode) 001_B 1 ...B ... 111_B 7

Field	Bits	Type	Description
MODE	[17:16]	rw	**Mode Selection** This bit field defines the basic operating mode of the module. In initialize mode, all outputs are at inactive level, an the module does not respond to the input signals. Changing the mode of the module must be done by switching first to initialize mode, and then to the other mode. The SCLK signal generated by the module is active only in the SPI mode. The CTS output generated by the module is active only in the ASC mode. 00_B Initialize mode 01_B ASC mode 10_B SPI mode 11_B LIN mode
MSB	28	rw	**Shift Direction** Defines the shift direction of the shift register. Relevant for the SPI mode. In ASC and LIN modes, should be set to zero. Parity bit is shifted out last independently of the shift direction. 0_B LSB first 1_B MSB first
CEN	29	rw	**Collision Detection Enable** Enables the collision detection mechanism. 0_B Disabled 1_B Enabled
PEN	30	rw	**Parity Enable** Enables the parity bit attached to the data bits. Parity bit can be used for ASC and SPI protocols. The standard LIN bytes do not use this parity bit. 0_B Disabled 1_B Enabled

Field	Bits	Type	Description
ODD	31	rw	**Parity Type** Defines the type of parity bit attached to the data bits. This setting is valid for all modes of operation (ASC, LIN, SPI). 0_B Even 1_B Odd
0	[5:0], 15, [27:18]	r	**Reserved** Read as 0; should be written with 0.

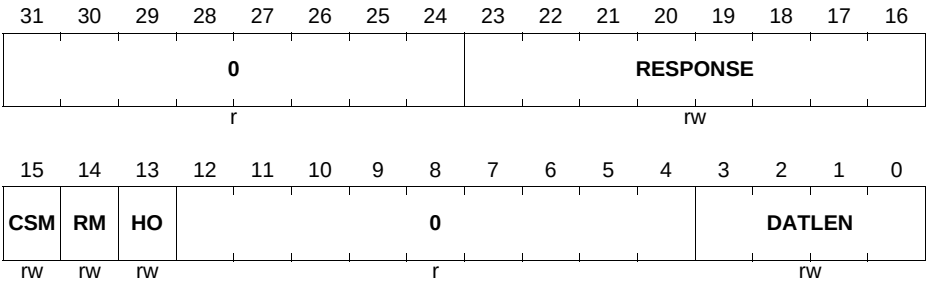
DATCON

DATCON register defines the number of bits in the ASC (affecting the LIN protocol, if used) and SPI frames, data length or the number of data bytes in a LIN response (if any) and the checksum mode. It additionly defines the time window for the LIN response.

In case the whole LIN response does not fit in this time window, an error interrupt is generated. The measurement starts at the end of the last bit of the header, and ends at the end of the last bit of the response.

(>> **Table 19-4**)

DATCON
Data Configuration Register **($1C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RESPONSE	[23:16]	rw	**Response Timeout Threshold Value** Defines the timer limit in the range of 1 to 256 bit times.
HO	13	rw	**Header Only** Defines if the LIN frame shall consist of a header and response or of a header only. 0_B Header and response expected 1_B Header only expected, response ignored
RM	14	rw	**Response Mode** Defines if the RESPONSE bit field defines a LIN Response or LIN Frame timeout threshold. See **Figure 19-23**. 0_B Frame 1_B Response

Field	Bits	Type	Description
CSM	15	rw	**Checksum Mode** Defines if the classic or the enhanced checksum will be calculated by the checksum block. 0_B Classic 1_B Enhanced
DATLEN	[3:0]	rw	**Data Length** Defines the number of bits in a character. In the ASC mode, standard length is 7, 8, or 9 bits. In the SPI mode, there is no standard length. In ASC and SPI modes, any length from 2 to 16 bits is possible, although not standard for some protocols. In LIN mode, standard length is 8 bits per character. Therefore, this field defines the number of data bytes of the response. 0000_B 1 0001_B 2 0010_B 3 0011_B 4 $...{}_B$ ... 1111_B 16
0	[31:24], [12:4]	r	**Reserved**

BRG

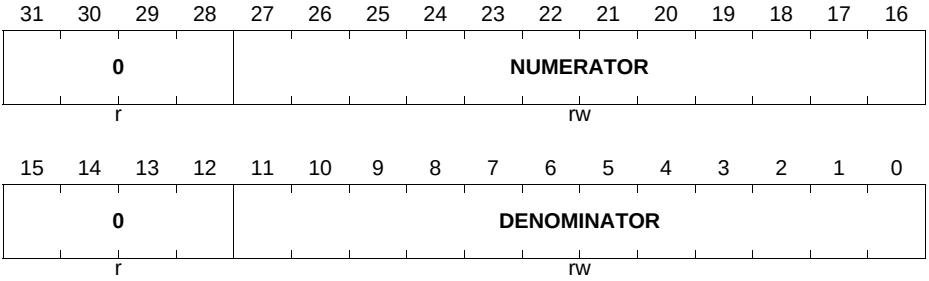
Configures the numerator and the denominator of the fractional divider in the baud rate generation block.

(>> **Table 19-4** register overview)

(>> **Baud Rate Generation**)

BRG

Baud Rate Generation Register (20_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
NUMERATOR	[27:16]	rw	**Numerator** Defines the numerator of the fractional divider in a range of 0 to 4095. Programmed by software. The setting of 0 is not allowed.
DENOMINATOR	[11:0]	rw	**Denominator** Programmed by software, in a range of 0 to 4095. The setting of 0 is not allowed If the module is used as ASC, SPI, LIN master and LIN slave without autobaud detection, this value determines the baud rate. In slave mode with autobaud detection, it contains the nominal value. For the value measured by the autobaud detection hardware, see the **BRD** register.
0	[15:12], [31:28]	r	**Reserved**

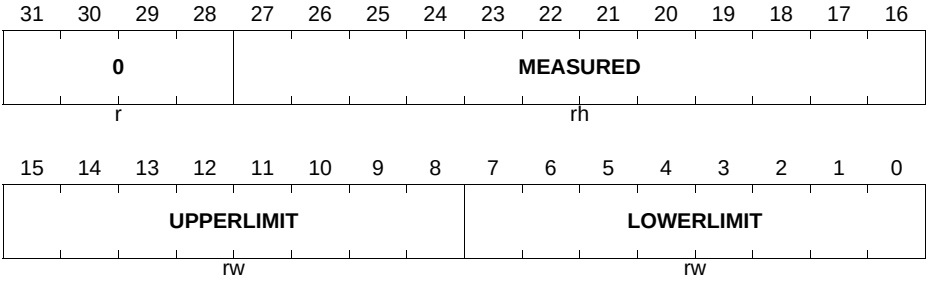
BRD

The BRD defines the properties specific for the automatic baud rate detection when the module operates as a LIN slave.

(>> **Table 19-4** register overview)

(>> **Auto Baud Rate Detection**)

BRD
Baud Rate Detection Register **(24_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
LOWER LIMIT	[7:0]	rw	**Lower Limit** This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000_B. See **Auto Baud Rate Detection**.
UPPER LIMIT	[15:8]	rw	**Upper Limit** This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000_B. See **Auto Baud Rate Detection**.
MEASURED	[27:16]	rh	**Measured Value of the Denominator** This bit field contains the measured value of the duration of 8-bits form the sync field of the LIN header in microtics. It is automatically loaded in the denominator of the fractional divider, in case of LIN slave operation with autobaud detection.
0	[31:28]	r	**Reserved**

LINCON

LINCON contains bits that control LIN specific features of the module.

(>> **Table 19-4** register overview)

(>> **LIN Protocol Control** chapter)

(>> **LIN Master Sequences**, **LIN Slave Sequences**)

LINCON
LIN Control Register **(28_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				ABD	MS	CSEN	0	CSI	0						
r				rw	rw	rw	r	rw	r						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															
r															

Field	Bits	Type	Description
CSI	23	rw	**Checksum Injection** Defines if the received checksum byte is written into the RXFIFO or not. See **LIN Protocol Control**. 0_B Not written 1_B Written
CSEN	25	rw	**Hardware Checksum Enable** Enables the hardware checksum generation and checking. 0_B Disabled 1_B Enabled
MS	26	rw	**Master Slave Mode** Configures if the module in LIN mode operates as master or as slave. 0_B Slave 1_B Master

Field	Bits	Type	Description
ABD	27	rw	**Autobaud Detection** Enables the autobaud detection feature in LIN slave mode. In all other operating modes of the module (LIN master, ASC, SPI) not effective. If the autobaud detection is disabled (the oscillator precision of the slave is sufficient), the measurement is still active and the **FLAGS**.LA will be set when the value is outside the **BRD**.LOWERLIMIT and .UPPERLIMIT range. Additionally the stop bit of the sync field is checked if correct. If not correct, a framing error is triggered. 0_B Disabled 1_B Enabled
0	24, [22:0], [31:28]	r	**Reserved** Read as 0; should be written with 0.

LINBTIMER

This register defines

- break detection limit if the module operates as LIN slave or
- length of the generated break pulse if the module operates as LIN master.

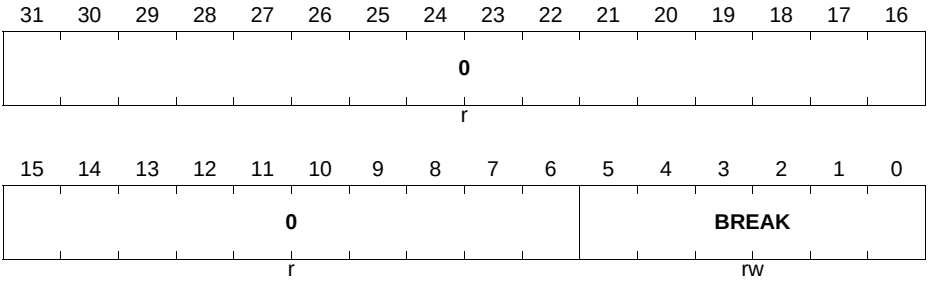
The break timer, if enabled, monitors the bus continuously.

(>> **Table 19-4** register overview)

(>> **LIN Break, Wake, Stuck Handling**)

(>> **LIN Master Sequences**, **LIN Slave Sequences**)

LINBTIMER
LIN Break Timer Register **($2C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BREAK	[5:0]	rw	**Break Pulse Generation and Detection** In LIN slave mode, this bit field defines the duration of the detection threshold for the break pulse. In LIN master mode, this bit field defines the duration of the transmitted break pulse. The time unit is bit time.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

LINHTIMER

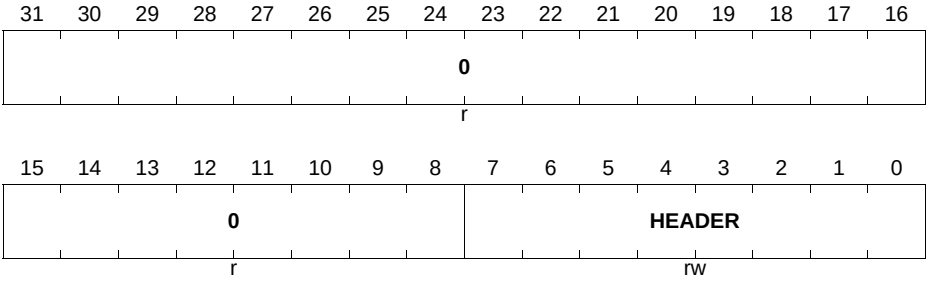
LINHTIMER register defines the time windows for the header of a LIN frame.

In master mode, the timer starts counting at the falling edge of the break pulse, and stops counting when the last bit of the header (including the stop bits) has been transmitted. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

In slave mode, the timer starts counting when the break pulse has been detected, after a low time of 10 or 11 bit times, and stops counting when the last bit of the header has been received. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

(>> **Table 19-4** register overview)

LINHTIMER
LIN Header Timer Register **(30_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
HEADER	[7:0]	rw	**Header Timeout Threshold Value** Defines the timer limit in the range of 1 to 256 bit times.
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

FLAGS

The FLAGS register contains all the flag bits of the ASCLIN module: the LIN phase flags (header and response transmit and receive), the overflow flags of the LIN timers, and the standard ASC error flags.

A corresponding interrupt triggering can be enabled using the **FLAGSENABLE** register.

(>> **Table 19-4** register overview)

(>> **LIN Master Sequences**, **LIN Slave Sequences**)

FLAGS
Flags Register **(34_H)** **Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
TH	0	rh	**Transmit Header End Flag** Signals the HEADER_TX_END event. Set by hardware, clear by software. If enabled, a transmit interrupt is triggered. 0_B No HEADER_TX_END event since the last clear by software 1_B New HEADER_TX_END event since the last clear by software
TR	1	rh	**Transmit Response End Flag** Signals that RESPONSE_TX_END event. Set by hardware, clear by software. If enabled, a transmit interrupt is triggered. 0_B No RESPONSE_TX_END event since the last clear by software 1_B New RESPONSE_TX_END event since the last clear by software

Field	Bits	Type	Description
RH	2	rh	**Receive Header End Flag** Signals that HEADER_RX_END event. Set by hardware, clear by software. If enabled, a receive interrupt is triggered. 0_B No HEADER_RX_END event since the last clear by software 1_B New HEADER_RX_END event since the last clear by software
RR	3	rh	**Receive Response End Flag** Signals that RESPONSE_RX_END event. Set by hardware, clear by software. If enabled, a receive interrupt is triggered. 0_B No RESPONSE_RX_END event since the last clear by software 1_B New RX_RESPOSE_END event since the last clear by software
FED	5	rh	**Falling Edge from Level 1 to Level 0 Detected** This bit is set by hardware when a falling edge is detected on the RX line. 0_B No falling edge detected 1_B Faling edge detected
RED	6	rh	**Rising Edge from Level 0 to Level 1 Detected** This bit is set by hardware when a rising edge is detected on the RX line. 0_B No rising edge detected 1_B Rising edge detected
TWRQ	13	rh	**Transmit Wake Request Flag** Signals that transmission of wake has been requested. No interrupt triggered. As soon as the wake pulse transmission starts, the bit is cleared by the hardware. 0_B No Transmit Wake Request pending 1_B Transmit Wake Request pending.
THRQ	14	rh	**Transmit Header Request Flag** Signals that transmission of header has been requested. No interrupt triggered. As soon as the header transmission starts, the bit is cleared by the hardware. 0_B No Transmit Header Request pending 1_B Transmit Header Request pending.

Field	Bits	Type	Description
TRRQ	15	rh	**Transmit Response Request Flag** Signals that transmission of response has been requested. No interrupt triggered. As soon as the response transmission starts, the bit is cleared by the hardware. 0_B No Transmit Response Request pending 1_B Transmit Response Request pending.
PE	16	rh	**Parity Error Flag** Signals parity error. If enabled, an error interrupt is triggered. Parity error occurs if the internally calculated parity bit is not equal to the received parity bit. 0_B Last message received error free 1_B Last message received with parity error
TC	17	rh	**Transmission Completed Flag** Signals an end of an ASC or SSC frame. This bit is set after the last stop bit transmission in ASC mode, or after the trailing delay in case of SPI mode. If enabled, an EX interrupt is triggered. Should be cleared by software. 0_B No end of frame event pending 1_B End of frame event pending
FE	18	rh	**Framing Error Flag** Signals framing error. If enabled, an error interrupt is triggered. Framing error occurs if “0” is received at a stop bit position. If autobaud detection is deactivated, then the sync field is checked for framing error. 0_B Last message received error free 1_B Last message received with error
HT	19	rh	**Header Timeout Flag** Signals violation of the header duration limit. If enabled, an error interrupt is triggered. 0_B No HEADER_OVERFLOW event since the last clear by software 1_B New HEADER_OVERFLOW event since the last clear by software

Field	Bits	Type	Description
RT	20	rh	**Response Timeout Flag** Signals violation of the response or frame duration limit as defined in **DATCON**.RM bit. If enabled, an error interrupt is triggered. 0_B No timout event since the last clear by software 1_B New timout event since the last clear by software
BD	21	rh	**Break Detected Flag** Signals a detection of a break pulse. If enabled, an error interrupt is triggered. Slave mode only. 0_B No BWS_OVERFLOW event since the last clear by software 1_B New BWS_OVERFLOW event since the last clear by software
LP	22	rh	**LIN Parity Error Flag** Signals parity error in the LIN identifier. If enabled, an error interrupt is triggered. Applies to LIN mode only. LIN parity error occurs if the internally calculated parity bits are not equal to the received parity bits. 0_B Last ID received error free 1_B Last ID received with parity error
LA	23	rh	**LIN Autobaud Detection Error Flag** Signals baudrate outside the range defined by **BRD**.LOWERLIMIT and **BRD**.UPPERLIMIT. 0_B No autobaud detection error 1_B Autobaud detection error
LC	24	rh	**LIN Checksum Error Flag** Signals checksum error when receiving response, if the internally calculated checksum is different than the received checksum. If enabled, an error interrupt is triggered. 0_B Last checksum error free 1_B Last checksum shows an error

Field	Bits	Type	Description
CE	25	rh	**Collision Detection Error Flag** When transmitting, signals if the transmitted data differs from the received data. If enabled, an error interrupt is triggered in case of a mismatch. Collision detection is mandatory only when supporting LIN version 2.1. 0_B No mismatch 1_B Mismatch detected
RFO	26	rh	**Receive FIFO Overflow Flag** Signals an overflow error. If enabled, an error interrupt is triggered. 0_B No overflow error pending 1_B Overflow error pending
RFU	27	rh	**Receive FIFO Underflow Flag** Signals an underflow error. If enabled, an error interrupt is triggered. See also **RxFIFO Overview**. 0_B No underflow error pending 1_B Underflow error pending
RFL	28	rh	**Receive FIFO Level Flag** An interrupt (if enabled) is generated when the RXFIFO filling level rises to INTLEVEL or above, each time when a data byte is delivered to the RXFIFO. This flag signals that the event from above occured. 0_B No receive interrupt pending 1_B Receive interrupt pending
TFO	30	rh	**Transmit FIFO Overflow Flag** Signals an overflow error. If enabled, an error interrupt is triggered. 0_B No overflow error pending 1_B Overflow error pending
TFL	31	rh	**Transmit FIFO Level Flag** A TXFIFO refill interrupt (if enabled) is generated when the filling level falls to INTLEVEL or below, each time when a data byte is taken out of the TXFIFO. This flag signals that the event from above occured. 0_B No transmit interrupt pending 1_B Transmit interrupt pending

Field	Bits	Type	Description
0	4, [12:7], 29	r	**Reserved** Read as 0; should be written with 0.

FLAGSSET

The FLAGSSET register contains the write only bits used to set the corresponding bits in the FLAGS register by software. Setting a flag bit triggers an interrupt, if the corresponding interrupt enable bit is set.

(>> **Table 19-4** register overview)

(>> **LIN Master Sequences**, **LIN Slave Sequences**)

(>> **FLAGS** register)

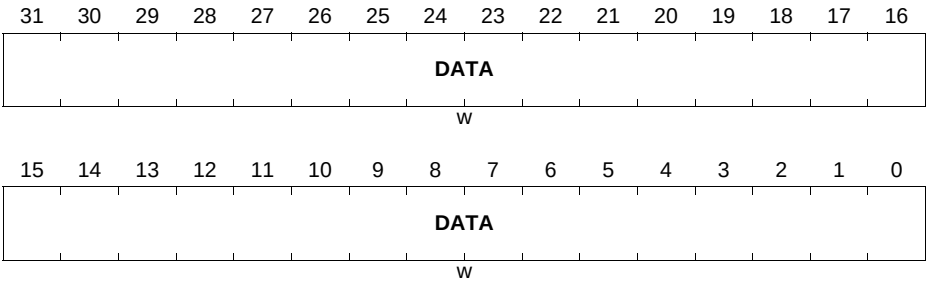
TFOE	30	rw	**Flag Enable Bit** This bit enables the interrupt for the flag at the corresponding position in the FLAGS register. 0_B Disabled 1_B Enabled
TFLE	31	rw	**Flag Enable Bit** This bit enables the interrupt for the flag at the corresponding position in the FLAGS register. 0_B Disabled 1_B Enabled
0	4, [15:7], 29	r	**Reserved** Read as 0; should be written with 0.

TXDATA

Writing data to this register enters the data to the TXFIFO.

(>> **Table 19-4**)

TXDATA
Transmit Data Register **(44_H)** **Reset Value: 0000 0000_H**



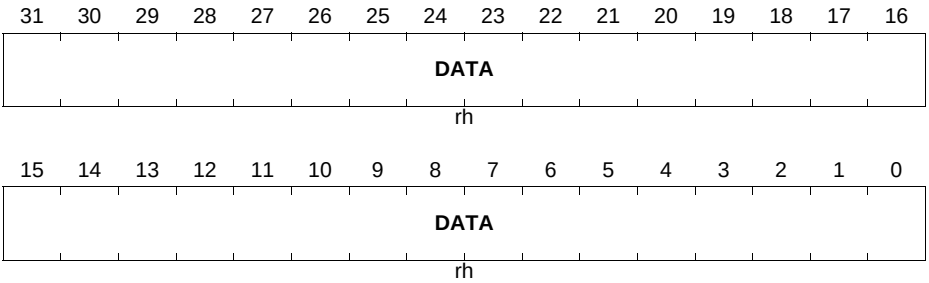
Field	Bits	Type	Description
DATA	[31:0]	w	**Data** Writing to this bit field writes the content to the TXFIFO, depending on the write width - 8, 16 or 32 bit. read from this register returns 0.

RXDATA

Reading data from this register takes data from the RXFIFO.

(>> **Table 19-4**)

RXDATA
Receive Data Register **(48_H)** **Reset Value: 0000 0000_H**



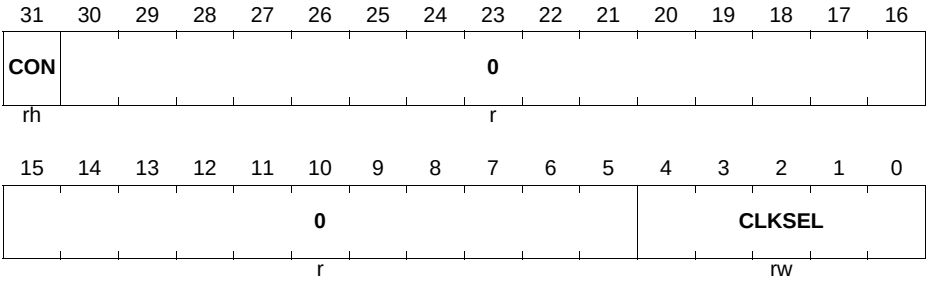
Field	Bits	Type	Description
DATA	[31:0]	rh	**Data** Reading from this bit field takes content from the RXFIFO, depending on the read width - 8, 16 or 32 bit. Write to this register has no effect.

CSR

This register is used to select the clock source for the baud rate generation, detection, timeouts and the SPI delays.

(>> **Table 19-4**)

CSR
Clock Selection Register **($4C_H$)** **Reset Value: 0000 0000$_H$**



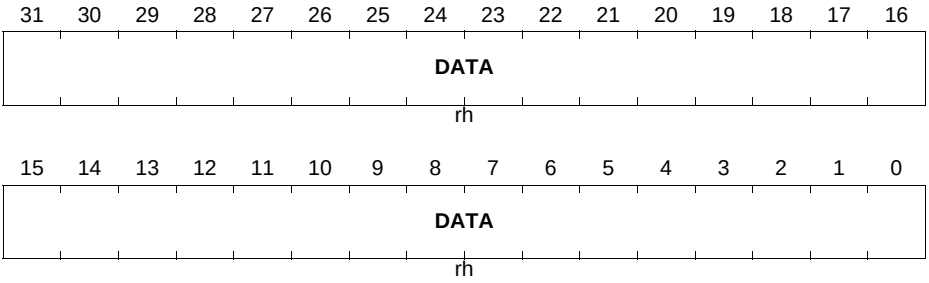
Field	Bits	Type	Description
CLKSEL	[4:0]	rw	**Baud Rate Logic Clock Select** 00000_B No clock supplied 00001_B f_{CLC} 00010_B XTAL Oscillator Clock f_{OSC0} 00100_B f_{ERAY} 01000_B $f_{ASCLINF}$ 10000_B $f_{ASCLINS}$ $...{}_B$ not allowed
CON	31	rh	**Clock On Flag** Shows if the clock in the bit time domain is switched on or off. Many configuration registers can be written only if this bit shows 0 (see **Table 19-4**). 0_B clock is off 1_B clock is on
0	[30:5]	r	**Reserved** Read as 0; should be written with 0.

RXDATAD

Reading data from this register takes data from the RXFIFO, but does not influence the read pointer. This virtual register provides non-destructive read to the RXFIFO.

(>> **Table 19-4**)

RXDATAD
Receive Data Debug Register (50_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
DATA	[31:0]	rh	**Data** Reading from this bit field takes content from the RXFIFO, depending on the read width - 8, 16 or 32 bit, but dooes not influence the read pointer of the RXFIFO. Write to this register has no effect.

Clock Reconfiguration

The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bitfield, and then a second write defining the new clock source. Between the first and the second write a delay of minimum $T_W \geq 4 * (1/f_A) + 2 * (1/f_{CLC})$ must be inserted by software, where f_A is the frequency being switched off with the first write. Exception: in case that the f_{CLC} is selected as a baud rate and bit timing logic clock (CSR.CLKSEL = 1), no delay cycles between the writes are necessary. In both cases, simply using one write defining the new clock source is not allowed.

Additionaly, always activate the asynchronous clock for at least two f_A cycles:

- after entering the INIT state and
- after device reset

This is an example of a correct sequence:

- CSR.CLKSEL = No_Clock (equals the reset state)
- Wait T_W or poll for CSR.CON = 0

- FRAMECON.MODE = INIT
- CSR.CLKSEL = Clock_On
- Wait T_W or poll for CSR.CON = 1
- CSR.CLKSEL = No_Clock
- Wait T_W or poll for CSR.CON = 0
- FRAMECON.MODE = ASC (or SPI or LIN)
- CSR.CLKSEL = Clock_On
- Wait T_W or poll for CSR.CON = 1

See also **LIN Master Sequences**

See also **LIN Slave Sequences**

Abort Sequence

If a header has been transmitted in ASCLIN master mode, and the corresponding response does not come, the waiting for the response can be aborted by first entering the INIT mode and then entering the LIN mode. The sequence is identical with the example sequence above.

19.19 Implementation

This section describes the product specific configuration of the ASCLIN module and its interconnection with the rest of the system. The TC21x/TC22x/TC23x contains 2 interfaces, ASCLIN0 and ASCLIN1.

19.19.1 BPI_FPI Module Registers

19.19.1.1 System Registers

Figure 19-33 shows all registers associated with the BPI_FPI module, configured for one kernel.

BPI_FPI Registers Overview

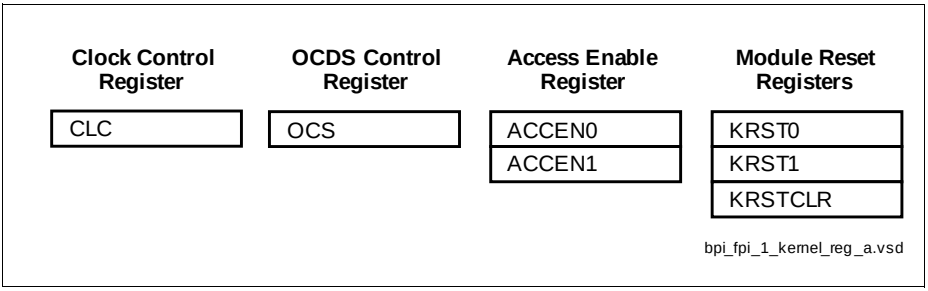


Figure 19-33 BPI_FPI Registers

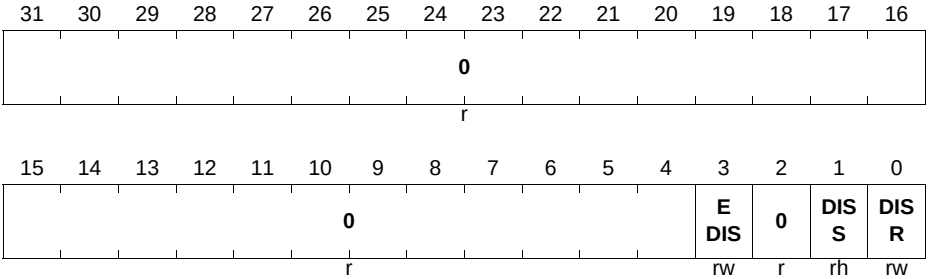
Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_A module clock signal, sleep mode and disable mode for the module.

(>> **Table 19-4** register overview)

CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode, that is if the sensitivity of the module to the sleep signal is enabled to react to it or disabled to ignore it. 0_B Enabled 1_B Disabled
0	[31:4], 2	r	**Reserved** Read as 0; must be written with 0.

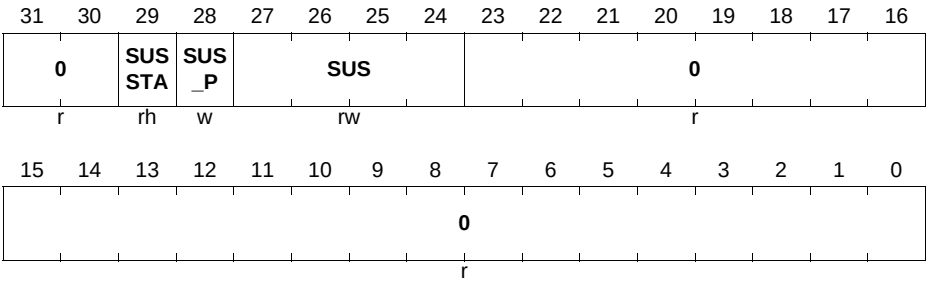
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

(>> **Table 19-4** register overview)

OCS
OCDS Control and Status **($E8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend **others**, reserved,
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

(>> **Table 19-4** register overview)

ACCEN0
Access Enable Register 0 **(FC_H)** **Reset Value: FFFF FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

(>> **Table 19-4** register overview)

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

0															
r															

Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

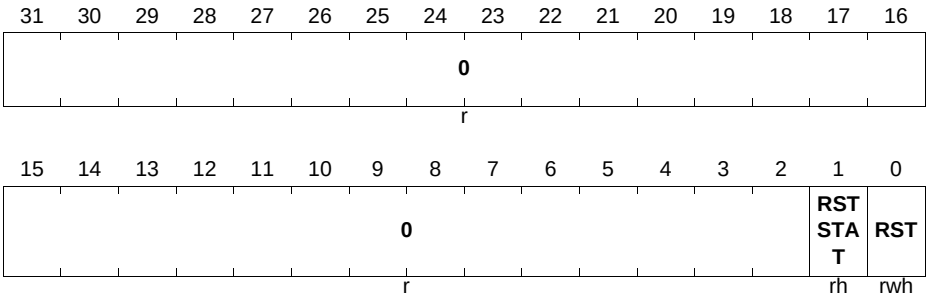
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

(>> **Table 19-4** register overview)

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.

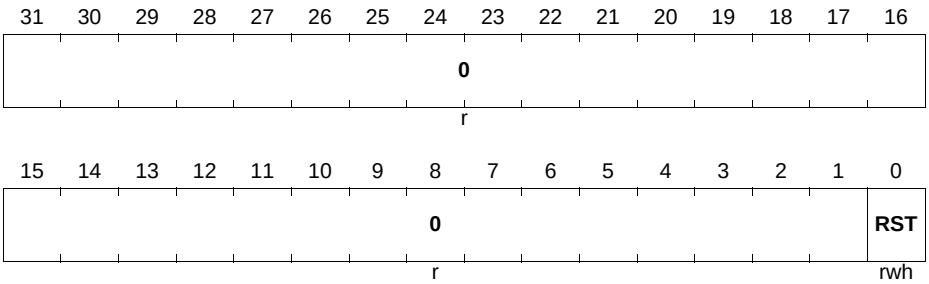
Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

(>> **Table 19-4** register overview)

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: 0000 0000$_H$**



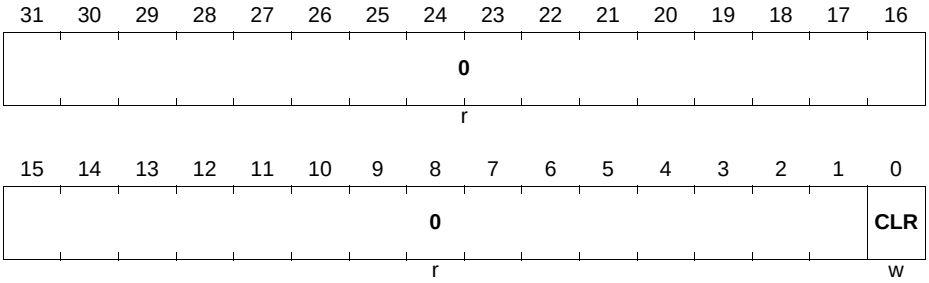
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

(>> **Table 19-4** register overview)

KRSTCLR
Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

19.20 On-Chip Connections

This section describes the on-chip connections of the ASCLINx module instances.

