If a Data Frame and a Remote Frame with the same identifier are transmitted at the same time, the Data Frame wins arbitration due to the dominant RTR bit following the identifier. In this way, the node that transmitted the Remote Frame receives the requested data immediately.

Remote frames are only defined in Classical CAN format. Remote frames and the corresponding RTR bit do not exist for CAN FD format. Remote frame requests do not change the format of the preconfigured reply data frames (i.e FDF and BRS bits of preconfigured data frames are not changed on remote frame requests, reply data frames may be in CAN base/extended or CAN FD base/extended).

21.1.3.3 Error Frames

An Error Frame is generated by any node that detects a bus error. An Error Frame consists of two fields, an Error Flag field followed by an Error Delimiter field. The Error Delimiter Field consists of 8 recessive bits and allows the bus nodes to restart bus communications after an error. There are, however, two forms of Error Flag fields. The form of the Error Flag field depends on the error status of the node that detects the error.

When an error-active node detects a bus error, the node generates an Error Frame with an active-error flag. The error-active flag is composed of six consecutive dominant bits that actively violate the bit-stuffing rule. All other stations recognize a bit-stuffing error and generate Error Frames themselves. The resulting Error Flag field on the CAN bus

therefore consists of six to twelve consecutive dominant bits (generated by one or more nodes). The Error Delimiter field completes the Error Frame. After completion of the Error Frame, bus activity returns to normal and the interrupted node attempts to re-send the aborted message.

If an error-passive node detects a bus error, the node transmits an error-passive flag followed, again, by the Error Delimiter field. The error-passive flag consists of six consecutive recessive bits, and therefore the Error Frame (for an error-passive node) consists of 14 recessive bits (i.e. no dominant bits). Therefore, the transmission of an Error Frame by an error-passive node will not affect any other node on the network, unless the bus error is detected by the node that is actually transmitting (i.e. the bus master). If the bus master node generates an error-passive flag, this may cause other nodes to generate Error Frames due to the resulting bit-stuffing violation. After transmission of an Error Frame an error-passive node must wait for 6 consecutive recessive bits on the bus before attempting to rejoin bus communications.

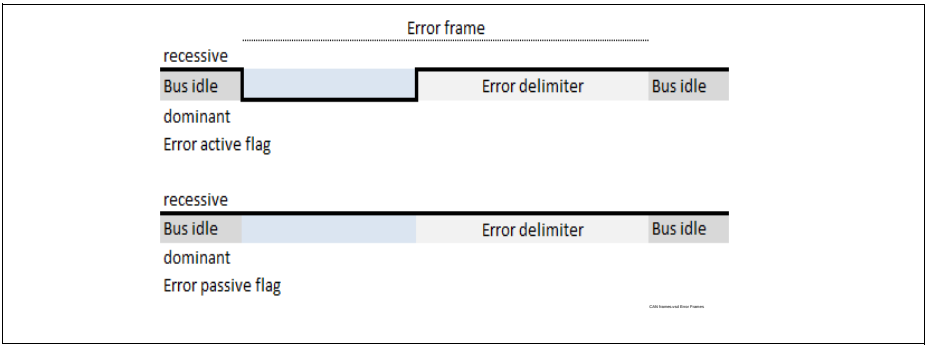

Figure 21-5 CAN Error Frames

A CAN FD node operating in the Data-Phase will switch back to the Arbitration Phase when starting an Error Flag.

21.1.3.4 Overload Frame

The Overload Frame consists of two bit fields which are Overload Flag and Overload Delimiter.

Overload conditions

If a CAN FD node samples a dominant bit at the eight bit (last bit) of an Error Delimiter or Overload Delimiter, or if a CAN FD Receiver samples a dominant bit at the last bit of End of Frame, it will start transmitting an Overload Frame (not an Error Frame). The Error Counters will not be incremented.

21.1.4 The Nominal Bit Time

One bit cell (this means one high or low pulse of the NRZ code) is composed by four segments. Each segment is an integer multiple of Time Quanta t_Q. The Time Quanta is the smallest discrete timing resolution used by a CAN node. The nominal bit time definition with its segments is shown in **Figure 21-6**.

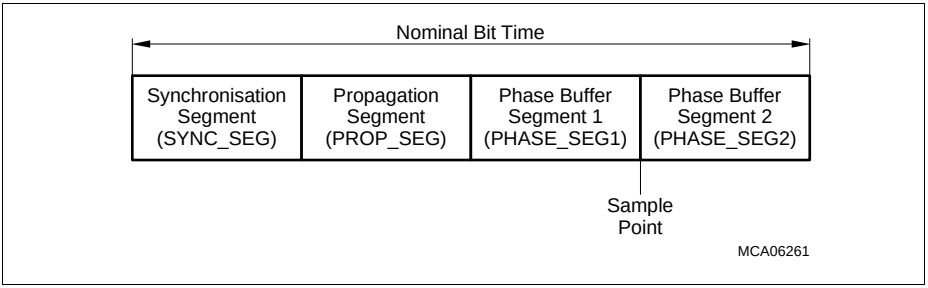

Figure 21-6 Partition of Nominal Bit Time

The Synchronization Segment (SYNC_SEG) is used to synchronize the various bus nodes. If there is a bit state change between the previous bit and the current bit, then the bus state change is expected to occur within this segment. The length of this segment is always 1 t_Q.

The Propagation Segment (PROP_SEG) is used to compensate for signal delays across the network. These delays are caused by signal propagation delay on the bus line and through the electronic interface circuits of the bus nodes.

The Phase Segments 1 and 2 (PHASE_SEG1, PHASE_SEG2) are used to compensate for edge phase errors. These segments can be lengthened or shortened by re-synchronization. PHASE_SEG2 is reserved for calculation of the subsequent bit level, and is ≥ 2 t_Q. At the sample point, the bus level is read and interpreted as the value of the bit cell. It occurs at the end of PHASE_SEG1.

The total number of t_Q in a bit time is between 8 and 25.

As a result of re-synchronization, PHASE_SEG1 can be lengthened or PHASE_SEG2 can be shortened. The amount of lengthening or shortening the phase buffer segments has an upper limit given by the re-synchronization jump width. The re-synchronization jump width may be between 1 and 4 t_Q, but it may not be longer than PHASE_SEG1.

21.1.4.1 CAN FD bit timing

The first part of a CAN FD frame until the BRS bit is transmitted with the Nominal Bit Rate. The bit rate is switched if the BRS bit is recessive, until the CRC Delimiter is reached or until the CAN FD controller sees an error condition that results in the starting

of an Error Frame. CAN FD Error Frames, as well as ACK Field, End of Frame, Overload Frames and all in CAN Format are transmitted with the Nominal Bit Rate

Synchronization Rules

Hard synchronization and Resynchronization are the two forms of synchronization. They obey the following rules,

- Hard synchronization is performed whenever there is a recessive to dominant edge during Bus Idle, Suspend Transmission, and second or third bits of Intermission. Hard synchronization is also performed at the recessive to the dominant edge from FDF to r0 in CAN FD format frames
- A transmitter shall not resynchronize while it transmits in the CAN FD data phase

21.1.5 Error Detection and Error Handling

The CAN protocol has sophisticated error detection mechanisms. The following errors can be detected:

- **Cyclic Redundancy Check (CRC) Error**
  With the CRC, the transmitter calculates special check bits for the bit sequence from the start of a frame until the end of the Data Field. This CRC sequence is transmitted in the CRC Field. The receiving node also calculates the CRC sequence using the same formula, and performs a comparison to the received sequence. If a mismatch is detected, a CRC error has occurred and an Error Frame is generated. The message is repeated.
- **Acknowledge Error**
  In the Acknowledge Field of a message, the transmitter checks whether a dominant bit is read during the Acknowledge Slot (that is sent out as a recessive bit). If not, no other node has received the frame correctly, an Acknowledge Error has occurred, and the message must be repeated. No Error Frame is generated.
- **Form Error**
  If a transmitter detects a dominant bit in one of the four segments End of Frame, Interframe Space, Acknowledge Delimiter, or CRC Delimiter, a Form Error has occurred, and an Error Frame is generated. The message is repeated.
- **Bit Error**
  A Bit Error occurs if a) a transmitter sends a dominant bit and detects a recessive bit or b) if the transmitter sends a recessive bit and detects a dominant bit when monitoring the actual bus level and comparing it to the just transmitted bit. In case b), no error occurs during the Arbitration Field (ID, RTR, IDE) and the Acknowledge Slot.
- **Stuff Error**
  If between Start of Frame and CRC Delimiter, six consecutive bits with the same polarity are detected, the bit-stuffing rule has been violated. A stuff error occurs and an Error Frame is generated. The message is repeated.

Detected errors are made public to all other nodes via Error Frames (except Acknowledge Errors). The transmission of the erroneous message is aborted and the frame is repeated as soon as possible. Furthermore, each CAN node is in one of the three error states (error-active, error-passive or bus-off) according to the value of the internal error counters. The error-active state is the usual state where the bus node can transmit messages and active-error frames (made of dominant bits) without any restrictions. In the error-passive state, messages and passive-error frames (made of recessive bits) may be transmitted. The bus-off state makes it temporarily impossible for the node to participate in the bus communication. During this state, messages can be neither received nor transmitted.

Basic CAN, Full CAN

There is one more CAN characteristic that is related to the interface of a CAN module (controller) and the host CPU: Basic-CAN and Full-CAN functionality.

In Basic-CAN devices, only basic functions of the protocol are implemented in hardware, such as the generation and the check of the bit stream. The decision, whether a received message has to be stored or not (acceptance filtering), and the complete message management must be done by software.

Full-CAN devices (this is the case for the MultiCAN+ controller as implemented in TC21x/TC22x/TC23x) manage the whole bus protocol in hardware, including the acceptance filtering and message management. Full-CAN devices contain message objects that handle autonomously the identifier, the data, the direction (receive or transmit) and the information of CAN operation. During the initialization of the device, the host CPU determines which messages are to be sent and which are to be received. The host CPU is informed by interrupt if the identifier of a received message matches with one of the programmed (receive-) message objects. The CPU load of Full-CAN devices is greatly reduced. When using Full-CAN devices, high baud rates and high bus loads with many messages can be handled.

21.2 Overview

The MultiCAN+ module provides a communication interface which is fully compliant with CAN specification V2.0B (active) and to CAN FD ISO11898-1 DIS version 2014, providing communications at up to 1 Mbit/s in Classical CAN (ISO 11898-1:2003(E) mode and/or CAN FD until 5 MBaud dataspeed (dependent on frequency and nodes)).

The MultiCAN+ module for the TC21x/TC22x/TC23x consists of 2[1)] module (i.e MultiCAN with 3 CAN nodes and MultiCAN1 with 3 CAN Nodes), representing 6[2)] serial communication interfaces. . Each CAN node communicates over two pins (TXD and RXD). The device ports which are used for TXD and RXD may be individually configured within the PORTS block. Several port configuration options are available to provide application-specific flexibility.

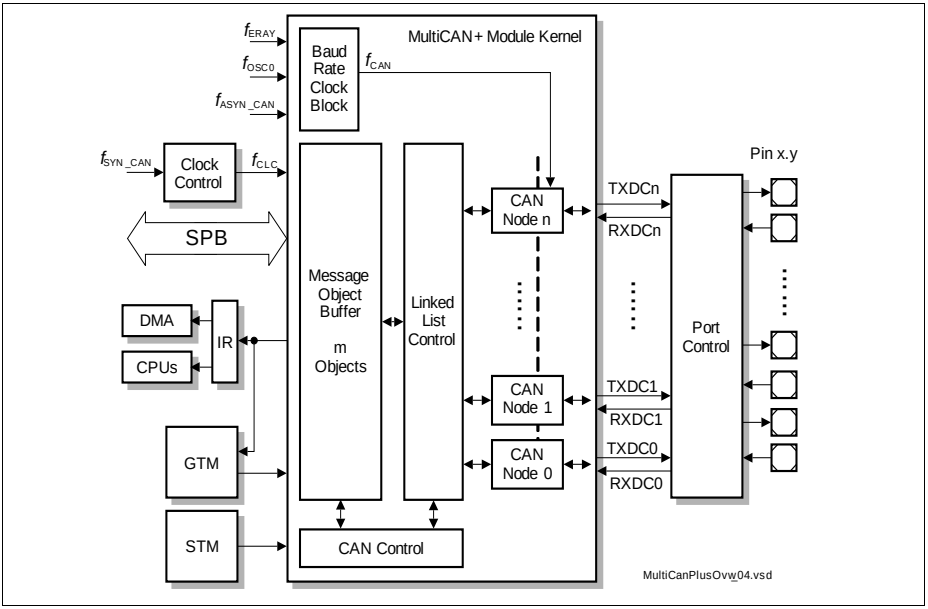

Figure 21-7 Overview of the MultiCAN+ Module with 3 nodes and 128 message objects in AURIX products.

The MultiCAN+ module contains 3/3 independently operating CAN nodes with Full-CAN functionality that are able to exchange Data and Remote Frames via a gateway function.

1) TC23x consists of 2 modules (MultiCAN and MultiCAN1), TC22x consists of 1module (MultiCAN).

2) TC23x has 6 CAN serial communication interfaces, TC22x has 3 CAN communication interfaces.

Each CAN node can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

All CAN nodes share a common set of 128/128 message objects. Each message object can be individually allocated to one of the CAN nodes.Besides serving as a storage container for incoming and outgoing frames, message objects can be combined to build gateways between the CAN nodes or to setup a FIFO buffer.

The message objects are organized in double-chained linked lists, where each CAN node has its own list of message objects. A CAN node stores frames only into message objects that are allocated to the message object list of the CAN node, and it transmits only messages belonging to this message object list. A powerful, command-driven list controller performs all message object list operations.

The bit timings for the CAN nodes are derived from the module timer clock (f_{CAN}) and are programmable up to a data rate of 1 Mbit/s in Classical CAN (ISO 11898-1:2003(E) mode or up to 5 MBaud in CAN FD mode. External bus transceivers are connected to a CAN node via a pair of receive and transmit pins.

21.2.1 Features List

The MultiCAN+ module provides the following features:

- Compliant with ISO 11898 and SAE J 1939
- CAN functionality according to CAN specification V2.0 B active
- Supports CAN with Flexible Data-Rate Specification CAN FD DIS version ISO11898-1 2014 with max. 64 data bytes[1)]
- Debug over CAN[2)]
- Dedicated control registers for each CAN node
- Data transfer rates up to 1 Mbit/swhen operating in Classical CAN mode per ISO 11898-1:2003(E)
- Supports up to 5MBaud, when operating in CAN FD mode.
- Support for asynchronous clock sources for baud rate generation by providing separate frequency domain and input:
  - System frequency clock f_{CLC}
  - Low-jitter E-Ray PLL clock
  - Direct oscillator clock (e.g. from ceramic resonator)
- Frequency jitter calibration based on external CAN messages during runtime
- Flexible and powerful message transfer control and error handling capabilities
- Advanced CAN bus bit timing analysis and baud rate detection for each CAN node via a frame counter
- Full-CAN functionality: A set of 128/128[3)] message objects can be individually

1) At time of release of this document ISO 11898-1 (Classical CAN and CAN FD) is in working draft mode, an errata sheet will document differences when ISO 11898-1 has been finalized.

2) Debug over CAN feature is available through CAN module only and not available on CAN1 module.

  - Allocated (assigned) to any CAN node
  - Configured as transmit or receive object
  - Setup to handle frames with 11-bit or 29-bit identifier
  - Identified by a timestamp via a frame counter
  - Configured to remote monitoring mode
- Advanced Acceptance Filtering
  - Each message object provides an individual acceptance mask to filter incoming frames
  - A message object can be configured to accept standard or extended frames or to accept both standard and extended frames
  - Message objects can be grouped into different priority classes for transmission and reception
  - The selection of the message to be transmitted first can be based on frame identifier, IDE bit and RTR bit according to CAN arbitration rules, or on its order in the list
- Advanced CAN node features
  - Analyzer Mode supports monitoring of bus traffic without actively participating on the bus
  - Internal Loop-Back Mode is available for test purposes
  - An internal timer is provided that can detect a receive or remote frame time-out; the message objects to be supervised are selectable
  - Data transmission from a node can be stopped without affecting reception
  - Programmable minimum delay between two consecutive messages
- Advanced message object functionality
  - Message objects can be combined to build FIFO message buffers of arbitrary size, limited only by the total number of message objects
  - Message objects can be linked to form a gateway that automatically transfers frames between 2 different CAN buses. A single gateway can link any two CAN nodes. An arbitrary number of gateways can be defined
- Advanced data management
  - The message objects are organized in double-chained lists
  - List reorganizations can be performed at any time, even during full operation of the CAN nodes
  - A powerful, command-driven list controller manages the organization of the list structure and ensures consistency of the list
  - Message FIFOs are based on the list structure and can easily be scaled in size during CAN operation
- Advanced interrupt handling
  - Message interrupts, node interrupts can be generated

3) MultiCAN has 128 Message Objects, MultiCAN1 has 128 Message Objects.

  - Interrupt requests can be routed individually to one of the 16 or 8 interrupt output lines
  - Message post-processing notifications can be combined flexibly into a dedicated register field of 256 notification bits
- Module internal SRAM with ECC protection
- Pretended Networking Operation for energy saving purposes
  - If direct oscillator clock is selected for baud rate generation, CPU clock can be slowed down or CPU Idle Mode can be entered
  - Three selectable message object can be transmitted periodically without CPU involvement, triggered by a CAN node timer or by STM or GTM modules.
  - Message objects are received without CPU involvement and can wake up the system via receive interrupt
  - AUTOSAR optimized and backward compatible with existing MultiCAN software

21.3 CAN Flexible Data-Rate (CAN FD)

CAN Flexible Data-Rate (CAN FD) builds on existing CAN (ISO 11898-1) specifications allowing higher data rates and larger payloads. This is achieved with a new CAN FD frame format different from existing Classical CAN format, both frame formats can coexist within the same network. Classical CAN nodes and CAN FD nodes can communicate with each other as long as CAN FD frame format is not being used.

CAN FD functionality is available on all nodes of MultiCAN+ module.

Feature Lists

- Supports CAN Flexible Data-Rate Specification V1.0

21.3.1 Transmitter Delay Compensation

The CAN protocol requires that transmitted data be compared with the received data from its local CAN transceiver to determine if there are any transmit errors. In the case of CAN FD data phase when a faster bit rate is used, resulting in shorter bit timing, the delay caused by the local transmitting loop delay will be greater than TSEG1 (time segment before sample point) causing a bit error to be detected. The transmitter loop delay limits the bit rate in the data phase of a CAN FD frame.

Thus to overcome this limitation, a Transmitter Delay Compensation feature is introduced where a new sample point (Secondary Sample Point) shall be used by transmitters in the data phase of a CAN FD frame, the sample point which does not account for the transceiver loop delay is ignored.

The Secondary Sample Point consists of the transmitter loop delay and a configurable Transmitter Delay Compensation offset (NTDCRx.TDCO). (i.e The secondary sample point is reached by counting the total delay consisting of the compensation offset and measured transceiver loop delay.)

The Transmitter loop delay is measured in each transmitted frame at the edge from the FDF bit to the following bit r0, between the edge of the transmitted bit and the edge of the received bit. (see **Figure 21-8**) The count down is started with the begin of the bit time (transmit point).

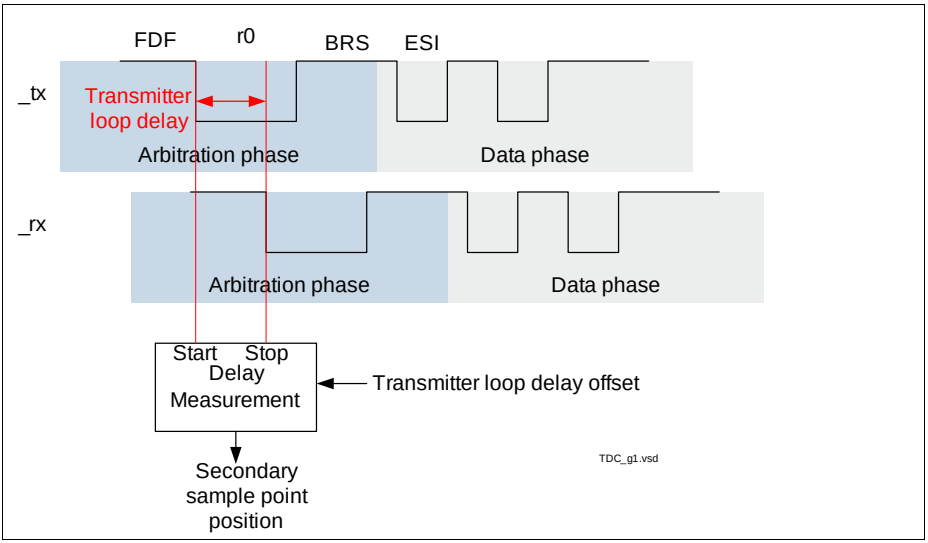

Figure 21-8 Transmitter Delay Loop measurement

Transmitter Delay compensation offset (NTDCRx.TDCO) is used to adjust the secondary sample point inside the bit time (e.g half of the bit time in the data phase). Finally the resulting Secondary Sample Point is rounded down to the next integer number of time quanta t_q and placed after the end of the transmitted bit. If a bit error is detected at the Secondary Sample Point, the transmitter will react to this bit error at the next sample point.

(i.e When a bit error is detected by the Transmitter Delay compensation unit, the error is reported at the next sample point and becomes visible (in error active case) at the transmit point that follows the regular sample point.)

Secondary Sample Point is used in the Data Phase of CAN FD and Sample Point is used in the Arbitration Phase of CAN FD. The Transmitter Delay compensation which determines the secondary sample point is able to handle a total delay (measured transceiver loop delay + compensation offset) which goes beyond the current bit time.

MultiCAN+ module allows the secondary sample point to be placed anywhere within the current and next 3 bit times (i.e covers up to 4 data phase bit rate). The maximum delay which can be compensated by MultiCAN+ delay compensation during the data phase is 4 bit times.

Note:

7. *CAN receive input line contributes to the measured loop delay.*
8. *Measurement granularity of the Transmitter Delay compensation is the fast time quantum given by the fast baud rate prescaler.*

21.4 MultiCAN+ Kernel Functional Description

This section describes the functionality of the MultiCAN+ module.

21.4.1 Module Structure

Figure 21-9 shows the general structure of the MultiCAN+ module.

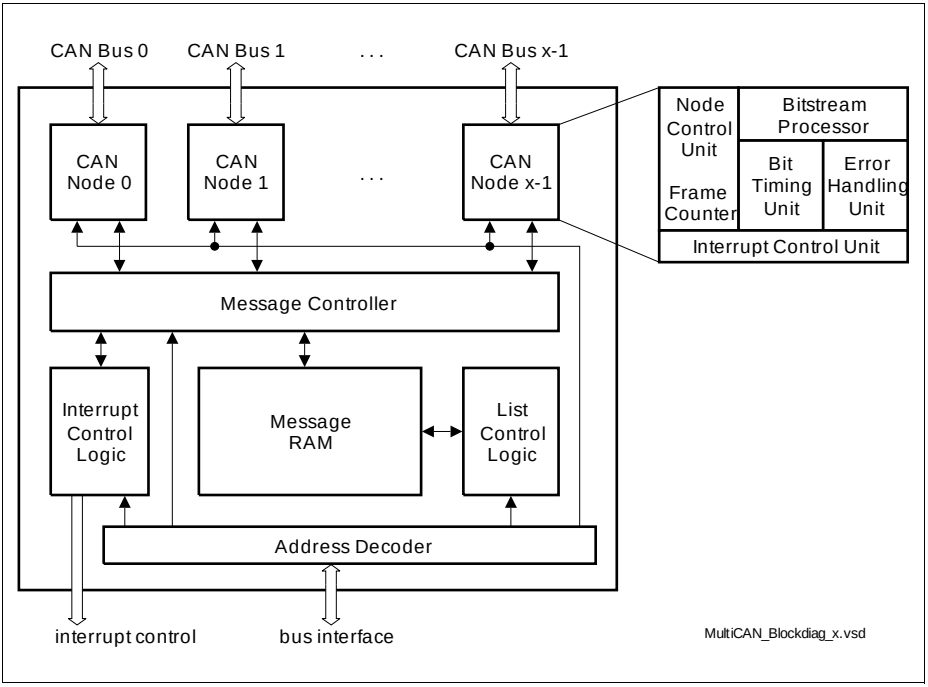

Figure 21-9 MultiCAN+ Block Diagram

CAN Nodes

Each CAN node consists of several sub-units.

- **Bitstream Processor**
  The Bitstream Processor performs data, remote, error and overload frame processing according to the ISO 11898 standard. This includes conversion between the serial data stream and the input/output registers.
- **Bit Timing Unit**
  The Bit Timing Unit determines the length of a bit time and the location of the sample point according to the user settings, taking into account propagation delays and phase shift errors. The Bit Timing Unit also performs resynchronization.

- **Error Handling Unit**
  The Error Handling Unit manages the receive and transmit error counter. Depending on the contents of both counters, the CAN node is set into an error-active, error passive or bus-off state.
- **Node Control Unit**
  The Node Control Unit coordinates the operation of the CAN node:
  – Enable/disable CAN transfer of the node
  – Enable/disable and generate node-specific events that lead to an interrupt request (CAN bus errors, successful frame transfers etc.)
  – Administration of the frame counter and of the node timers
- **Interrupt Control Unit**
  The Interrupt Control Unit in the CAN node controls the interrupt generation for the different conditions that can occur in the CAN node.

Message Controller

The Message Controller handles the exchange of CAN frames between the CAN nodes and the message objects that are stored in the Message RAM. The Message Controller performs several functions:

- Receive acceptance filtering to determine the correct message object for storing of a received CAN frame
- Transmit acceptance filtering to determine the message object to be transmitted first, individually for each CAN node
- Transfer contents between message objects and the CAN nodes, taking into account the status/control bits of the message objects
- Handling of the FIFO buffering and gateway functionality
- Aggregation of message-pending notification bits

List Controller

The List Controller performs all operations that lead to a modification of the double-chained message object lists. Only the list controller is allowed to modify the list structure. The allocation/deallocation or reallocation of a message object can be requested via a user command interface (command panel). The list controller state machine then performs the requested command autonomously.

Interrupt Control

The general interrupt structure is shown in **Figure 21-10**. The interrupt event can trigger the interrupt generation. The interrupt pulse is generated independently of the interrupt flag in the interrupt status register. The interrupt flag can be reset by software by writing a 0 to it.

If enabled by the related interrupt enable bit in the interrupt enable register, an interrupt pulse can be generated at one of the 16 or 8 interrupt output lines INT_Om of the MultiCAN+ module. If more than one interrupt source is connected to the same interrupt node pointer (in the interrupt node pointer register), the requests are combined to one common line.

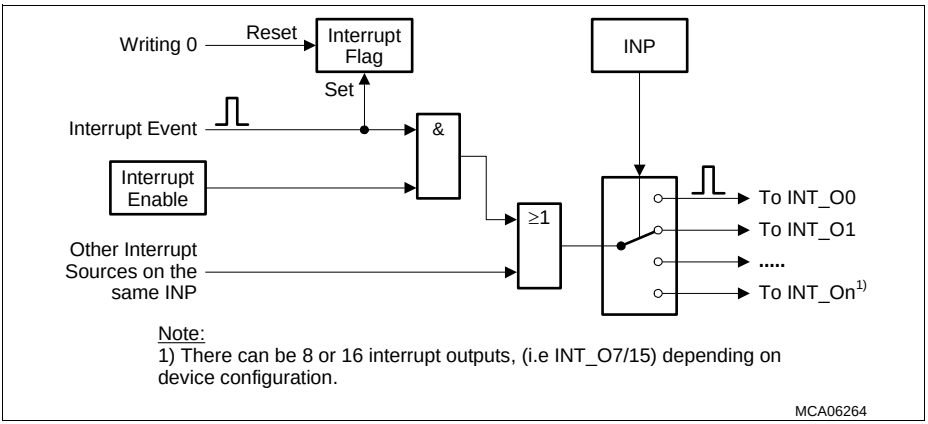

Figure 21-10 General Interrupt Structure

21.4.2 Clock Control

The CAN module timer clock f_{CAN} of the functional blocks of the MultiCAN+ module is derived from the asynchronous, higher precision clock f_A or from the synchronous clock source. The Fractional Divider is used to generate f_{CAN} used for bit timing calculation, The frequency of f_{CAN} is identical for all CAN nodes. The register file operate with the module control clock f_{CLC}. See also **“MultiCAN+ Clock Generation” on Page 21-21**.

The output clock f_{CAN} of the Fractional Divider is based on the clock f_A, but only every nth clock pulse is taken. The suspend signal (coming as acknowledge from the MultiCAN+ module in response to a OCDS suspend request) freezes or resets the Fractional Divider. The clock select and fractional divider are reset together with the CAN module kernel when the module kernel reset is triggered.

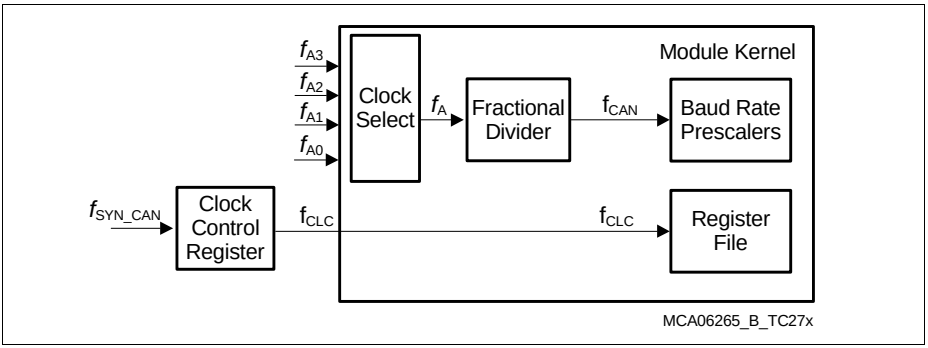

Figure 21-11 MultiCAN+ Clock Generation

The f_{SYN_CAN} is identical to f_{SPB}. f_{Ai} is the asynchronous clock input.

Table 21-2 indicates the minimum operating frequencies in MHz for f_{CLC} that are required for a baud rate of 1 Mbit/s for the active CAN nodes. If a lower baud rate is desired, the values can be scaled linearly (e.g. for a maximum of 500 kbit/s, 50% of the indicated value are required).

For CAN FD operations, please refer to **Table 21-3** for the minimum operating frequency in MHz for f_{CLC} that are required.

The values imply that the CPU (or DMA) executes maximum accesses to the MultiCAN+ module. The values may contain rounding effects.