Port/Pin Connections

The connections of the ASCLIN modules to the pins / ports is described in the chapters regarding the pinning and the ports.

Input signals not connected to ports/pins are connected to the following voltage levels:

- The unconnected ARX signals in the lower half range (RHA to RXD) are connected to (active) low level, “0”
- The unconnected ARX signals in the upper half range (RXE to RXH) are connected to (inactive) high level, “1”
- The unconnected ACTS signals are connected to low level “0”, which is after reset the inactive level (but disabled via **IOCR**.CTSEN bit field, meaning don’t care)

Table 19-5 shows an overview for TC23x how bits and bit fields must be programmed for the required I/O functionality of the ASCLIN I/O lines.

Table 19-5 ASCLIN I/O Control Selection and Setup

ASCLIN Module	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
ASC0	ARX0A / P14.1	ASC_IOCR.ALTI = 000_B	P14_IOCR0.PC1 = $0XXXX_B$	I

ASCLIN Connection to Itself

the following connection is defined for each ASCLIN instance:

ARTS -> ACTSD

This connection can be useful in the SPI mode, where frequently the transmission and the reception of data are performed in parallel. If this connection is selected by using **IOCR**.CTS, the TXFIFO will deliver data for transmission only if there is a free space in the RXFIFO. If not, the TXFIFO will wait for emtying of the RXFIFO by software and then automaticaly continue the transmission.

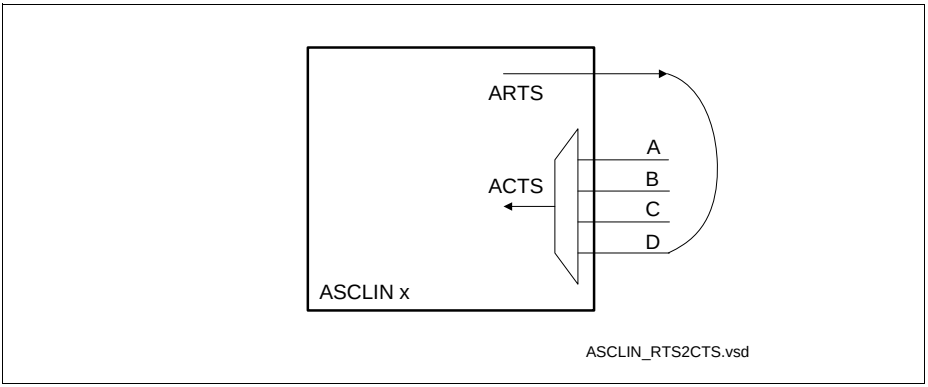

Figure 19-34 ASCLIN ARTS to ACTS Connection

19.21 ASC at CAN Support

The ASC Tx and Rx signals are overlayed with CAN Rx and Tx signal. See the Ports chapter and the Pinning chapter for the particular pin assignements.

A virgin device with a completely erased flash memory can be booted via ASC at CAN pins. See the Boot chapter for details on the implementation.

20 Queued Synchronous Peripheral Interface (QSPI)

The main purpose of the QSPI module is to provide synchronous serial communication with external devices using clock, data-in, data-out and slave select signals. The focus of the module is set to fast and flexible communication: either point-to-point or master-to-many slaves communication.

Parallel requests from on chip bus masters to a module will be executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the module in between. Module hardware semaphores are not supported.

>> **Registers Overview**

>> **BPI_FPI Module Registers**

20.1 Feature List

This section describes the features of the QSPI module.

- Master and Slave Mode operation
  - Full-duplex operation
  - Half-duplex operation
  - Automatic slave select control
  - Four-wire and three-wire type of connection
- Flexible data format
  - Programmable number of data bits: 2 to 32 data bits (plus parity: 3 to 33 bits)
  - 4 to 32 data bits possible for 50 Mbit/s
  - Programmable shift direction: LSB or MSB shift first
  - Programmable clock polarity: Idle low or idle high state for the shift clock
  - Programmable clock phase: data shift with leading or trailing edge of the shift clock
- Baud rate generation
  - Flexible baud rate and delays (leading, trailing, idle) generation
- Interrupt generation
  - On a transmitter FIFO event
  - On a receiver FIFO event
  - On an error condition (receive, baud rate, transmit error, parity error)
  - On a phase transition (start of frame, end of frame ...)
- QSPI supports control and data handling by the DMA controller
- Flexible QSPI pin configuration
- Hardware supported parity mode
  - Odd / even / no parity
- Seven slave select inputs $\overline{\text{SLSIB..H}}$ in Slave Mode
- Sixteen programmable slave select outputs SLSO[15:0] in Master Mode
  - Automatic SLSO generation with programmable timing
  - Programmable active level and enable control

  - External demultiplexing of the slave select outputs support
- Several module reset options
  - State machine reset per software (only the state machine)
  - Module reset per software (both FIFOs, all registers and the state machine)
  - Automatic stop option of the state machine in slave mode after baud rate error
- Loop-Back mode
- Interoperability with SSC and USIC modules of Infineon microcontroller families, and with popular (Q)SPI interfaces of multiple suppliers
- Communication stop on RxFIFO full
  - Shift register full and RxFIFO full can pause the communication
  - Interrupt generation
- High Speed Input Capture (HSIC)
  - Provides input capture functionality for ADAS applications
  - 15-bit counter with resolution of f_{BAUD2}

20.2 Overview

This section gives a top-level overview of the QSPI.

20.2.1 External Signals

The communication between two devices using QSPI generally uses four signals:

- serial clock SCLK
- data in master to slave direction MTSR (Master Transmit Slave Receive)
- data in slave to master direction MRST (Master Receive Slave Transmit)
- slave select signal SLS

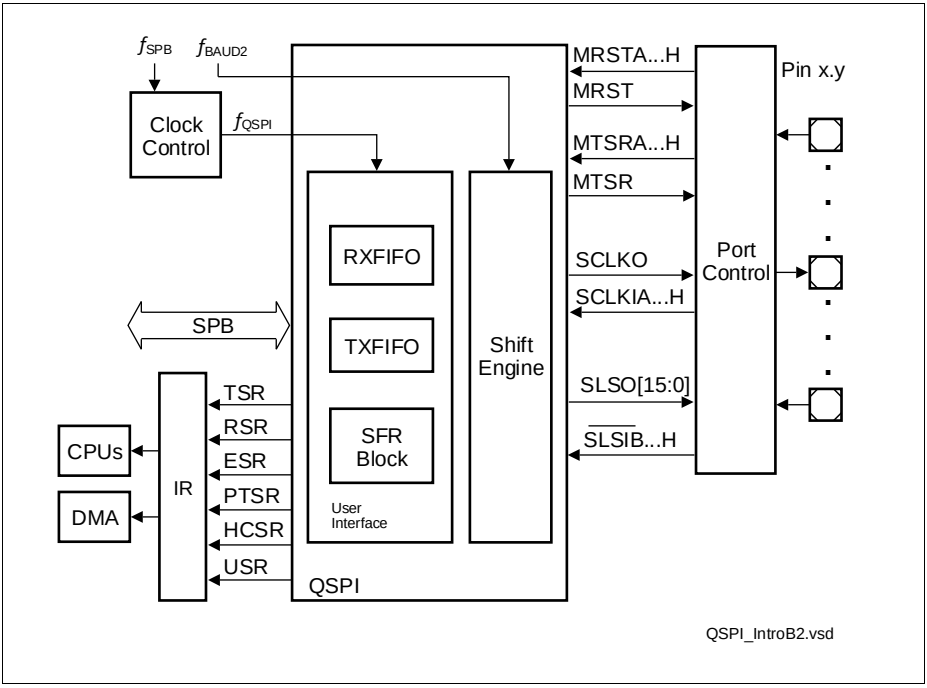

Figure 20-1 External Signals of the QSPI Module

20.2.2 Operating Modes

The QSPI operates in one of two modes regarding the generation of the serial clock and slave select signals: master or slave mode. The master generates and drives the clock and select signals, the slave receives these signals.

The QSPI operates in one of three modes regarding the direction of the communication and depending whether the transmission and the reception appear simultaneously or not: duplex, half-duplex and simplex mode.

This gives six possible combinations for the operating mode of the QSPI: master duplex, half-duplex, and simplex; slave duplex, half-duplex, and simplex.

Note: The half-duplex mode can be implemented either by short-cut connection between two different pins on the pcb, one data output and one data input pin, or by using single pins mapped to both data input and data output signals. See the pinning and port chapters for the pinning definition of a particular product. The module itself does not differentiate between the full-duplex, half-duplex or simplex connection.

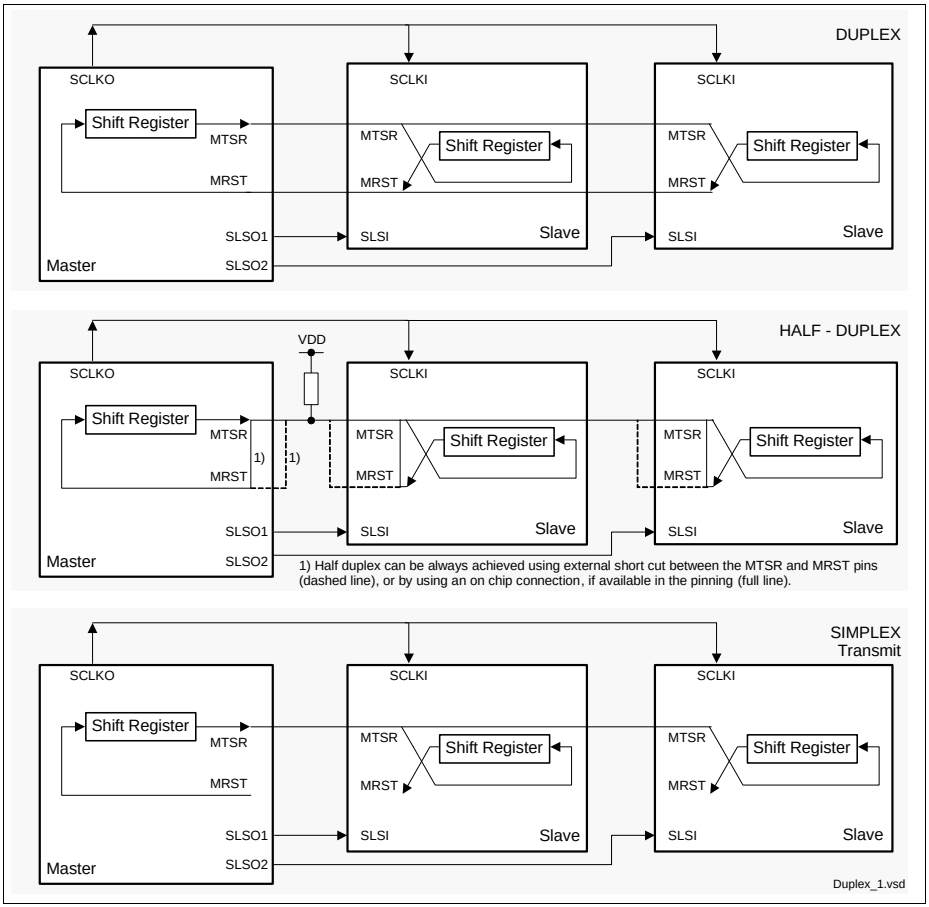

Figure 20-2 Operating Modes and Types of Connections

20.2.3 Queue Support Overview

The term "Queue Support" is used in this context to describe the functionality implemented for comfortable switching of the timing configuration of the QSPI frames, depending on the slave select signal which is to be activated. The main feature of the module is the possibility to take both the configuration and data to the TXFIFO, and to track down which TXFIFO entry is configuration, and which data. The QSPI module expects 32 basic configuration bits to be moved with one move (for example DMA move) from some on-chip general purpose RAM to the TXFIFO. These 32 configuration bits from the TXFIFO and the configuration bits from the 8 configuration extension registers **ECON**z contained in the QSPI module, define together the full configuration of the module (see **Figure 20-3**). One extension register is used for two slave selects: ECON0 for SLSO0 and SLSO8, ECON1 for SLSO1 and SLSO9 ...

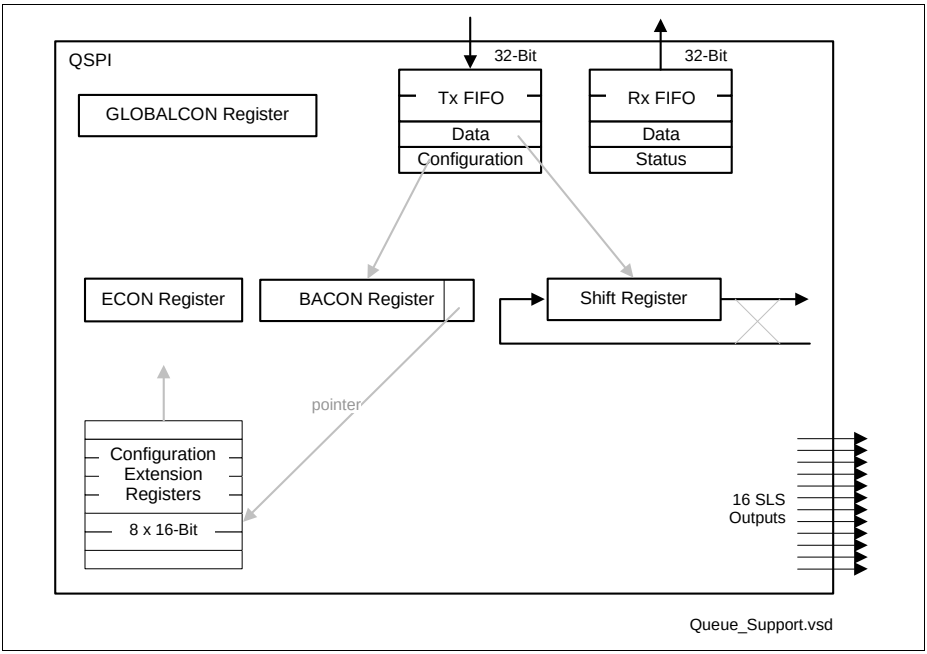

Figure 20-3 Queue Support Overview

20.2.4 Architecture Overview

The **Figure 20-4** shows the main blocks of the QSPI module. The TxFIFO and RxFIFO provide the user interface. The Shift Register and the “Miscellaneous Logic” block build the state machine of the module. The “Configuration Extensions” block provides comprehensive capabilities for configuring the QSPI frames.

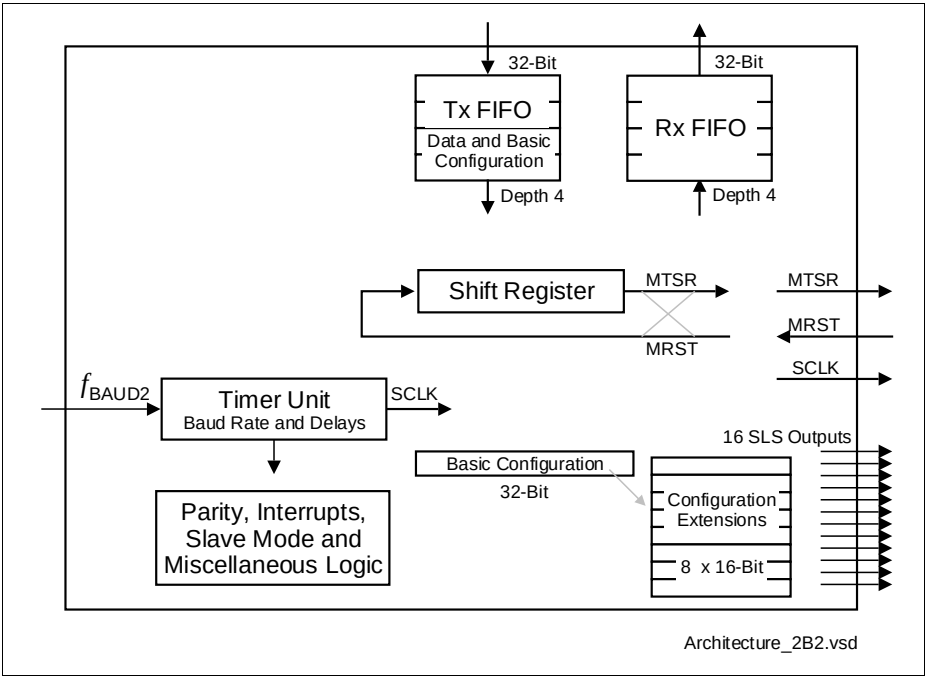

Figure 20-4 QSPI - Architecture Overview

20.2.5 Three Wire Connection

The term "Three Wire Connectiont" is used in this context to describe a connection without slave select signal. This connection relies solely on counting bits for determining the end of the current frame and resetting the shift register state machine, instead of using the slave select signal for this purpose. This way of communication is less robust than communication with slave select, but it saves a pin on both master and slave device.

The name “three wire connection” is true only in case of full-duplex connection, where exactly three signals (clock, data-in, data-out) are needed. In case of half-duplex and simplex connections only two signals (clock, data-in/data-out common data line) are necessary.

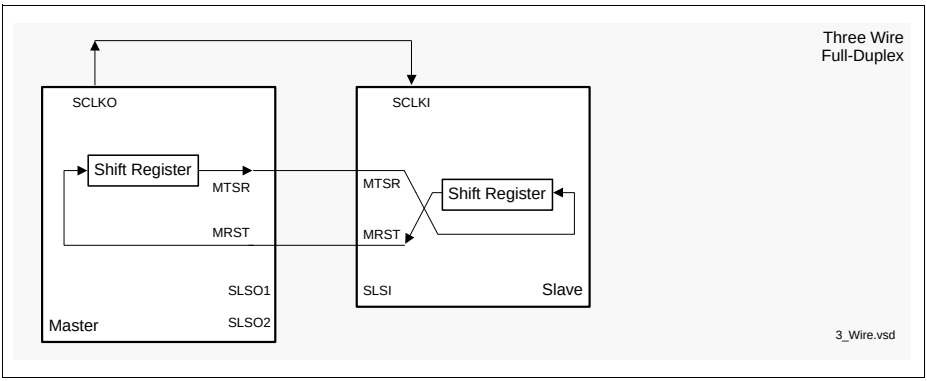

Figure 20-5 Three Wire Connection

20.3 Abstract Overview

An abstract overview of the QSPI module is shown in **Figure 20-6**. This document describes the QSPI module according to this view: the State Machine with its configuration and status capabilities, the User Interface, and the Interrupts (in this order).

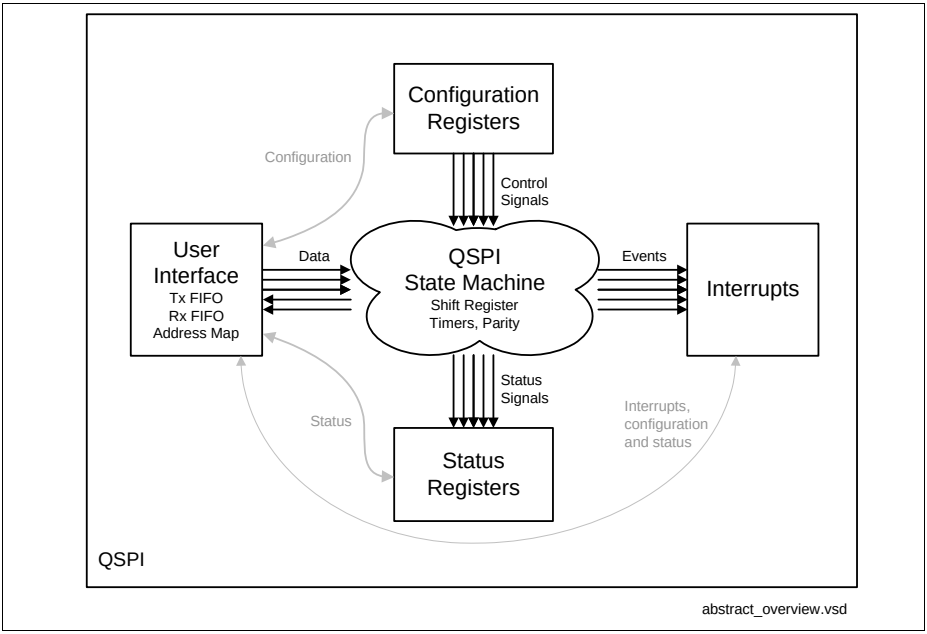

Figure 20-6 QSPI - Abstract Overview

20.4 Frequency Domains

The state machine of the QSPI is placed in a separate frequency domain operating with a frequency f_{BAUD2} which can be:

- integer multiple of the SPB bus frequency
- equal to the SPB frequency
- lower than the SPB frequency, derived by integer division

The baud rate is determined by the f_{BAUD2} frequency divided by an integer equal or greater than four.

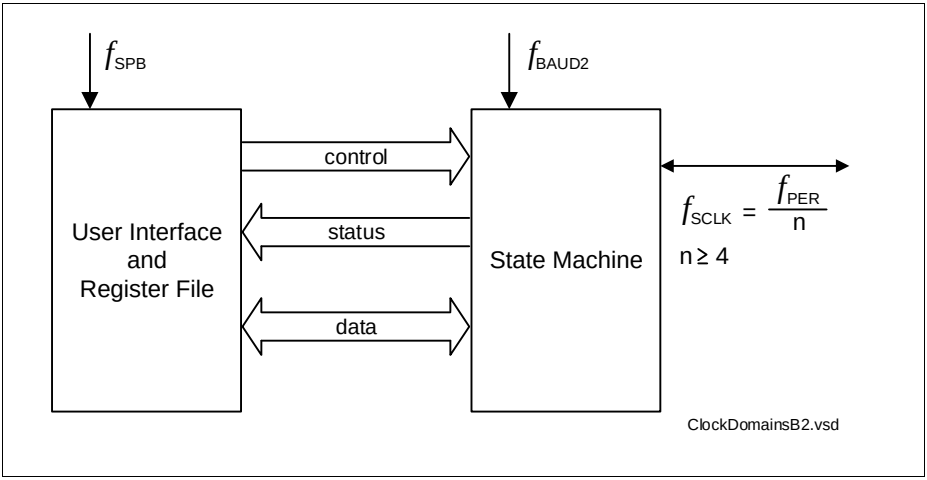

Figure 20-7 QSPI - Frequency Domains

20.5 Master Mode State Machine

In master mode, the QSPI module generates the timings, the serial clock, and the slave select signals.

20.5.1 Phases of one Communication Cycle

This section describes the possibilities available for configuring the length of the phases of the QSPI communication: timing delays, data length, duty cycle and data sampling.

A QSPI frame starts with activating a slave select signal SLSO (at transition from idle to leading delay phase), and ends with its deactivation (at transition from trailing delay to wait or idle phase). It is a sequence of five phases: idle delay, leading delay, data phase, trailing delay and an optional wait phase. The idle phase is subdivided in two phases of equal length: idle A and idle B.

Figure 20-8 shows a full and a compressed view of a QSPI frame and its phases. The full view shows all four signals needed for a QSPI connection. The compressed view represents the phases in a single row, in a way suitable to discuss their properties.

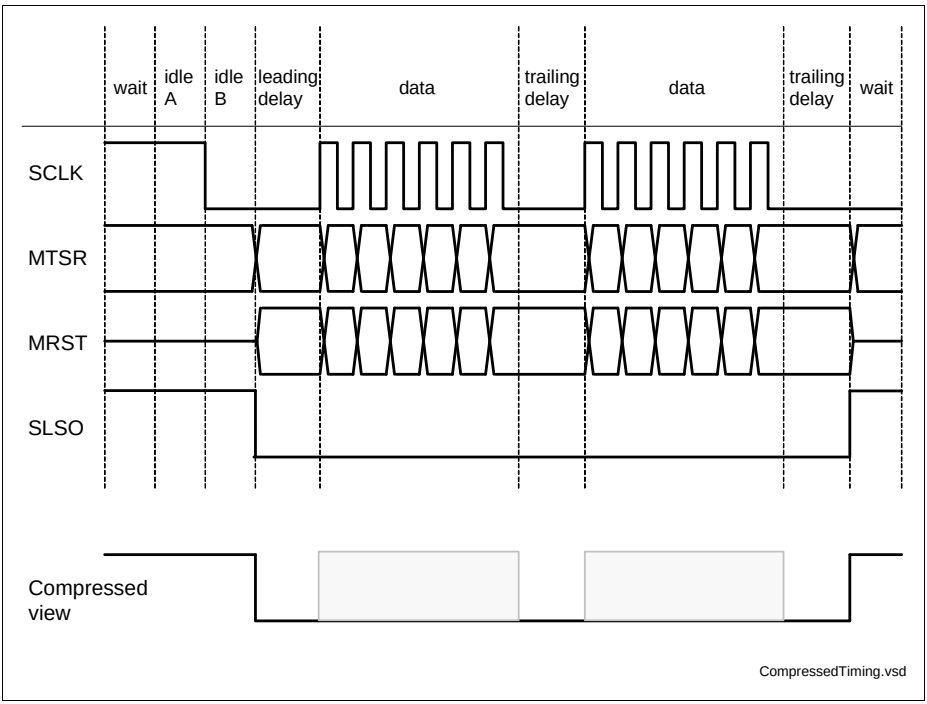

Figure 20-8 Phases of a QSPI Frame (Example for Data Length of 5 Bits)

The flexible timing control of the QSPI allows to program each phase in a very wide time range, with sufficient precision. Some examples of QSPI frames, in compressed view, with different lengths of the phases, are shown in **Figure 20-9**.

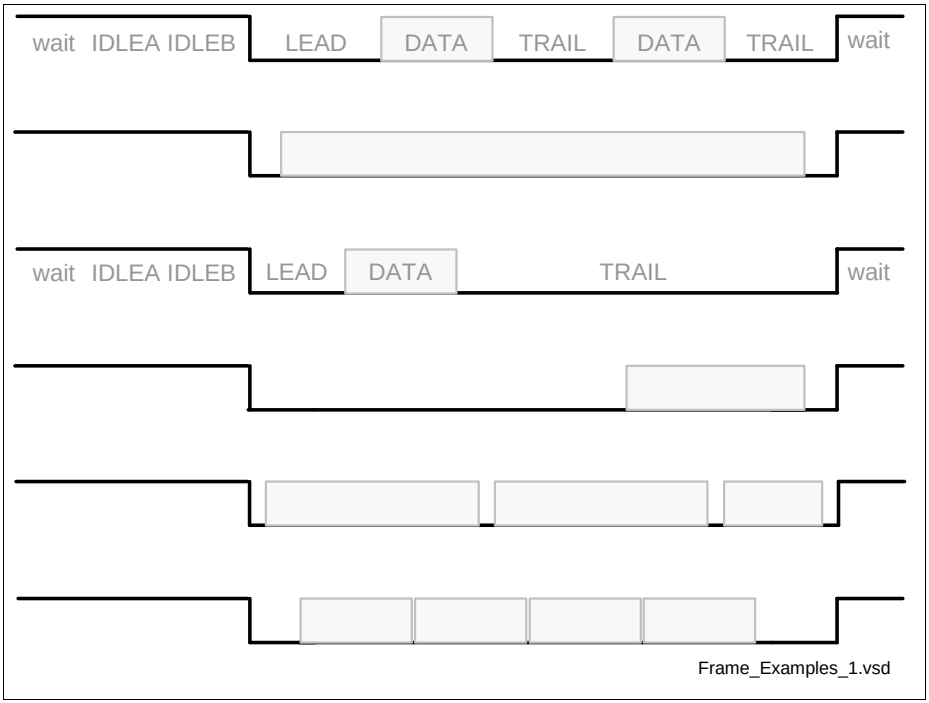

Figure 20-9 Examples of QSPI Frames in Compressed View

The length of the phases is programmed using the corresponding bit fields in the register **BACON**. There are four main bit fields defining the length of the phases in t_Q units and several modifier bit fields defining their range and granularity:

- IDLE
- LEAD
- DATA
- TRAIL

The WAIT phase is simply a loop waiting for a write to the Tx FIFO, without predefined duration, and consequently without a defining bit field.

The IDLE bit field defines two sub-phases with the same length IDLEA and IDLEB. At the transition between them the polarity of the serial clock signal for the next slave is set / changed.

In addition, the flexible timing control allows to program the duty cycle and the sampling point properties of the serial clock. This allows to improve to a certain extent the achievable baud rate taking into account the clock asymmetries and the loop-delay.

The **ECON** bit fields A, B and C define the length of the corresponding bit segments.

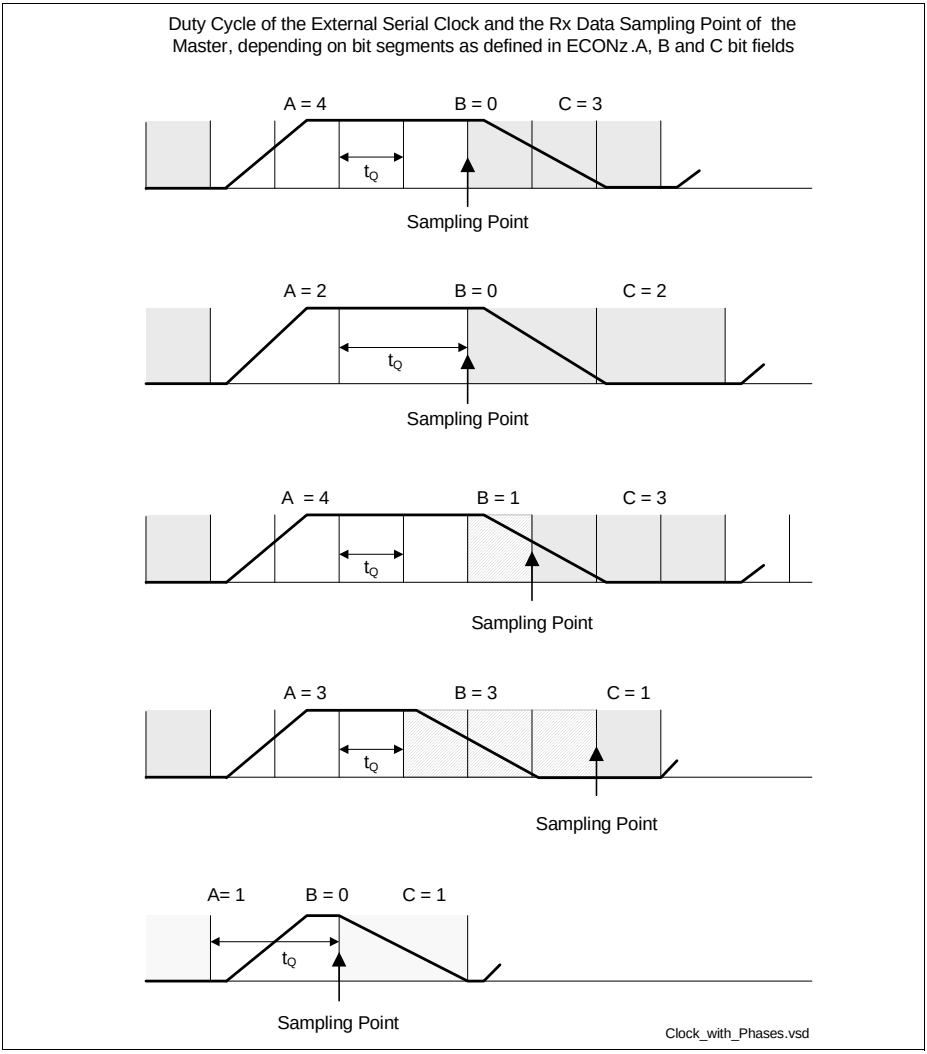

Figure 20-10 Control of the Duty Cycle and the Sampling Point of the Serial Clock

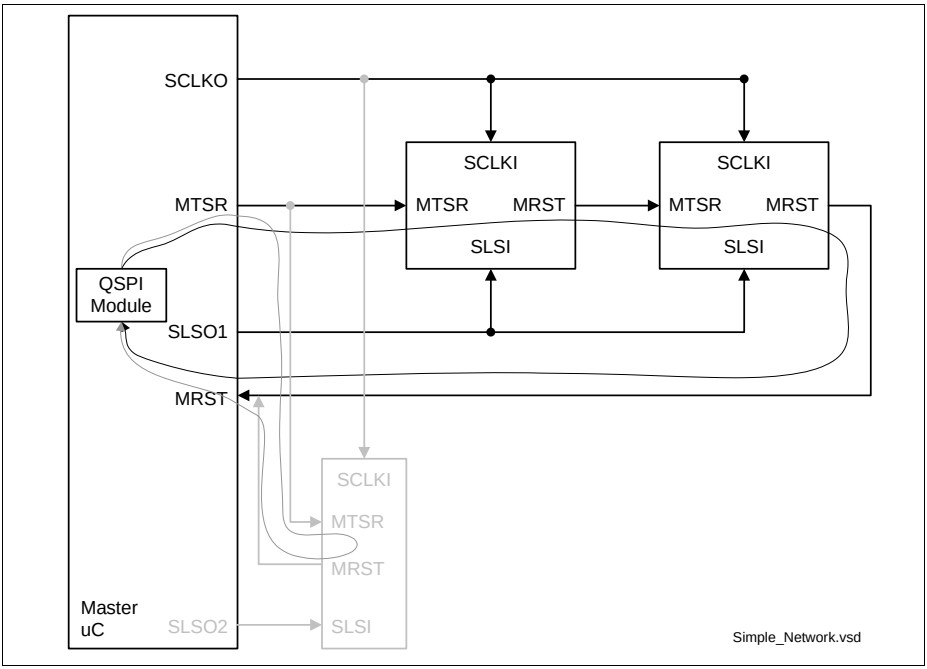

Figure 20-11 Closed-loop delays in a simple network consisting of one daisy-chain and one point to point connection in parallel

The purpose of the duty cycle control is:

- to compensate the influence of the path and pad asymmetry on the duty cycle
- to compensate the considerable asymmetry of the edges in case of half-duplex connection implemented as open-drain driver with pull-up resistor
- to adjust the duty cycle optimally to the timing properties of the master and slave, and to the properties of the connection (distance and capacitive load)
- to help achieve optimal baud rate, especially at higher baud rates which need an odd division factor (for example 5 = 3 high time + 2 low time or 5 = 2 high time + 3 low time)

The purpose of the sampling point control is to allow reliable reception of the data transmitted by the slave, at as high as possible baud rates.

In master receive direction the slave transmitted data reaches the master considerably late relative to the shift edge of the serial clock. This is caused by the loop delay consisting of:

- the traveling time of the shift clock edge from the master to the slave
- the reaction time of the slave
- the traveling time of the data from the slave to the master

Last but not least, the flexible timing control allows to control the phase and the polarity of the shift clock.

The clock polarity is configured by bit field **ECON**z.CPOL. This bit field sets the clock idle polarity to low or high.

The clock phase is configured by bit field **ECON**z.CPH. This bit field sets the initial clock delay to 0 or Bit Segment A, as defined by the bit field **ECON**z.A.

The CPOL and CPH settings control the master mode. The slave mode timing behavior is fixed to CPOL=0 and CPH=1, and these values must be programmed in the **ECON** register pointed by **BACON**.CS.

The **Figure 20-12** shows the QSPI timings for clock phase CPH = 0.

ECON.CPH = 0 is used when communicating with a slave that delivers a valid value of the first bit immediately after being selected with an SLS signal. In such a case the first clock edge in a frame is used to latch the first bit. The second edge delivers the second bit value, and so on. The last edge in a frame delivers a bit with don't care value.

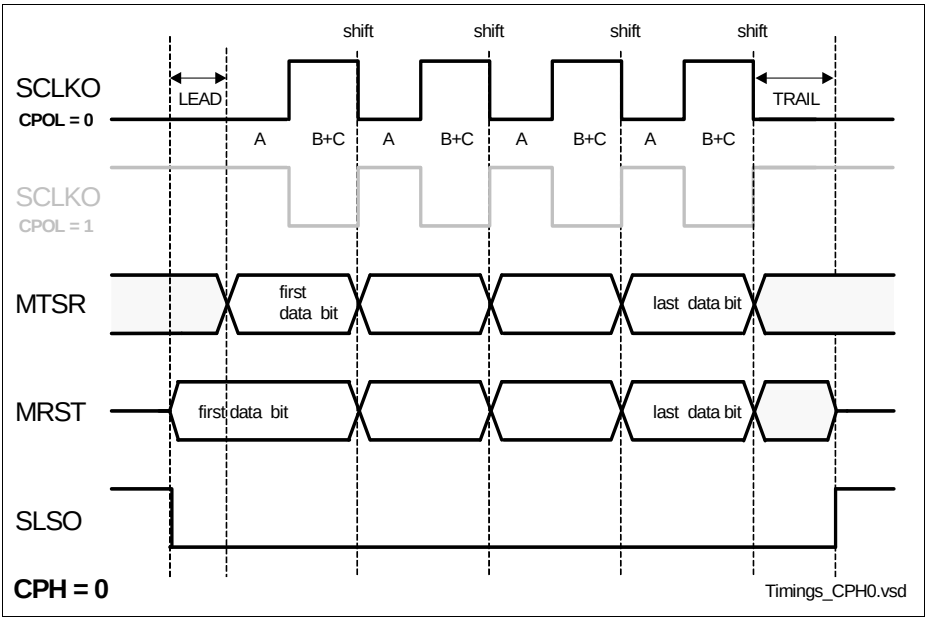

Figure 20-12 Timing of a transfer with CPH = 0 (Example for Data Length of 4 Bits)

The trailing delay starts after the last shift clock period of a data block and is followed either by the deactivating edge of SLSO, or a new data block in continuous mode.

Attention: If CPH = 0, then the total delay between the SLSO activating edge and the first edge of the serial clock SCLKO is LEAD + ECONz.A

Figure 20-13 shows the QSPI timings for clock phase CPH = 1.

ECON.CPH = 1 is used when communicating with a slave that delivers a bit with a random or don't care value immediately after being selected with the SLSO signal. In such a case the first clock edge in a frame is used by the slave to shift out the first valid data bit. The second edge latches this bit value, and so on. The last edge in a frame is used to latch the last valid data bit, which normally remains driven until the end of the frame.

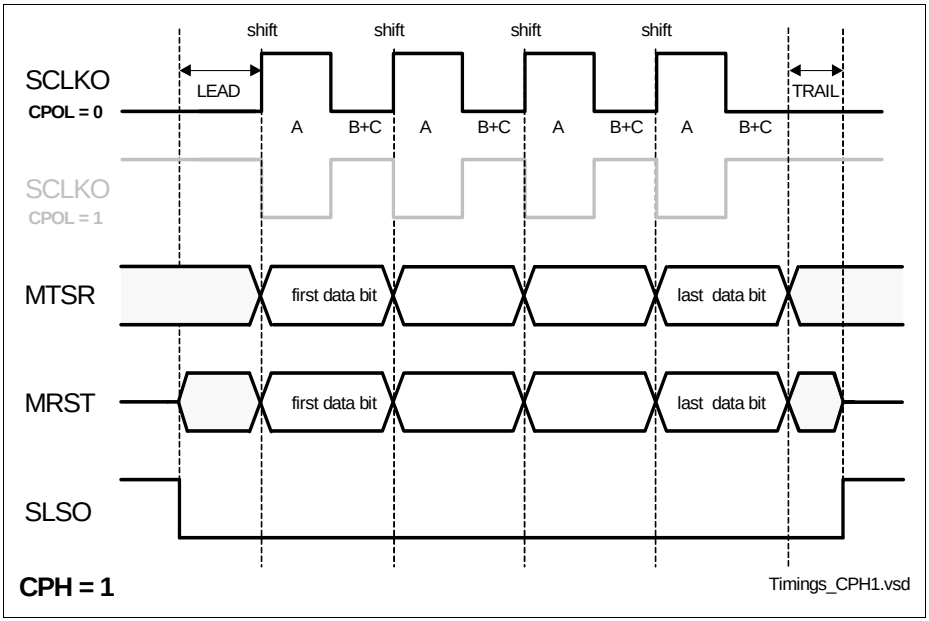

Figure 20-13 Timing of a transfer with CPH = 1 (Example for Data Length of 4 Bits)

The leading delay lasts between the active edge of the SLSO and the first shift clock edge.

Attention: If CPH = 1, then the total delay between the last edge of the SCLKO and the SLSO deactivating edge is TRAIL + ECONz.B + ECONz.C

20.5.2 Configuration Extensions

This section describes the possibilities available for configuring the phases of the QSPI communication: timing delays, data lengths, their ranges and granularity.

The QSPI module controls 16 communication channels, which are individually programmable. Each channel is associated to one slave select output and to the corresponding timing and other properties (baud rate, delays, data width, parity...).

The 16 slave select channels of the QSPI module are subdivided in two groups of 8 slave select channels:

- Channels 0 to 7
- Channels 8 to 15, channel 8 having the same **ECON** settings as channel 0, channel 9 as channel 1, and so on.

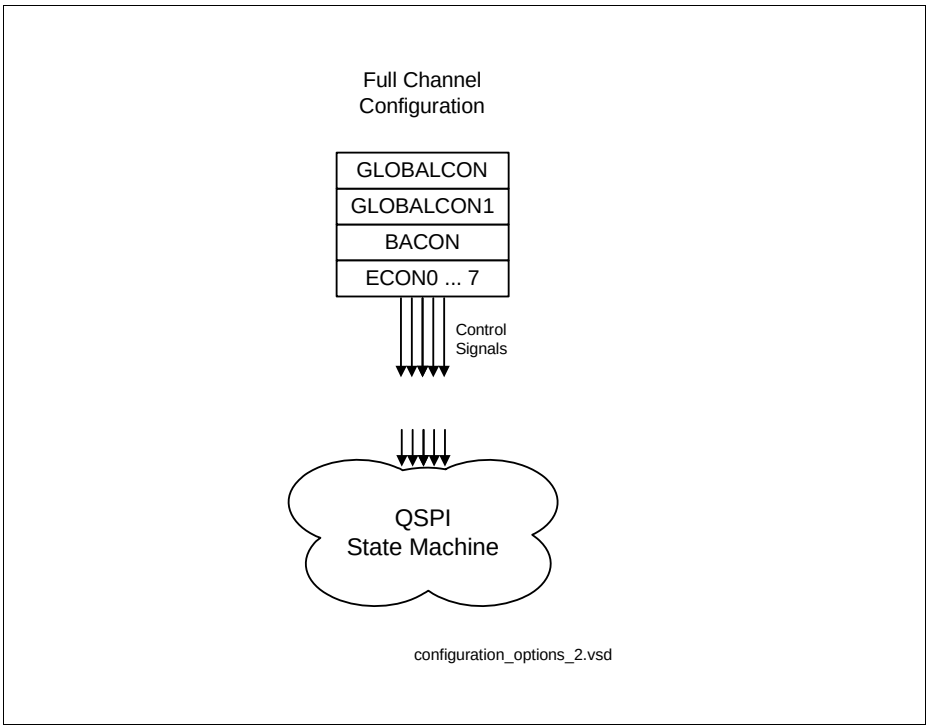

Figure 20-14 Flexible Configuration Concept

20.5.3 Details of the Baud Rate and Phase Duration Control

The QSPI phases correspond to states of a simple state machine defining a sequence of simple states and loops. Due to the strict sequential nature of the communication cycle one timer is enough to define the length of each phase. The length of each phase is defined in time quanta, and the length of a time quantum is defined by a time quantum timer. Each QSPI slave select channel has its own time quantum length, based on the module time quantum length:

T_{BAUD2} clock period -> one module time quantum -> one channel time quantum

Each QSPI module generates a module time quantum which is further downscaled to a channel quantum. This affects both the delays and the baud rates. The assumption is that the pad strength setting, the capacitive load and the corresponding QSPI network layout properties do not allow extreme differences in the baud rates for the different slaves connected to one module. They all have similar speed range: high speed, or medium speed, or low speed. Mixing very high speed and very low speed slaves does not make much sense. Many slaves produce high accumulated capacitive load on the clock and data outputs, which influences the possible baud rates for all slaves. Variations in the baud rates of the slaves of one module in the range of 6:1 is possible by varying the bit segment phases in each channel. Additional two-bit counter per slave allows for additional scaling of 1, 2, 4, or 8, making a total bit-time variation of 48:1 between the channels in one module possible.

Each QSPI slave select channel has its own set of phase lengths, depending on $T_{BAUD2} = 1 / f_{BAUD2}$

- $T_{SCLKz} = T_{BAUD2}$ * **GLOBALCON**.TQ * **ECON**z.Q * (A + B + C)
- $T_{LEAD} = T_{BAUD2}$ * **BACON**.LPRE * **BACON**.LEAD
- $T_{TRAIL} = T_{BAUD2}$ * **BACON**.TPRE * **BACON**.TRAIL
- $T_{IDLEA,B} = T_{BAUD2}$ * **BACON**.IPRE * **BACON**.IDLE
- $T_{STROBE} = T_{BAUD2}$ * **GLOBALCON**.TQ * **ECON**z.Q * **GLOBALCON**.STROBE

*Note: The equations above contain the representative decimal values of the bit-fields in corresponding units, not their actual binary bit-value. For the formulas using the actual binary values of the bit-fields, see **Figure 20-16** and **Figure 20-17**.*

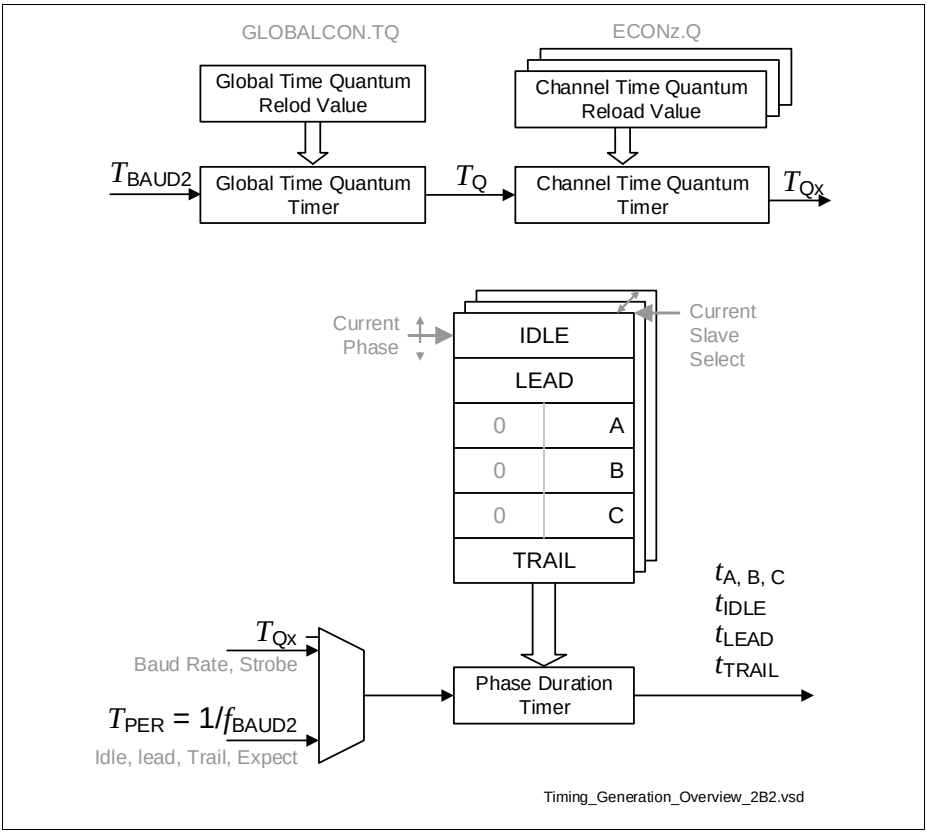

Figure 20-15 Phase Duration Control, Overview

20.5.4 Calculation of the Baud Rates and the Delays

This section gives another alternative view to the calculation of the baud rate and the duration of the delays.

The baud rate generation chain for a channel starts with a common TQ divider. The resulting global time quantum is used by the dedicated Q and A,B,C dividers to generate the baud rates per channel (slave select). See **Figure 20-16**.

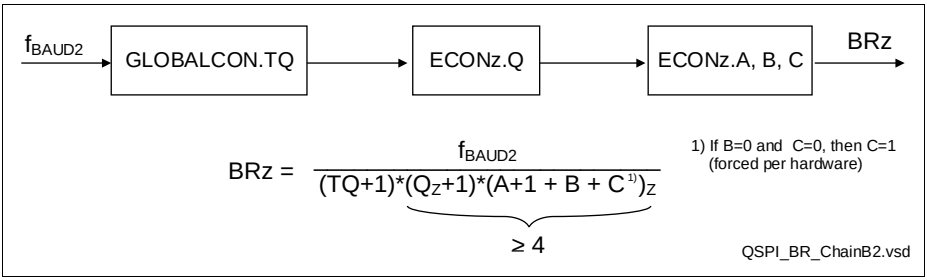

Figure 20-16 Baud Rate Calculation

Attention: The following condition must be satisfied: (Q+1)*(A+1 +B +C) >= 4. Or alternatively formulated: bit length must be at least 4*T_Q.

Each delay of an active channel (slave select) has a separate and independent divider chain starting with a power-of-four prescaler and an n-divider. See **Figure 20-17**.

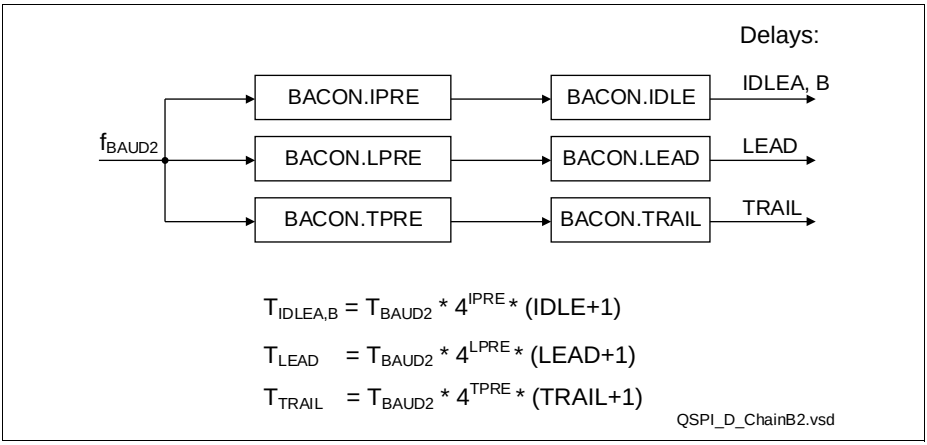

Figure 20-17 Calculation of the delays

20.5.5 State Diagram of Standard Communication Cycle

Figure 20-18 shows the top view of the standard communication cycle of the QSPI state machine in a hierarchical way. The “Data” state consists of a loop of several “Bit” states, where the number of repetitions is defined with the data width bit field. Each “Bit” state consists of a simple sequence of “A”, “B”, and “C” states.

A complete (or standard) communication cycle containing all phases, starting with activating the slave select and ending with its deactivation, is executed only if the bit **BACON**.LAST = 1. Otherwise, the slave select remains active and the module waits for more FIFO data entries.

The Phase Transition Interrupt PT (events PTI1 and PTI2) signal one out of all phase transitions which are shown in **Figure 20-18**, selected by the bit fields **GLOBALCON**.PT1 and PT2.

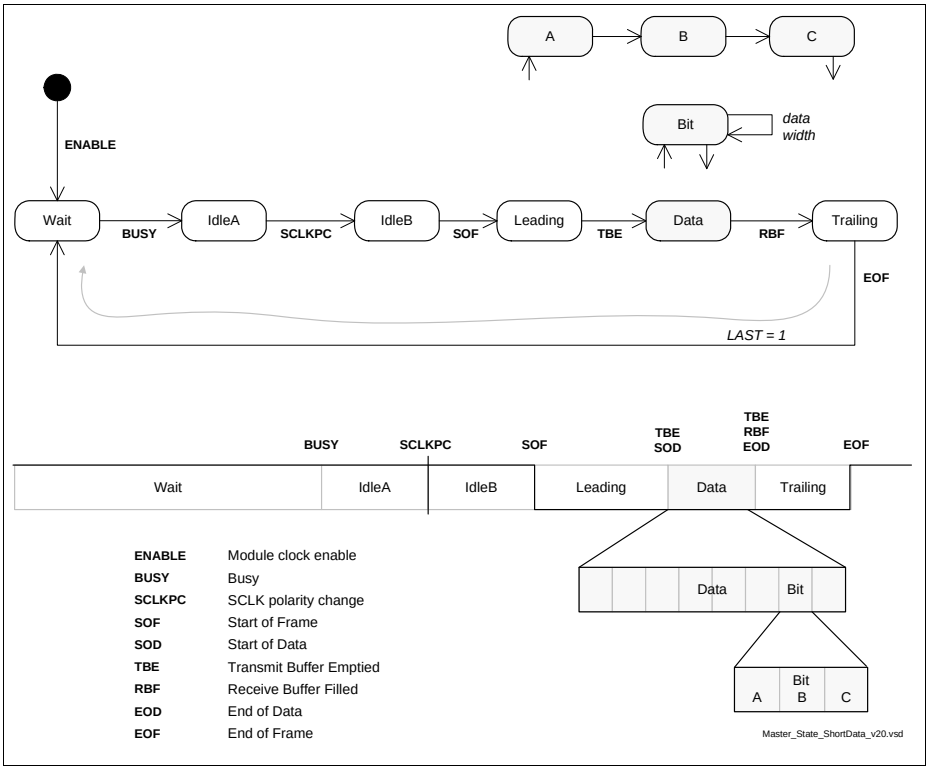

Figure 20-18 Standard Communication Cycle of the State Machine (Short Data)

(>>**Interrupts**)

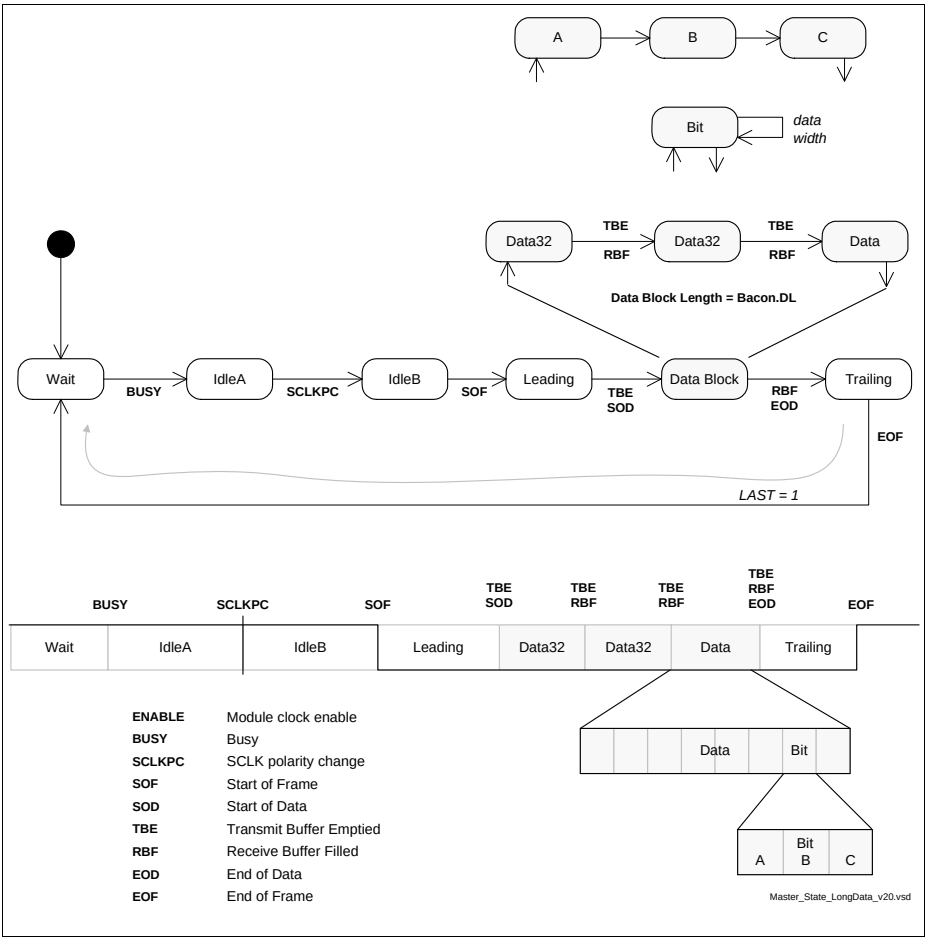

Figure 20-19 Standard Communication Cycle of the State Machine (Long Data)

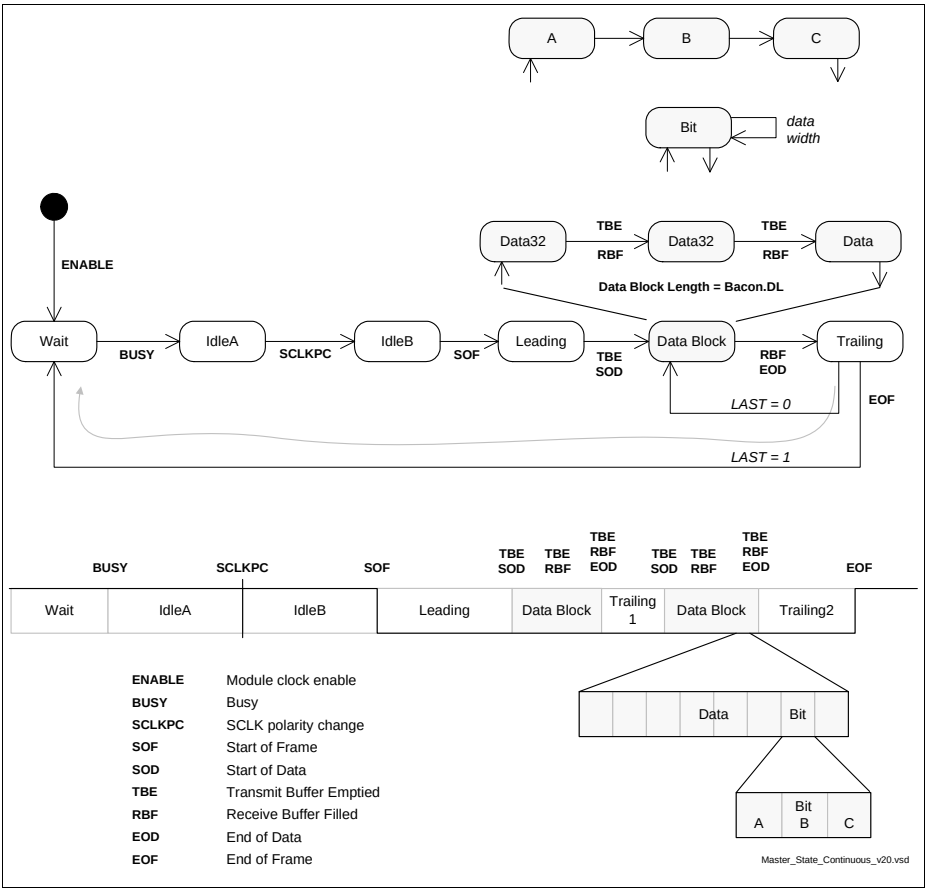

Figure 20-20 Standard Communication Cycle of the State Machine (Continuous)

20.5.6 Expect Phase

Figure 20-21 shows the EXPECT state in the QSPI state machine diagram. This state can be entered in the long data mode and in the continuous mode, where one frame consists of more than one TXFIFO entries. Its purpose is to provide monitoring of the latencies on the FPI bus. In this case, after one FIFO entry has been shifted out and the module expects more bits to shift, according to the **BACON**.DL, a time-out counting starts. If the expected FIFO entry does not come in time, a time-out occurs.

The duration of the EXPECT state is zero if at the end of the current DATA state the new data is already available in the FIFO.

The duration of the EXPECT state can be anywhere between zero and the programmed upper limit, if the next data is written into the TXFIFO any time within the allowed time window. In this case the current frame continues with the SLSO signal remaining active.

The duration of the EXPECT state is exactly maximum if the data did not come in time. Then the current frame is stopped, but the SLSO is not deactivated. A TO (Time - Out) interrupt is raised. The state machine continues the EXPECT state in a loop, waiting for the software intervention, generating an interrupt signal after each expect time interval.

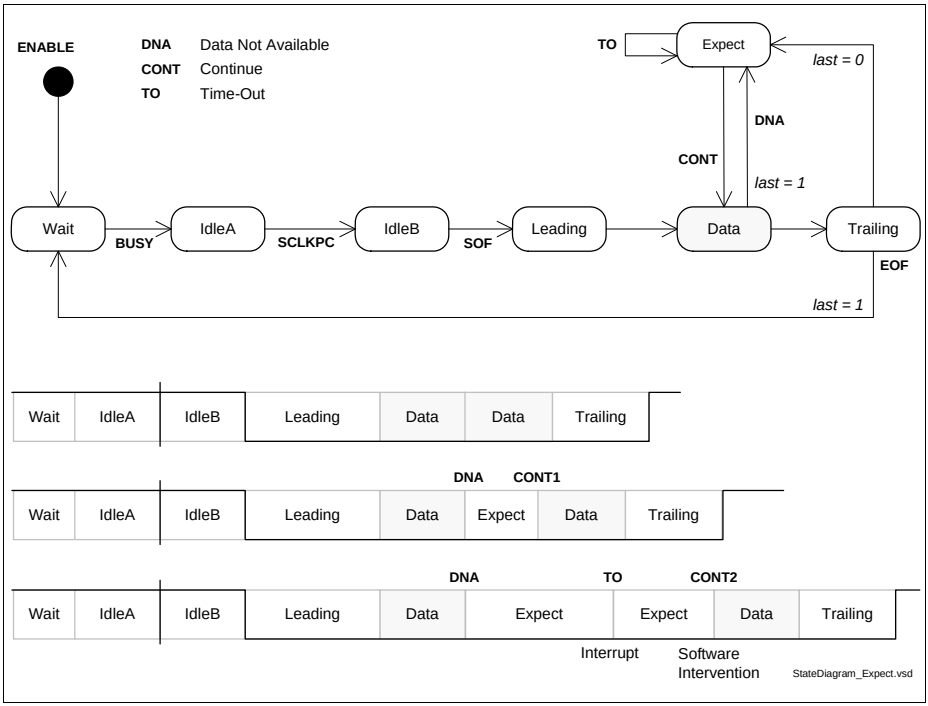

Figure 20-21 EXPECT Cycles of the QSPI State Machine

20.5.7 External Slave Select Expansion

In this mode the bit field **BACON**.CS drives directly the SLSO1 to SLSO4 signals, not demultiplexed by the QSPI, but chip-externally. **SSOC**.AOL bits can invert the SLSO0...4 signal levels individually; **SSOC**.OEN bits enable them. See also **GLOBALCON**.DEL0.

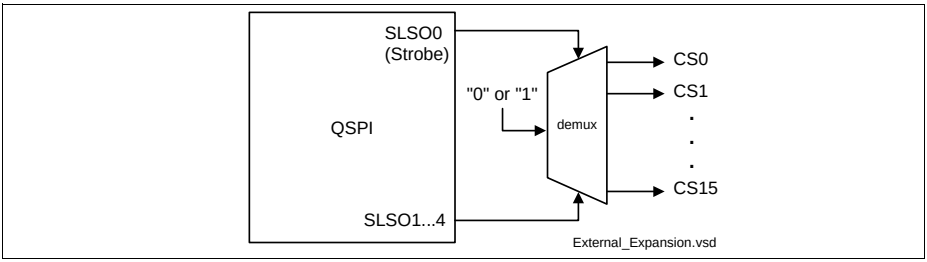

Figure 20-22 Demultiplexing the Slave Select Signals Externally

In order to ensure glitch free selection, a strobe signal is provided, driven at SLSO0 pin. This signal is delayed relative to the SLSO1...4 signals for LS (Lead_Strobe) and TS (Trail_Strobe) delays, equal in duration and configurable in the range of 1 to 16* f_{BAUD2}. The duration of the LS and TS delays is set in the **GLOBALCON**.STROBE.

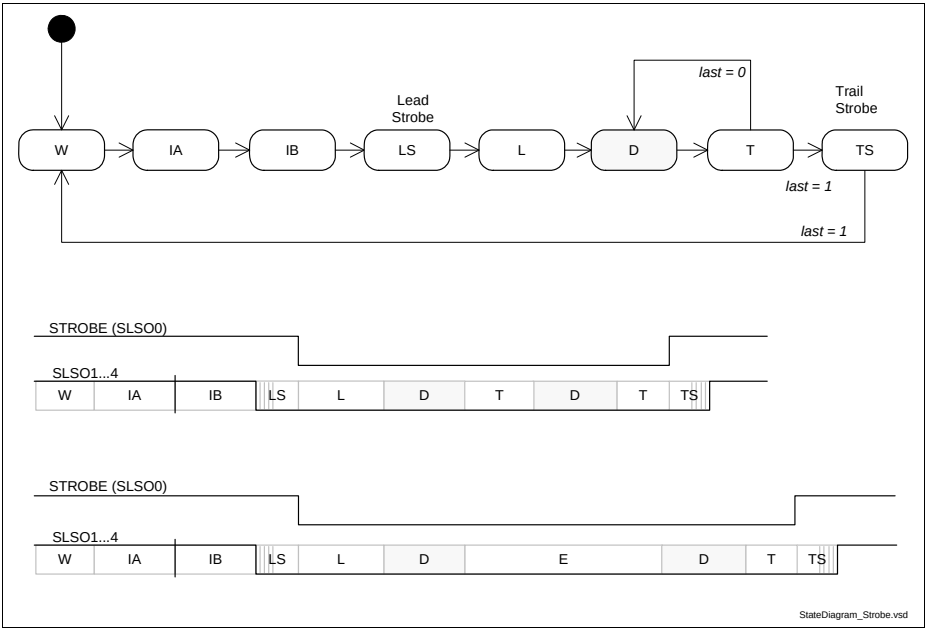

Figure 20-23 State Machine and SLS Signals in Strobed Mode

20.6 User Interface

This section describes the possibilities available for transferring data between the on-chip RAM memories and the QSPI module using the transmit and receive FIFOs. The QSPI features one 4 x 32-bit Tx FIFO and one 4 x 32-bit Rx FIFO. The address ranges for writing data and configuration to the Tx FIFO and for reading data and configuration from the Rx FIFO consist of address locations with special properties:

- Tx FIFO
  - DATA_ENTRY - writes to any of these eight functionally identical locations are always interpreted as data
  - BACON_ENTRY - writes to this location are always interpreted as configuration
  - MIX_ENTRY - writes to this location are interpreted as data or configuration, based on a set of rules
- Rx FIFO
  - RX_EXIT - reads from this location deliver either data or data and status, based on a set of rules.