Table 21-2 Minimum Operating Frequencies[1)2)] [MHz]

Number of allocated message objects MO[3)],	Number of Active CAN Nodes				
	1	**2**	**3**	**4**	**5**
16 MO	12	19	26	33	40
32 MO	15	23	30	37	44
64 MO	21	28	37	46	53
128 MO	40	45	50	55	61
256 MO	72	77	82	88	93

1) In the case of 15 time quanta, the minimum operating frequency required is 15MHz.

2) To guarantee the minimum operating frequencies when low power mode (pretended networking mode) is enabled (i.e when frequency of f_{SPB} is reduced), f_{SYN_CAN} and f_{CLC} are switched from f_{SPB} to f_{CAN} when SCU register CCUCON.LPDIV>0.

3) Only those message objects have to be taken into account that are allocated to a CAN node. The unallocated message objects have no influence on the minimum operating frequency.

Table 21-3 Minimum Operating Frequencies for CAN FD [MHz]

No. of allocated MO[1)]	No. of Active CAN Nodes	Acceleration Factor[2)3)]				
		1	2	3	4	5
16 MO	1	20	40	60	80	100
	2	39	48	72	96	-
	3	58	58	84	-	-
	4	77	77	96	-	-
	5	96	96	-	-	-
32 MO	1	20	40	60	80	100
	2	39	48	72	96	-
	3	58	58	84	-	-
	4	77	77	96	-	-
	5	96	96	-	-	-
64 MO	1	27	40	60	80	100
	2	39	51	72	96	-
	3	58	65	84	-	-
	4	77	79	96	-	-
	5	96	96	-	-	-
128 MO	1	47	65	75	81	100
	2	57	79	91	99	-
	3	67	93	-	-	-
	4	77	-	-	-	-
	5	96	-	-	-	-

1) Only those message objects have to be taken into account that are allocated to a CAN node. The unallocated message objects have no influence on the minimum operating frequency.
When message objects are configured as transmit or receive FIFO structures i.e MOFCRn.MMC = 0001/0010, only the base object of 1 is counted towards the minimum frequency requirement, all other slave objects on the FIFO do not count towards the minimum frequency requirement. See **Section 21.4.12.5**

2) Acceleration Factor is the ratio of the Data Bit Rate to Nominal Bit Rate. The Nominal Bit Rate is taken as 1Mbit/s in table above. As an example, an acceleration factor(A.F) of 4 refers to a Data Bit Rate of 4Mbit/s and Nominal Bit Rate is 1Mbit/s.
Only the node operating with the highest baudrate need to be considered when several nodes operate at different acceleration factor. e.g When 1node operate at A.Fof 3 and 3 nodes operate at A.F of 2, the minimum operating frequency required is determined by the node operate at A.F of 3.

3) Please note that other combinations of acceleration factor are possible, values here are for illustrative purposes only. Values with dash '-' indicates required f_{CLC} exceeding the maximum frequency capability off product SCU typically at 100MHz.

The baud rate generation of the MultiCAN+ being based on f_A, this frequency has to be chosen carefully to allow correct CAN bit timing. The required value of f_A is given by an integer multiple (n) of the CAN baud rate multiplied by the number of time quanta per CAN bit time. For example, to reach 1 Mbit/s with 20 tq per bit time, possible values of f_A are given by formula [n × 20] MHz, with n being an integer value, starting at 1.

In order to minimize jitter, it is not recommended to use the fractional divider mode for high baud rates.

Additionally, for correct operation of the MultiCAN, the following conditions have to be fulfilled,

$$\text{Baudrate}_{max} = [(8 \times T_{CAN}) + (8 \times T_{CLC}) + (4 \times \text{No. of active CAN nodes} \times T_{CLC})] \quad (21.1)$$

also

$$\text{NBTR.SJW} < \text{NBTR.TSEG1}$$

As an example, when f_{CLC} = 10MHz, f_{CAN} = 20MHz, No of active CAN nodes =2,

Baudrate_{max}=[(8x50ns) + (8x100ns) + (4x2x100ns)] = 2000ns = 500 KBaud

Table 21-4 below illustrates the minimum CAN module timer clock f_{CAN} and Module Control Clock f_{CLC} that's required to support a baudrate generation of 500KBaud. If a higher baudrate is desired, the values need to be calculated as per **Equation (21.1)**.

Table 21-4 Minimum Operating Frequencies [MHz] required for 500KBaud

No. of active CAN nodes	$f_{CAN} = f_{CLC}$ (MHz)	$f_{CAN} \neq f_{CLC}$ (MHz)[1]	
		f_{CAN}	f_{CLC}
1	10	16	8
		20	8
		24	8
		80	7
2	12	16	11
		20	10
		24	10
		80	9
3	14	16	14
		20	13
		24	12
		80	11

1) To guarantee the minimum operating frequencies when low power mode (pretended networking mode) is enabled (i.e when frequency of f_{SPB} is reduced), f_{SYN_CAN} and f_{CLC} are switched from f_{SPB} to f_{CAN} when SCU register CCUCON.LPDIV>0.

21.4.3 Port Input Control

It is possible to select the input lines for the RXDCANx inputs for the CAN nodes. The selected input is connected to the CAN node and is also available to wake-up the system. More details are defined in **Section 21.7.5.2** on **Page 21-170**.

21.4.4 OCDS Suspend

The OCDS suspend of MultiCAN+ is controlled with the **OCS** register. MultiCAN+ module provides the following Suspend Modes:

Hard Suspend Mode (VERSION: RW ACCESS NEEDS KERNEL CLOCKING) (All actions are immediately stopped)

The Hard Suspend mode is not to be used in normal CAN applications, this mode is meant for debugging the peripheral IP within a controlled environment.

In Hard Suspend Mode, the MultiCAN+ module clocks f_{CLC} and f_{CAN} are switched off. Reading and writing of registers is possible but will enable the kernel clock for a few cycles. In this mode, there is a very high probability that the communication with other CAN devices is made impossible and that the CAN bus is blocked (e.g. if the suspended CAN module just sends a dominant level). A reset operation must be executed to leave Hard Suspend Mode.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a MultiCAN+ kernel reset might not be sufficient to bring the system into a defined state.

Soft Suspend Mode (The current action is finished)

In Soft Suspend Mode, the MultiCAN+ module clock f_{CLC} is kept running. Module functions are stopped automatically after internal actions have been finished before it enters the suspended state with **OCS**.SUSSTA set (for example, after a CAN frame has been sent out). Due to this behavior, the communication network is not blocked. All registers are accessible for read and write actions. As a result, the debugger can stop the module actions and modify registers. These modifications are taken into account after the Suspend Mode is left. Soft Suspend mode does not influence the kernel clock.

The Hard Suspend Mode can be enabled/disabled only for the complete MultiCAN+ module. The Soft Suspend Mode can be individually enabled for each CAN node.

The user has to be aware that the Soft Suspend Mode can corrupt the TTCAN timing values, because the counter clock can be disabled. In order to guarantee correct TTCAN

behavior, a TTCAN node should not enter any Suspend Mode if the consistency of the timing data must be ensured.

Note: During suspend mode, kernel registers may be accessed only when the kernel clock is running.

21.4.5 OCDS Trigger Bus (OTGB) Interface

The MultiCAN Trigger Set is shown in **Table 21-5**. Its output is on OTGB0 or OTGB1 controlled by the **OCS** register.

Table 21-5 TS16_CAN Trigger Set MultiCAN

Bits	Name	Description
[7:0]	MON	Message Object Number for transmit and receive direction. Only valid when TT or RT is active and FMI is inactive.
[11:8]	NN	Node Number for transmit and receive direction. Only valid when TT or RT is active and FMI is inactive.
12	TT	Transmit Trigger. Active for one clock cycle when the transmit message is setup.
13	RT	Receive Trigger. Active for one clock cycle after End-of-Frame (EOF) processing for a receive message.
14	FMI	Foreign Message Indicator. The received message will not be copied to any message object. Only valid when RT is active.
15		Reserved

MCDS Trigger Setup

Table 21-6 lists the qualification methods for TC16_CAN with MCDS. The methods are not exclusive and can be combined.

Table 21-6 TS16_CAN MCDS Trigger Setup

Qualification	Method
Transmit and/or receive messages	Positive edge sensitivity on TS16_CAN.TT and/or RT. Configured in the OTGM MCDS I/F.
No foreign messages.	MCDS data value condition TS16_CAN < 4000_H
Specific message object	MCDS masked data value comparison. TS16_CAN & $00FF_H$ == message object number
Specific node	MCDS masked data value comparison. TS16_CAN & $0F00_H$ == (node number) << 8

21.4.6 CAN Node Control

Each CAN node may be configured and run independently of the other CAN node. Each CAN node is equipped with its own node control logic to configure the global behavior and to provide status information.

Note: In the following descriptions, index “x” stands for the node number and index “n” represents the message object number.

Configuration Mode is activated when bit NCRx.CCE is set to 1. This mode allows CAN bit timing parameters and the error counter registers to be modified.

CAN Analyzer Mode

CAN Analyzer Mode is activated when bit NCRx.CALM is set to 1. In this operation mode, Data And Remote Frames are monitored without active participation in any CAN transfer (CAN transmit pin is held on recessive level). Incoming Remote Frames are stored in a corresponding transmit message object, while arriving data frames are saved in a matching receive message object.

In CAN Analyzer Mode, the entire configuration information of the received frame is stored in the corresponding message object, and can be evaluated by the CPU to determine their identifier, IDE bit information and data length code (ID and DLC optionally if the Remote Monitoring Mode is active, bit MOFCRn.RMM = 1). Incoming frames are not acknowledged, and no Error Frames are generated. If CAN Analyzer Mode is enabled, Remote Frames are not responded to by the corresponding Data Frame, and Data Frames cannot be transmitted by setting the transmit request bit MOSTATn.TXRQ. Receive interrupts are generated in CAN Analyzer Mode (if enabled) for all error free received frames.

The node-specific interrupt configuration is also defined by the Node Control Logic via the NCRx register bits TRIE, ALIE and LECIE:

- If control bit TRIE is set to 1, a transfer interrupt is generated when the NSRx register has been updated (after each successfully completed message transfer).
- If control bit ALIE is set to 1, an alert interrupt is generated when a “bus-off” condition has been recognized or the Error Warning Level has been exceeded or under-run. Additionally, list or object errors lead to this type of interrupt.
- If control bit LECIE is set to 1, a last error code interrupt is generated when an error code > 0 is written into bit field NSRx.LEC by hardware.

Setting bit TXDIS in register NCRx stops the transmit activity of this node without affecting reception; bit CANDIS disables the node completely.

The Node x Status Register NSRx provides an overview about the current state of the respective CAN node x, comprising information about CAN transfers, CAN node status, and error conditions.

The CAN frame counter can be used to check the transfer sequence of message objects or to obtain information about the instant a frame has been transmitted or received from the associated CAN bus. CAN frame counting is performed by a 16-bit counter, controlled by register NFCRx. Bit fields NFCRx.CFMOD and NFCRx.CFSEL determine the operation mode and the trigger event incrementing the frame counter.

21.4.6.1 Bit Timing Unit

According to the ISO 11898 standard, a CAN bit time is subdivided into different segments (**Figure 21-12**). Each segment consists of multiples of a time quantum t_q. The magnitude of t_q is adjusted by Node x Bit Timing Register bit fields NBTRx.BRP and NBTRx.DIV8, both controlling the baud rate prescaler (register NBTRx is described on **Page 21-106**). The baud rate prescaler is driven by the module timer clock f_{CAN} (generation and control of f_{CAN} is described on **Page 21-165**).

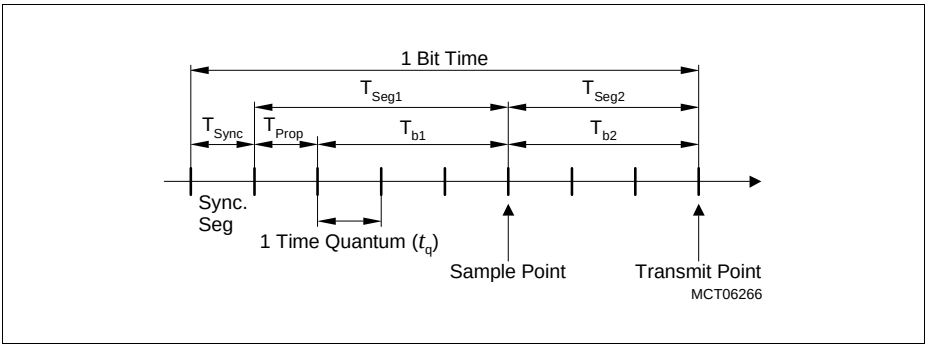

Figure 21-12 CAN Bus Bit Timing Standard

The Synchronization Segment (T_{Sync}) allows a phase synchronization between transmitter and receiver time base. The Synchronization Segment length is always one t_q. The Propagation Time Segment (T_{Prop}) takes into account the physical propagation delay in the transmitter output driver on the CAN bus line and in the transceiver circuit. For a working collision detection mechanism, T_{Prop} must be two times the sum of all propagation delay quantities rounded up to a multiple of t_q. The phase buffer segments 1 and 2 (T_{b1}, T_{b2}) before and after the signal sample point are used to compensate for a mismatch between transmitter and receiver clock phases detected in the synchronization segment.

The maximum number of time quanta allowed for re-synchronization is defined by bit field NBTRx.SJW. The Propagation Time Segment and the Phase Buffer Segment 1 are combined to parameter T_{Seg1}, which is defined by the value NBTRx.TSEG1. A minimum of 3 time quanta is demanded by the ISO standard. Parameter T_{Seg2}, which is defined by the value of NBTRx.TSEG2, covers the Phase Buffer Segment 2. A minimum of 2 time

quanta is demanded by the ISO standard. According to ISO standard, a CAN bit time, calculated as the sum of T_{Sync}, T_{Seg1} and T_{Seg2}, must not fall below 8 time quanta.

Calculation of the bit time:

t_q	$= (BRP + 1) / f_{CAN}$	if DIV8 = 0
	$= 8 \times (BRP + 1) / f_{CAN}$	if DIV8 = 1
T_{Sync}	$= 1 \times t_q$	
T_{Seg1}	$= (TSEG1 + 1) \times t_q$	(min. 3 t_q)
T_{Seg2}	$= (TSEG2 + 1) \times t_q$	(min. 2 t_q)
bit time	$= T_{Sync} + T_{Seg1} + T_{Seg2}$	(min. 8 t_q)

To compensate phase shifts between clocks of different CAN controllers, the CAN controller must synchronize on any edge from the recessive to the dominant bus level. The hard synchronization is enabled (at the start of frame), the bit time is restarted at the synchronization segment. Otherwise, the re-synchronization jump width T_{SJW} defines the maximum number of time quanta, a bit time may be shortened or lengthened by one re-synchronization. The value of SJW is defined by bit field NBTRx.SJW.

T_{SJW}	$= (SJW + 1) \times t_q$
T_{Seg1}	$\geq T_{SJW} + T_{prop}$
T_{Seg2}	$\geq T_{SJW}$

The maximum relative tolerance for f_{CAN} in classical CAN format and CAN FD format depends on the Phase Buffer Segments, re-synchronization jump width and the bit time.