20.6.1 Transmit and Receive FIFOs

The Tx_FIFO is filled with both configuration and data entries, which are distributed to the **BACON** and the shift register at the exit of the Tx_FIFO. The TxFIFO keeps track if an entry is configuration or data. The control and the data elements are automatically distributed to the **BACON** and shift register. If no data is available, the new BACON is pending.

If a frame is finished and there is data in the FIFO

- in short mode, a new frame starts automatically with the same configuration as the last one.
- in long mode, the extra data are ignored.

TXFIFO error conditions:

- FPI bus write to a full TXFIFO generates an overflow interrupt. The write is ignored.
- In case of slave mode, (**GLOBALCON**.MS = 1X), in case of an underflow, only “1” are delivered.

RXFIFO error conditions:

- FPI bus read from an empty RXFIFO generates an underflow interrupt, and delivers only “1” bits.
- Hardware attempt to write a full RXFIFO with data or status generates an overflow interrupt. The write attempt is ignored by the RXFIFO.
- If the **GLOBALCON**.SRF bit is set, the communication is stopped in case of full FIFO in master mode. In slave mode, the bit is ignored, no stop can be done.
- If the FPI bus frequency is very slow, and the baud rate very high, it can happen that some data is lost on the way between the shift register and a not full RXFIFO. In such a case, an overflow interrupt is generated, although the RXFIFO is not full.

The Rx_FIFO can be filled with both status and received data entries, depending on **GLOBALCON**.SI.

Note: If a 8-bit or 16-bit write is executed to the TXFIFO entry addresses, the data is mapped 1:1 to its location within the 32-bit wide TXFIFO entry, and the rest is padded with zeros.

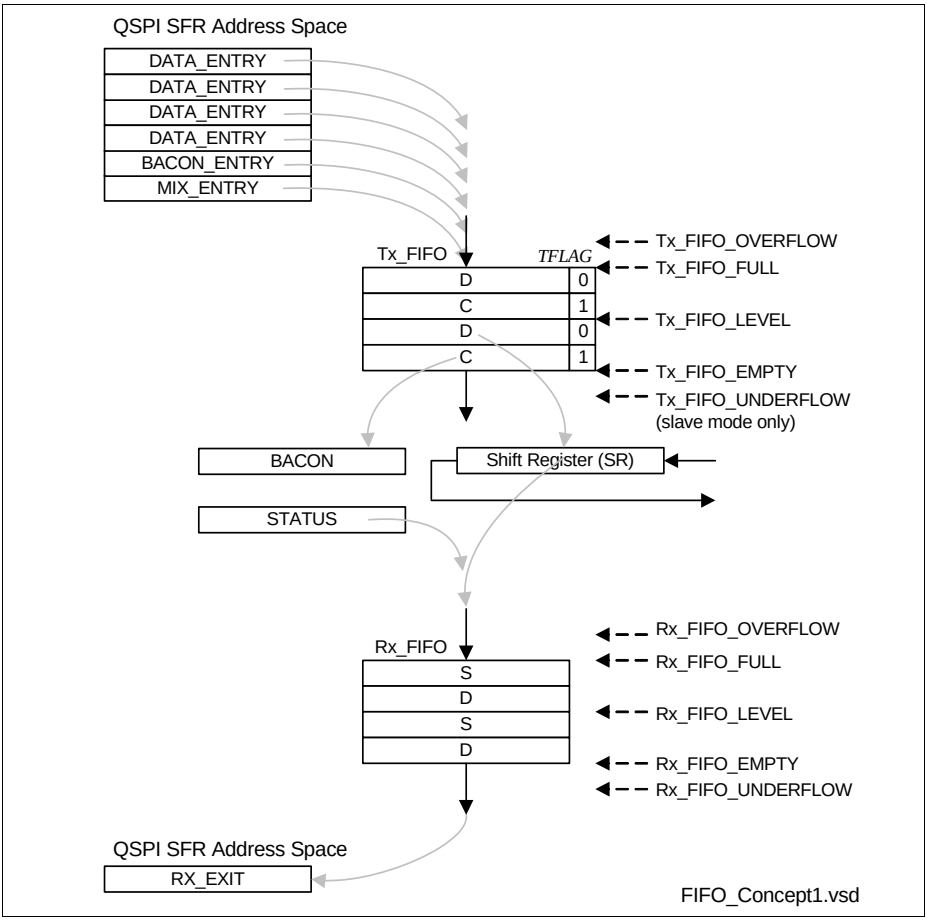

Figure 20-24 Architecture of the Tx and Rx FIFOs

(>>**Interrupts**)

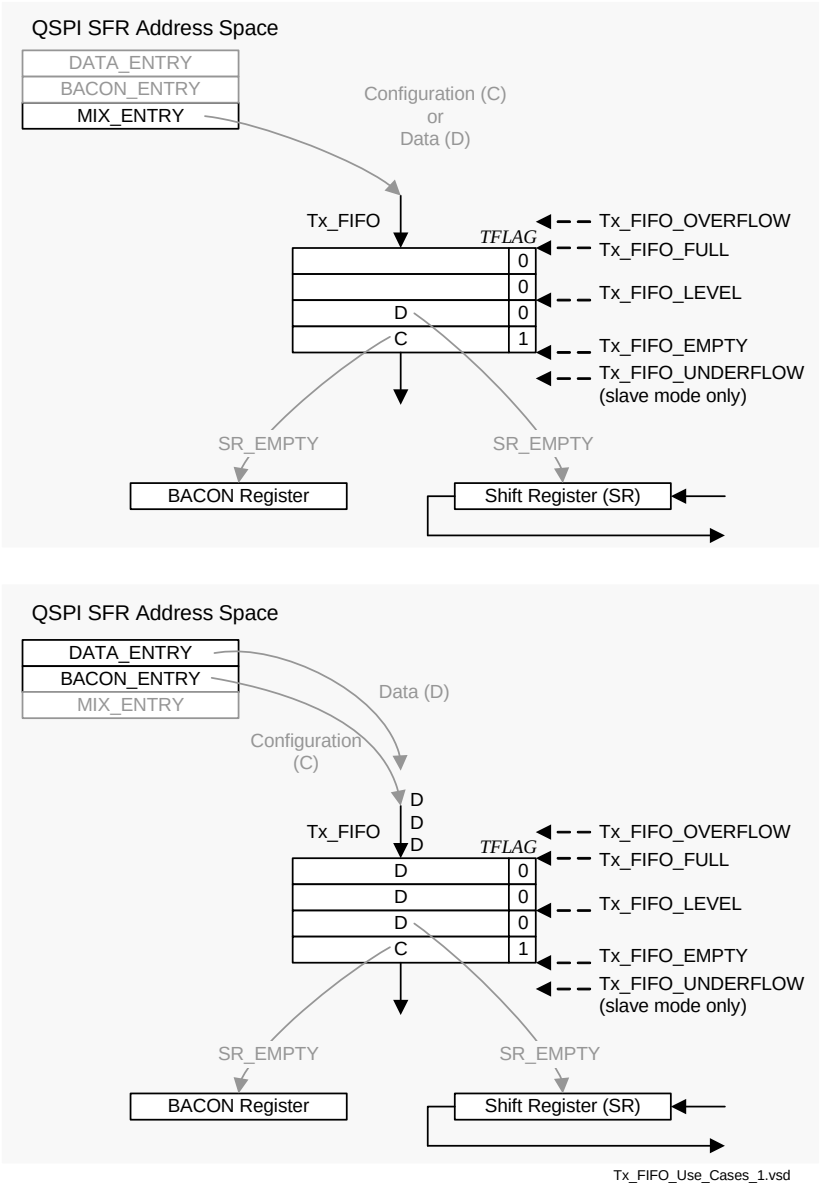

Figure 20-25 Using Tx FIFO Mix and Bacon / Data Entries

20.6.1.1 Short Data Mode

In Short Data Mode, the QSPI module transmits single data with a length of 2 to 32 bits in one frame. This mode is defined by **BACON**.LAST = 1 and **BACON**.BYTE = 0.

The transfer cycle is a sequence of the following phases: W?_I_L_D_T. The symbol “?” means that the phase is optional (duration of 0 allowed).

For example, a Tx_FIFO event can be used to trigger one DMA transfer (consisting of two 32-bit moves) to transfer both the BACON and DATA entries from an on-chip RAM memory to the QSPI module.

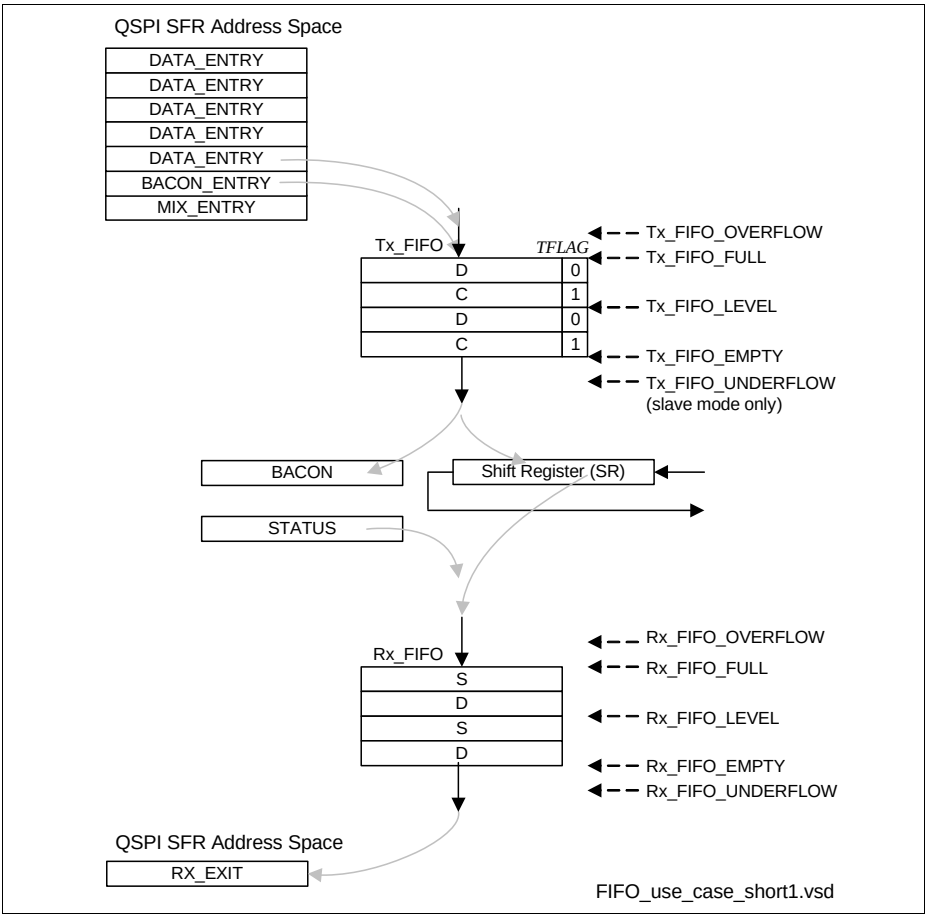

Figure 20-26 User Interface in Short Data Mode

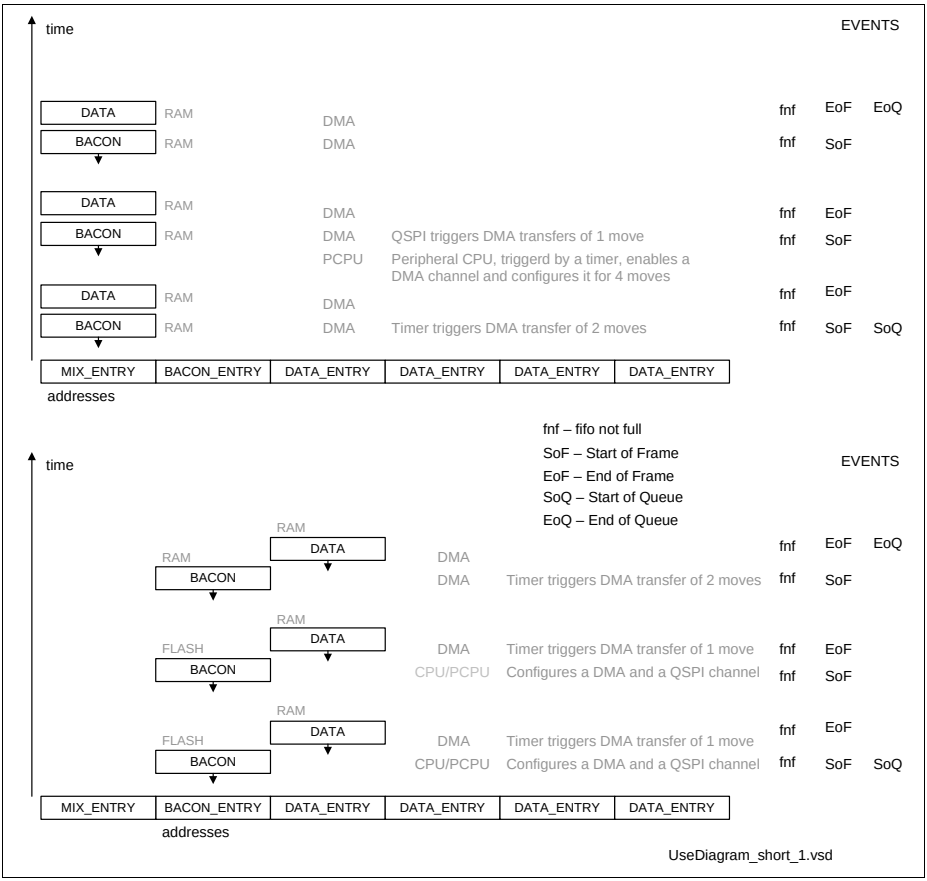

Figure 20-27 Use Diagram of the User Interface in Short Data Mode

20.6.1.2 Long Data Mode

In Long Data Mode, the QSPI module transmits bursts of up to 32 bytes (256 bits) in one frame. This mode is defined by programming **BACON**.LAST = 1 and **BACON**.BYTE = 1.

One transfer cycle in long data mode is a sequence of the following phases: W?_I_L_D_T. The W_I_L_D_T_I_L_D_T sequence is possible. The symbol “?” indicates that the phase is optional (duration of 0 allowed). Each “D” indicates a data length as defined with **BACON**.DL and **BACON**.BYTE, that is, up to 256 bits. One “D” is made of a number of 32-bit TXFIFO entries “d” and one rest at the end “b”, which can be written as D=ddddddb.

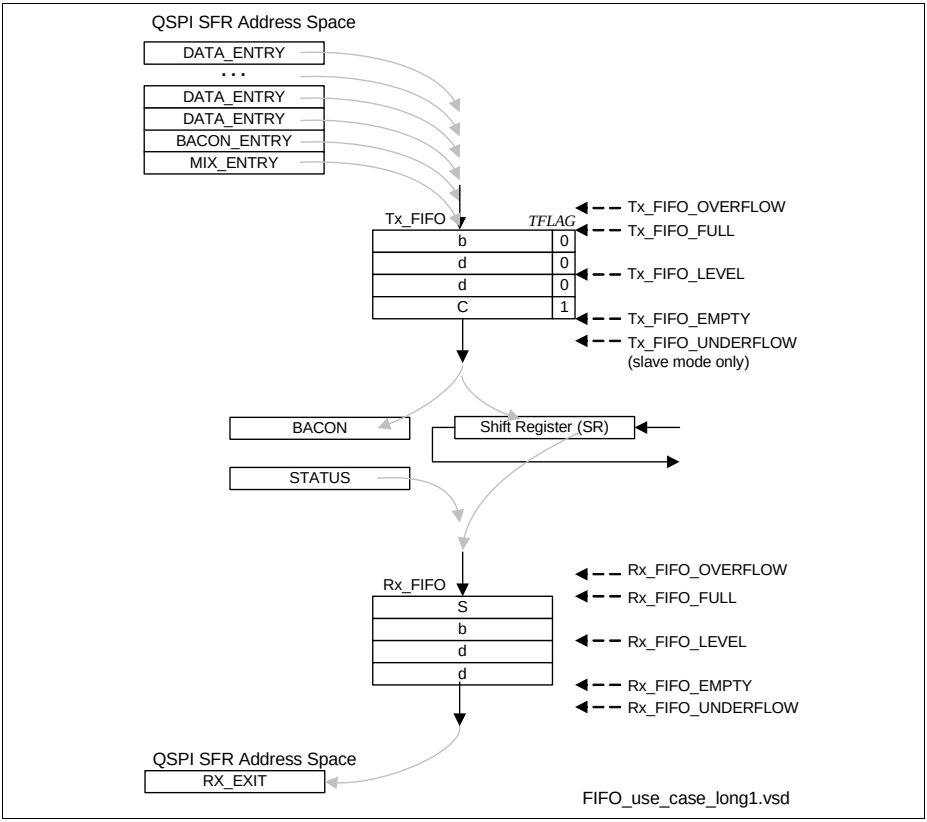

Figure 20-28 User Interface in Long Data Mode

In a DMA transfer example, a Tx_FIFO_EMPTY event can be used to trigger one DMA transfer (consisting of, for example, four 32-bit moves) to transfer the BACON and three DATA entries from RAM memory to the QSPI module. The three data words could

contain 80 bits (10 bytes) of data. The three data words could also contain 40 bits (5 bytes), 64 bits (8 bytes) plus one dummy word. In this way short bursts of up to 96 bits can be transmitted.

In such 4 words DMA transfer example, the Tx_FIFO event can be used to transfer two 32-bit words per transfer.

If a configuration word is written when a data word is expected, the configuration word is ignored, and an Unexpected Configuration Error is raised.

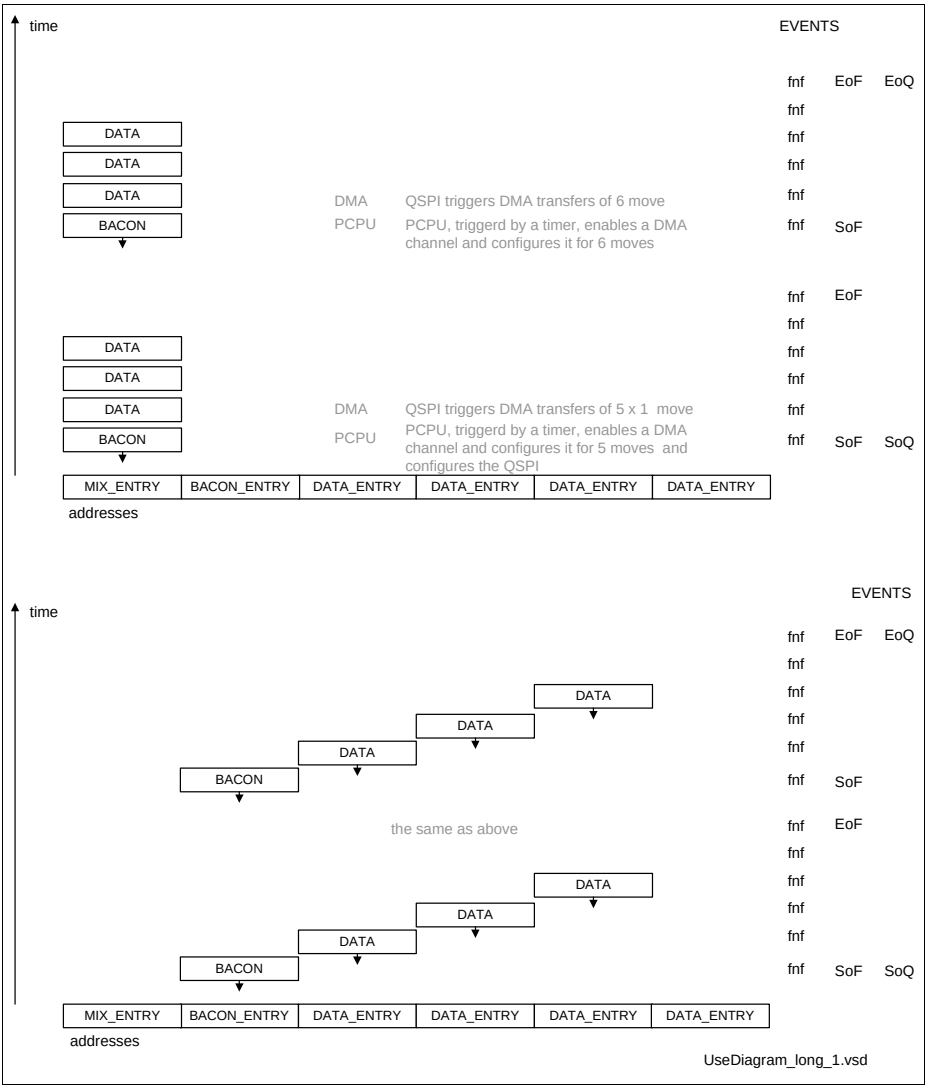

Figure 20-29 Use Diagram of the User Interface in Long Data Mode

20.6.1.3 Continuous Data Mode

In Continuous Data Mode, the QSPI transmits a stream of data with an arbitrary length with an active slave select signal. It can be used with both short and long data.

This mode starts by programming a control word containing **BACON**.LAST = 0 and the first data. The communication continues with the subsequent data entries written. The mode ends with a control word containing **BACON**.LAST = 1 and the last data. If LAST = 0, then TRAIL is a delay between data blocks. The W_I_L_D_T_D_T_D_T sequence appears. Each “D” represents data block as defined with **BACON**.DL and **BACON**.BYTE (up to 256 bits). If LAST = 1 then TRAIL is trailing delay, see **Figure 20-9**.

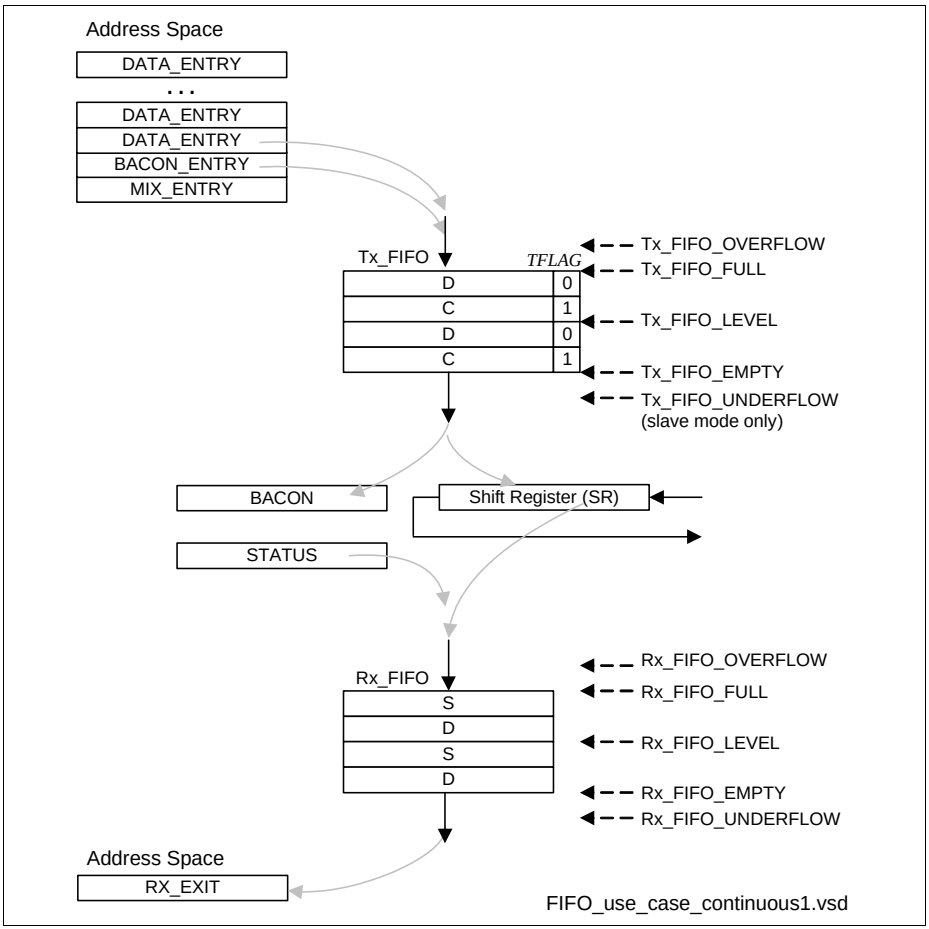

Figure 20-30 User Interface in Continuous Data Mode

The **Figure 20-31** shows an example of continuous data mode using short data. Here, the CPU starts the stream by writing BACON to the BACON_ENTRY address, and afterwards a DMA transfers the whole stream except the last BACON and DATA.

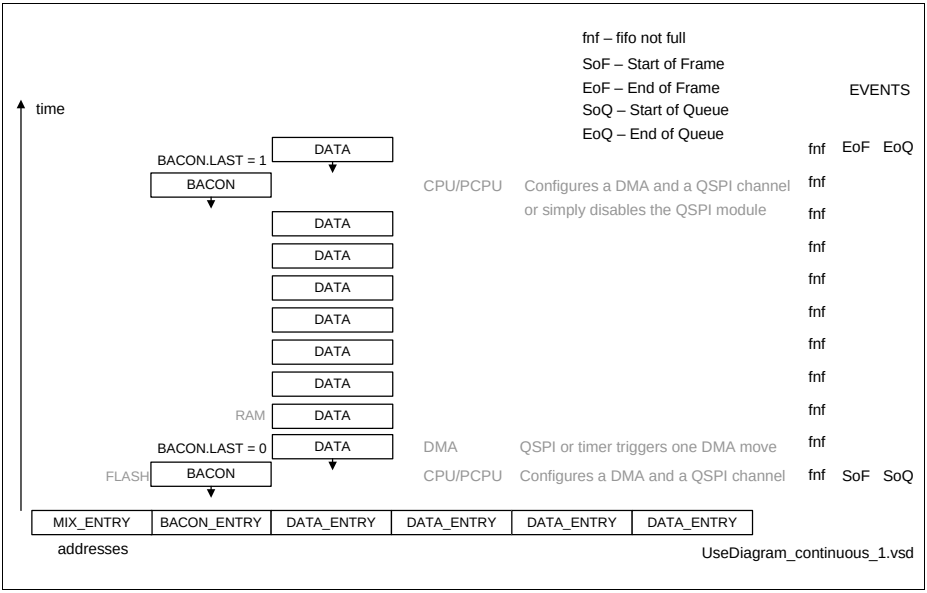

Figure 20-31 Use Diagram of Continuous Data Mode with Short Data

The **Figure 20-32** shows an example of continuous data mode using long data. Here, the first BACON must be repeated after each data block, but on the other hand, the whole transfer can be done using only the MIX entry and one single DMA channel, without CPU involvement. The loss of efficiency because of the unnecessary extra BACONS can be minimized by using long data blocks.

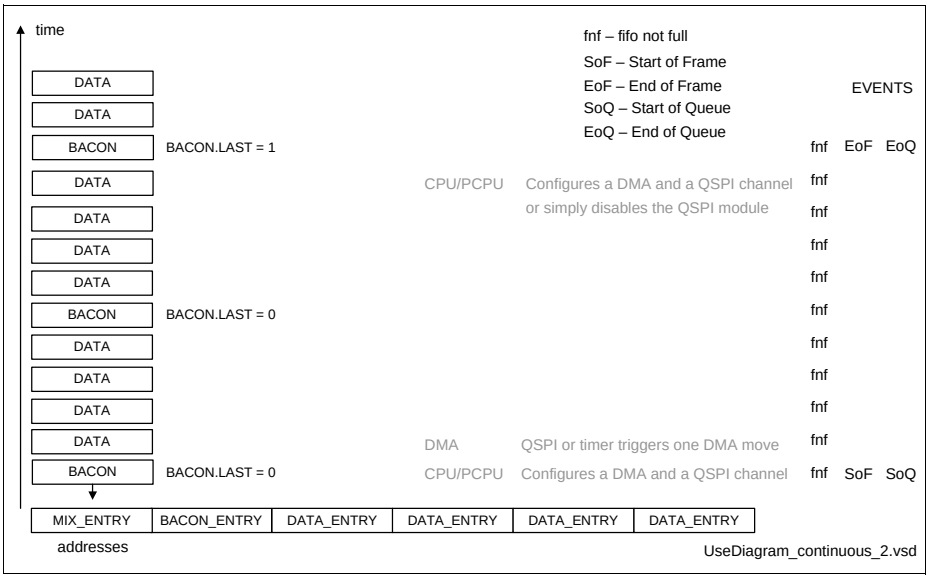

Figure 20-32 Use Diagram of Continuous Data Mode with Long Data

20.6.1.4 Single Configuration - Multiple Frames Behavior

If longer sequences of data with length of up to 16 bit have to be sent to single slave in separate frames, then the DMA move for the repeating configuration word can be saved. An example of a TxFIFO contents and the resulting message sequence is shown in **Figure 20-33**.

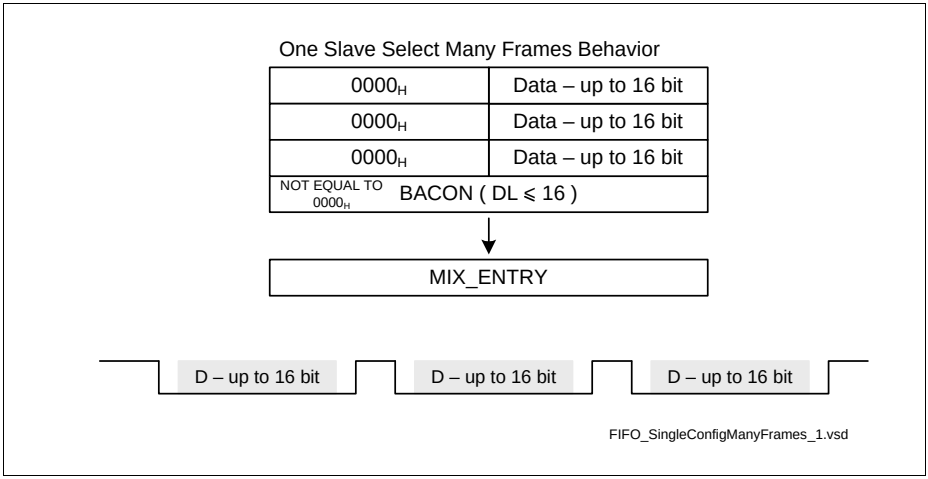

Figure 20-33 Multiple Frames to One Channel (Example of up to 16 Bit Data)

In order to support sending short multiple frames to single channel without having to send the same configuration each time, the TXFIFO follows this rule:

- If **BACON**.DL less or equal 15 (up to 16 bit data length)
- if MIX_ENTRY address is used
- then if the upper 16 bit of a 32-bit MIX_ENTRY are 0, the entry is considered data, else configuration. Note that there is no valid configuration word with upper 16 bits equal to 0.
- In such a case the TXFIFO marks the entry as data.

*Note: In case the **BACON**.LAST = 0, the slave select remains active between the frames. The behavior is equal to the continuous mode. The disadvantage of this method is that only up to 16 bits data can be transferred with one FPI bus move. The advantage is that continuous mode is possible using the mix entry.*

20.6.1.5 Big Endian Data Format

The bit-field **ECON**.BE activates the permutation of the data bytes written to the shift register and read from it to the big endian format and back.

ECON.BE allows for switching between big and little endian per slave (SLSO signal).

See **Figure 20-34** and **Figure 20-35**.

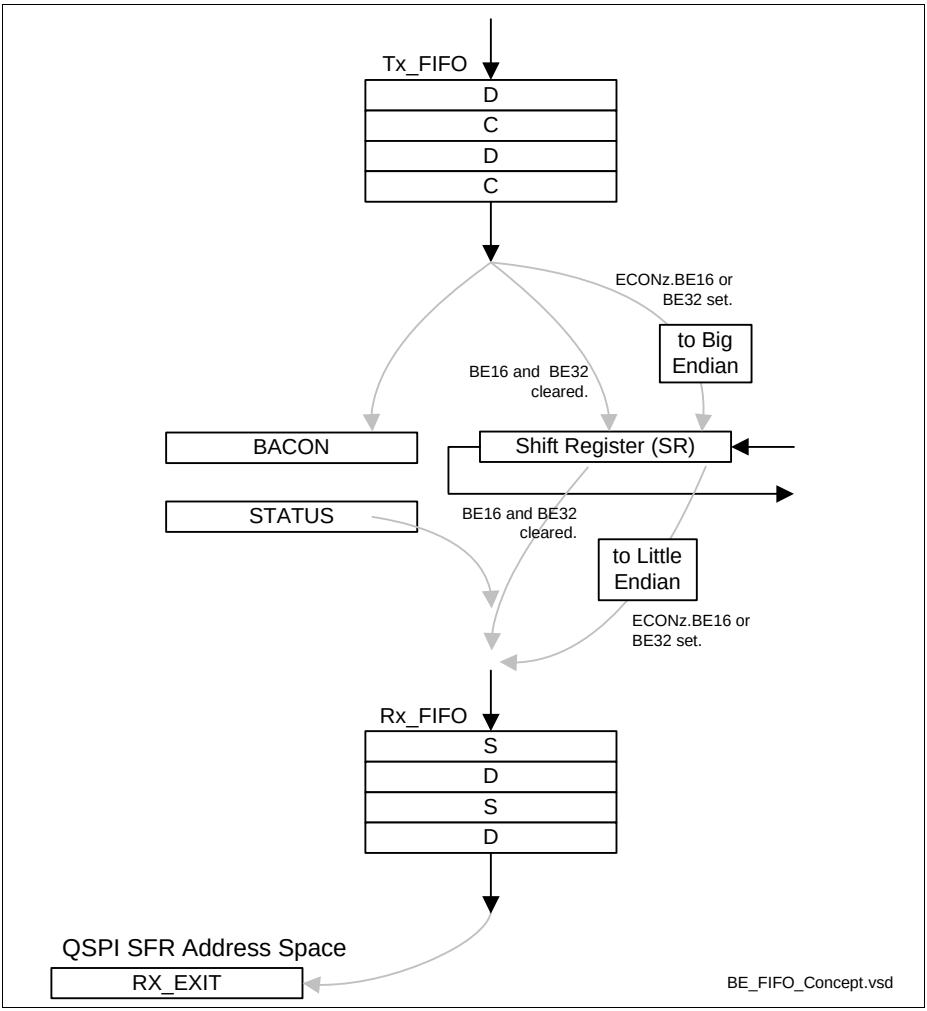

Figure 20-34 Big Endian Data Path

Converting data from little to big endian and other way around requires one and the same permutation of the data bytes, as shown in **Figure 20-34**, One permutation block is located before and one after the shift register, so that only data can be permutated, and not **BACON** or **STATUS**.

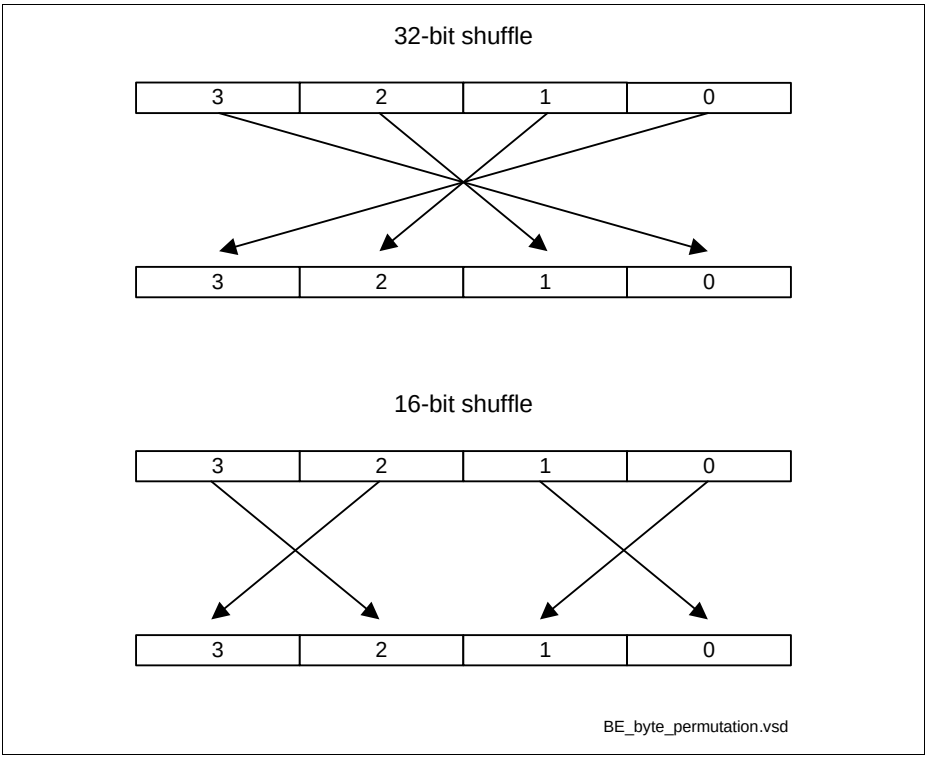

Figure 20-35 Endianness Byte Permutation

The endianness byte permutation should be used only for 16-bit and 32-bit data (and multiples of it), and not for other data lengths.

20.6.2 Loop-Back Mode

Loop Back mode is a master mode test feature used for establishing a module internal connection between the transmit and the receive signal, the same as if the transmit and receive pins would be short connected. It is actived by setting the **GLOBALCON**.LB bit.

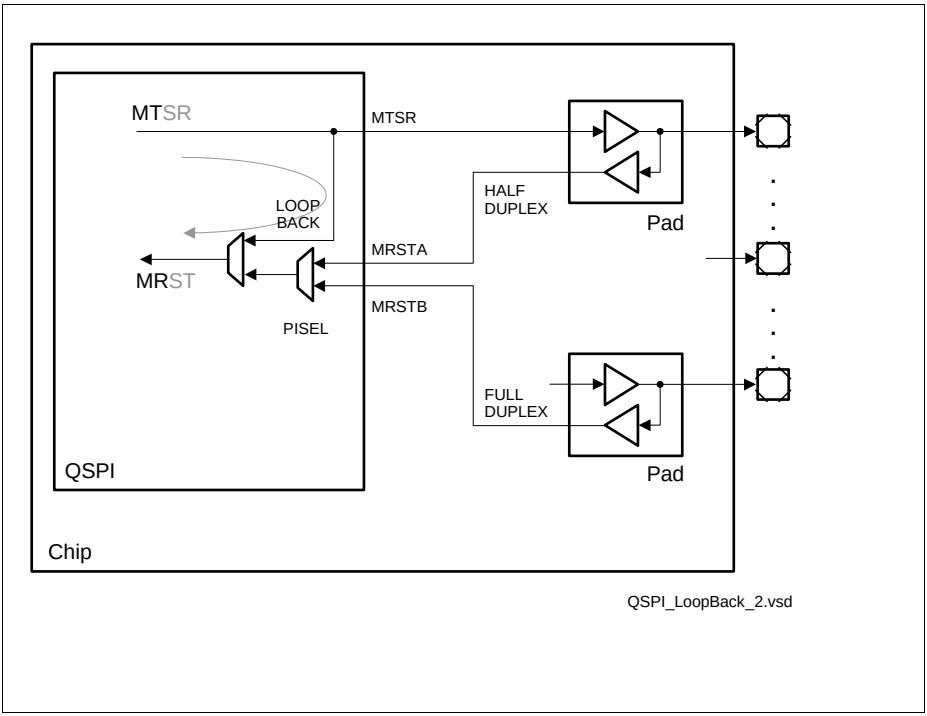

Figure 20-36 Loop-Back Mode

20.7 Interrupts

There are several types of interrupts:

- Interrupts related to the user interface
  - FIFO related interrupts
- Interrupts related to the shift engine (state machine)
  - error interrupts
  - phase transition interrupts

According to this classification, here follows the complete list of all the interrupts:

- FIFO related interrupts
  - TX - Transmit FIFO Interrupt, requests feeding of the TXFIFO, but does not signal the error events of overflow and underflow (see **Figure 20-24**)
  - RX - Receive FIFO Interrupt, requests emptying of the RxFIFO , but does not signal the error events of overflow and underflow (see **Figure 20-24**)
- ERR Error Interrupt
  - signals every error condition
  - signals TX_FIFO_OVERFLOW, TX_FIFO_UNDERFLOW
  - signals RX_FIFO_OVERFLOW, RX_FIFO_UNDERFLOW
- PT - Phase transition interrupt, signalling two out of all phase transitions in the QSPI communication cycle (see **Figure 20-18** and **Figure 20-21**)
  - PT1 event
  - PT2 event
- U - User Interrupt
  - triggered by the PT1 event during the time **BACON**.UINT bit keeps this event enabled.

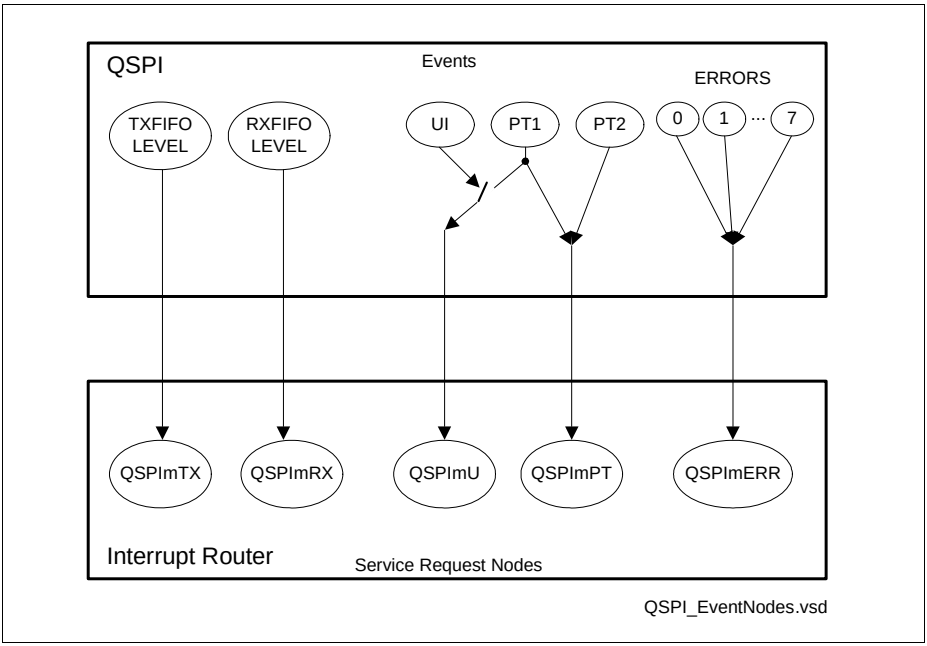

Figure 20-37 Events and Interrupts Overview

20.7.1 Slave Mode SLSI Interrupt

In slave mode, deactivating the SLSI signal (SLSI rising edge) triggers the PT interrupt, if PT2 enabled.

20.7.2 Interrupt Flags Behavior

An state of an event flag (low or high) does not influence the flow of its event signal. If an event occures recurrently, and the event flag remains set (if not cleared by the software interrupt handler), the interrupt flag (which is cleared by hardware, by an ICU, when the interrupt wins an arbitration round) would receive recurrent triggers, and the flag would be constantly set all the time.

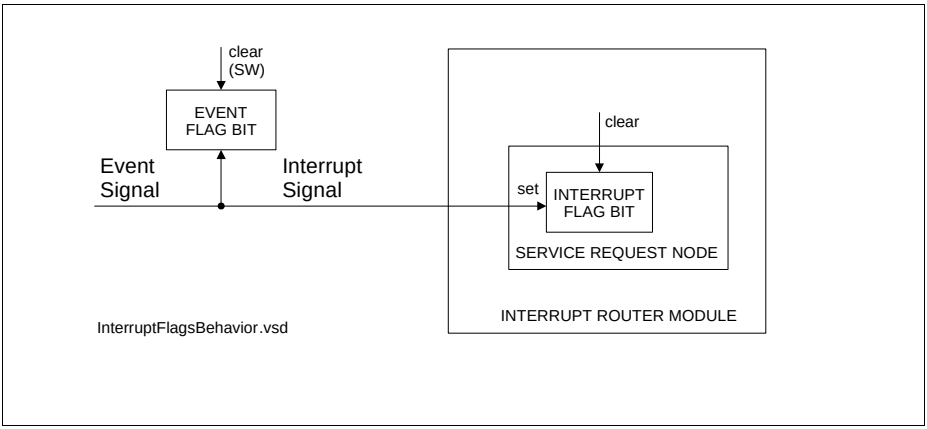

Figure 20-38 Events and Interrupts Overview

20.7.3 TXFIFO Interrupt Generation

The TXFIFO provides two interrupt generation modes, selected by the bit-field **GLOBALCON1**.TXFM:

- Single Move Mode
- Batch Move Mode
- Combined Mode

The RXFIFO and the TXFIFO can use the interrupt generation modes independently of each other.

Single Move Mode

The purpose of the Single Move Mode is to keep the TXFIFO as full as possible, refilling the TXFIFO by writing to it as soon as there is a free element.

The single move mode supports primarily a DMA operation using single move per TXFIFO interrupt. In this mode the DMA keeps the TXFIFO full. A DMA request is triggered each time a write to the TXFIFO is performed, and there is at least one empty element available. If the write makes the TXFIFO full (no more empty elements), an interrupt is not generated in order to prevent overflow. It is generated later when the shift register (or BACON) reads one element from the TXFIFO, making it not full.

The **Figure 20-39**, shows the filling levels of the TXFIFO, and the events associated with each filling level triggering a TXFIFO refill interrupt.

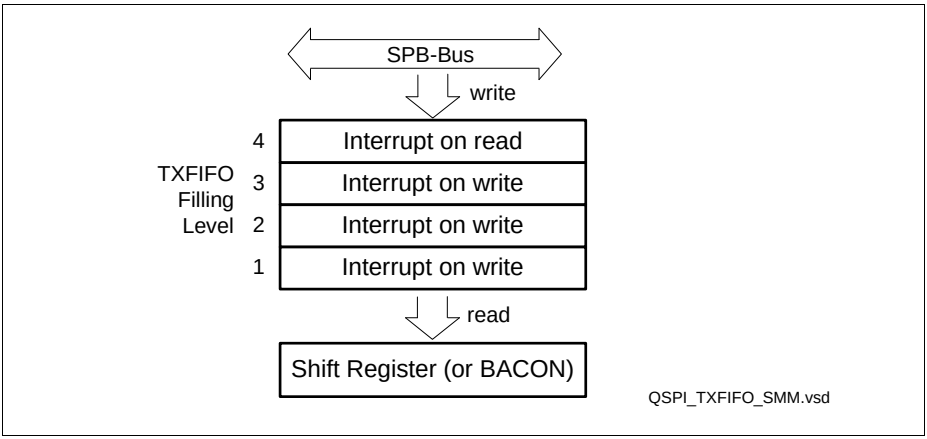

Figure 20-39 Interrupt Generation in the Single Move Mode

In order to initiate the very first chain of the refill interrupts after power-on reset, it is necessary that the software either performs one write to the TXFIFO, or sets the interrupt flag in the TXFIFO interrupt node. Afterwards, the (DMA) interrupt-chain is self sustaining until the whole transaction is over.

Attention: In Single Move Mode multiple software writes or block DMA moves would lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.

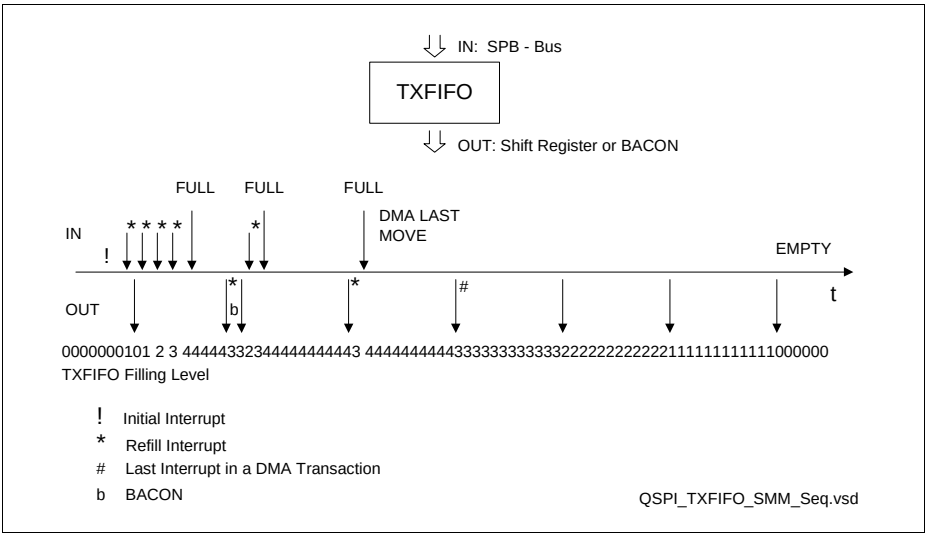

Figure 20-40 TXFIFO - Interrupt Operation in Single Move Mode

Batch Move Mode

Batch Move Mode supports the following use case:

- CPU servicing the TXFIFO

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more then one TXFIFO elements are empty. For example, a CPU can be interrupted less frequently and it can perform more than one moves per interrupt.

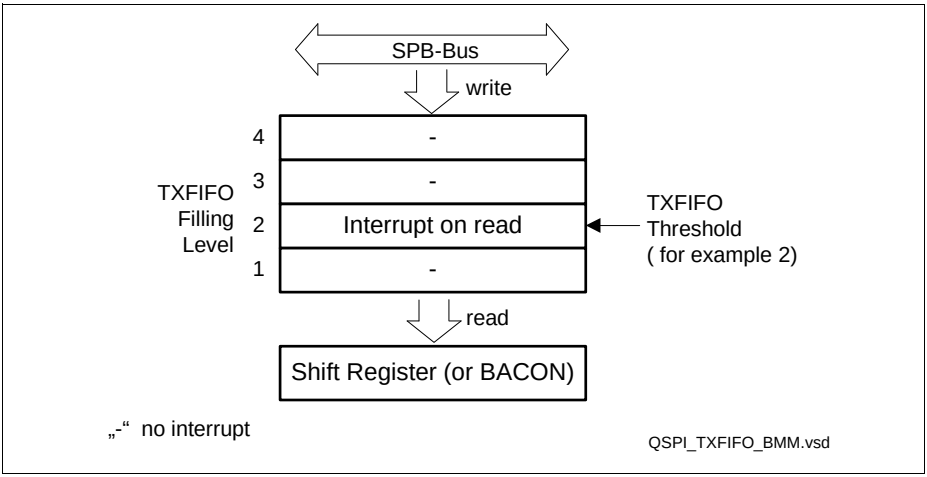

Figure 20-41 TXFIFO - Interrupt Generation in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the TXFIFO, when the filling level falls below the programmed threshold, implying that there are at least the predefined number of empty TXFIFO elements available.

Attention: The TXFIFO must be refilled until the filling level has risen above the interrupt threshold (ensured by polling the filling level), in order to guarantee that the next interrupt will occur.

At high baud rates and short frames, it could be possible that a couple of frames have been transmitted until the moment the TXFIFO is refilled. For example, if the threshold is set to three full elements, then the interrupt will be set when the filling level falls below three, making two elements free. If the refill moment of the TXFIFO is delayed so long that two frames have been transmitted (or frame and BACON), the TXFIFO will become empty, and refill sequence of two will not reach the level of three. So, the next interrupt would never come unless the filling level is being polled and the CPU keeps refilling in a loop until the threshold has been passed (ideally the TXFIFO would be filled completely with each batch of moves).

Combined Mode

TXFIFO generates interrupt each time a data is fetched from it below the pre-programmed threshold, as defined in the **GLOBALCON1**.TXFIFOINT. Consequently, it generates two close interrupts when delivering BACON and the first following data. If the BACON TX interrupt is not serviced until the DATA1 TX interrupt comes, which will always be the case due to their time proximity, the BACON TX interrupt will be lost. Therefore, it is recommended that a DMA should always perform two moves per interrupt trigger (transfer size of two). Otherwise, the TXFIFO average filling level will go down with the time and at the end remain oscillating between zero and one (except in continuous mode). The DMA transaction loss event that may be raised by the DMA should be ignored.

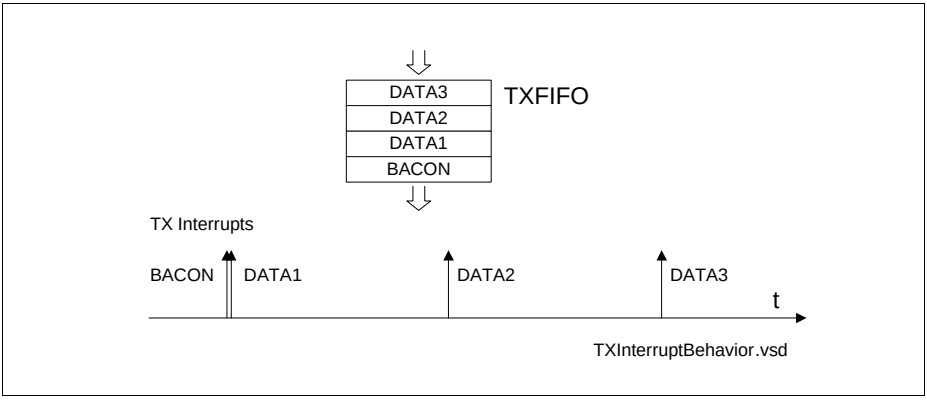

Figure 20-42 Events and Interrupts Overview

20.7.4 RXFIFO Interrupt Generation

The RXFIFO provides two interrupt generation modes, selected by the bit field **GLOBALCON1**.RXFM:

- Single Move Mode
- Batch Move Mode
- Combined Mode

Single Move Mode

The purpose of the Single Move Mode is to keep the RXFIFO as empty as possible, by fetching the received elements one by one as soon as possible.

The single move mode supports primarily a DMA operation using single move per RXFIFO interrupt. In this mode the DMA keeps the RXFIFO as empty as possible. A DMA request is triggered each time a read from the RXFIFO is performed, and the RXFIFO is afterwards still not empty. If the read makes the RXFIFO empty, an interrupt is not generated in order to prevent underflow. It is generated later when the shift register (or STATUS) writes new element to the empty RXFIFO.

The **Figure 20-39**, shows the filling levels of the RXFIFO, and the events associated with each filling level triggering a RXFIFO refill interrupt.

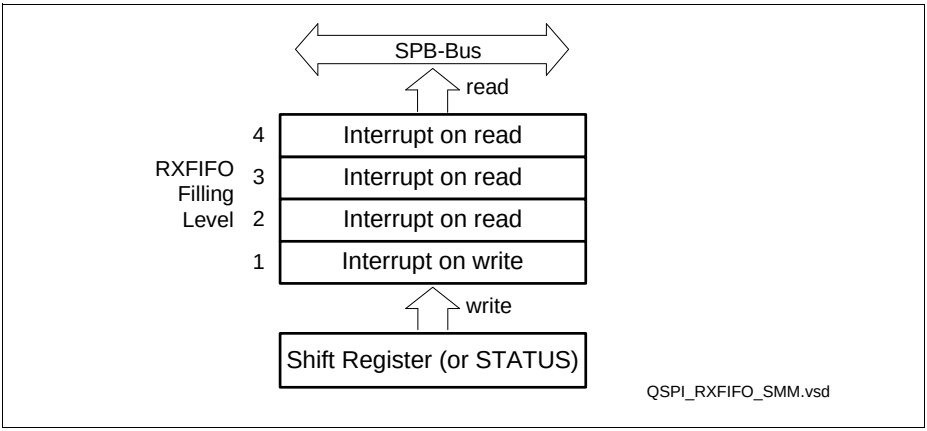

Figure 20-43 RXFIFO - Interrupt Triggering in the Single Move Mode

The initial RXFIFO interrupt is triggered by the Shift Register, after it delivers the first received element. Afterwards, the DMA trigger-chain of refetch interrupts is self sustaining until the whole transaction is over. At the end of the DMA transaction, there is no service request remaining active in the service request node, due to the fact that the read of the last element in the RXFIFO does not trigger an interrupt.

Attention: In Single Move Mode multiple software reads or block DMA moves lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.

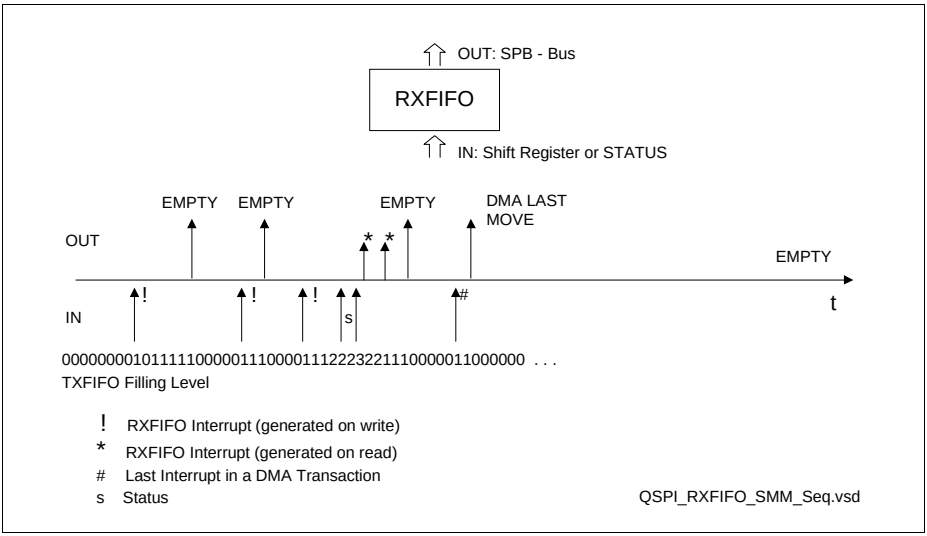

Figure 20-44 RXFIFO - Interrupt Operation in Single Move Mode

Batch Move Mode

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more then one RXFIFO elements are full. For example, a CPU can be interrupted less frequently and it can perform more than one move per interrupt.

Batch Move Mode supports the following use case:

- CPU servicing the RXFIFO

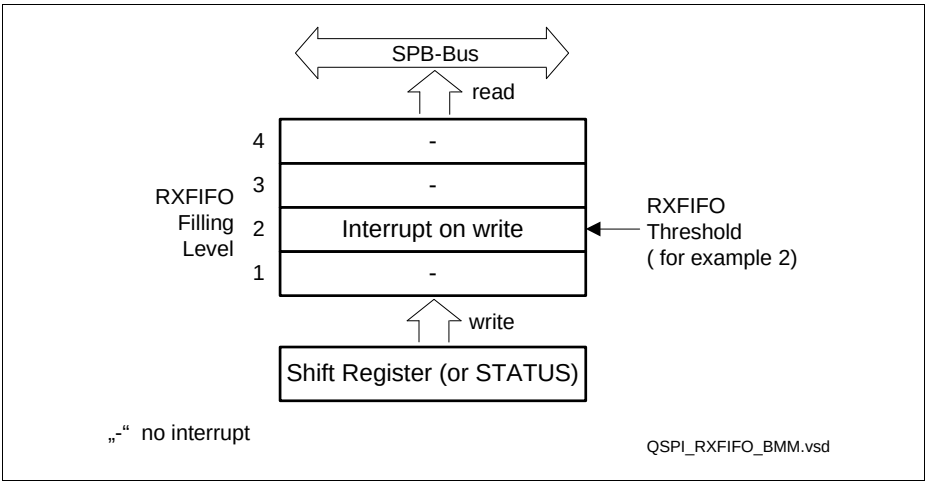

Figure 20-45 RXFIFO - Interrupt Triggering in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the RXFIFO, when the filling level rises above the programmed threshold, implying that there are at least the predefined number of full RXFIFO elements available.

Attention: It must be guaranteed that the CPU keeps emptying the RXFIFO and polling the RXFIFO filling level until the filling level has fallen below the interrupt threshold (or the RXFIFO is empty), in order to guarantee that next interrupt will occur.

At high baud rates and short frames, it could be possible that more than one frames have been received until the moment the RXFIFO is reemptied. For example, if the threshold is set to two full elements, then the interrupt will be set when the filling level rises above two. If the emptying moment of the RXFIFO is delayed so long that two additional frames has been received (or a frame and STATUS), the RXFIFO will become full, and reempty sequence of two will not reach the level of two. So, the next interrupt would never come. This effect can not occur with threshold levels of 3 and 4. The threshold level of 1 is possible, but does not make much sense (use single move mode instead).

Combined Mode

RXFIFO generates interrupt each time a data is written to it above the preprogrammed level, as defined in the **GLOBALCON1**.RXFIFOINT. Consequently, it generates two close interrupts when filled with data and STATUS. If the data RX interrupt is not serviced until the STATUS RX interrupt comes, which will always be the case due to their time proximity, the STATUS RX interrupt will be lost. In such a case, it is recommended that the DMA performs two moves per interrupt trigger (transfer size of two). Otherwise, the RXFIFO average filling level will go up with the time and at the end overflow.

20.7.5 DMA Transfer Example

Transmitting one compact RAM queue using DMA could consist of the following steps:

- The user software configures one appropriate DMA channel (source address, destination address, one move per transfer, number of transfers per transaction, gating mode, single mode, interrupt at the end of the transaction etc...)
- A not full TxFIFO from some QSPI module constantly generates pending DMA request
- A timer triggers a software routine that enables the DMA channel
- The DMA channel reads the queue elements from some on-chip general purpose RAM and writes them to the QSPI, one element at a time. One DMA transfer is one move long. One whole queue takes one transaction.
- The DMA channel generates an interrupt at the end of the transaction
- The DMA channel disables itself at the end of the transaction (single mode) and waits for further software actions.

The sequence is identical for the receive direction.

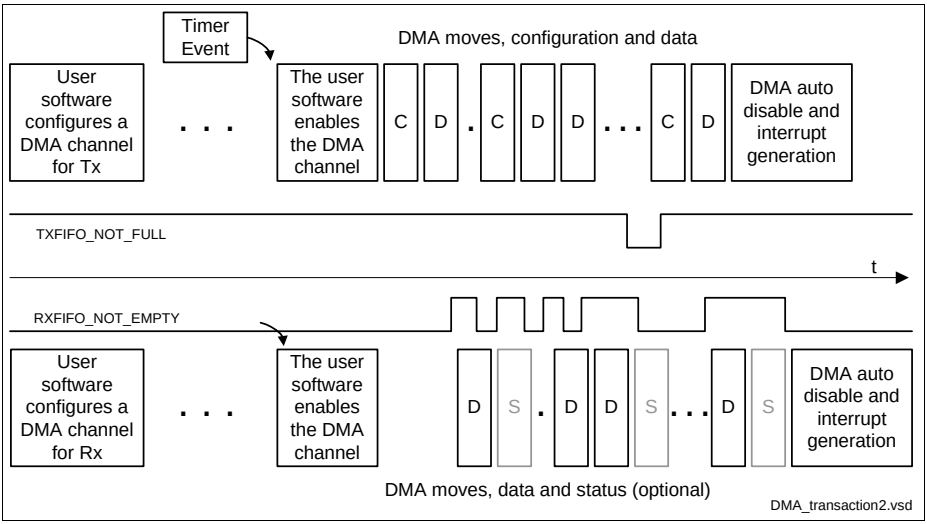

Figure 20-46 Example of transmitting a compact RAM Queue per DMA

20.8 Slave Mode

The slave mode is entered by setting the bit field **GLOBALCON**.MS to value 1x. Before entering the slave mode, the related parameters must be configured, including pin selection for SCLKI, SLSI and MTSR, pin input level, and pull-up/pull-down configuration. Subsequently state machine reset should be performed and afterwards the slave mode should be entered.

In slave mode data is being pushed into or out of the module through the serial pins by an external master. The RXFIFO must be regularly emptied by the system in order to avoid data loss, and the TXFIFO must be regularly fed by the system to avoid delivering all “1” data in case of empty TXFIFO.

If the slave mode relies on a slave select signal to mark the start and, in parallel to the bit counting, the end of a frame, then deactivating the slave signal by the master automatically resets the shift register state machine to wait state.

If the slave mode relies solely on bit counting for determining the frame end, then any SCLKI clock period longer than two bit times is treated as an end of a frame and simultaneously as a baud rate error.

In slave mode, the module simply immediately responds to external clock edges. Therefore, the settings for the leading, trailing, idle delays, and duty cycle and sampling point are irrelevant. From all timing settings, only the data length and the baud rate divider setting are relevant. The baud rate setting is important because of its role of watchdog timer of the incoming serial clock.

Generally, the slave mode supports the same user interface as the master mode. This means the BACON-Data sequences remain the same. The SRF bit is ignored.

Limit the data length setting in the slave mode to the range of 2 to 32 bits. The byte setting **BACON**.BYTE is to be set to zero, that is, it always defines bits.

In case of receive only (simplex receive) the user software must reset the module in order to switch to transmit and receive mode (full duplex). Generally, mode reconfiguration (slave mode to master mode) requires module reset which resets the internal state machines and counters.

In case of slave transmit, the user software must write data to the TXFIFO before the first SCLKI edge of a frame arrives. If the TXFIFO is empty at this point of time, an underflow occures, all “1” data is delivered, and underflow error interrupt is triggered if enabled. If the TXFIFO is written at the same time when the first SCLKI edge starts the shifting, the underflow occures, interrupt will be triggered and data from the TXFIFO will be transmitted possibly corrupted - the first bit will be “1”.

In case of TXFIFO / RXFIFO underflow the fifos deliver all “1” data .

In case of TXFIFO / RXFIFO overflow, the last data is lost. In such case data or optionally status in the RXFIFO can be lost.