Classical CAN Format

df_{CAN}	$\leq \min (T_{b1}, T_{b2}) / [2 \times (13 \times \text{bit time} - T_{b2})]$	AND
df_{CAN}	$\leq T_{SJW} / 20 \times \text{bit time}$	

CAN FD Format

df_{CAN}	$\leq \min (T_{b1(N)}, T_{b2(N)}) / [2 \times (13 \times \text{bit time}_{(N)} - T_{b2(N)})]$	AND
df_{CAN}	$\leq T_{SJW(N)} / 20 \times \text{bit time}_{(N)}$	AND
df_{CAN}	$\leq T_{SJW(D)} / 20 \times \text{bit time}_{(D)}$	AND

$df_{CAN} \leq \min (T_{b1(D)}, T_{b2(D)}) / (2 \times [(6 \times \text{bit time}_{(D)} - T_{b2(D)}) \times BRP_{(D)} / BRP_{(N)} + (7 \times \text{bit time}_{(N)})] ($ AND

$df_{CAN} \leq [T_{SJW(D)} - (BRP_{(N)} / BRP_{(D)} - 1)] / (2 \times [(2 \times \text{bit time}_{(N)} - T_{b2(N)}) \times BRP_{(N)} / BRP_{(D)} + T_{b2(D)} + 4 \times \text{bit time}_{(D)}])$

A valid CAN bit timing must be written to the CAN Node Bit Timing Register NBTR and Fast Node Bit Timing Register before resetting the INIT bit in the Node Control Register, i.e. before enabling the operation of the CAN node.

The Node Bit Timing Register may be written only if bit CCE (Configuration Change Enable) is set in the corresponding Node Control Register.

21.4.6.2 Bitstream Processor

Based on the message objects in the message buffer, the Bitstream Processor generates the remote and Data Frames to be transmitted via the CAN bus. It controls the CRC generator and adds the checksum information to the new remote or Data Frame. After including the SOF bit and the EOF field, the Bitstream Processor starts the CAN bus arbitration procedure and continues with the frame transmission when the bus was found in idle state. While the data transmission is running, the Bitstream Processor continuously monitors the I/O line. If (outside the CAN bus arbitration phase or the acknowledge slot) a mismatch is detected between the voltage level on the I/O line and the logic state of the bit currently sent out by the transmit shift register, a CAN LEC error interrupt request is generated, and the error code is indicated by the Node x Status Register bit field NSRx.LEC.

The data consistency of an incoming frame is verified by checking the associated CRC field. When an error has been detected, a CAN LEC error interrupt request is generated and the associated error code is presented in the Node x Status Register NSRx. Furthermore, an Error Frame is generated and transmitted on the CAN bus. After decomposing a faultless frame into identifier and data portion, the received information is transferred to the message buffer executing remote and Data Frame handling, interrupt generation and status processing.

21.4.6.3 Error Handling Unit

The Error Handling Unit of a CAN node x is responsible for the fault confinement of the CAN device. Its two counters, the Receive Error Counter REC and the Transmit Error Counter TEC (bit fields of the Node x Error Counter Register NECNTx, see **Page 21-113**) are incremented and decremented by commands from the Bitstream Processor. If the Bitstream Processor itself detects an error while a transmit operation is running, the Transmit Error Counter is incremented by 8. An increment of 1 is used when the error condition was reported by an external CAN node via an Error Frame generation. For error analysis, the transfer direction of the disturbed message and the

node that recognizes the transfer error are indicated for the respective CAN node x in register NECNTx. Depending on the values of the error counters, the CAN node is set into error- active, error-passive, or bus-off state.

The CAN node is in error-active state if both error counters are below the error-passive limit of 128. The CAN node is in error-passive state, if at least one of the error counters is equal to or greater than 128.

The bus-off state is activated if the Transmit Error Counter is equal to or greater than the bus-off limit of 256. This state is reported for CAN node x by the Node x Status Register flag NSRx.BOFF. The device remains in this state, until the “bus-off” recovery sequence is finished. Additionally, Node x Status Register flag NSRx.EWRN is set when at least one of the error counters is equal to or greater than the error warning limit defined by the Node x Error Count Register bit field NECNTx.EWRNLVL. Bit NSRx.EWRN is reset if both error counters fall below the error warning limit again (see **Page 21-96**).

21.4.6.4 CAN Frame Counter

Each CAN node is equipped with a frame counter that counts transmitted/received CAN frames or obtains information about the time when a frame has been started to transmit or be received by the CAN node. CAN frame counting/bit time counting is performed by a 16-bit counter that is controlled by Node x Frame Counter Register NFCRx (see **Page 21-114**). Bit field NFCRx.CFSEL determines the operation mode of the frame counter:

- **Frame Count Mode:**
  After the successful transmission and/or reception of a CAN frame, the frame counter is copied into the CFCVAL bit field of the MOIPRn register of the message object involved in the transfer. Afterwards, the frame counter is incremented.
- **Time Stamp Mode:**
  The frame counter is incremented with the beginning of a new bit time. When the transmission/reception of a frame starts, the value of the frame counter is captured and stored to the CFC bit field of the NFCRx register. After the successful transfer of the frame the captured value is copied to the CFCVAL bit field of the MOIPRn register of the message object involved in the transfer.
- **Bit Timing Mode:**
  Used for baud rate detection and analysis of the bit timing (**Chapter 21.4.8.3**).
- **Error Count Mode:**
  The frame counter is incremented when an error frame is received or an error is detected by the node (010_B to 110_B) (see **Table 21-12** for **Encoding of the LEC Bit field**). If the NFCRx.CFCIE interrupt bit is enabled, the NFCRx.CFCOV overflow flag will be set when the frame counter overflows.

21.4.6.5 Node Timing Functions

A CAN node offers the following timing functions:

- A receive time-out mode that can detect reception of message objects; the message objects to be supervised are selectable.
- Without CPU involvement, a selectable message object can be transmitted periodically, triggered by a timer, a System Timer (STM) or General Timer Module (GTM).

The clocking options for the node timer is controlled by Node Timer Clock Control Register, **CAN_NTCCRx (x = 0-2)**, the node timing functions for Receive Timeout Mode is controlled by Node x Timer Receive Timeout Register, **CAN_NTRTRx (x = 0-2)** and for Transmit Trigger Mode is controlled by Node x Timer A/B/C Transmit Trigger Registers, **CAN_NTATTRx (x = 0-2)**, **CAN_NTBTTRx (x = 0-2)**, **CAN_NTCTTRx (x = 0-2)**.

Modes with Timer Usage

A CAN node timer is driven by the CAN bit time clock, divided by a prescaler selected via bit field TPSC in the corresponding timer control register. The timers are enabled by writing to the RELOAD bits in the relevant node timer registers; then it decrements from its initial value. The further behavior depends on the selected timer mode:

- **Receive Timeout Mode:**
  By setting bit MOFCRn.RXTOE, a receive time-out check is enabled for message object n, which may be a receive or remote data object. If any of the participating message objects is received before the timer is 0, the timer will be reloaded. When the timer reaches 0, it will stop. Bit TE in NTRTRx register will be set. With bit TEIE = 1, a node interrupt will be generated.
- **Transmit Trigger Mode:**
  When the timer reaches 0, Bit MOSTATn.TXRQ of the message object n selected by bit field TXMO in the timer control register will be set.

Transmit Trigger by System Timer or General Timer Module

For Node x Timer the trigger for transmission of a message can also be set by a System Timer (STM) trigger event or General Timer Module (GTM) trigger event. See **Figure 21-13**.
Bit NTCCRx.TRIGSRC in the timer clock control register enables this feature and the timer is started once values are written to the RELOAD bits of the relevant NTATTx, NTBTTx, or NTCTTx registers. In transmit trigger mode, when a trigger event occurs (STM or GTM), the node timer will be decremented per trigger event timing prescaled by (TPSC+1) till it reaches zero where Bit MOSTATn.TXRQ of the message object n selected by bit field TXMO in the timer control register will be set.

Note: The transmit request bits (i.e NTATTx.TXMO / NTBTTx.TXMO / NTCTTx.TXMO) in the timer control register of a node is able to trigger transmit request (MOSTATn.TXRQ) of message object in a list belonging to any other CAN nodes.

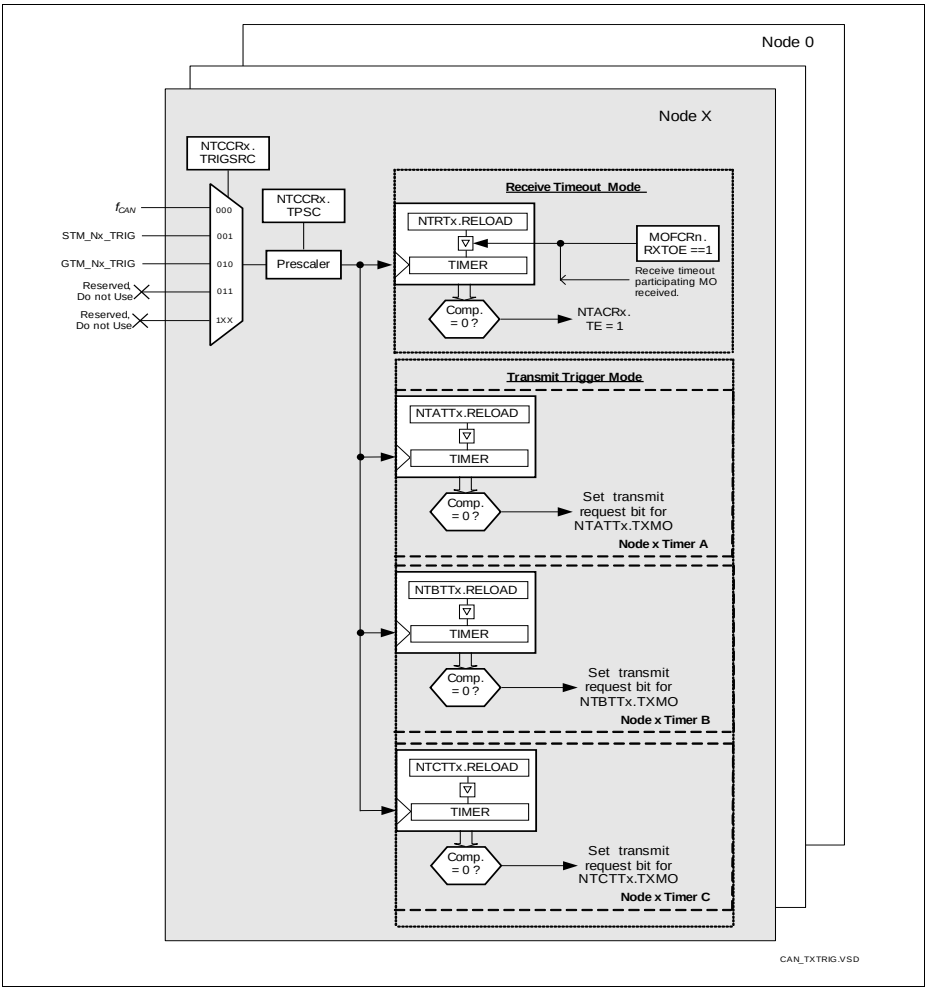

Figure 21-13 CAN Node Timing Modes

21.4.6.6 CAN Node Interrupts

Each CAN node has four five hardware triggered interrupt request types that are able to generate an interrupt request upon:

- The successful transmission or reception of a frame
- A CAN protocol error with a last error code
- An alert condition: Transmit/receive error counters reach the warning limit, bus-off state changes, a List Length Error occurs, or a List Object Error occurs
- An overflow of the frame counter
- A node timer A, C or D event

Besides the hardware generated interrupts, software initiated interrupts can be generated using the Module Interrupt Trigger Register MITR. Writing a 1 to bit n of bit field MITR.IT generates an interrupt request signal on the corresponding interrupt output line INT_On. When writing MITR.IT more than one bit can be set resulting in activation of multiple INT_On interrupt output lines at the same time. See also **“Interrupt Control” on Page 21-174** for further processing of the CAN node interrupts.

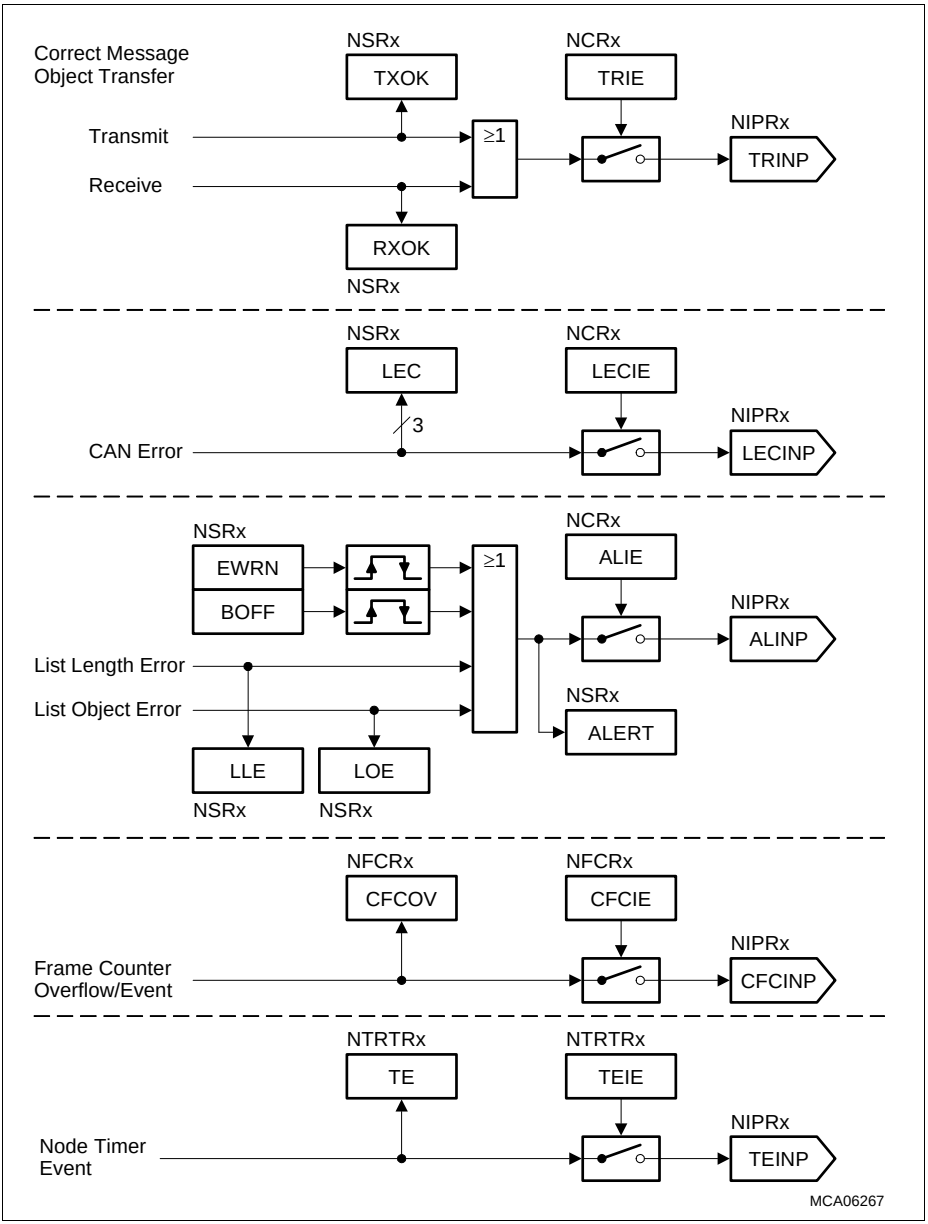

Figure 21-14 CAN Node Interrupts

21.4.7 Message Object List Structure

This section describes the structure of the message object lists in the MultiCAN+ module.

21.4.7.1 Basics

The message objects of the MultiCAN+ module are organized in double-chained lists, where each message object has a pointer to the previous message object in the list as well as a pointer to the next message object in the list. The MultiCAN+ module provides 16 lists. Each message object is allocated to one of these lists. In the example in **Figure 21-15**, the three message objects (3, 5, and 16) are allocated to the list with index 2 (List Register LIST2).

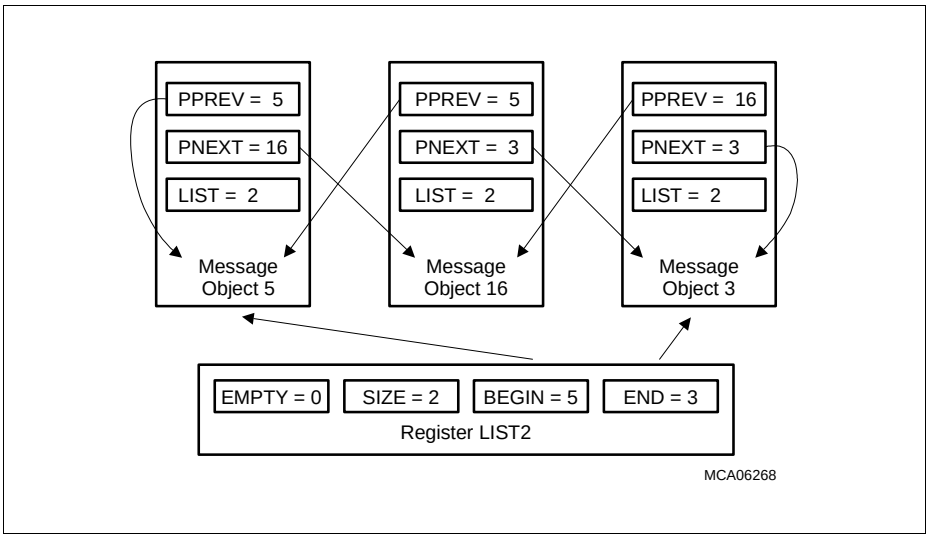

Figure 21-15 Example Allocation of Message Objects to a List

Bit field BEGIN in the List Register (for definition, see **Page 21-87**) points to the first element in the list (object 5 in the example), and bit field END points to the last element in the list (object 3 in the example). The number of elements in the list is indicated by bit field SIZE of the List Register (SIZE = number of list elements - 1, thus SIZE = 2 for the 3 elements in the example). The EMPTY bit of the List Register indicates whether or not a list is empty (EMPTY = 0 in the example, because list 2 is not empty).

Each message object n has a pointer PNEXT in its Message Object n Status Register MOSTATn (see **Page 21-128**) that points to the next message object in the list, and a pointer PPREV that points to the previous message object in the list. PPREV of the first message object points to the message object itself because the first message object has

no predecessor (in the example message object 5 is the first message object in the list, indicated by PPREV = 5). PNEXT of the last message object also points to the message object itself because the last message object has no successor (in the example, object 3 is the last message object in the list, indicated by PNEXT = 3).

Bit field MOSTATn.LIST indicates the list index number to which the message object is currently allocated. The message object of the example are allocated to list 2. Therefore, all LIST bit fields for the message objects assigned to list 2 are set to LIST = 2.

21.4.7.2 List of Unallocated Elements

The list with list index 0 has a special meaning: it is the list of all unallocated elements. An element is called unallocated if it belongs to list 0 (MOSTATn.LIST = 0). It is called allocated if it belongs to a list with an index not equal to 0 (MOSTATn.LIST > 0).

After reset, all message objects are unallocated. This means that they are assigned to the list of unallocated elements with MOSTATn.LIST = 0. After this initial allocation of the message objects caused by reset, the list of all unallocated message objects is ordered by message number (predecessor of message object n is object n-1, successor of object n is object n+1).

21.4.7.3 Connection to the CAN Nodes

Each CAN node is linked to one unique list of message objects. A CAN node performs message transfer only with the message objects that are allocated to the list of the CAN node. This is illustrated in **Figure 21-16**. Frames that are received on a CAN node may only be stored in one of the message objects that belongs to the CAN node; frames to be transmitted on a CAN node are selected only from the message objects that are allocated to that node, as indicated by the vertical arrows.

There are more lists (16) than CAN nodes (3). This means that some lists are not linked to one of the CAN nodes. A message object that is allocated to one of these unlinked lists cannot receive messages directly from a CAN node and it may not transmit messages.

FIFO and gateway mechanisms refer to message numbers and not directly to a specific list. The user must take care that the message objects targeted by FIFO/gateway belong to the desired list. The mechanisms make it possible to work with lists that do not belong to the CAN node.

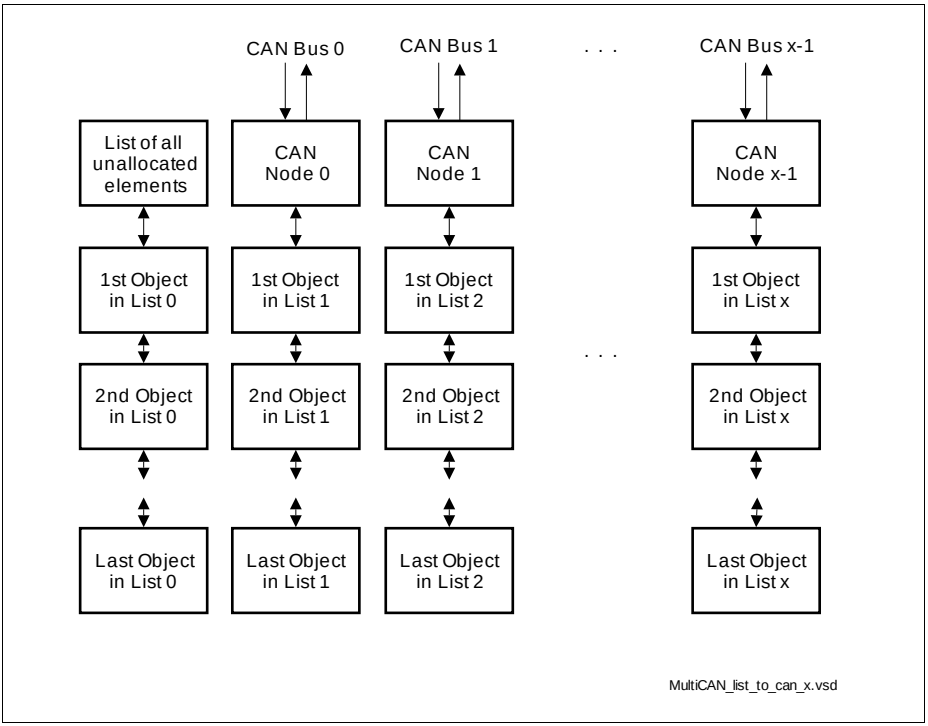

Figure 21-16 Message Objects Linked to CAN Nodes

21.4.7.4 List Command Panel

The list structure cannot be modified directly by write accesses to the LIST registers and the PPREV, PNEXT and LIST bit fields in the Message Object Status Registers, as they are read only. The list structure is managed by and limited to the list controller inside the MultiCAN+ module. The list controller is controlled via a command panel allowing the user to issue list allocation commands to the list controller. The list controller has two main purposes:

1. Ensure that all operations that modify the list structure result in a consistent list structure.
2. Present maximum ease of use and flexibility to the user.

The list controller and the associated command panel allows the programmer to concentrate on the final properties of the list, which are characterized by the allocation of message objects to a CAN node, and the ordering relation between objects that are allocated to the same list. The process of list (re-)building is done in the list controller.

Table 21-7 gives an overview on the available panel commands while Table 21-11 on Page 21-81 describes the panel commands in more detail.

Table 21-7 Panel Commands Overview

Command Name	Description
No Operation	No new command is started.
Initialize Lists	Run the initialization sequence to reset the CTRL and LIST field of all message objects.
Static Allocate	Allocate message object to a list.
Dynamic Allocate	Allocate the first message object of the list of unallocated objects to the selected list.
Static Insert Before	Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object.
Dynamic Insert Before	Insert a new message object before a given destination object.
Static Insert Behind	Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object.
Dynamic Insert Behind	Insert a new message object behind a given destination object.

A panel command is started by writing the respective command code into the Panel Control Register bit field PANCTR.PANCMD (see Page 21-80). The corresponding command arguments must be written into bit fields PANCTR.PANAR1 and PANCTR.PANAR2 before writing the command code, or latest along with the command code in a single 32-bit write access to the Panel Control Register.

With the write operation of a valid command code, the PANCTR.BUSY flag is set and further write accesses to the Panel Control Register are ignored. The BUSY flag remains active and the control panel remains locked until the execution of the requested command has been completed. After a reset and resetting the CLC.DISR (see Page 21-167) register, the list controller builds up list 0. Afterwards the BUSY bit is set, dependent on core speed this might be visible. During list controller initialization, BUSY is set and other accesses to the CAN RAM are forbidden. The CAN RAM can be accessed again when BUSY becomes inactive.

Note: The CAN RAM is automatically initialized after reset by the list controller in order to ensure correct list pointers in each message object. The end of this CAN RAM initialization is indicated by bit PANCTR.BUSY becoming inactive.

In case of a dynamic allocation command that takes an element from the list of unallocated objects, the PANCTR.RBUSY bit is also set along with the BUSY bit (RBUSY = BUSY = 1). This indicates that bit fields PANAR1 and PANAR2 are going to be updated by the list controller in the following way:

1. The message number of the message object taken from the list of unallocated elements is written to PANAR1.
2. If ERR (bit 7 of PANAR2) is set to 1, the list of unallocated elements was empty and the command is aborted. If ERR is 0, the list was not empty and the command will be performed successfully.

The results of a dynamic allocation command are written before the list controller starts the actual allocation process. As soon as the results are available, RBUSY becomes inactive (RBUSY = 0) again, while BUSY still remains active until completion of the command. This allows the user to set up the new message object while it is still in the process of list allocation. The access to message objects is not limited during ongoing list operations. However, any access to a register resource located inside the RAM delays the ongoing allocation process by one access cycle.

As soon as the command is finished, the BUSY flag becomes inactive (BUSY = 0) and write accesses to the Panel Control Register are enabled again. Also, the “No Operation” command code is automatically written to the PANCTR.PANCMD field. A new command may be started any time when BUSY = 0.

All fields of the Panel Control Register PANCTR except BUSY and RBUSY may be written by the user. This makes it possible to save and restore the Panel Control Register if the Command Panel is used within independent (mutually interruptible) interrupt service routines. If this is the case, any task that uses the Command Panel and that may interrupt another task that also uses the Command Panel should poll the BUSY flag until it becomes inactive and save the whole PANCTR register to a memory location before issuing a command. At the end of the interrupt service routine, the task should restore PANCTR from the memory location.

Before a message object that is allocated to the list of an active CAN node shall be moved to another list or to another position within the same list, bit MOSTATn.MSGVAL (“Message Valid”) of message object n must be cleared.

21.4.8 CAN Node Analyzer Mode

The chapter describes the CAN node analyzer capabilities of the MultiCAN+ module.

21.4.8.1 Analyzer Mode

The CAN Analyzer Mode makes it possible to monitor the CAN traffic for each CAN node individually without affecting the logical state of the CAN bus. The CAN Analyzer Mode for CAN node x is selected by setting Node x Control Register bit NCRx.CALM.

In CAN Analyzer Mode, the transmit pin of a CAN node is held at a recessive level permanently. The CAN node may receive frames (Data, Remote, and Error Frames) but is not allowed to transmit. Received Data/Remote Frames are not acknowledged (i.e. acknowledge slot is sent recessive) but will be received and stored in matching message objects as long as there is any other node that acknowledges the frame. The complete message object functionality is available, but no transmit request will be executed. CAN Analyzer mode works for both Classical CAN format and CAN FD format.

21.4.8.2 Loop-Back Mode

The MultiCAN+ module provides a Loop-Back Mode to enable an in-system test of the MultiCAN+ module as well as the development of CAN driver software without access to an external CAN bus.

The loop-back feature consists of an internal CAN bus (inside the MultiCAN+ module) and a bus select switch for each CAN node (see **Figure 21-17**). With the switch, each CAN node can be connected either to the internal CAN bus (Loop-Back Mode activated) or the external CAN bus, respectively to transmit and receive pins (normal operation). The CAN bus that is not currently selected is driven recessive; this means the transmit pin is held at 1, and the receive pin is ignored by the CAN nodes that are in Loop-Back Mode.

The Loop-Back Mode is selected for CAN node x by setting the Node x Port Control Register bit NPCRx.LBM. All CAN nodes that are in Loop-Back Mode may communicate together via the internal CAN bus without affecting the normal operation of the other CAN nodes that are not in Loop-Back Mode.

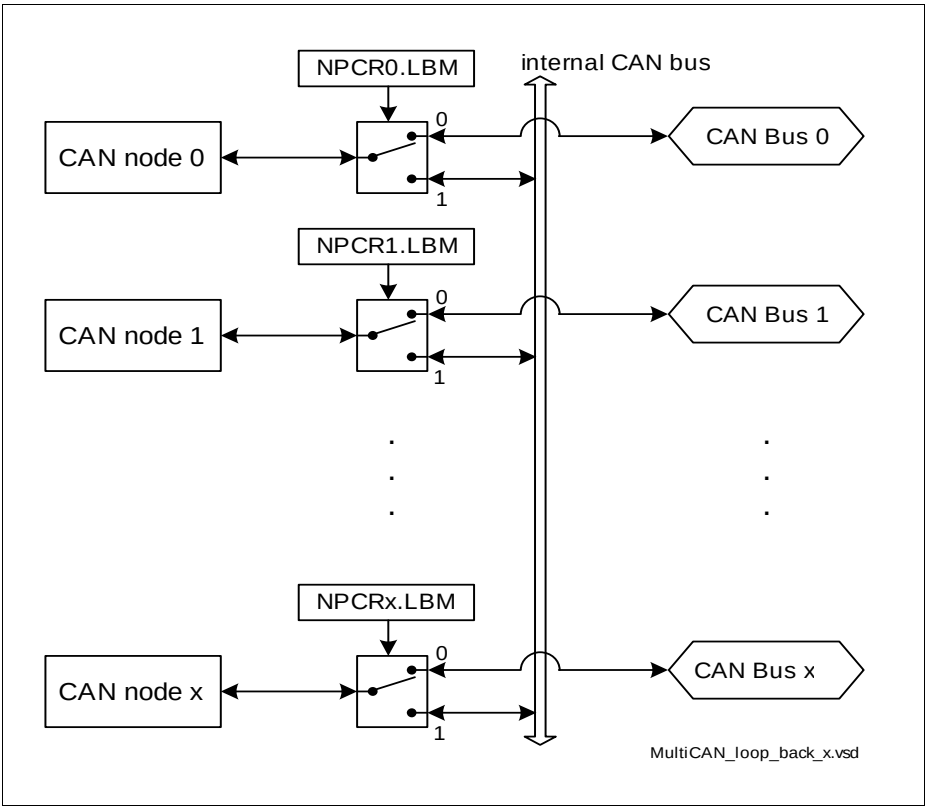

Figure 21-17 Loop-Back Mode

21.4.8.3 Bit Timing Analysis

Detailed analysis of the bit timing can be performed for each CAN node using the analysis modes of the CAN frame counter. The bit timing analysis functionality of the frame counter may be used for automatic detection of the CAN baud rate, as well as to analyze the timing of the CAN network.