The bit counting in the slave mode operates according to the following rules:

- The incoming bits (or shift clock shift edges) are counted and when the number defined in the **BACON**.DL is reached, the bits are transferred in the RXFIFO
- If the SLSI input is deactivated, the internal bit counter is reseted.

In slave mode, sleep requests may be enabled only when there is no pending transmit queue and no pending transmission and the TXFIFO is empty.

20.8.1 Shift Clock Phase and Polarity in Slave Mode

In slave mode the shift clock phase and polarity are fixed to CPH=1 and CPOL=0 (have to be programmed accordingly in the **ECON** register selected by **BACON**.CS) and slave select polarity is fixed to low active. The baud rate that the slave expects is defined in the **ECON** register pointed at by the **BACON**.CS.

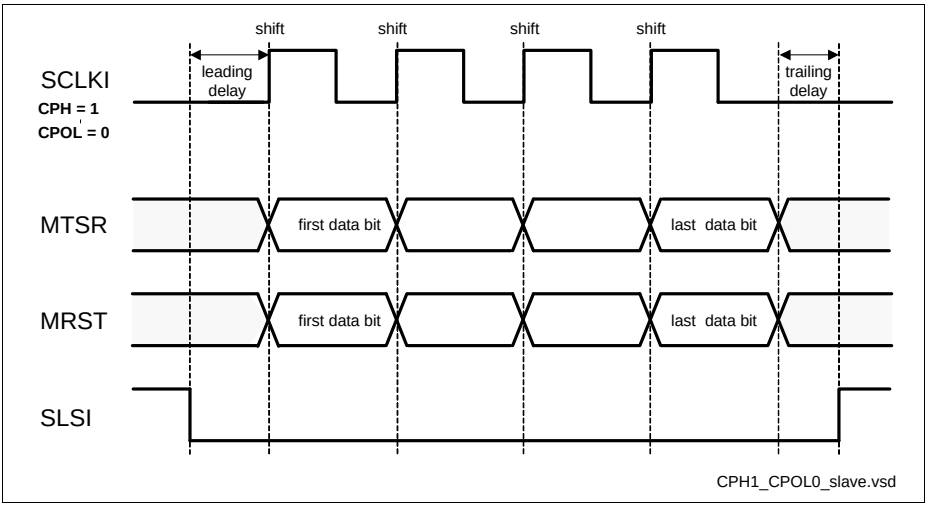

Figure 20-47 Slave transfer, CPH = 1, CPOL = 0

20.8.2 Shift Clock Monitoring

The QSPI module provides two mechanisms for monitoring the shift clock input signal in slave mode. These mechanisms monitor:

- if the receiving shift clock frequency (baud rate) lies within a certain range and
- if there are spikes on the shift clock input.

In case such disturbances are detected, the reaction is always the same:

- the corresponding error flags in **STATUS**.ERRORFLAGS are set, which can be cleared with **FLAGSCLEAR**.ERRORCLEARS
- the common error interrupt is raised if enabled in **GLOBALCON1**.ERRORENS and
- the bit **GLOBALCON**.EN is automatically cleared, if this feature is enabled by the bit **GLOBALCON**.AREN. The user software can activate a reset afterwards

In case of too high baud rate error , baud rate detection and spike detection both react, where spike detection is more effective. Spike detection reacts immediately, baud rate detection requires several bits with higher baud rate. Baud rate detection uses a window two nominal bit times wide and counts the real bit times: double baud rate error requires at least four real shift clock pulses to be detected, triple baud rate error requires six and so on. Baud rate detection does not react to all spikes smaller than one kernel clock period.

In case of too low baud rate error, baud rate detection reacts immediately, spike detection ignores this case.

20.8.2.1 Baud Rate Error Detection

If the shift clock has less than half or more then double the expected baud rate, then:

- the corresponding flag is set in **STATUS**.ERRORFLAGS
- error interrupt is raised if enabled in **GLOBALCON1**.ERRORENS
- automatic clear of **GLOBALCON**.EN follows, if enabled by **GLOBALCON**.AREN.

20.8.2.2 Spike Detection

Short spikes on the clock line due to ground bouncing or clock ringing due to over/undershoots would cause one or more extra bits to be written to the front end receive fifo of the slave. This extra bit, if no measures are taken by the software, would cause all the subsequent received frames to be corrupted (shifted).

The spike detection mechanism operates up to 50MBaud and checks if a bouncing spike has occurred on the clock line near to the correct receiving clock edges.

If a spike is detected, the software should use **GLOBALCON**.RESETS bitfield, and should clear the corresponding status flags. Alternatively a complete module reset may be performed via registers **KRST0**/**KRST1**.

The spike detection is based on two mechanisms:

- detection of two close writes to the front end receive FIFO by detecting filling level of two
- using an inverted watchdog set to ca. 75% to 80% SCLKI clock period, which is the optimal range.

The inverted watchdog is a timer which starts to count triggered on the write event to the front-end receive fifo of the slave.During the time the watchdog counts, no edge is allowed to occur. An edge in the forbidden time raises a spike error event.

If a spike occures in the last 25% of the SCLKI period, when the watchdog has stopped counting, the watchdog will be triggered to count by the spike. The next regular edge will violate the forbidden time and raise a spike event.

The watchdog counts **ECON**.B + **ECON**.C time quantas. The following constraint applies: 50% *T_{SCLKI}<**ECON**.B + **ECON**.C <100%*T_{SCLKI}.

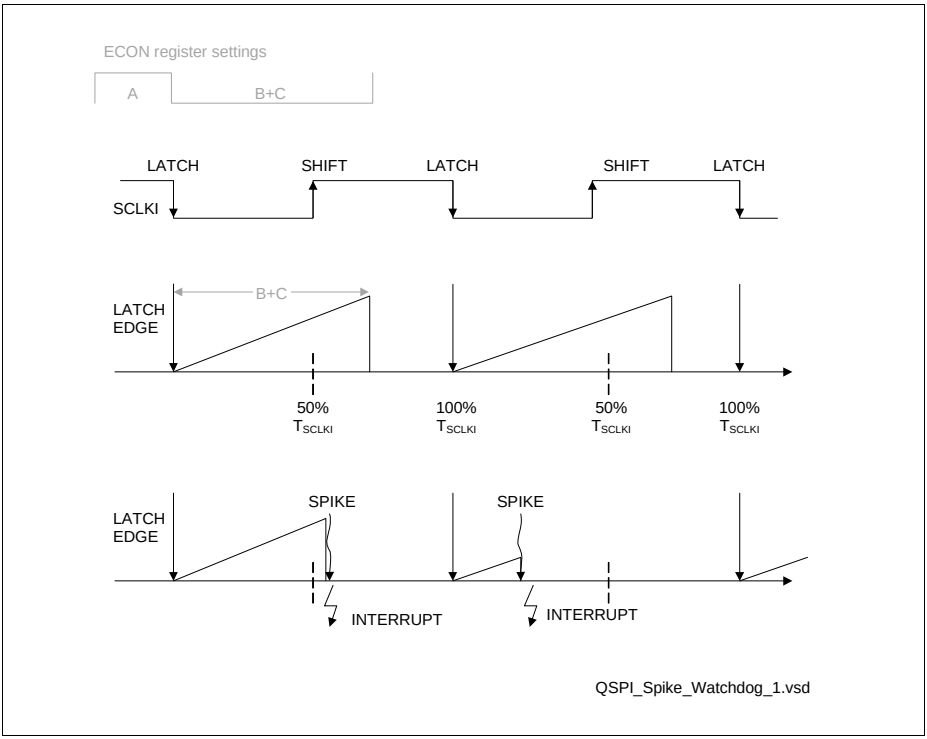

Figure 20-48 Spike Watchdog

20.8.2.3 Shift Clock Monitor Flags

The spike detection mechanism sets the flag **STATUS1**.SPD if it has detected a spike. The baud rate error detection mechanism sets the flag **STATUS1**.BRD if it has detected excessive baud rate deviation.

Writing 1 to SPD and BRD sets the bit and causes an interrupt if enabled. Writing 0 has no effect.

Both signals are ORed. This combined signal is shown in **STATUS**.ERRORFLAGS and raises an interrupt if enabled in **GLOBALCON1**.ERRORENS. Automatic clear of **GLOBALCON**.EN follows, if enabled by **GLOBALCON**.AREN.

If the **STATUS**.ERRORFLAGS[2] bit is cleared via **FLAGSCLEAR**.ERRORCLEARS[2], the both flags SPD and BRD are automatically cleared.

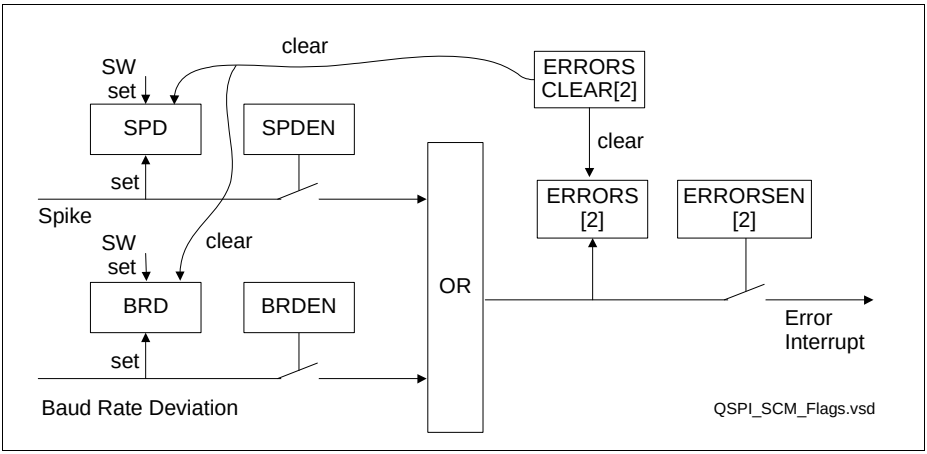

Figure 20-49 Shift Clock Monitor Flags

20.8.3 Parity

Parity settings for transmit and receive are defined by the corresponding bit fields in the **BACON** register.

The parity bit is concatenated to the data bits at transmission time. That means that a frame containing 16 bit data is 17 bits long (data + 1 parity). The transmitted parity bit can be read from the **STATUS**.TPV bit.

The parity bit is removed from the received bits at receive time automatically. The received parity bit can be read from the **STATUS**.RPV bit.

Attention: Parity is available only if the bit field BACON.BYTE = 0, that is, only for data of up to 32 bits length, that is, only in short mode.

Attention: The parity bit is concatenated to the data at the LSB location. If the bit field BACON.MSB = 0 it is shifted out first, else it is shifted out last.

20.9 Kernel Registers

This section describes the kernel registers of the QSPI module. All QSPI kernel register names described in this section will be referenced in other parts of the TC21x/TC22x/TC23x User's Manual by the module name prefix "QSPI0_" for the QSPI0 interface, "QSPI1_" for the QSPI1 interface and so on.

All registers in the QSPI address spaces are reset with the application reset (definition see SCU section "Reset Operation").

QSPI Kernel Register Overview

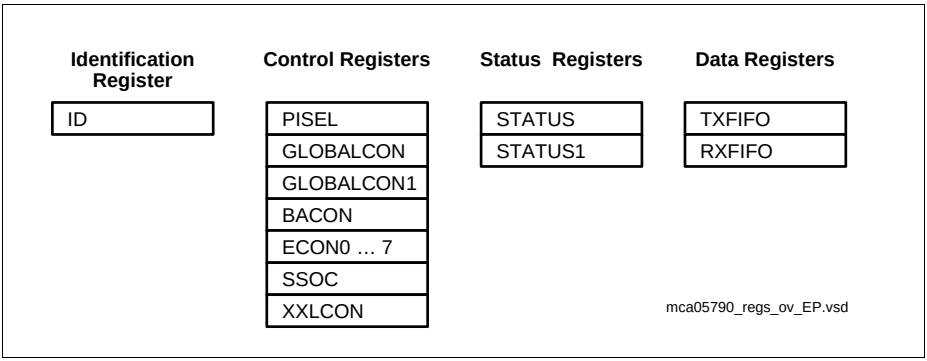

Figure 20-50 QSPI Kernel Registers

The following tables give the overview of the QSPI base addresses and registers.

Table 20-1 Registers Address Space

Module	Base Address	End Address	Note
QSPI0	$F0001C00_H$	$F0001CFF_H$	–
QSPI1	$F0001D00_H$	$F0001DFF_H$	–

ACCEN0	Access Enable Register 0	FC_H	SV, SE	FFFF FFFF

1) The absolute register address is Module Base Address (**Table 20-1**) + Offset Address (shown in this column)
2) All registers have read access mode U, SV. Read access to reserved addresses delivers bus error (BE). All registers belong to application reset except OCS, which belongs to debug reset.

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - SafetyENDINIT

20.9.1 Kernel Registers

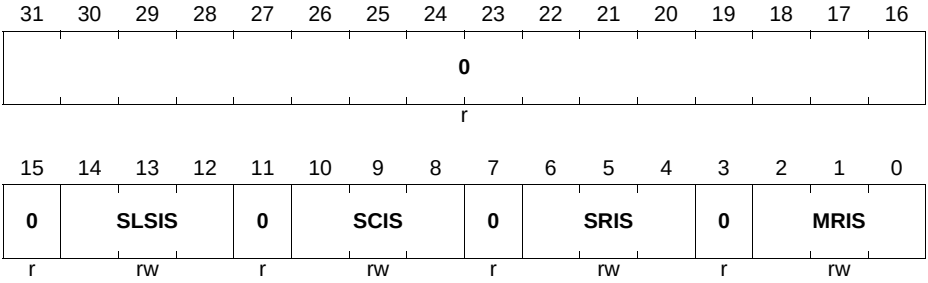
PISEL

The PISEL register controls the input signal selection of the SSC module.

(>> **Table 20-2** register overview)

PISEL

Port Input Select Register **(04_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
MRIS	[2:0]	rw	**Master Mode Receive Input Select** MRIS selects one out of eight MRST receive input lines (0 to 7 correspondingly), used in Master Mode. The signal suffixes “A” to “H” correspond to the bit field values of 0 to 7: MRSTxA ->0, MRSTxB->1 ...
SRIS	[6:4]	rw	**Slave Mode Receive Input Select** SRIS selects one out of eight MTSR receive input lines (0 to 7 correspondingly), used in Slave Mode. The signal sufixes “A” to “H” correspond to the bit field values of 0 to 7: MTSRxA ->0, MTSRxB->1 ...
SCIS	[10:8]	rw	**Slave Mode Clock Input Select** SCIS selects one out of eigjt module kernel SCLK input lines (0 to 7 correspondingly) that is used as clock input line in slave mode. The signal sufixes “A” to “H” correspond to the bit field values of 0 to 7: SCLKIxA ->0, SCLKIxB->1 ...

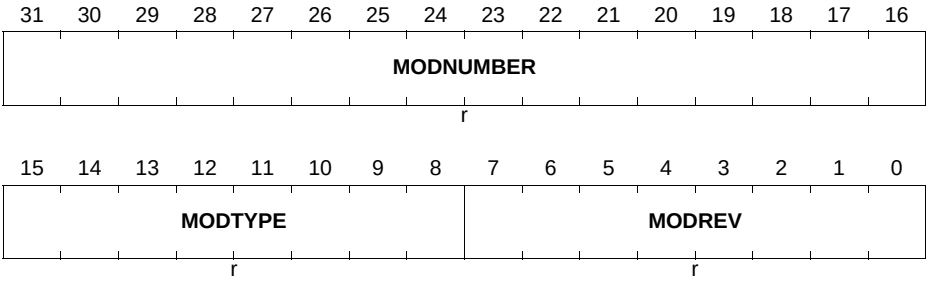
Field	Bits	Type	Description
SLSIS	[14:12]	rw	**Slave Mode Slave Select Input Selection** 000_B Slave select input lines are deselected; QSPI is operating without slave select input functionality. 001_B $\overline{SLSI}$ input line A is selected for operation 010_B $\overline{SLSI}$ input line B is selected for operation 011_B $\overline{SLSI}$ input line C is selected for operation 100_B $\overline{SLSI}$ input line D is selected for operation 101_B $\overline{SLSI}$ input line E is selected for operation 110_B $\overline{SLSI}$ input line F is selected for operation 111_B $\overline{SLSI}$ input line G is selected for operation The SLSIS must be programmed properly before the slave mode is set with **GLOBALCON**.MODE and the module is set to RUN mode.
0	[31:15], 11, 7, 3	r	**Reserved** Read as 0; should be written with 0.

ID

The Module Identification Register ID contains read-only information about the module version.

(>> **Table 20-2** register overview)

ID
Module Identification Register (08$_H$) Reset Value: 00C0 C0XX$_H$



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field is C0$_H$. It defines a 32-bit module.
MOD NUMBER	[31:16]	r	**Module Number Value** This bit field together with MODTYPE uniquely identifies a module.

GLOBALCON

GLOBALCON contains configuration parameters which affect all channels.

(>> **Table 20-2** register overview)

GLOBALCON
Global Configuration Register (10_H) Reset Value: 000F 30FF$_H$

Field	Bits	Type	Description
TQ	[7:0]	rw	**Global Time Quantum Length** Common n-divider scaling the baud rates of all channels in direction of higher or lower baud rates. Must not be changed during a running transaction. 0_D division by 1 1_D division by 2 $\ldots_D$ ... 255_D division by 256
SI	9	rw	**Status Injection** Selects if the status register content injection into the RxFIFO is enabled or disabled. The status injections, if enabled, is performed after each data block, depending on the **BACON**.DL and BYTE setting. 0_B disabled 1_B enabled
EXPECT	[13:10]	rw	**Time-Out Value for the Expect Phase** expressed in T_{QSPI} units 0_D 64 (2^6) 1_D 128(2^7) $\ldots_D$ ... 15_D 2097152 (2^{21} = 2 Mega)

Field	Bits	Type	Description
LB	14	rw	**Loop-Back Control** Selects if the transmit output is internally connected to the receive input for test purposes. 0_B Loop-Back inactive 1_B Loop-Back active For detailed description, see the **Loop-Back Mode** section.
DEL0	15	rw	**Delayed Mode for SLSO0** Switches the delayed mode for external multiplexer enabling on and off 0_B Delayed mode off 1_B Delayed mode on
STROBE	[20:16]	rw	**Strobe Delay for SLSO0 in Delayed Mode** Defines the length of the SLSO0 delay in T_Q time units as defined for channel z (T_Q units) selected by the current **BACON**.CS, if **GLOBALCON**.DEL0 = 1. 00000_B 1 00001_B 2 $\ldots_B$ ... 11111_B 32
SRF	21	rw	**Stop on RxFIFO Full** If this bit is set, the data fetching out of the TxFIFO by the shift register stops when the RxFIFO is full, in order to prevent RxFIFO overflow. Master mode only. 0_B Feature disabled 1_B Feature enabled
STIP	22	rw	**Slave Transmit Idle State Polarity** This bit determines the logic level of the Slave Mode transmit signal MRST when the QSPI slave select input signals are inactive (PISEL.SLSIS $\neq 000_B$). 0_B MRST = 0 when QSPI is deselected in Slave Mode. 1_B MRST = 1 when QSPI is deselected in Slave Mode

Field	Bits	Type	Description
EN	24	rwh	**Enable Bit** Used to request transition between PAUSE and RUN mode per software. Cleared by hardware automatically at leaving the following states: disabled, suspend and sleep. In order to determine if the requested state has actually been reached, the **STATUS**.PHASE bit field should be polled. See also **Operation Modes**. 0_B PAUSE requested 1_B RUN requested
MS	[26:25]	rw	**Master Slave Mode** Selects if the module operates in master or slave mode. This bit field must be configured before the first write to the TXFIFO. 00_B Master Transmit and Receive 01_B Reserved 10_B Slave Transmit and Receive 11_B Slave Transmit and Receive
AREN	27	rw	**Automatic Reset Enable** Enables the reset of the **GLOBALCON**.EN on baud rate and spike error in slave mode. 0_B disabled 1_B enabled
RESETS	[31:28]	w	**Bits for resetting sub-modules per software** Write to this bit field triggers a reset operation. The reset operation is not a single cycle operation, but takes several clock cycles, not more than the least common multiple of CCUCON0.SPBDIV and CCUCON0.BAUD2DIV (the configured division ratios, not the content of the bit fields). 0000_B No reset triggered 0111_B State Machine, TXFIFO and RXFIFO reset, registers not reseted 1111_B Module reset **others**, reserved For resetting the whole module, use **KRST0** / **KRST1** reset mechanism.

Field	Bits	Type	Description
0	8, 23	r	**Reserved** Read as 0; should be written with 0.

Note: If the EN bit is cleared first, and then the partial state machine reset activated, then the state machine goes into PAUSE state.

GLOBALCON1

GLOBALCON1 contains bit fields for control of the extension of the slave select signals by using an external demultiplexer.

(>> **Table 20-2** register overview)

GLOBALCON1
Global Configuration Register 1 (14_H) Reset Value: $0005\ 0000_H$

TXEN	9	rw	**Tx Interrupt Event Enable** Enables the Tx interrupt. 0_B Disabled 1_B Enabled
RXEN	10	rw	**RX Interrupt Event Enable** Enables the Rx interrupt. 0_B Disabled 1_B Enabled

Field	Bits	Type	Description
PT1EN	11	rw	**Interrupt on PT1 Event Enable** Enables the PT interrupt on an PT1 event, as selected by the PT1 bit field. 0_B Disabled 1_B Enabled
PT2EN	12	rw	**Interrupt on PT2 Event Enable** Enables the PT interrupt on an PT2 event, as selected by the PT2 bit field. 0_B Disabled 1_B Enabled
USREN	15	rw	**Interrupt on USR Event Enable** Enables the USR interrupt on an USR event, as selected by the PT1 bit field. 0_B Disabled 1_B Enabled
TXFIFOINT	[17:16]	rw	**Transmit FIFO Interrupt Threshold** If the TXFIFO filling level is equal or less than this threshold, than each move of data or configuration from the TXFIFO triggers a transmit interrupt. Reset value of the level is 01_B. 00_B 1 01_B 2 10_B 3 11_B 4
RXFIFOINT	[19:18]	rw	**Receive FIFO Interrupt Threshold** If the RXFIFO filling level is equal or greater than this threshold, than each move of data or status (if enabled) into the RXFIFO triggers a receive interrupt. Reset value of the level is 01_B. 00_B 0 01_B 1 10_B 2 11_B 3

Field	Bits	Type	Description
PT1	[22:20]	rw	**Phase Transition Event 1** Selects the first phase transition to trigger the PT interrupt. 000_B BUSY (end of WAIT phase) 001_B SCLKPC (serial clock polarity change) 010_B SOF (Start of Frame) 011_B TBE (Transmit Buffer Emptied) 100_B RBF (Receive Buffer Filled) 101_B EOF (End of Frame) 110_B DNA (Data not Available = Start of Expect) 111_B CONT (End of EXPECT phase)
PT2	[25:23]	rw	**Phase Transition Event 2** Selects the second phase transition to trigger the PT interrupt. In master mode, the following events are available: 000_B BUSY (end of WAIT phase) 001_B SCLKPC (serial clock polarity change) 010_B SOF (Start of Frame) 011_B TBE (Transmit Buffer Emptied) 100_B RBF (Receive Buffer Filled) 101_B EOF (End of Frame) 110_B DNA (Data not Available = Start of Expect) 111_B CONT (End of EXPECT phase) In slave mode, the SLSI deactivated event is the only option available for PT2. For this purpose, always use the setting 101 (EOF).
TXFM	[27:26]	rw	**TXFIFO Mode** Selects between the Single Move Mode and the Batch Move Mode. 00_B Combined Move Mode 01_B Single Move Mode 10_B Batch Move Mode 11_B reserved
RXFM	[29:28]	rw	**RXFIFO Mode** Selects between the Single Move Mode and the Batch Move Mode. 00_B Combined Move Mode 01_B Single Move Mode 10_B Batch Move Mode 11_B reserved

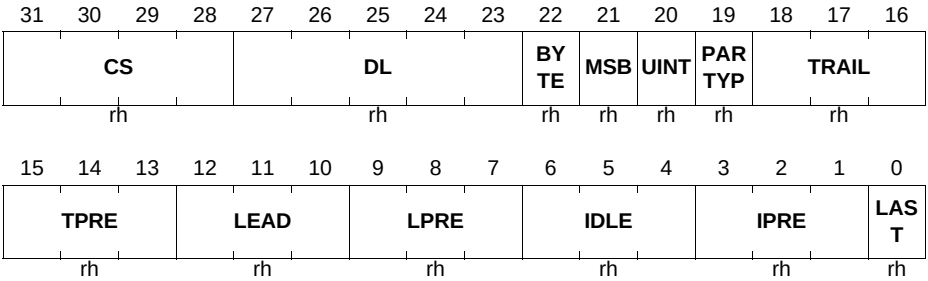
Field	Bits	Type	Description
0	30, 31, 13,14	r	**Reserved** Read as 0; should be written with 0.

BACON

Defines the basic configuration parameters for the current slave select. It can be read by software, or written through a write to the TXFIFO.

(>> **Table 20-2** register overview)

BACON
Basic Configuration Register (18_H) Reset Value: 0F87 1C71$_H$



Field	Bits	Type	Description
LAST	0	rh	**Last Word in a Frame** Defines if the following data word is last in the current frame or not 0_B Not Last 1_B Last
IPRE	[3:1]	rh	**Prescaler for the Idle Delay** Length in T_{BAUD2} units 000_B 1 001_B 4 010_B 16 …$_B$ ... 111_B 16384
IDLE	[6:4]	rh	**Idle Delay Length** Defines the length of both idle delays, IDLEA and IDLEB, in T_{BAUD2} units pre scaled with IPRE 0_D 1 units 1_D 2 unit …$_D$ ... 7_D 8 units

Field	Bits	Type	Description
LPRE	[9:7]	rh	**Prescaler for the Leading Delay** Length in T_{BAUD2} units 000_B 1 001_B 4 010_B 16 $\ldots_B$ ... 111_B 16384
LEAD	[12:10]	rh	**Leading Delay Length** Defines the length of the leading delay, in T_{BAUD2} units pre scaled with LPRE 0_D 1 units 1_D 2 unit $\ldots_D$ ... 7_D 8units
TPRE	[15:13]	rh	**Prescaler for the Trailing Delay** Length in T_{BAUD2} units 000_B 1 001_B 4 010_B 16 $\ldots_B$ ... 111_B 16384
TRAIL	[18:16]	rh	**Trailing Delay Length** Defines the length of the leading delay, in T_{BAUD2} units pre scaled with TPRE 0_D 1 units 1_D 2 unit $\ldots_D$ ... 7_D 8 units
PARTYP	19	rh	**Parity Type** Valid for both receive and transmit direction 0_B Even parity 1_B Odd parity

Field	Bits	Type	Description
UINT	20	rh	**User Interrupt at the PT1 Event in the Subsequent Frames** This bit is an enable signal for the PT1 event routed to the User Interrupt Service Request. The interrupt signals are generated until disabled with the next BACON. 0_B Disabled 1_B Enabled
MSB	21	rh	**Shift MSB or LSB First** This bit sets the shift direction of the shift register. If the MSB option is set, and the data is a block longer than 32 bits, the block must be fed into the TXFIFO in reverse direction, from the end of the block until its beginning. 0_B Shift LSB first 1_B Shift MSB first
BYTE	22	rh	**Byte** Defines if data length is expressed in bits or bytes 0_B DL defines the data length in bits 1_B DL defines the data length in bytes
DL	[27:23]	rh	**Data Length** Defines the data length in bits or bytes of one data block, depending on the setting of the bit field BYTE 0_D 2 bits if BYTE=0; XXL mode if BYTE=1 1_D 2 bits or bytes $\cdots_D$ ... 31_D 32 bits or bytes For the maximum baud rate of 50 MBaud, the minimum data length possible is four.
CS	[31:28]	rh	**Channel Select** Selects the channel to which the subsequent data entry belongs (channel = the SLSO signal to be activated and the corresponding **ECON** configuration extension) This bit field selects one slave in a range of 0 to 15, by driving one SLSO signal out of 16 available. In case of an external demux mode, this bit field appears on the lines SLS01 to SLSO4 as it is, additionally inverted or not, as defined in the **SSOC** register.

If an application does not use the SLSO signals of the QSPI module, but uses software channel selection, then the alternate function multiplexer in the ports must be configured so that the signal SLSO is not selected, but the coresponding bit Pn.OUT.

Alternatively, to emulate SLSO functionality, the software can disable (low) all the **SSOC**.OEN bits, and then toggle the **SSOC**.AOL bits.

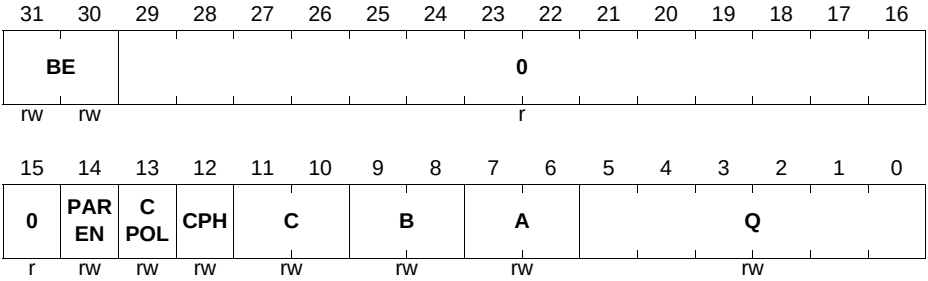
ECON

Configuration extensions for channels 0 to 15. Register x defines several timing characteristics for two channels: z and z+8.

(>> **Table 20-2** register overview)

(>> **Figure 20-12**, **Figure 20-13** timing diagrams)

ECONz (z = 0 - 7)
Configuration Extension z **(20_H + z*4_H)** **Reset Value: 0000 1450$_H$**



Field	Bits	Type	Description
Q	[5:0]	rw	**Time Quantum** Defines the time quantum length used by A, B, and C to define the baud rate and duty cycle by. This prescaler cascades the prescaler **GLOBALCON**.TQ. 000000_B 1 000001_B 2 $..._B$ ... 111111_B 64
A	[7:6]	rw	**Bit Segment 1** Length expressed in time quantums of **ECON**z.Q. 00_B 1 01_B 2 10_B 3 11_B 4

Field	Bits	Type	Description
B	[9:8]	rw	**Bit Segment 2** Length expressed in time quantums of ECONz.Q. 00_B 0 01_B 1 10_B 2 11_B 3
C	[11:10]	rw	**Bit Segment 3** Length expressed in time quantums of ECONz.Q. 00_B 0 (if B=0, than C is minimum 1 per hardware) 01_B 1 10_B 2 11_B 3
CPH	12	rw	**Clock Phase** Delay of one half SCLK clock cycle. 0_B Disabled 1_B Enabled
CPOL	13	rw	**Clock Polarity** Idle level of the shift clock signal at the SCLK pin 0_B Idle level low 1_B Idle level high
PAREN	14	rw	**Enable Parity Check** This bit field enables both the parity generation in transmit and parity check in receive direction. 0_B Disabled 1_B Enabled
BE	[31:30]	rw	**Permutate bytes to / from Big Endian** 00_B Disabled 01_B 16-bit big endian 10_B 32-bit big endian 11_B Disabled
0	[29:15]	r	**reserved**

STATUS

Status register contains bits flagging the current status of the module and its sub-modules.

Note: It is not recommended to set the STATUS register flags per software for purposes other than testing. In such cases, use write instructions only, not read-modify-write instructions or bit instructions which compile to read-modify-write instructions.

Note: When using the RXFIFO status injection feature, only bits 22 to 31 reflect the status at the moment of injection, that is for the latest frame. Due to pipeline effects, the other bits contain not-latest information.

(>> **Table 20-2** register overview)

STATUS
Status Register **(40_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Writing 0 has no effect. 000000000_B No Error 000000001_B Parity Error 000000010_B Unexpected Configuration Error 000000100_B Baud Rate Error (slave mode) 000001000_B TXFIFO overflow (software error) 000010000_B TXFIFO underflow (slave mode) 000100000_B RXFIFO overflow 001000000_B RXFIFO underflow (software error) 010000000_B EXPECT time out error 100000000_B SLSI misplaced inactivation (slave mode)

Field	Bits	Type	Description
TXF	9	rwh	**Transmit Interrupt Request Flag** Flags an occurrence of a request to feed the TXFIFO, which is generated when an element is fetched from the FIFO, and the FIFO filling level is equal or less than the set threshold level. Writing 1 sets the flag and triggers an interrupt if **GLOBALCON1**.TXEN = 1. Writing 0 has no effect.
RXF	10	rwh	**Receive Interrupt Request Flag** Flags an occurrence of a request to empty the RXFIFO, which is generated when an element is written into the FIFO, and the FIFO filling level is equal or greater than the set threshold level. Writing 1 sets the flag and triggers an interrupt if **GLOBALCON1**.RXEN = 1. Writing 0 has no effect.
PT1F	11	rwh	**Phase Transition 1 Flag** Flags an occurrence of a PT1 event, as selected with the **GLOBALCON1**.PT1, and triggers an interrupt if **GLOBALCON1**.PT1EN = 1. Writing 1 sets the flag and triggers an error interrupt. Writing 0 has no effect.
PT2F	12	rwh	**Phase Transition 2 Flag** In master mode, flags an occurrence of a PT2 event, as selected with the **GLOBALCON1**.PT2, and triggers an interrupt if **GLOBALCON1**.PT2EN = 1. In slave mode, set by the SLSI deactivated event. Writing 1 sets the flag and triggers an error interrupt. Writing 0 has no effect.
USRF	15	rwh	**User Interrupt Request Flag** Flags an occurrence of an USR event. Writing 1 sets the flag and triggers an interrupt if **GLOBALCON1**.USREN = 1. Writing 0 has no effect.