Bit timing analysis for CAN node x is selected when bit field NFCRx.CFMOD = 10_B. Bit timing analysis does not affect the operation of the CAN node.

The bit timing measurement results are written into the NFCRx.CFC bit field. Whenever NFCRx.CFC is updated in bit timing analysis mode, bit NFCRx.CFCOV is also set to indicate the CFC update event. The value of NFCRx.CFC is valid one module cycle later when NFCRx.CFCOV is set. If NFCRx.CFCIE is set, an interrupt request can be generated (see **Figure 21-14**).

Automatic Baud Rate Detection

For automatic baud rate detection, the time between the observation of subsequent dominant edges on the CAN bus must be measured. This measurement is automatically performed if bit field NFCRx.CFSEL = 000_B. With each dominant edge monitored on the CAN receive input line, the time (measured in f_{CAN} clock cycles) between this edge and the most recent dominant edge is stored in the NFCRx.CFC bit field.

Synchronization Analysis

The bit time synchronization is monitored if NFCRx.CFSEL = 010_B. The time between the first dominant edge and the sample point is measured and stored in the NFCRx.CFC bit field. The bit timing synchronization offset may be derived from this time as the first edge after the sample point triggers synchronization and there is only one synchronization between consecutive sample points.

Synchronization analysis can be used, for example, for fine tuning of the baud rate during reception of the first CAN frame with the measured baud rate.

Driver Delay Measurement

The delay between a transmitted edge and the corresponding received edge is measured when NFCRx.CFSEL = 011_B (dominant to dominant) and NFCRx.CFSEL = 100_B (recessive to recessive). These delays indicate the time needed to represent a new bit value on the physical implementation of the CAN bus.

21.4.9 Message Acceptance Filtering

The chapter describes the Message Acceptance Filtering capabilities of the MultiCAN+ module.

21.4.9.1 Receive Acceptance Filtering

When a CAN frame is received by a CAN node, a unique message object is determined in which the received frame is stored after successful frame reception. A message object is qualified for reception of a frame if the following six conditions are met.

- The message object is allocated to the message object list of the CAN node by which the frame is received.
- Bit MOSTATn.MSGVAL in the Message Object Status Register (see **Page 21-128**) is set.
- Bit MOSTATn.RXEN is set.
- Bit MOSTATn.DIR is equal to bit RTR of the received frame.
  If bit MOSTATn.DIR = 1 (transmit object), the message object accepts only Remote Frames. If bit MOSTATn.DIR = 0 (receive object), the message object accepts only Data Frames.

- If bit MOAMRn.MIDE = 1, the IDE bit of the received frame becomes evaluated in the following way: If MOARn.IDE = 1, the IDE bit of the received frame must be set (indicates extended identifier). If MOARn.IDE = 0, the IDE bit of the received frame must be cleared (indicates standard identifier).
  If bit MOAMRn.MIDE = 0, the IDE bit of the received frame is “don’t care”. In this case, message objects with standard and extended frames are accepted.
- The identifier of the received frame matches the identifier stored in the Arbitration Register of the message object as qualified by the acceptance mask in the MOAMRn register. This means that each bit of the received message object identifier is equal to the bit field MOARn.ID, except those bits for which the corresponding acceptance mask bits in bit field MOAMRn.AM are cleared. These identifier bits are “don’t care” for reception. **Figure 21-18** illustrates this receive message identifier check.

Among all messages that fulfill all six qualifying criteria the message object with the highest receive priority wins receive acceptance filtering and becomes selected to store the received frame. All other message objects lose receive acceptance filtering.
The following priority scheme is defined for the message objects:
A message object a (MOa) has higher receive priority than a message object b (MOb) if the following two conditions are fulfilled (see **Page 21-145**):

1. MOa has a higher priority class than MOb. This means, the 2-bit priority bit field MOARa.PRI must be equal or less than bit field MOARb.PRI.
2. If both message objects have the same priority class (MOARa.PRI = MOARb.PRI), MOb is a list successor of MOa. This means that MOb can be reached by means of successively stepping forward in the list, starting from a.

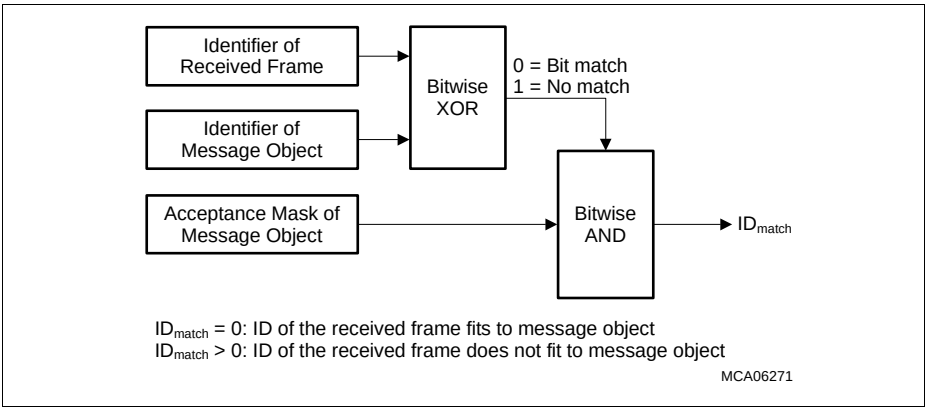

Figure 21-18 Received Message Identifier Acceptance Check

21.4.9.2 Transmit Acceptance Filtering

A message is requested for transmission by setting a transmit request in the message object that holds the message. If more than one message object have a valid transmit request for the same CAN node, one of these message objects is chosen for transmission, because only a single message object can be transmitted at one time on a CAN bus.

A message object is qualified for transmission on a CAN node if the following four conditions are met (see also **Figure 21-19**).

1. The message object is allocated to the message object list of the CAN node.
2. Bit MOSTATn.MSGVAL is set.
3. Bit MOSTATn.TXRQ is set.
4. Bit MOSTATn.TXEN0 and MOSTATn.TXEN1 are set.

A priority scheme determines which one of all qualifying message objects is transmitted first. It is assumed that message object a (MOa) and message object b (MOb) are two message objects qualified for transmission. MOb is a list successor of MOa. For both message objects, CAN messages CANa and CANb are defined (identifier, IDE, and RTR are taken from the message-specific bit fields and bits MOARn.ID, MOARn.IDE and MOSTATn.DIR).
If both message objects belong to the same priority class (identical PRI bit field in register MOARn), MOa has a higher transmit priority than MOb if one of the following conditions is fulfilled.

- PRI = 10_B and CAN message MOa has higher or equal priority than CAN message MOb with respect to CAN arbitration rules (see **Table 21-19** on **Page 21-146**).
- PRI = 01_B or PRI = 11_B (priority by list order).

The message object that is qualified for transmission and has highest transmit priority wins the transmit acceptance filtering, and will be transmitted first. All other message objects lose the current transmit acceptance filtering round. They get a new chance in subsequent acceptance filtering rounds.

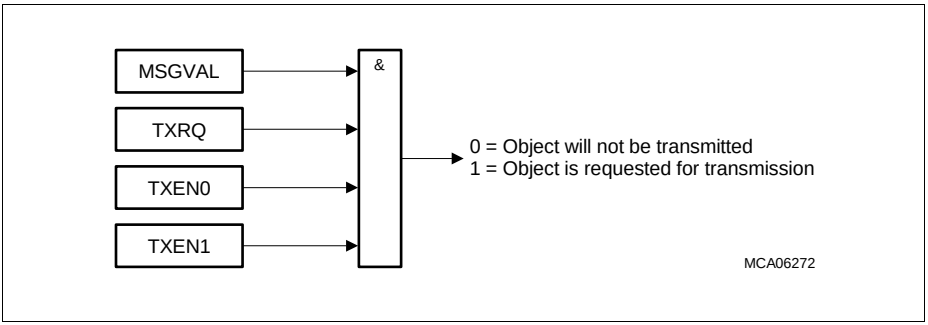

Figure 21-19 Effective Transmit Request of Message Object

21.4.10 Message Postprocessing

After a message object has successfully received or transmitted a frame, the CPU can be notified to perform a postprocessing on the message object. The postprocessing of the MultiCAN+ module consists of two elements:

1. Message interrupts to trigger postprocessing.
2. Message pending registers to collect pending message interrupts into a common structure for postprocessing.

21.4.10.1 Message Object Interrupts

When the storage of a received frame into a message object or the successful transmission of a frame is completed, a message interrupt can be issued. For each message object, a transmit and a receive interrupt can be generated and routed to one of the sixteen CAN interrupt output lines (see **Figure 21-20**). A receive interrupt occurs also after a frame storage event that has been induced by a FIFO or a gateway action. The status bits TXPND and RXPND in the Message Object n Status Register are always set after a successful transmission/reception, whether or not the respective message interrupt is enabled.

A third FIFO full interrupt condition of a message object is provided. If bit field MOFCRn.OVIE (Overflow Interrupt Enable) is set, the FIFO full interrupt will be activated depending on the actual message object type.

In case of a Receive FIFO Base Object (MOFCRn.MMC = 0001_B), the FIFO full interrupt is routed to the interrupt output line INT_Om as defined by the transmit interrupt node pointer MOIPRn.TXINP.

In case of a Transmit FIFO Base Object (MOFCRn.MMC = 0010_B), the FIFO full interrupt becomes routed to the interrupt output line INT_Om as defined by the receive interrupt node pointer MOIPRn.RXINP.

See also **“Interrupt Control” on Page 21-174** for further processing of the message object interrupts.

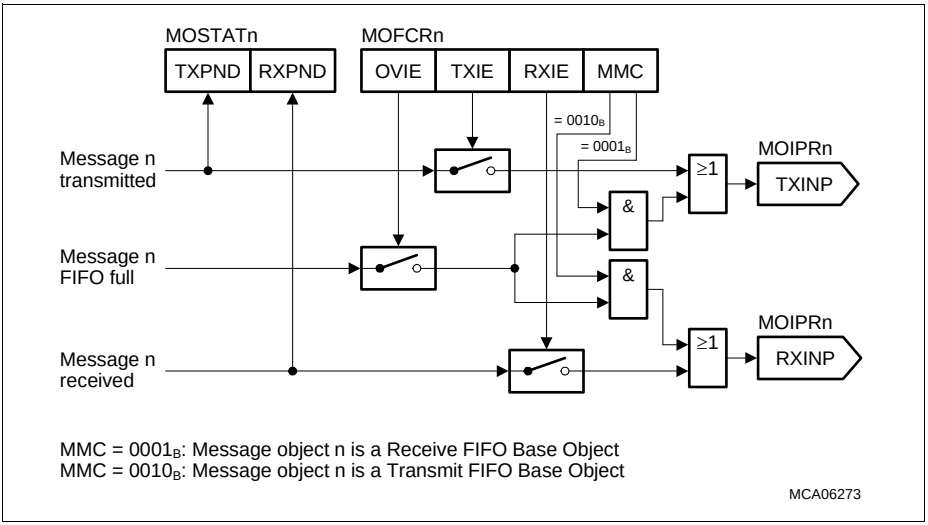

Figure 21-20 Message Interrupt Request Routing

21.4.10.2 Pending Messages

When a message interrupt request is generated, a message pending bit is set in one of the Message Pending Registers. There are 8 Message Pending Registers, MSPNDk (k = 0-7) with 32 pending bits available each. The general **Figure 21-21** shows the allocation of the message pending bits in case that the maximum possible number of eight Message Pending Registers are implemented and available on the chip.

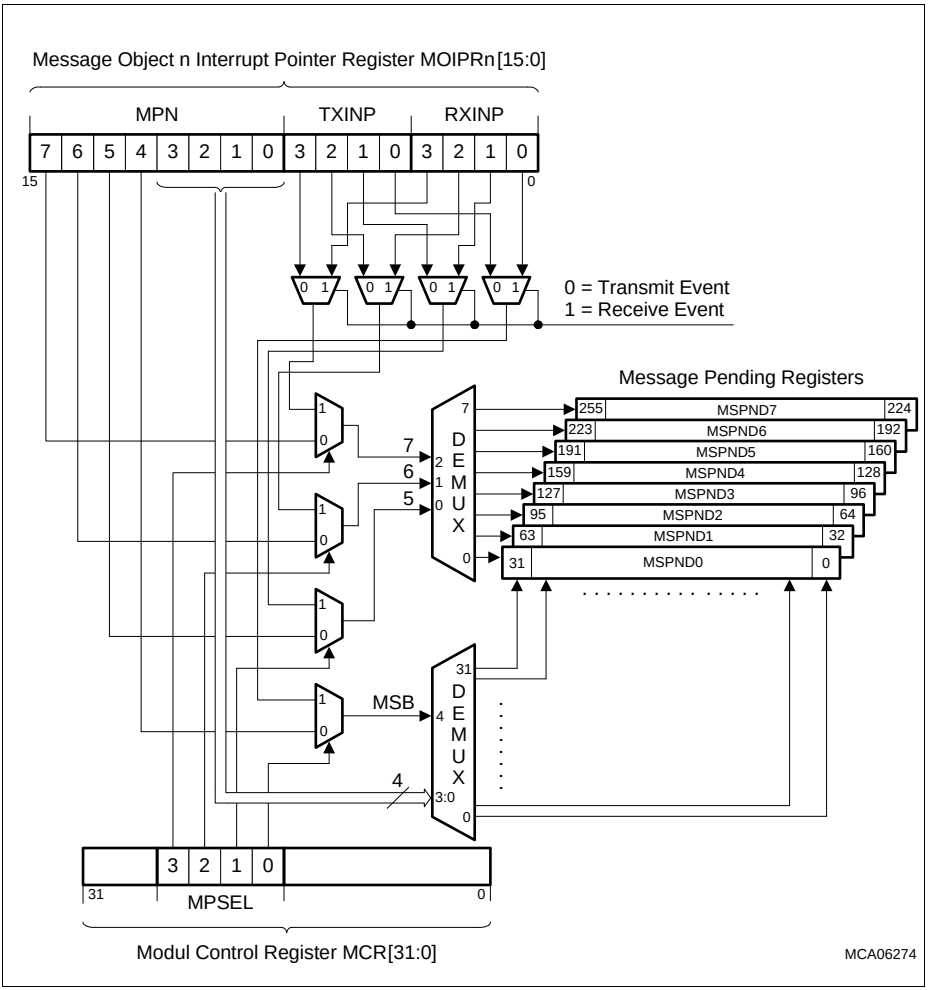

Figure 21-21 Message Pending Bit Allocation

The location of a pending bit is defined by two demultiplexers selecting the number k of the MSPNDk registers (3-bit demux), and the bit location within the corresponding MSPNDk register (5-bit demux).

Allocation Case 1

In this allocation case, bit field MCR.MPSEL = 0000_B (see **Page 21-84**). The location selection consists of 2 parts:

- The upper three bits of MOIPRn.MPN (MPN[7:5]) select the number k of a Message Pending Register MSPNDk in which the pending bit will be set.
- The lower five bits of MOIPRn.MPN (MPN[4:0]) select the bit position (0-31) in MSPNDk for the pending bit to be set.

Allocation Case 2

In this allocation case, bit field MCR.MPSEL is taken into account for pending bit allocation. Bit field MCR.MPSEL makes it possible to include the interrupt request node pointer for reception (MOIPRn.RXINP) or transmission (MOIPRn.TXINP) for pending bit allocation in such a way that different target locations for the pending bits are used in receive and transmit case. If MPSEL = 1111_B, the location selection operates in the following way:

- At a transmit event, the upper 3 bits of TXINP determine the number k of a Message Pending Register MSPNDk in which the pending bit will be set. At a receive event, the upper 3 bits of RXINP determine the number k.
- The bit position (0-31) in MSPNDk for the pending bit to be set is selected by the lowest bit of TXINP or RXINP (selects between low and high half-word of MSPNDk) and the four least significant bits of MPN.

General Hints

The Message Pending Registers MSPNDk can be written by software. Bits that are written with 1 are left unchanged, and bits which are written with 0 are cleared. This makes it possible to clear individual MSPNDk bits with a single register write access. Therefore, access conflicts are avoided when the MultiCAN+ module (hardware) sets another pending bit at the same time when software writes to the register.

Each Message Pending Register MSPNDk is associated with a Message Index Register MSIDk (see **Page 21-90**) which indicates the lowest bit position of all set (1) bits in Message Pending Register k. The MSIDk register is a read-only register that is updated immediately when a value in the corresponding Message Pending Register k is changed by software or hardware.

21.4.11 Message Object Data Handling

This chapter describes the handling capabilities for the Message Object Data of the MultiCAN+ module.

21.4.11.1 Frame Reception

After the reception of a message, it is stored in a message object according to the scheme shown in **Figure 21-22**. The MultiCAN+ module not only copies the received data into the message object, and it provides advanced features to enable consistent data exchange between MultiCAN+ and CPU.

MSGVAL

Bit MSGVAL (Message Valid) in the Message Object n Status Register MOSTATn is the main switch of the message object. During the frame reception, information is stored in the message object only when MSGVAL = 1. If bit MSGVAL is reset by the CPU, the MultiCAN+ module stops all ongoing write accesses to the message object. Now the message object can be re-configured by the CPU with subsequent write accesses to it without being disturbed by the MultiCAN+.

RTSEL

When the CPU re-configures a message object during CAN operation (for example, clears MSGVAL, modifies the message object and sets MSGVAL again), the following scenario can occur:

1. The message object wins receive acceptance filtering.
2. The CPU clears MSGVAL to re-configure the message object.
3. The CPU sets MSGVAL again after re-configuration.
4. The end of the received frame is reached. As MSGVAL is set, the received data is stored in the message object, a message interrupt request is generated, gateway and FIFO actions are processed, etc.

After the re-configuration of the message object (after step 3 above) the storage of further received data may be undesirable. This can be achieved through bit MOSTATn.RTSEL (Receive/Transmit Selected) that makes it possible to disconnect a message object from an ongoing frame reception.

When a message object wins the receive acceptance filtering, its RTSEL bit is set by the MultiCAN+ module to indicate an upcoming frame delivery. The MultiCAN+ module checks RTSEL whether it is set on successful frame reception to verify that the object is still ready for receiving the frame. The received frame is then stored in the message object (along with all subsequent actions such as message interrupts, FIFO & gateway actions, flag updates) only if RTSEL = 1.

When a message object is invalidated during CAN operation (resetting bit MSGVAL), RTSEL should be cleared before setting MSGVAL again (latest with the same write

access that sets MSGVAL) to prevent the storage of a frame that belongs to the old context of the message object. Therefore, a message object re-configuration should consist of the following steps:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL bit and set MSGVAL again

RXEN

Bit MOSTATn.RXEN enables a message object for frame reception. A message object can receive CAN messages from the CAN bus only if RXEN = 1. The MultiCAN+ module evaluates RXEN only during receive acceptance filtering. After receive acceptance filtering, RXEN is ignored and has no further influence on the actual storage of a received message in a message object.

Bit RXEN enables the “soft phase out” of a message object: after clearing RXEN, a currently received CAN message for which the message object has won acceptance filtering is still stored in the message object but for subsequent messages the message object no longer wins receive acceptance filtering.

RXUPD, NEWDAT and MSGLST

An ongoing frame storage process is indicated by the RXUPD (Receive Updating) flag in the MOSTATn register. RXUPD is set with the start and cleared with the end of a message object update, which consists of frame storage as well as flag updates.

After storing the received frame (identifier, IDE bit, DLC; including the Data Field for Data Frames), the NEWDAT (New Data) bit of the message object is set. If NEWDAT was already set before it becomes set again, bit MSGLST (Message Lost) is set to indicate a data loss condition.

The RXUPD and NEWDAT flags can help to read consistent frame data from the message object during an ongoing CAN operation. The following steps are recommended to be executed:

1. Clear NEWDAT bit.
2. Read message content (identifier, data etc.) from the message object.
3. Check that both, NEWDAT and RXUPD, are cleared. If this is not the case, go back to step 1.
4. When step 3 was successful, the message object contents are consistent and has not been updated by the MultiCAN+ module while reading.

Bits RXUPD, NEWDAT and MSGLST have the same behavior for the reception of Data as well as Remote Frames.

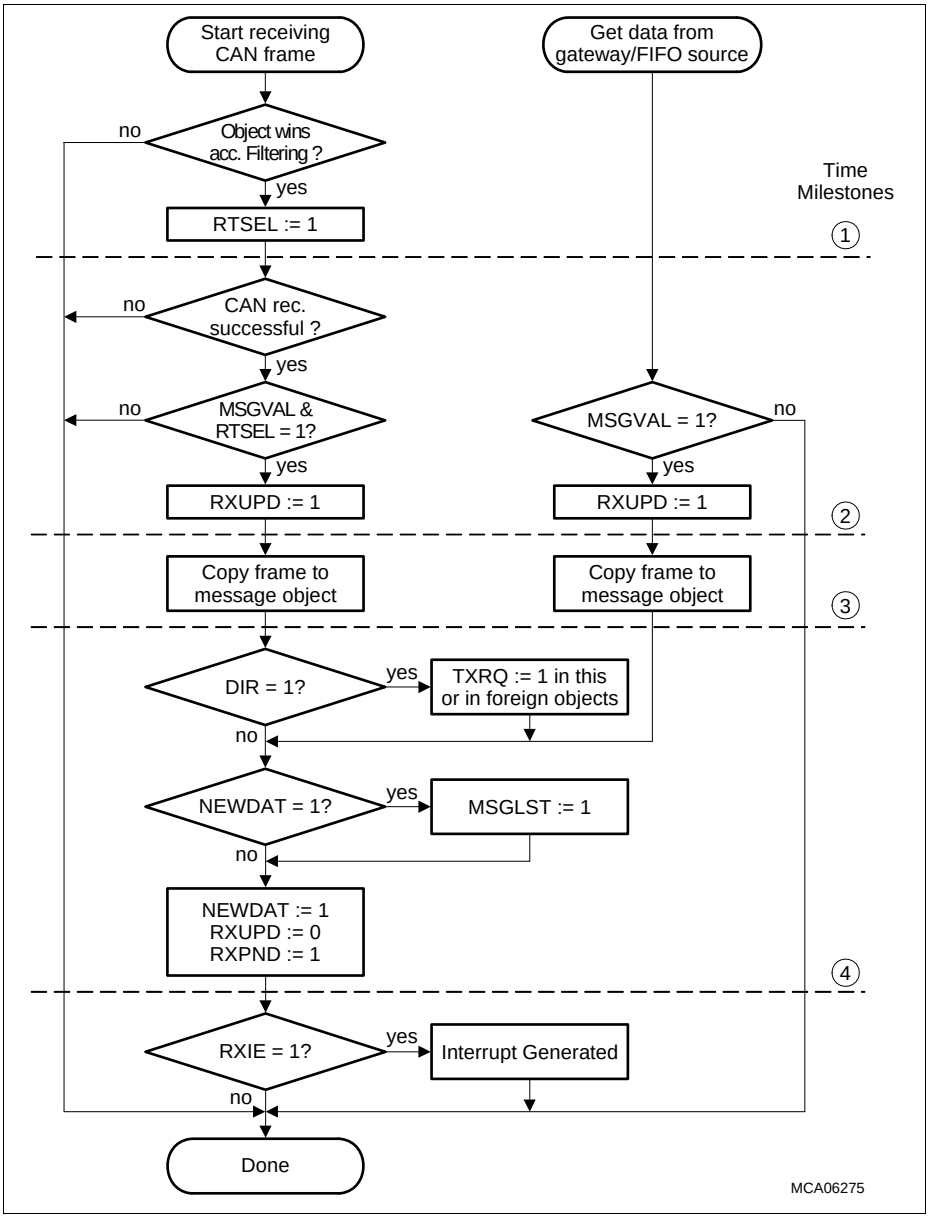

Figure 21-22 Reception of a Message Object

21.4.11.2 Frame Transmission

The process of a message object transmission is shown in **Figure 21-23**. Along with the copy of the message object content to be transmitted (identifier, IDE bit, RTR = DIR bit, DLC, including the Data Field for Data Frames) into the internal transmit buffer of the assigned CAN node, several status flags are also served and monitored to control consistent data handling.

The transmission process of a message object starting after the transmit acceptance filtering is identical for Remote and Data Frames.

MSGVAL, TXRQ, TXEN0, TXEN1

A message can only be transmitted if all four bits in registers MOSTATn, MSGVAL (Message Valid), TXRQ (Transmit Request), TXEN0 (Transmit Enable 0), TXEN1 (Transmit Enable 1) are set as shown in **Figure 21-19**. Although these bits are equivalent with respect to the transmission process, they have different semantics:

Table 21-8 Message Transmission Bit Definitions

Bit	Description
MSGVAL	**Message Valid** This is the main switch bit of the message object.
TXRQ	**Transmit Request** This is the standard transmit request bit. This bit must be set whenever a message object should be transmitted. TXRQ is cleared by hardware at the end of a successful transmission, except when there is new data (indicated by NEWDAT = 1) to be transmitted. When bit MOFCRn.STT (“Single Transmit Trial”) is set, TXRQ becomes already cleared when the contents of the message object are copied into the transmit frame buffer of the CAN node. A received remote request (after a Remote Frame reception) sets bit TXRQ to request the transmission of the requested data frame.
TXEN0	**Transmit Enable 0** This bit can be temporarily cleared by software to suppress the transmission of this message object when it writes new content to the Data Field. This avoids transmission of inconsistent frames that consist of a mixture of old and new data. Remote requests are still accepted when TXEN0 = 0, but transmission of the Data Frame is suspended until transmission is re-enabled by software (setting TXEN0).

Table 21-8 Message Transmission Bit Definitions (cont'd)

Bit	Description
TXEN1	**Transmit Enable 1** This bit is used in transmit FIFOs to select the message object that is transmit active within the FIFO structure. For message objects that are not transmit FIFO elements, TXEN1 can either be set permanently to 1 or can be used as a second independent transmission enable bit.

RTSEL

When a message object has been identified to be transmitted next after transmission acceptance filtering, bit MOSTATn.RTSEL (Receive/Transmit Selected) is set.

When the message object is copied into the internal transmit buffer, bit RTSEL is checked, and the message is transmitted only if RTSEL = 1. After the successful transmission of the message, bit RTSEL is checked again and the message postprocessing is only executed if RTSEL = 1.

For a complete re-configuration of a valid message object, the following steps should be executed:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL and set MSGVAL

Clearing of RTSEL ensures that the message object is disconnected from an ongoing/scheduled transmission and no message object processing (copying message to transmit buffer including clearing NEWDAT, clearing TXRQ, time stamp update, message interrupt, etc.) within the old context of the object can occur after the message object becomes valid again, but within a new context.

NEWDAT

When the contents of a message object have been transferred to the internal transmit buffer of the CAN node, bit MOSTATn.NEWDAT (New Data) is cleared by hardware to indicate that the transmit message object data is no longer new.

When the transmission of the frame is successful and NEWDAT is still cleared (if no new data has been copied into the message object meanwhile), TXRQ (Transmit Request) is cleared automatically by hardware.

If, however, the NEWDAT bit has been set again by the software (because a new frame should be transmitted), TXRQ is not cleared to enable the transmission of the new data.

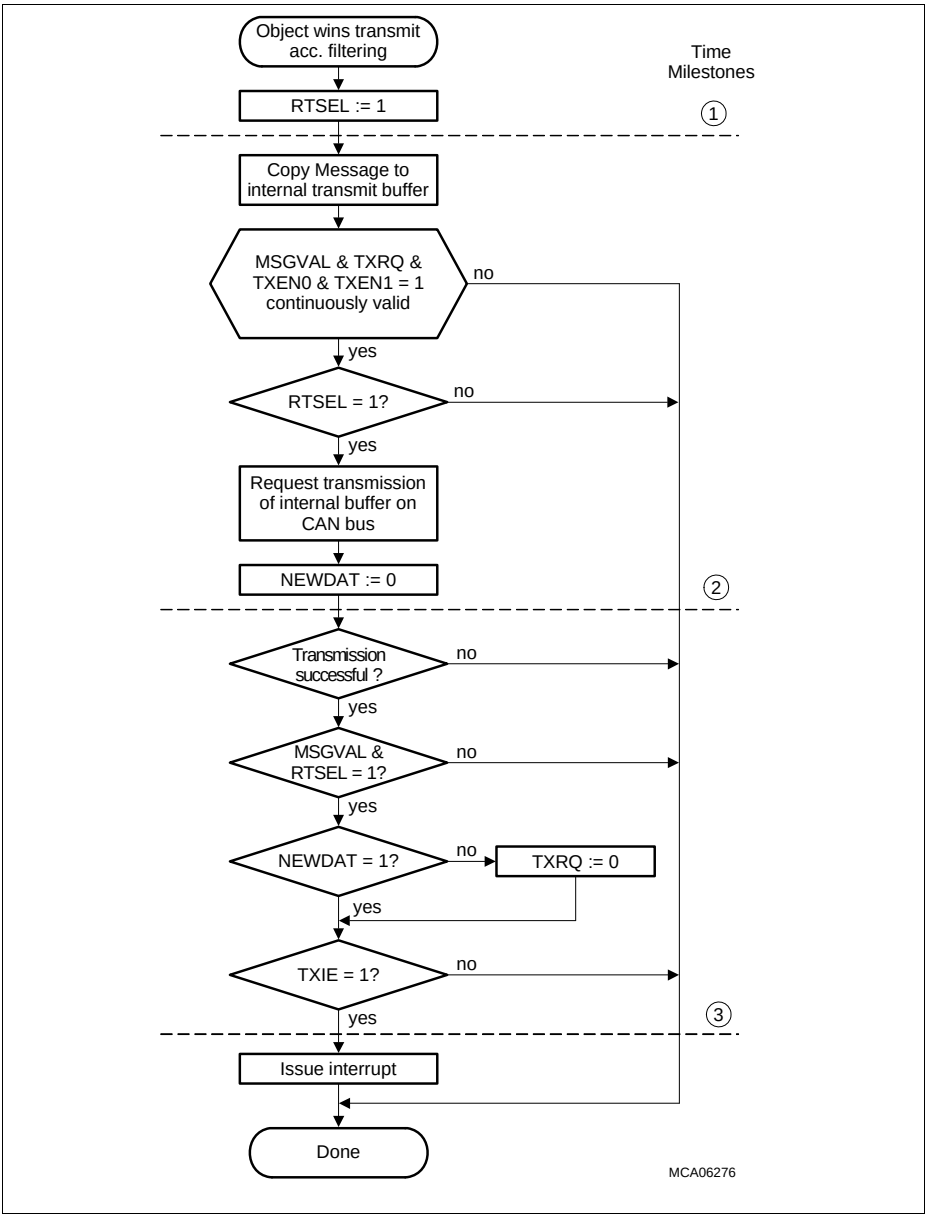

Figure 21-23 Transmission of a Message Object

21.4.12 Message Object Functionality

This chapter describes the functionality of the Message Objects in the MultiCAN+ module.