Field	Bits	Type	Description
TXFIFO LEVEL	[18:16]	rh	**TXFIFO Filling Level** Shows how many entries in the TXFIFO are waiting for transmission 000_B 0 001_B 1 010_B 2 011_B 3 100_B 4 $..._B$ reserved
RXFIFO LEVEL	[21:19]	rh	**RXFIFO Filling Level** Shows how many entries in the RXFIFO are waiting for software to move them to RAM 000_B 0 001_B 1 010_B 2 011_B 3 100_B 4 $..._B$ reserved
SLAVESEL	[25:22]	rh	**Currently Active Slave Select Flag** Displays the currently active slave select.
RPV	26	rh	**Received Parity Value** Displays the last received parity bit, if parity was enabled. Else if the parity is disabled, reads 0.
TPV	27	rh	**Transmitted Parity Value** Displays the last transmitted parity bit, if parity was enabled. Else 0.

Field	Bits	Type	Description
PHASE	[31:28]	rh	**Flags the ongoing phase** Displays the current phase number. Relevant only in master mode. In slave mode this bit field indicates always 0. 0000_B Wait 0001_B Idle A 0010_B Idle B 0011_B Lead 0100_B Data 0101_B Trail 0110_B Expect 0111_B Lead Strobe 1000_B Trail Strobe Not 0 means busy.
0	13, 14	r	**Reserved** Read as 0; should be written with 0.

Note: Slave TXFIFO underflow error is activated if the transmission has been started by the master at the time when the slave FIFO was empty, or at the same moment updated. In the second case inconsistent data will be transmitted.

Note: Reading the TXFIFO filling level bit field returns a value which can be used to calculate how many writes can be performed by a CPU without causing an overflow (in case no DMA is programmed to access the TXFIFO in parallel). For example, if the TXFIFO level was one, maximum three (TXFIFO depth of four minus one) write accesses are possible. Due to the volatility of the bit field, the filling level can go down in some nanoseconds after the read.

Note: Reading the RXFIFO filling level bit field returns a value which shows directly how many reads can be performed by a CPU without causing an underflow. Due to the volatility of the bit field, the filling level can go up in some nanoseconds after the read.

Note: Reading the PHASE bit field shows a previous phase of the frame, and a PT1F and PT2F flags indicate previous phase transitions.
If the communication speed is not too high or the phases duration not very short compared to the software latency delays, which would normally be the case, these would be the latest completed phase and the latest phase transitions.
Nevertheless, in case of high baud rates, the duration of the phases must be taken

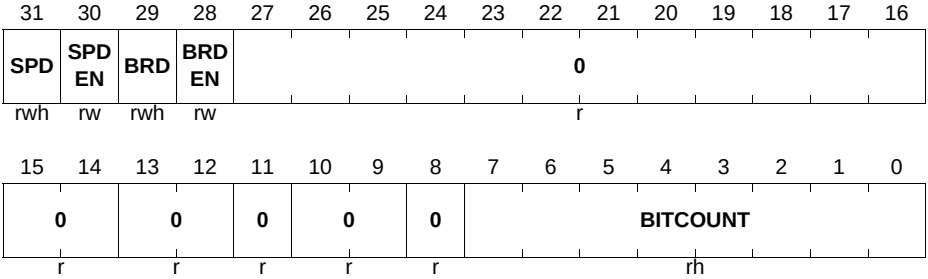
into consideration, but only if these bit fields are used in an application, and not only for debugging purposes.

STATUS1

(>> **Table 20-2** register overview)

STATUS1

Status Register 1 **(44_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BITCOUNT	[7:0]	r	**Number of the bit shifted out** Supports up to 256 bits. BITCOUNT = 0 indicates two states: no transmission and transmission of the first bit. The differentiation can be made by reading the phase information. BITCOUNT = 1 indicates transmission of the second bit and so on until 256. After transmission of the last bit the counter goes to zero.
BRDEN	28	rw	**Baud Rate Deviation Enable** Enables the signal path. 0_B disabled 1_B enabled
BRD	29	rwh	**Baud Rate Deviation Flag** Shows if baud rate deviation has been detected. Write of 1 sets the bit and raises the event per software. Write of 0 has no effect. 0_B no event 1_B event detected
SPDEN	30	rw	**Spike Detection Enable** Enables the signal path. 0_B disabled 1_B enabled

Field	Bits	Type	Description
SPD	31	rwh	**Spike Detection Flag** Shows if spike has been detected. Write of 1 sets the bit and raises the event per software. Write of 0 has no effect. 0_B no event 1_B event detected
0	[27:8]	r	**Reserved** Read as 0; should be written with 0.

If the **STATUS**.ERRORFLAGS[2] bit is cleared via **FLAGSCLEAR**.ERRORCLEARS[2], the both flags SPD and BRD are automatically cleared.

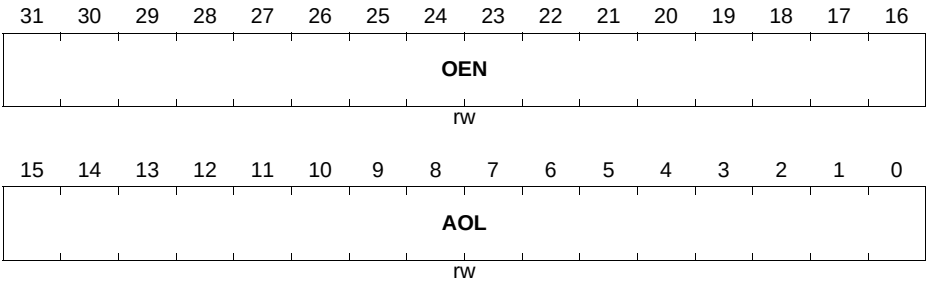
SSOC

SSOC controls the level of each slave select and enables/disables each one individually.

(>> **Table 20-2** register overview)

SSOC

Slave Select Output Control Register (48$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
OEN	[31:16]	rw	**Enable Bits for the SLSO Outputs** In disabled state the SLSO output drives the idle level as defined by the AOL bit field. “0” at certain position means that the corresponding SLSO is disabled. “1” means enabled.
AOL	[15:0]	rw	**Active Output Level for the SLSO Outputs** The idle level is the inverted one. “0” at certain position means active low level for the corresponding SLSO. “1” means active high.

FLAGSCLEAR

(>> **Table 20-2** register overview)

FLAGSCLEAR
Flags Clear Register **(54_H)** **Reset Value: $0000\ 0000_H$**

0	13, 14	rw	**Reserved** Read as 0; should be written with 0.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

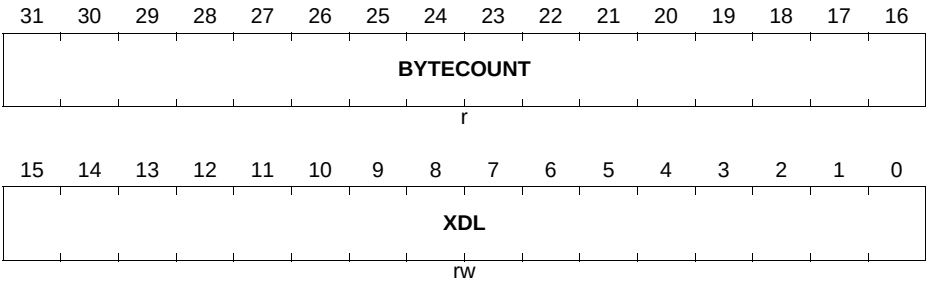
XXLCON

The XXLCON register provides counter for sending frames with very long blocks of data by extending the long data mode. It avoids a need for further BACON entries, like those needed in continuous mode.

Data length in this register overrides the **BACON**.DL setting in XXL mode, when **BACON**.BYTE=1 and **BACON**.DL=0. The data is sent to the slave as defined by **BACON**.CS bit field.

(>> **Table 20-2** register overview)

XXLCON
Extra Large Data Configuration Register(58_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
XDL	[15:0]	rw	**Extended Data Length** Defines the length of the data block in bytes in range of 2 to 65536. Overrides **BACON**.DL when **BACON**.BYTE=1 and and **BACON**.DL=0. 0_D 2 bytes 1_D 2 bytes $\ldots_D$ ... 65535_D 65536 bytes

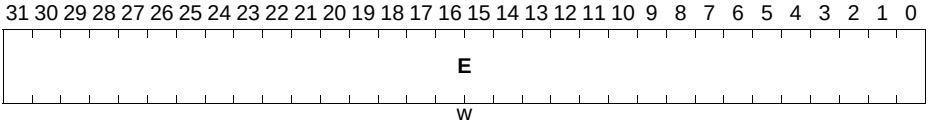
Field	Bits	Type	Description
BYTECOUNT	[31:16]	r	**Extended Data Length** In the XXL mode, shows the current state of the internal byte down counter (bytes remaining to be sent). In short and long modes, the value of this bit field is don't care. 0_D zero bytes 1_D two bytes $..._D$ ... 65535_D 65536 bytes

MIXENTRY

(>> **Table 20-2** register overview)

MIXENTRY

MIX_ENTRY Register **($5C_H$)** **Reset Value: 0000 0000$_H$**



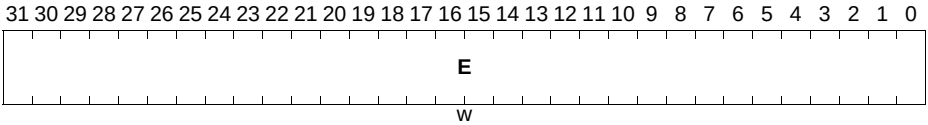
Field	Bits	Type	Description
E	[31:0]	w	**Entry Point to the TxFIFO**

BACONENTRY

(>> **Table 20-2** register overview)

BACONENTRY

BACON_ENTRY Register **(60_H)** **Reset Value: 0000 0000$_H$**



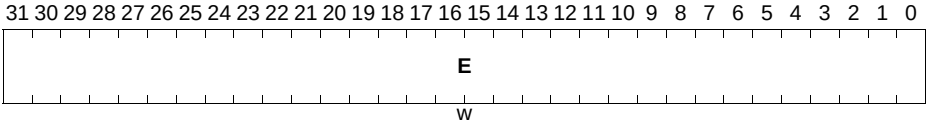
Field	Bits	Type	Description
E	[31:0]	w	**Entry Point to the TxFIFO**

DATAENTRY

(>> **Table 20-2** register overview)

DATAENTRYx (x=0-7)

DATA_ENTRY Register x **(64_H + x*4_H)** **Reset Value: 0000 0000_H**



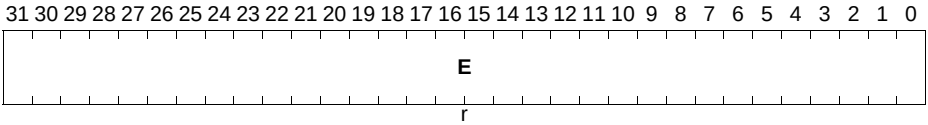
Field	Bits	Type	Description
E	[31:0]	w	**Entry Point to the TxFIFO**

RXEXIT

(>> **Table 20-2** register overview)

RXEXIT

RX_EXIT Register **(90_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
E	[31:0]	r	**Read Point from the RxFIFO**

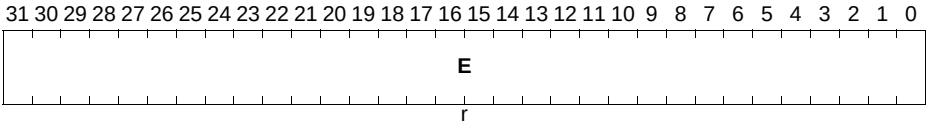
Note: The RXFIFO has a property that a read access from an empty RXFIFO generates an underflow interrupt, and delivers only “1” bits, which overrules the reset value. Therefore reading from a non initialized RXFIFO delivers all “1” and not all ”0”.

RXEXITD

The register **RXEXITD** provides a non-destructive address, showing the next available value in the RXFIFO.

(>> **Table 20-2** register overview)

RXEXITD
RX_EXIT Debug Register **(94_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
E	[31:0]	r	**Read Point from the RxFIFO**

*Note: This register provides a non-volatile access to the RXFIFO. It delivers the same value as **RXEXIT**, but without affecting read pointer and the filling level of the RXFIFO .*

20.10 Operation Modes

Generally, the QSPI module transmits a RAM queue of an arbitrary length, fed by a DMA module, and makes pauses between the queues. The QSPI module does not know anything about the queue length or the current position within the queue or the future schedule of the messages that may come.

If the QSPI module gets a request for switching off the clock or pausing the module, it disables all service request lines.

The QSPI module provides two options for switching off the clocks or pausing the module: hard suspend (as soon as possible regarding for example the length of interrupt request pulses), and soft suspend (transition to the PAUSE state with finishing the current frame). The requests can be triggered by hardware signals (disable, suspend, sleep) or by software write to **GLOBALCON**.EN bit.

Disable, Pause and Run

After being enabled by clearing the CLC.DISR bit, the QSPI enters the PAUSE state. In this state, the QSPI module can be initialized, the TXFIFO pre-filled, and then, by setting the **GLOBALCON**.EN bit, put into a RUN state.

The software requests PAUSE state of the running module by clearing the **GLOBALCON**.EN bit. The software can detect that the QSPI module has reached the PAUSE state by polling for the **GLOBALCON**.EN=0 and **STATUS**.PHASE=0 (indicating WAIT state, master mode only).

In PAUSE state, the user interface of the module is active. The registers and the FIFOs can be read and written. However, both the receive and transmit state machines are inactive, in master as well as in the slave mode. This allows for reconfiguration of the module without affecting the serial bus.

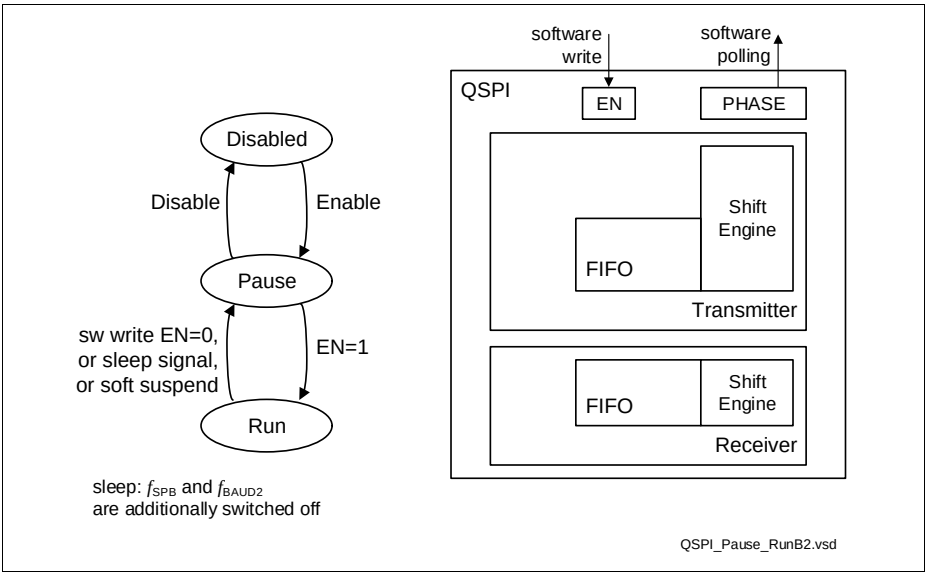


Figure 20-51 Pause and Run Overview

The concept of the PAUSE state is reused for handling the soft OCDS suspend and Sleep requests. In contrast to active Pause state and OCDS suspend, the sleep state has the special property that (due to the low power requirement) both FPI and QSPI clocks are switched off.

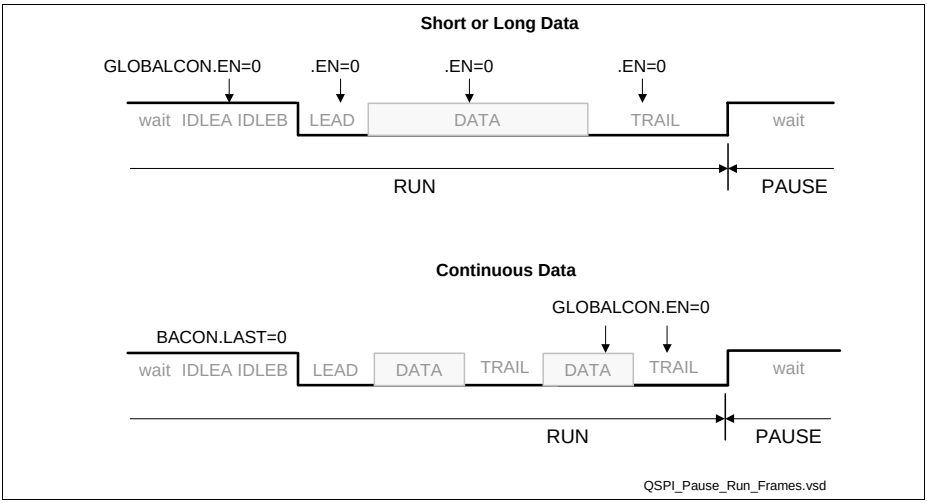

Figure 20-52 Entering the Pause State

If a running module receives a request to PAUSE, it waits for the end of the TRAIL phase.

For all modes (Short, Long and Continuous), the PAUSE state is indicated by **GLOBALCON**.EN=0 and **STATUS**.PHASE=0, master mode only.

20.10.1 OCDS Suspend

The OCDS hard suspend request, for debugging purposes, simply freezes the QSPI module in the current state. No signal is changed including the service request lines, which remain frozen in the current state.

The QSPI responds to an OCDS soft suspend request by entering the PAUSE state immediately after the subsequent end of a trail phase, and then sending acknowledge (see **Figure 20-53**). The behavior is the same as for entering the **Sleep Mode**.

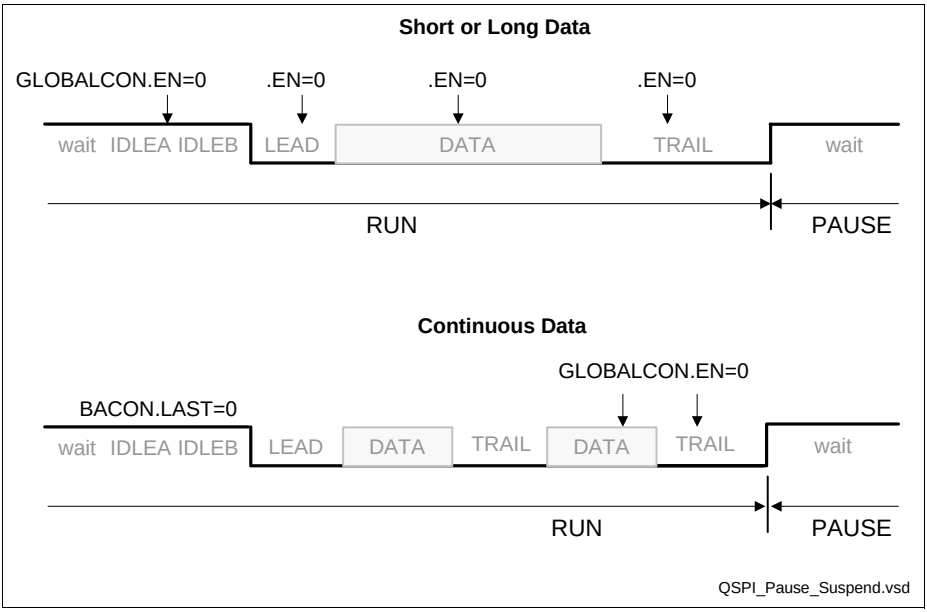

Figure 20-53 Entering the Sleep, Soft Suspend, and Disable State

Reading the FIFO entries by the Cerberus (detected by the FPI master tag) does not modify the FIFO content nor the read and write pointers.

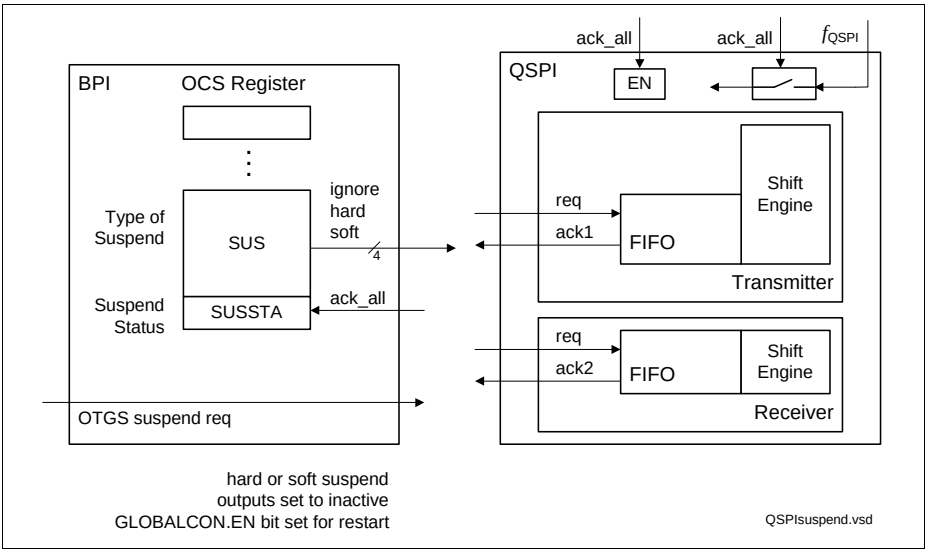

Figure 20-54 Suspend Overview

Note: In Hard Suspend Mode the QSPI kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a QSPI kernel reset might not be sufficient to bring the system into a defined state.

20.10.2 Sleep Mode

Sleep signal is a system wide hardware signal requesting from all modules to go to low power saving state as soon as possible. For the QSPI module, going to sleep mode can be disabled or enabled by setting or clearing the CLC.EDIS bit. The module enters the sleep as soon as possible and remains in this state as long as the hardware sleep signal is active. Upon deactivation of the sleep signal, the QSPI wakes in PAUSE state (**GLOBALCON**.EN bit is cleared by the QSPI module) and waits for the software to enable the **GLOBALCON**.EN bit.

If CLC.EDIS bit is cleared, the sleep mode is enabled and the module enters the sleep state:

in master mode

- after ending the TRAIL delay if a transmission is in progress
- or immediately if the module is in WAIT state

in slave mode

- after the bit counter has counted the full predefined number of bits as defined in GLOBALCON.DL and BYTE bit fields.
- immediately if the module is in wait state, no transmission ongoing and shift register empty and TXFIFO empty
- or immediately if the SLSI is inactive (the one selected by PISEL)

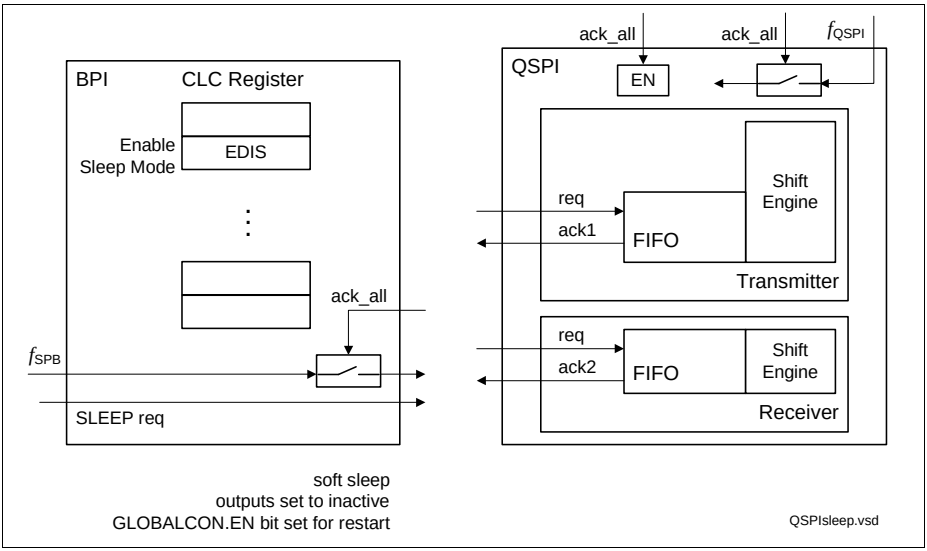

Figure 20-55 Sleep Overview

It is responsibility of the user software to have the sleep enabled in a safe time intervals, where no race conditions or pipeline effects between the QSPI module and the DMA can occur in case of sleep request.

Note: CLC disable request and sleep request block immediately kernel register write accesses. This includes also the TXFIFO access. Therefore if the module expects more data (like in long or continuous mode), it will enter the expect phase and remain there and never do an acknowledge and enter the required state. Periodic timeout interrupts will be generated. Therefore it is not recommended to request a sleep or disable during an ongoing long or continuous transfer.

20.10.3 Disabling the QSPI

The software can switch off the QSPI module by setting the CLC.DISR bit. It is responsibility of the user software to issue a disable request in a safe time interval, where no race conditions or pipeline effects between the QSPI module and the DMA can occur. This is no issue if the switch-off procedure is one-way, that is no continuation of operation without reinitialization/reset of the module is expected. **GLOBALCON**.EN bit is cleared.

The QSPI module itself behaves in the following way.

in master mode like entering the sleep mode:

- after ending the TRAIL delay if a transmission is in progress
- or immediately if the module is in WAIT state

in slave mode

- after the bit counter has counted the full predefined number of bits as defined in GLOBALCON.DL and BYTE bit fields, if a transmission is ongoing or
- immediately if the module is in wait state, no transmission ongoing and shift register empty and TXFIFO empty

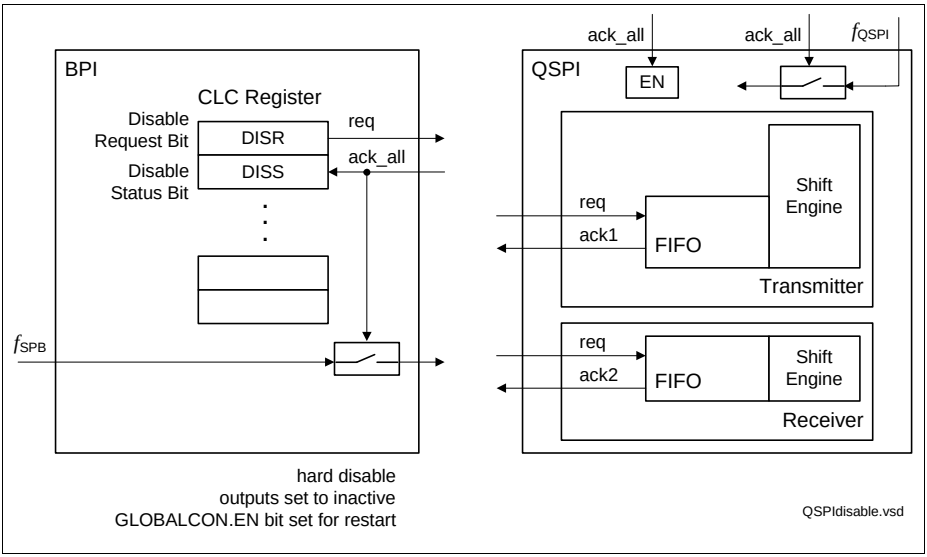

Figure 20-56 Disable Overview

20.11 Reset Behavior

There are two sources of reset:

- BPI (Bus Peripheral Interface)
- Reset bits in the kernel register - **GLOBALCON**.RESETS

BPI reset puts the whole QSPI module in reset state. All outputs get the reset value.

Software writing the **GLOBALCON**.RESETS bit field contains bits for resetting: TXFIFO, RXFIFO, shift state machine, register file. Setting all the bits in a single write resets the whole module.

20.12 QSPI Module Implementation

This section describes the interfaces of the QSPI module instances with the clock control, port connections, interrupt control, and address decoding. There are 4 module instances, QSPI0 to QSPI3.

20.12.1 Module Identification Registers

The reset values of the QSPIx_ID module identification registers are 00C0 C0XX$_H$.

20.12.2 Interfaces of the QSPI Modules

Figure 20-57 shows the implementation details and interconnections of the QSPI module.

Each of the QSPI modules is supplied with a separate clock control, interrupt control, and address decoding logic. Two interrupt outputs can be used to generate DMA requests. The QSPIx I/O lines are connected to the ports as described in the pinning and ports chapters.

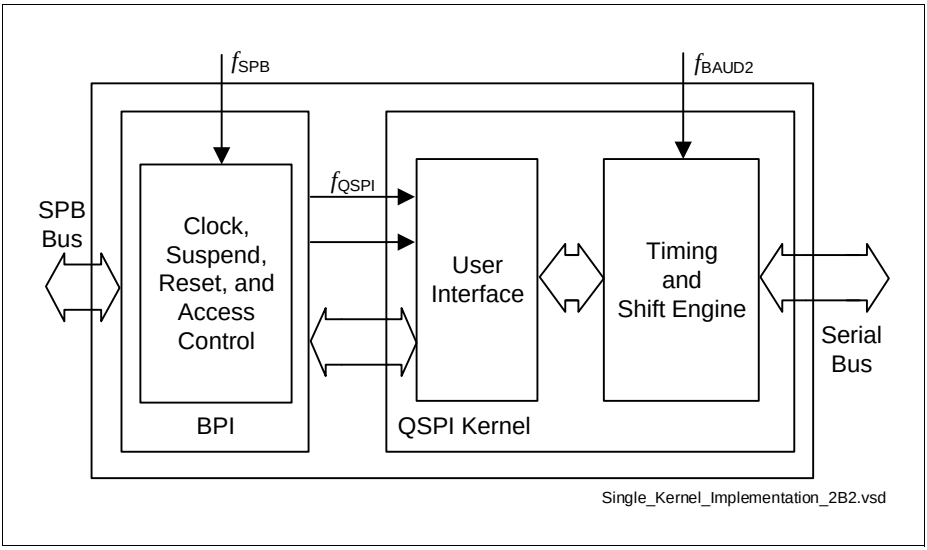

Figure 20-57 Module Implementation Overview

20.12.3 On-Chip Connections

This section describes the on-chip connections of the QSPIx module instances.

SCU Connections

Wake-up from sleep is done by the SCU.ERU triggering a software interrupt on a programmable edge on SLSI pin.

DMA Requests

There are no dedicated DMA request lines. The interrupt or service request signals are general purpose request signals that can be routed to each service provider.

Port/Pin Connections

The connections of the QSPI modules to the pins / ports is described in the chapters regarding the pinning and the ports.

The MTSR and MRST signals are also mapped to LVDS output and input pads. For details see the Ports chapter and the Pinning chapter.

Note: If LVDSH receiver pad is used, the software must take into account the corresponding control and configuration bits, located in the HSCT module and in the corresponding port registers.

Input signals not connected to ports/pins are connected to the following voltage levels:

- The unconnected SCLKI signals are connected to low level “0”
- The unconnected SLSI signals are connected to (inactive) high level “1”
- The unconnected MRST input signals are connected to low level “0”.

20.12.4 QSPI Related External Registers

Figure 20-58 summarizes the module-related external registers which are required for QSPI programming. These are:

- port registers and
- service request node registers,

described in the corresponding chapters.

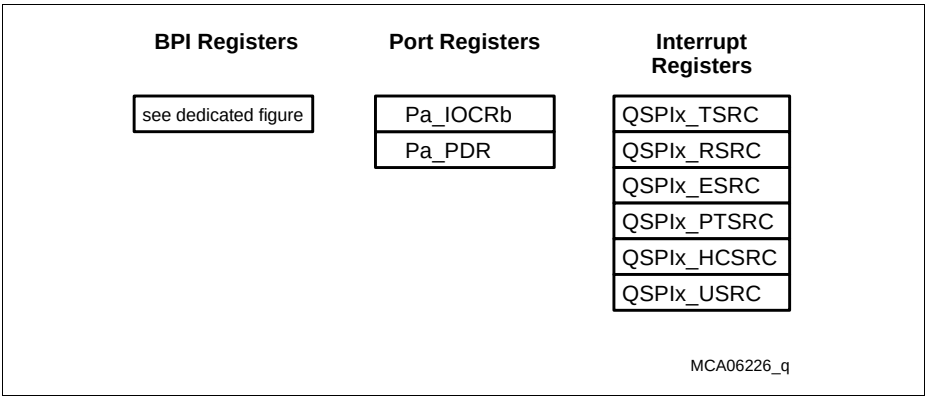

Figure 20-58 Implementation-specific Special Function Registers

20.12.4.1 BPI_FPI Module Registers

System Registers

Figure 20-59 shows all registers associated with the BPI_FPI module, configured for one kernel. The Offset Address in the following BPI_FPI register table and in the BPI_FPI register descriptions are proposals. In a standard 32 bit peripheral the CLC should be mapped to offset address 00h, module ID to 08h. The proposal for the new BPI_FPI register is to map them to the end of the peripheral address range.

BPI_FPI Registers Overview

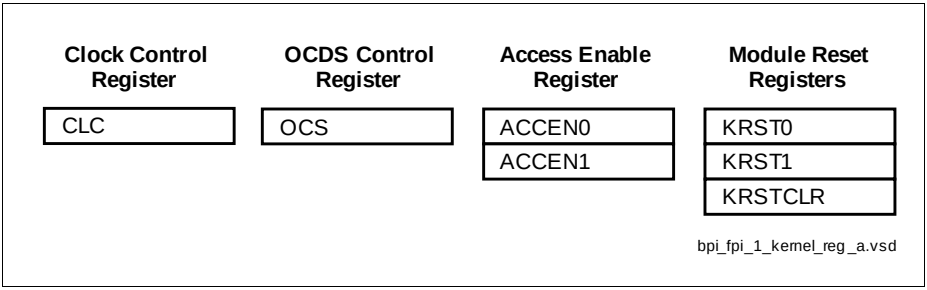

Figure 20-59 BPI_FPI Registers

The writes of the bus masters to the QSPI module is controlled by Access Protection registers ACCENx.

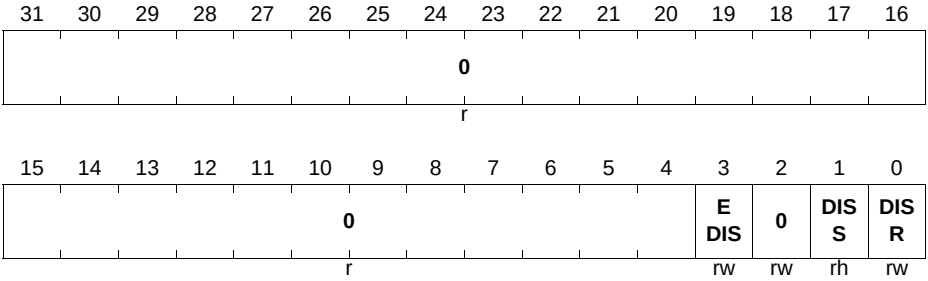
The QSPI implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the $f_{<>}$ module clock signal, sleep mode and disable mode for the module.

CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to enable the module's sleep mode. 0_B Enabled 1_B Disabled
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.
0	2	rw	**Reserved** Should be written with 0.

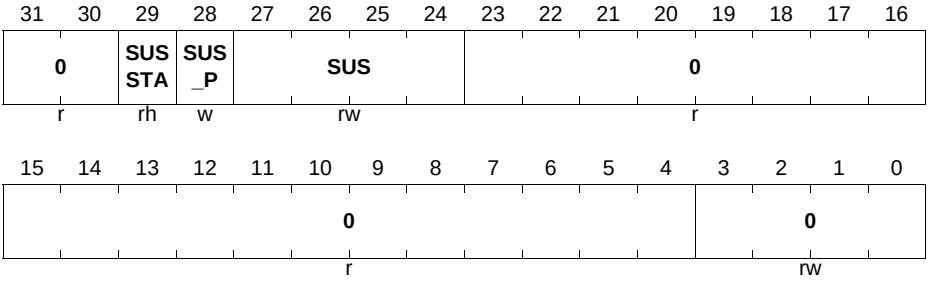
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

OCS

OCDS Control and Status (E8$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0. The bits [4:0] are rw (readable and writable).

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0
Access Enable Register 0 **(FC_H)** **Reset Value: FFFF FFFF$_H$**

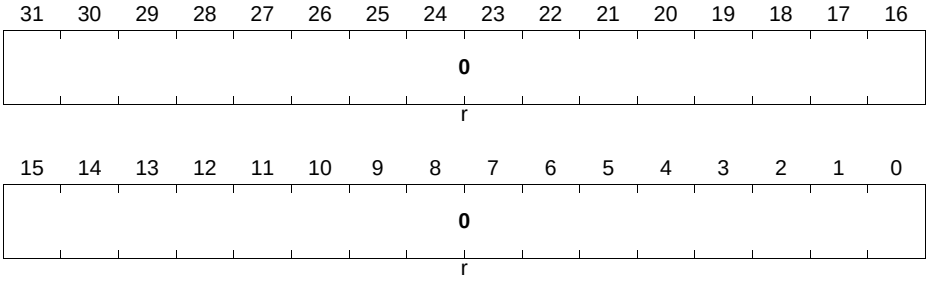
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

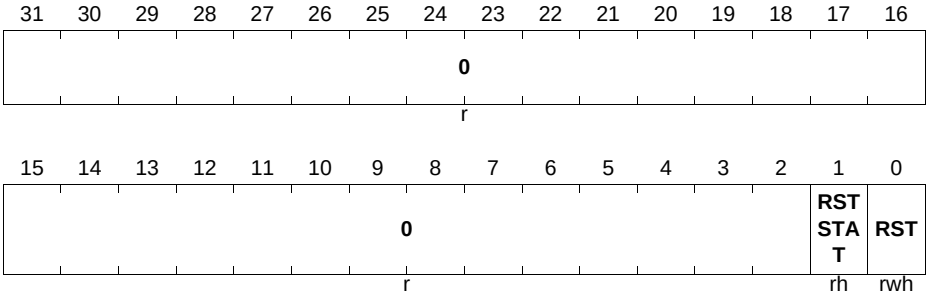
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**



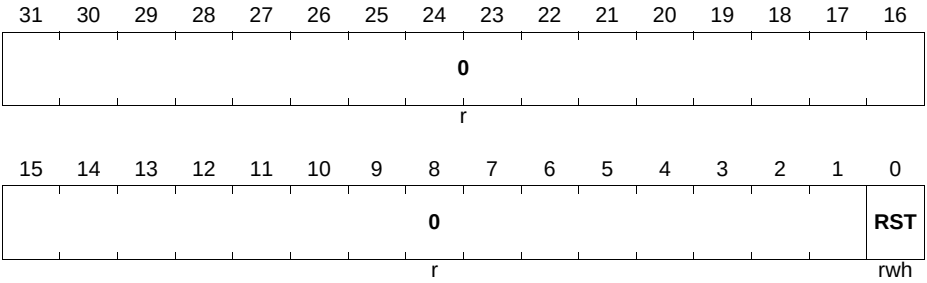
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST

bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: $0000\ 0000_H$**



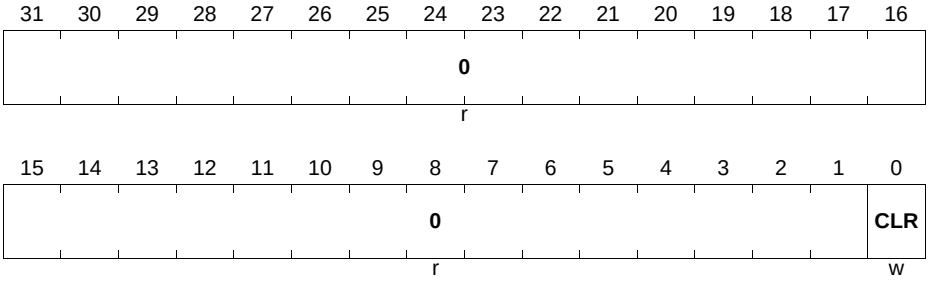
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

20.12.4.2 Interrupt Control Registers

The interrupts of the QSPI module are controlled by six service request control registers, located in the IR (Interrupt Router) module:

- QSPIxTX Transmit Interrupt
- QSPIxRX Receive Interrupt
- QSPIxERR Error Interrupt
- QSPIxPT Phase Transition Interrupt
- QSPIxHC High Speed Capture Interrupt
- QSPIxU User Interrupt

20.13 High Speed Input Capture

The HSIC sub-module provides high precision measurement of relatively low speed input signals. It contains 15-bit timer can be configured to continuously measure:

- whole period (rising edge to rising edge),
- high time (rising edge to falling edge) or
- low time (falling edge to rising edge)
- whole period (falling edge to falling edge)

The resolution of the counter is f_{BAUD2}. The result is provided in a capture register and an interrupt is raised after each capture.

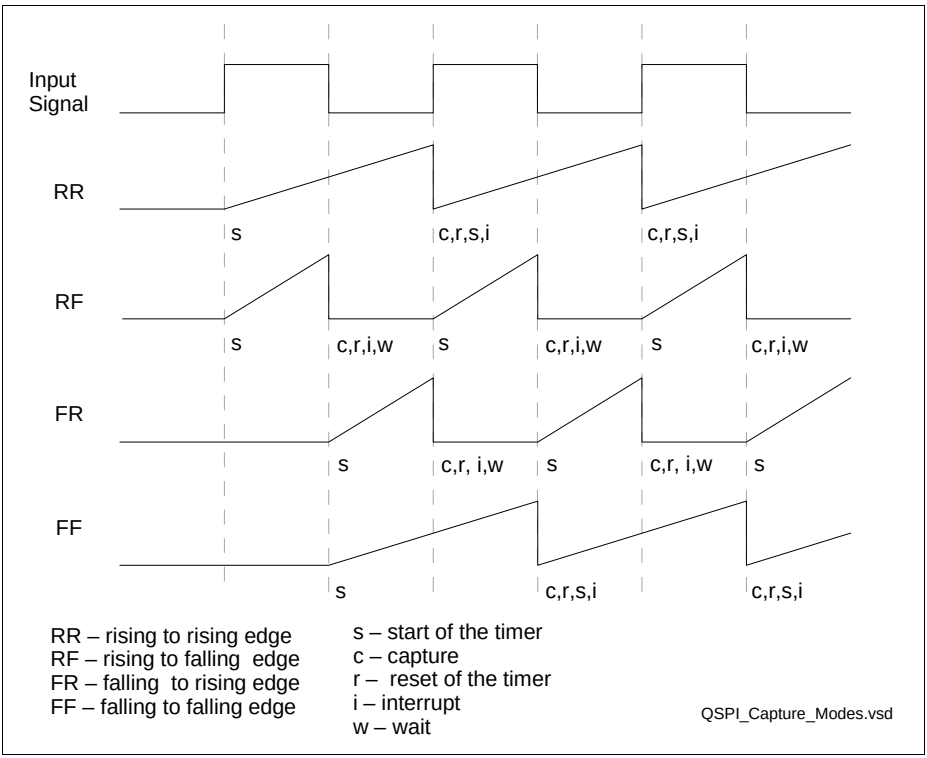


Figure 20-60 HSIC Modes of Operation

Each capture event causes the content of a 15-bit counter to be captured to the **CAPCON**.CAP bit field, see **Figure 20-61**.

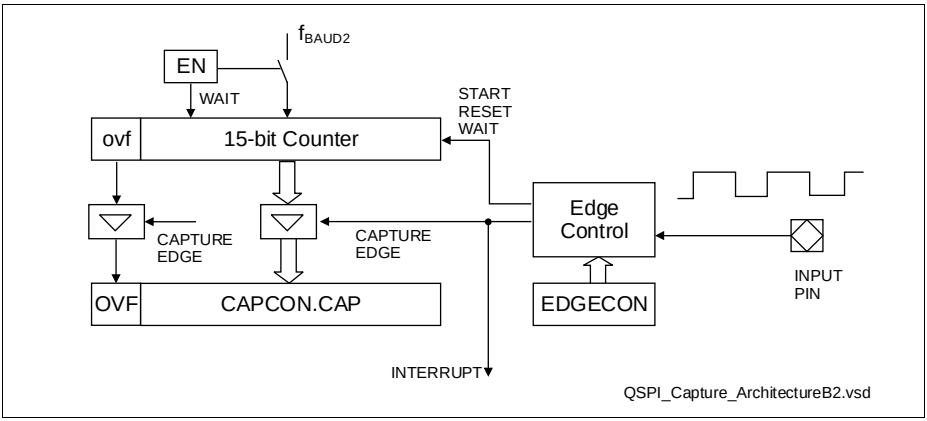

Figure 20-61 Capture Timer Architecture

The interrupt raised by the capture event is routed to the HC interrupt, see **Figure 20-62**. The flag bit, set, clear and select bits are located in the **CAPCON** register.

The first interrupt after enabling the HSIC block by setting **CAPCON**.EN may deliver random **CAPCON**.CAP value, depending on the level of the input signal at the moment of enabling. Therefore, the software should discard the first value captured immediately after enabling the HSIC block.

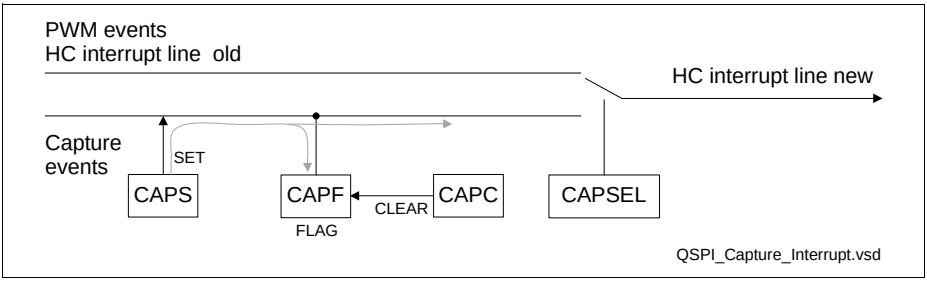

Figure 20-62 HSIC Interrupt Path

Disable Request

Clearing the disable request bit **CLC**.DISR switches the clock of the whole QSPI module including the HSIC block on.

Setting the bit **QSPI2_CAPCON**.EN enables the HSIC sub-module. The counter first enters wait state, waiting for the first start edge as defined in the **QSPI2_CAPCON**.EDGECON. Afterwards, it operates according to the **Figure 20-60**.

If **CLC**.DISR is cleared when **QSPI2_CAPCON**.EN = 1, the counter is cleared to zero, waits for the next start edge (as defined in **QSPI2_CAPCON**.EDGECON) to start counting, and continues operating according to the **Figure 20-60**.

Debug Suspend

Suspend of the QSPI module causes suspend of the HSIC; separate suspend is not possible. Nevertheless, the targeted use cases are either HSIC timer active, or QSPI communication, but not both.

Active and enabled hard debug suspend signal stops the HSIC block immediately (QSPI kernel disabled). After the suspend signal is deactivated, the counter continues counting. Writing to a register in hard suspend state causes the HSIC block to receive a couple of clock cycles, which causes the counter to increase its value.

Active and enabled soft debug suspend signal stops the HSIC block immediately (QSPI kernel disabled). After the suspend signal is deactivated, the counter is cleared to zero, waits for the next start edge (as defined in **QSPI2_CAPCON**.EDGECON) to start counting, and continues operating according to the **Figure 20-60**.

Sleep Mode

Active and enabled sleep signal stops the HSIC block. After the sleep signal is deactivated, the counter is cleared to zero, waits for the next start edge (as defined in **QSPI2_CAPCON**.EDGECON) to start counting, and continues operating according to the **Figure 20-60**.

Reset

Each reset of the QSPI module causes reset of the HSIC sub-module; separate reset is not possible.

20.13.1 HSIC Registers

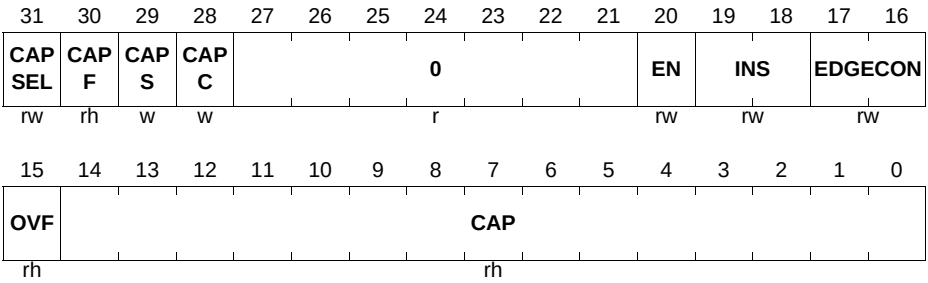
20.13.1.1 Register Description

CAPCON

CAPCON is the only control register for the HSIC sub-module. It contains the configuration, control bits and the captured value of the counter.

(>> **Table 20-2** register overview)

QSPI2_CAPCON
Capture Control Register **($A0_H$)** **Reset Value: 0000 0000$_H$**
QSPI3_CAPCON
Capture Control Register **($A0_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CAP	[14:0]	rh	**Captured Value** Provides the latest capture value from the capture timer.
OVF	15	rh	**Overflow Flag** Signals if an overflow event of the capture timer occured in the latest measurement. Shows a value of 1 if one or more overflows of the capture timer occured during the latest measurement. Each capture event refreshes this bit with the new value.

Field	Bits	Type	Description
EDGECON	[17:16]	rw	**Edge Configuration** Configure the capture mode of the counter, definig which edge starts the counting, which edge captures its contents. 00_B RR mode (rising edge to rising edge) 01_B RF mode (rising edge to falling edge) 10_B FR mode (falling edge to rising edge) 11_B FF mode (falling edge to falling edge)
INS	[19:18]	rw	**Input Selection** Selects one of four input lines for the capture signal. 00_B INA selected 01_B INB selected 10_B INC selected 11_B IND selected
EN	20	rw	**Enable Bit of the Capture Timer** Enables the capture timer clock. Enabled timer waits for the next start edge as defined in EDGECON, before it starts counting. 0_B disabled 1_B enabled
CAPC	28	w	**Capture Flag Clear** Writing 1 to this bit clears the flag CAPF. Writing 0 has no effect. Returns 0 on read.
CAPS	29	w	**Capture Flag Set** Writing 1 to this bit sets the flag CAPF. Writing 0 has no effect. Returns 0 on read.
CAPF	30	rh	**Capture Flag** Indicates if a capture event has occured since the last clear event by the bit CAPC.
CAPSEL	31	rw	**Capture Interrupt Select Bit** Select if the capture events are routed to the HC interrupt line. 0_B not routed (capture interrupt disabled) 1_B routed (capture interrupt enabled)
0	[27:21]	r	**reserved**

20.13.2 HSIC Implementation

HSIC block is available in the QSPI2 and QSPI3.

20.13.2.1 Connection to the pins

For the connections to the pins, see the pinning chapter.

The unconnected input lines are tied to zero.

21 Controller Area Network Controller (MultiCAN+)

This chapter describes the MultiCAN+ controller of the TC21x/TC22x/TC23x. It contains the following sections:

- CAN basics (see **Page 21-2**)
- Overview of the CAN Module in the TC21x/TC22x/TC23x (see **Page 21-12**)
- CAN Flexible Data Rate in TC21x/TC22x/TC23x (see **Page 21-16**)
- Functional description of the MultiCAN+ Kernel (see **Page 21-18**)
- MultiCAN+ Kernel register description (see **Page 21-72**)
- TC21x/TC22x/TC23x implementation-specific details (port connections and control, interrupt control, address decoding, clock control, see **Page 21-152**).

Table 21-1 Fixed Module Constants

Constant	Description
n_objects	**Number of Message Objects available.**
n_interrupts	**Number of Interrupt Output Lines available.**
n_pendings **n_pendingregs**	**Number of Message Pending Bits available.** There are n_pendings/32 message pending registers.
n_lists	**Number of Lists available for allocation of Message Objects.**
n_nodes	**Number of CAN Nodes available** As each CAN node has its own list in addition to the list of un-allocated elements, the relation n_nodes < n_lists is true.

21.1 CAN Basics

CAN is an asynchronous serial bus system with one logical bus line. It has an open, linear bus structure with equal bus participants called nodes. A CAN bus consists of two or more nodes.

The bus logic corresponds to a “wired-AND” mechanism. Recessive bits (equivalent to the logic 1 level) are overwritten by dominant bits (logic 0 level). As long as no bus node is sending a dominant bit, the bus is in the recessive state. In this state, a dominant bit from any bus node generates a dominant bus state. The maximum CAN bus speed is, by definition, 1 Mbit/s. This speed limits the CAN bus to a length of up to 40 m. For bus lengths longer than 40 m, the bus speed must be reduced.

The binary data of a CAN frame is coded in NRZ code (Non-Return-to-Zero). To ensure re-synchronization of all bus nodes, bit stuffing is used. This means that during the transmission of a message, a maximum of five consecutive bits can have the same polarity. Whenever five consecutive bits of the same polarity have been transmitted, the transmitter will insert one additional bit (stuff bit) of the opposite polarity into the bit stream before transmitting further bits. The receiver also checks the number of bits with the same polarity and removes the stuff bits from the bit stream (= destuffing).

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC Sequence. The stuff bits will be inserted at fixed positions.

21.1.1 Addressing and Bus Arbitration

In the CAN protocol, address information is defined in the identifier field of a message. The identifier indicates the contents of the message and its priority. The lower the binary value of the identifier, the higher is the priority of the message.

For bus arbitration, CSMA/CD with NDA (Carrier Sense Multiple Access/Collision Detection with Non-Destructive Arbitration) is used. If bus node A attempts to transmit a message across the network, it first checks that the bus is in the idle state (“Carrier Sense”) i.e. no node is currently transmitting. If this is the case (and no other node wishes to start a transmission at the same moment), node A becomes the bus master and sends its message. All other nodes switch to receive mode during the first transmitted bit (Start-Of-Frame bit). After correct reception of the message (acknowledged by each node), each bus node checks the message identifier and stores the message, if required. Otherwise, the message is discarded.

If two or more bus nodes start their transmission at the same time (“Multiple Access”), bus collision of the messages is avoided by bit-wise arbitration (“Collision Detection / Non-Destructive Arbitration” together with the “Wired-AND” mechanism, dominant bits override recessive bits). Each node that sends also reads back the bus level. When a recessive bit is sent but a dominant one is read back, bus arbitration is lost and the transmitting node switches to receive mode. This condition occurs for example when the message identifier of a competing node has a lower binary value and therefore sends a

message with a higher priority. In this way, the bus node with the highest priority message wins arbitration without losing time by having to repeat the message. Other nodes that lost arbitration will automatically try to repeat their transmission once the bus returns to idle state. Therefore, the same identifier can be sent in a Data Frame only by one node in the system. There must not be more than one node programmed to send Data Frames with the same identifier.

Standard message identifier has a length of 11 bits. CAN specification 2.0B extends the message identifier lengths to 29 bits, i.e. the extended identifier.

21.1.2 CAN Frame Formats

Four different data frame formats are supported which differ in the length of the Arbitration Field and Control Field:

- Classical CAN Base format: 11-bit long identifier, constant bit rate
- Classical CAN Extended format: 29-bit long identifier, constant bit rate
- CAN FD Base format: 11-bit long identifier, dual bit rate
- CAN FD Extended format: 29-bit long identifier, dual bit rate

In addition for Classical CAN remote frames exist, for 11-bit and 29bit identifiers.

21.1.3 CAN Frame Types

There are three types of CAN frames:

- Data Frames
- Remote Frames
- Error Frames

A Data Frame contains a Data Field of 0 to 8 bytes in length. A Remote Frame contains no Data Field and is typically generated as a request for data (e.g. from a sensor). Data and Remote Frames can use an 11-bit “Standard” identifier or a 29-bit “Extended” identifier. An Error Frame can be generated by any node that detects a CAN bus error.

21.1.3.1 Data Frames

There are four types of Data Frames defined (see **Figure 21-1**):

- Standard Data Frame Classical CAN Format
- Extended Data Frame Classical CAN Format
- Standard Data Frame CAN FD Format
- Extended Data Frame CAN FD Format

11-bit Data Frame (CAN Format)

A Data Frame begins with the Start-Of-Frame bit (SOF = dominant level) for hard synchronization of all nodes. The SOF is followed by the Arbitration Field consisting of 12 bits, the 11-bit identifier (reflecting the contents and priority of the message), and the

RTR (Remote Transmission Request for Classical CAN) bit. With RTR at dominant level, the frame is marked as Data Frame. With RTR at recessive level, the frame is defined as a Remote Frame.

The next field is the Control Field consisting of 6 bits. The first bit of this field is the IDE (Identifier Extension) bit and is at dominant level for the Standard Data Frame. The following bit is reserved and defined as a dominant bit. The remaining 4 bits of the Control Field are the Data Length Code (DLC) that specifies the number of bytes in the Data Field. The Data Field can be 0 to 8 bytes wide. The Cyclic Redundancy (CRC) Field that follows the data bytes is used to detect possible transmission errors. It consists of a 15-bit CRC sequence completed by a recessive CRC delimiter bit.

The final field is the Acknowledge Field. During the ACK Slot, the transmitting node sends out a recessive bit. Any node that has received an error free frame acknowledges the correct reception of the frame by sending back a dominant bit, regardless of whether or not the node is configured to accept that specific message. This behavior assigns the CAN protocol to the “in-bit-response” group of protocols. The recessive ACK delimiter bit, which must not be overwritten by a dominant bit, completes the Acknowledge Field.

Seven recessive End-of-Frame (EOF) bits finish the Data Frame. Between any two consecutive frames, the bus must remain in the recessive state for at least 3 bit times (called Inter Frame Space). If after the Inter Frame Space, no other nodes attempt to transmit the bus remains in idle state with a recessive level.

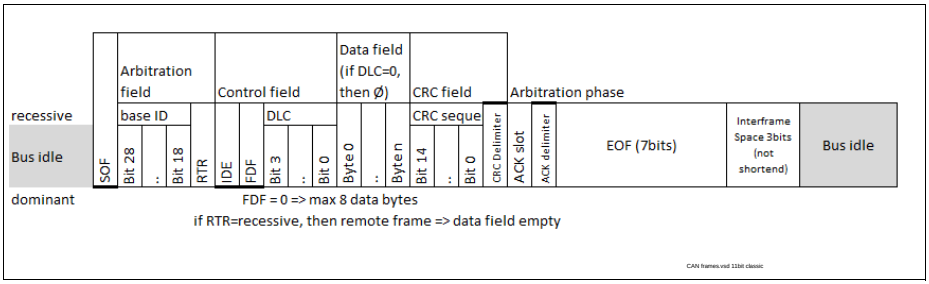


Figure 21-1 Classical 11bit ID CAN Data Frame

Extended Data Frame (Classical CAN Format)

In the Extended CAN Data Frame, the message identifier of the standard frame has been extended to 29-bit. A split of the extended identifier into two parts, an 11-bit least significant section (as in classical CAN frame) and an 18-bit most significant section, ensures that the Identifier Extension bit (IDE) can remain at the same bit position in both standard and extended frames.

In the Extended CAN Data Frame, the SOF bit is followed by the 32-bit Arbitration Field. The first 11 bits are the least significant bits of the 29-bit Identifier (“Base-ID”). These 11 bits are followed by the recessive Substitute Remote Request (SRR) bit. The SRR is

further followed by the recessive IDE bit, which indicates the frame to be an Extended CAN frame. If arbitration remains unresolved after transmission of the first 11 bits of the identifier, and if one of the nodes involved in arbitration is sending a classical CAN frame, then the CAN frame will win arbitration due to the assertion of its dominant IDE bit. Therefore, the SRR bit in an Extended CAN frame is recessive to allow the assertion of a dominant RTR bit by a node that is sending a CAN Remote Frame. The SRR and IDE bits are followed by the remaining 18 bits of the extended identifier and the RTR bit.

Control field and frame termination is identical to the Classical Data Frame.

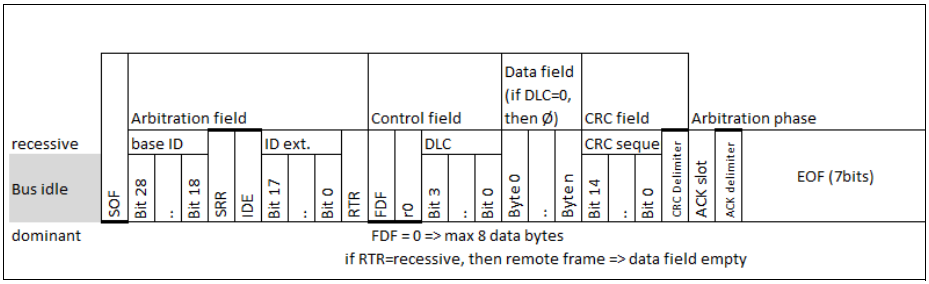

Figure 21-2 Classical 29 bit ID CAN Data Frame

Standard and Extended Data Frame (CAN FD Format)

Data frames for CAN FD with 11bit identifier are shown in **Figure 21-3**.

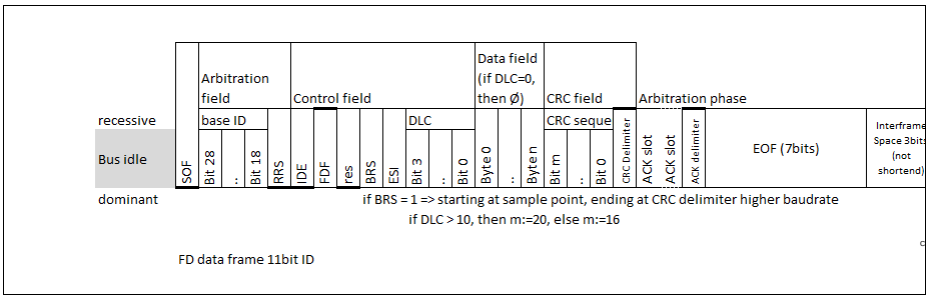

Figure 21-3 CAN FD 11bit ID Data Frames

Extended data frames for CAN FD are shown in **Figure 21-4**.

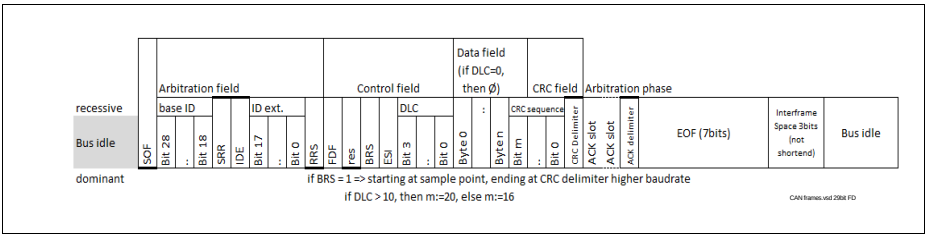

Figure 21-4 CAN FD 29bit ID Data Frames

The difference between Standard / Extended Data Frames in CAN and CAN FD format are highlighted below:

1. In the Arbitration Field:
   a) CAN Format Frames contain the RTR bit, where in CAN FD Format it is replaced with the dominant r1(reserved) bit.
   b) The reserved r0, r1 (bits) are sent dominant. Receivers accept dominant and recessive bits.
2. In the Control Field:
   a) CAN FD Format Frames consists of the additional (FDF) CAN FD format bit, (BRS) bit rate switch bit and (ESI) error state indicator bit.
   b) CAN FD format (FDF) bit comes after the IDE bit for frames with 11-bit identifier and it comes after the r1 (reserved) bit with 29-bit identifier. FDF is the new name for the previous r0 bit.
   c) Bit Rate Switch (BRS) bit switches the bit rate from standard bit rate of Arbitration Phase to preconfigured bit rate of the Data Phase when the bit is transmitted recessive. The bit rate is not switched when BRS bit is transmitted dominant.
   d) Error State Indicator (ESI) bit is transmitted dominant by error active nodes and recessive by error passive nodes.
   e) Data Length Code (DLC) bits indicates the number of bytes in the Data Field.
3. In the CRC Field:
   a) CRC sequence bits for CAN FD uses CRC_17 for data field up to sixteen bytes long and CRC_21 for data field longer than sixteen bytes. CRC calculation consists of the SOF, Arbitration Field, Control Field and (if present) Data field, supplemented with nCRC bits of ‘0’.
   Stuff-bits are included in CRC calculation. All CRC sequences (CRC_15, 17, 21) are calculated for all nodes, where the node that wins the arbitration send the CRC sequence selected by values of the FDF bit and DLC. Receivers only consider the selected CRC polynomial to check for CRC error
   b) CRC Delimiter for CAN FD consists of one or two recessive bits that has the function of switching the Data phase to Arbitration phase when the sample point reaches the first bit of the CRC Delimiter.
   Transmitter sends only one recessive bit as CRC delimiter, but accepts two

recessive bits before the edge from recessive to dominant of the Acknowledge slot. Receiver sends Acknowledge bit after the first CRC Delimiter.

c) Due to a weakness of the CRC in a certain situation, and additional checksum is needed. For example a software checksum inside the last data byte. This is a weakness in the standard and not of the module. Therefore with DIS2015 the CRC field of CAN FD will be changed.

4. In the ACK Field:
   a) For ACK slot, CAN FD nodes accept a two bit long dominant phase of overlapping ACK bits as a valid ACK, to compensate for phase shifts between Receivers.

21.1.3.2 Remote Frames

Normally, data transmission is performed on an autonomous basis with the data source node (e.g. a sensor) sending out a Data Frame. It is also possible, however, for a destination node (or nodes) to request the data from the source. For this purpose, the destination node sends a Remote Frame with an identifier that matches the identifier of the required Data Frame. The appropriate data source node will then send a Data Frame as a response to this remote request.

There are 2 differences between a Remote Frame and a Data Frame.

- The RTR bit is in the recessive state in a Remote Frame.
- There is no Data Field in a Remote Frame.