21.4.12.1 Standard Message Object

A message object is selected as standard message object when bit field MOFCRn.MMC = 0000_B (see **Page 21-114**). The standard message object can transmit and receive CAN frames according to the basic rules described in the previous sections. Additional services such as Single Data Transfer Mode or Single Transmit Trial (see following sections) are available and can be individually selected.

21.4.12.2 Single Data Transfer Mode

Single Data Transfer Mode is a useful feature in order to broadcast data over the CAN bus without unintended duplication of information. Single Data Transfer Mode is selected via bit MOFCRn.SDT.

Message Reception

When a received message stored in a message object is overwritten by a new received message, the contents of the first message are lost and replaced with the contents of the new received message (indicated by MSGLST = 1).

If SDT is set (Single Data Transfer Mode activated), bit MSGVAL of the message object is automatically cleared by hardware after the storage of a received Data or Remote Frame. This prevents the reception of further messages.

Message Transmission

When a message object receives a series of multiple remote requests, it transmits several Data Frames in response to the remote requests. If the data within the message object has not been updated in the time between the transmissions, the same data can be sent more than once on the CAN bus.

In Single Data Transfer Mode (SDT = 1), this is avoided because MSGVAL is automatically cleared after the successful transmission of a Data or Remote Frame.

21.4.12.3 Single Transmit Trial

If the bit STT in the message object function register is set (STT = 1), the transmission request is cleared (TXRQ = 0) when the frame contents of the message object have been copied to the internal transmit buffer of the CAN node. Thus, the transmission of the message object is not tried again when it fails due to CAN bus errors.

21.4.12.4 Message Object Format (Classical CAN & CAN FD)

Message objects are used for transmission or reception of CAN data frames. The transmit and receive behavior of a Classical CAN node in Classical CAN (ISO 11898-1:2003(E)) or CAN FD (ISO11898-1 DIS version 2014) are determined by a node control register bit (i.e NCRx.FDEN) and two message object function control register bits (i.e MOFCRn.FDF and MOFCRn.BRS) as shown in **Table 21-18**.

A CAN node which has been set to work in Classical CAN mode i.e (NCRx.FDEN = 0) would be able to transmit message objects programmed for Classical CAN Frames (i.e MOFCRn.FDF = 0, MOFCRn.BRS = 0/1) only. When receiving Classical CAN data frames in a node that works in Classical CAN mode the message object function control register bits (i.e MOFCRn.FDF and MODFCRn.BRS) are not used and not updated.

In the case when a CAN node set to work in a particular mode (e.g Classical CAN mode) and receives a message object request for transmission or reception that does not correspond with the CAN mode (i.e MOFCRn.FDF = 1, MOFCRn.BRS = 0/1), the transmission would be cancelled (i.e corresponding MOSTATn.TXRQ cleared) and CAN frame not received in message object. The CAN node is not blocked and able to transmit or receive other message objects.

However a CAN node that has been set to work in CAN FD mode i.e (NCRx.FDEN = 1) is able to transmit and receive Classical CAN Data Frames, Long Data Frames or Long + Fast Data Frames. For message object transmission, message object function control bits (i.e MOFCRn.FDF & MOFCRn.BRS) determines the CAN frame format to be used and functions as status register bits during message reception.

Note: Remote Frame Requests do not change MOFCRn.FDF and MOFCRn.BRS bits.

21.4.12.5 Message Object FIFO Structure

In case of high CPU load it may be difficult to process a series of CAN frames in time. This may happen if multiple messages are received or must be transmitted in short time.

Therefore, a FIFO buffer structure is available to avoid loss of incoming messages and to minimize the setup time for outgoing messages. The FIFO structure can also be used to automate the reception or transmission of a series of CAN messages and to generate a single message interrupt when the whole CAN frame series is done.

There can be several FIFOs in parallel. The number of FIFOs and their size are limited only by the number of available message objects. A FIFO can be installed, resized and de-installed at any time, even during CAN operation.

The basic structure of a FIFO is shown in **Figure 21-24**. A FIFO consists of one base object and n slave objects. The slave objects are chained together in a list structure (similar as in message object lists). The base object may be allocated to any list. Although **Figure 21-24** shows the base object as a separate part beside the slave objects, it is also possible to integrate the base object at any place into the chain of slave objects. This means that the base object is slave object, too (not possible for gateways).

The absolute object numbers of the message objects have no impact on the operation of the FIFO.

The base object does not need to be allocated to the same list as the slave objects. Only the slave object must be allocated to a common list (as they are chained together). Several pointers (BOT, CUR and TOP) that are located in the Message Object n FIFO/Gateway Pointer Register MOFGPRn link the base object to the slave objects, regardless whether the base object is allocated to the same or to another **list** than the slave objects.

The smallest FIFO would be a single message object which is both, FIFO base and FIFO slave (not very useful). The biggest possible FIFO structure would include all message objects of the MultiCAN+ module. Any FIFO sizes between these limits are possible.

In the FIFO base object, the FIFO boundaries are defined. Bit field MOFGPRn.BOT of the base object points to (includes the number of) the bottom slave object in the FIFO structure. The MOFGPRn.TOP bit field points to (includes the number of) the top slave object in the FIFO structure. The MOFGPRn.CUR bit field points to (includes the number of) the slave object that is actually selected by the MultiCAN+ module for message transfer. When a message transfer takes place with this object, CUR is set to the next message object in the list structure of the slave objects (CUR = PNEXT of current object). If CUR was equal to TOP (top of the FIFO reached), the next update of CUR will result in CUR = BOT (wrap-around from the top to the bottom of the FIFO). This scheme represents a circular FIFO structure where the bit fields BOT and TOP establish the link from the last to the first element.

Bit field MOFGPRn.SEL of the base object can be used for monitoring purposes. It makes it possible to define a slave object within the list at which a message interrupt is generated whenever the CUR pointer reaches the value of the SEL pointer. Thus SEL makes it possible to detect the end of a predefined message transfer series or to issue a warning interrupt when the FIFO becomes full.

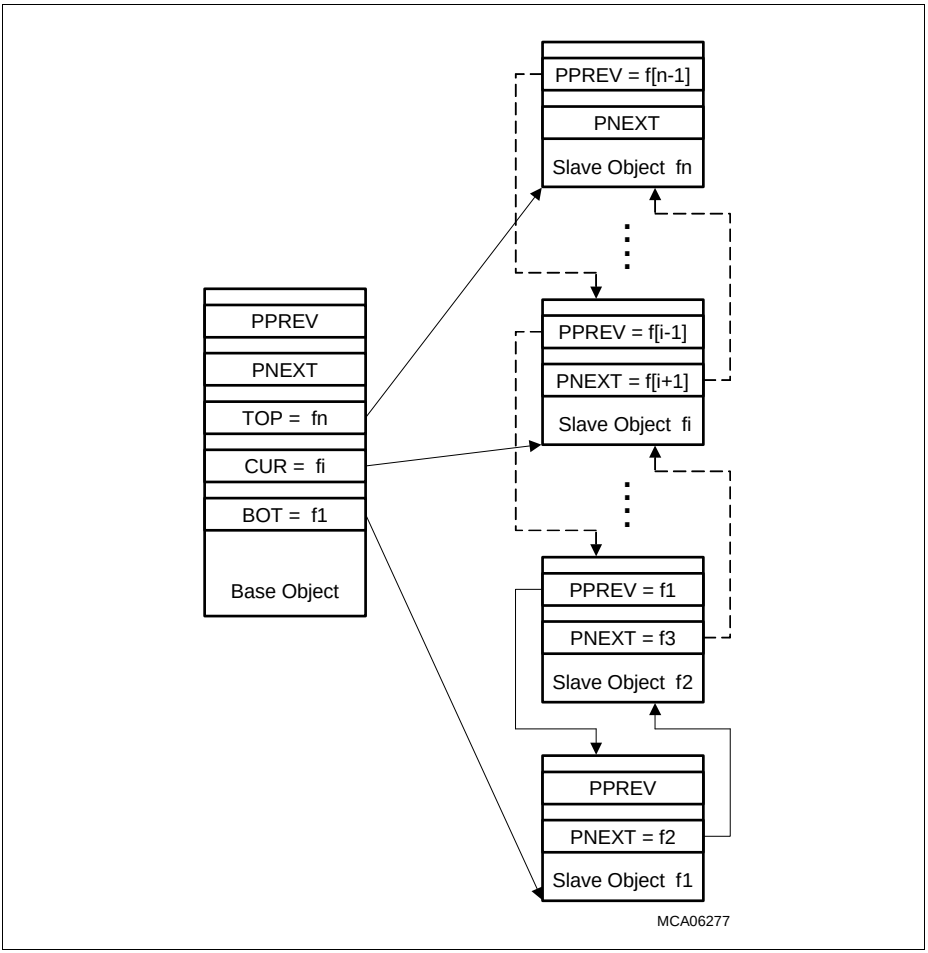

Figure 21-24 FIFO Structure with FIFO Base Object and n FIFO Slave Objects

21.4.12.6 Receive FIFO

The Receive FIFO structure is used to buffer incoming (received) Remote or Data Frames.

A Receive FIFO is selected by setting MOFCRn.MMC = 0001_B in the FIFO base object. This MMC code automatically designates a message object as FIFO base object. The message modes of the FIFO slave objects are not relevant for the operation of the Receive FIFO.

When the FIFO base object receives a frame from the CAN node it belongs to, the frame is not stored in the base object itself but in the message object that is selected by the base object's MOFGPRn.CUR pointer. This message object receives the CAN message as if it is the direct receiver of the message. However, MOFCRn.MMC = 0000_B is implicitly assumed for the FIFO slave object, and a standard message delivery is performed. The actual message mode (MMC setting) of the FIFO slave object is ignored. For the slave object, no acceptance filtering takes place that checks the received frame for a match with the identifier, IDE bit, and DIR bit.

With the reception of a CAN frame, the current pointer CUR of the base object is set to the number of the next message object in the FIFO structure. This message object will then be used to store the next incoming message.

If bit field MOFCRn.OVIE ("Overflow Interrupt Enable") of the FIFO base object is set and the current pointer MOFGPRn.CUR becomes equal to MOFGPRn.SEL, a FIFO overflow interrupt request is generated. This interrupt request is generated on interrupt node TXINP of the base object immediately after the storage of the received frame in the slave object. Transmit interrupts are still generated if TXIE is set.

A CAN message is stored in FIFO base and slave object only if MSGVAL = 1.

In order to avoid direct reception of a message by a slave message object, as if it was an independent message object and not a part of a FIFO, the bit RXEN of each slave object must be cleared. The setting of the bit RXEN is "don't care" only if the slave object is located in a list not assigned to a CAN node.

21.4.12.7 Transmit FIFO

The Transmit FIFO structure is used to buffer a series of Data or Remote Frames that must be transmitted. A transmit FIFO consists of one base message object and one or more slave message objects.

A Transmit FIFO is selected by setting MOFCRn.MMC = 0010_B in the FIFO base object. Unlike the Receive FIFO, slave objects assigned to the Transmit FIFO must explicitly set their bit fields MOFCRn.MMC = 0011_B. The CUR pointer in all slave objects must point back to the Transmit FIFO Base Object (to be initialized by software).

The MOSTATn.TXEN1 bits (Transmit Enable 1) of all message objects except the one which is selected by the CUR pointer of the base object must be cleared by software. TXEN1 of the message (slave) object selected by CUR must be set. CUR (of the base object) may be initialized to any FIFO slave object.

When tagging the message objects of the FIFO as valid to start the operation of the FIFO, then the base object must be tagged valid (MSGVAL = 1) first.

Before a Transmit FIFO becomes de-installed during operation, its slave objects must be tagged invalid (MSGVAL = 0).

The Transmit FIFO uses the TXEN1 bit in the Message Object Status Register of all FIFO elements to select the actual message for transmission. Transmit acceptance filtering evaluates TXEN1 for each message object and a message object can win transmit acceptance filtering only if its TXEN1 bit is set. When a FIFO object has transmitted a message, the hardware clears its TXEN1 bit in addition to standard transmit postprocessing (clear TXRQ, transmit interrupt etc.), and moves the CUR pointer in the next FIFO base object to be transmitted. TXEN1 is set automatically (by hardware) in the next message object. Thus, TXEN1 moves along the Transmit FIFO structure as a token that selects the active element.

If bit field MOFCRn.OVIE (“Overflow Interrupt Enable”) of the FIFO base object is set and the current pointer CUR becomes equal to MOFGPRn.SEL, a FIFO overflow interrupt request is generated. The interrupt request is generated on interrupt node RXINP of the base object after postprocessing of the received frame. Receive interrupts are still generated for the Transmit FIFO base object if bit RXIE is set.

21.4.12.8 Gateway Mode

The Gateway Mode makes it possible to establish an automatic information transfer between two independent CAN buses without CPU interaction.

The Gateway Mode operates on message object level. In Gateway mode, information is transferred between two message objects, resulting in an information transfer between the two CAN nodes to which the message objects are allocated. A gateway may be established with any pair of CAN nodes, and there can be as many gateways as there are message objects available to build the gateway structure.

Gateway Mode is selected by setting MOFCRs.MMC = 0100_B for the gateway source object s. The gateway destination object d is selected by the MOFGPRd.CUR pointer of the source object. The gateway destination object only needs to be valid (its MSGVAL = 1). All other settings are not relevant for the information transfer from the source object to the destination object.

Gateway source object behaves as a standard message object with the difference that some additional actions are performed by the MultiCAN+ module when a CAN frame has been received and stored in the source object (see **Figure 21-25**):

1. If bit MOFCRs.DLCC is set, the data length code MOFCRs.DLC is copied from the gateway source object to the gateway destination object.
2. If bit MOFCRs.IDC is set, the identifier MOARs.ID and the identifier extension MOARs.IDE are copied from the gateway source object to the gateway destination object.
3. If bit MOFCRs.DATC is set, the data bytes stored in the two data registers MODATALs and MODATAHs are copied from the gateway source object to the gateway destination object. All 8 data bytes are copied, even if MOFCRs.DLC indicates less than 8 data bytes.
4. If bit MOFCRs.GDFS is set, the transmit request flag MOSTATd.TXRQ is set in the gateway destination object.
5. The receive pending bit MOSTATd.RXPND and the new data bit MOSTATd.NEWDAT are set in the gateway destination object.
6. A message interrupt request is generated for the gateway destination object if its MOSTATd.RXIE is set.
7. The current object pointer MOFGPRs.CUR of the gateway source object is moved to the next destination object according to the FIFO rules as described on **Page 21-57**. A gateway with a single (static) destination object is obtained by setting MOFGPRs.TOP = MOFGPRs.BOT = MOFGPRs.CUR = destination object.

The link from the gateway source object to the gateway destination object works in the same way as the link from a FIFO base to a FIFO slave. This means that a gateway with an integrated destination FIFO may be created; in **Figure 21-24**, the object on the left is the gateway source object and the message object on the right side is the gateway destination objects.

The gateway operates equivalent for the reception of data frames (source object is receive object, i.e. DIR = 0) as well as for the reception of Remote Frames (source object is transmit object).

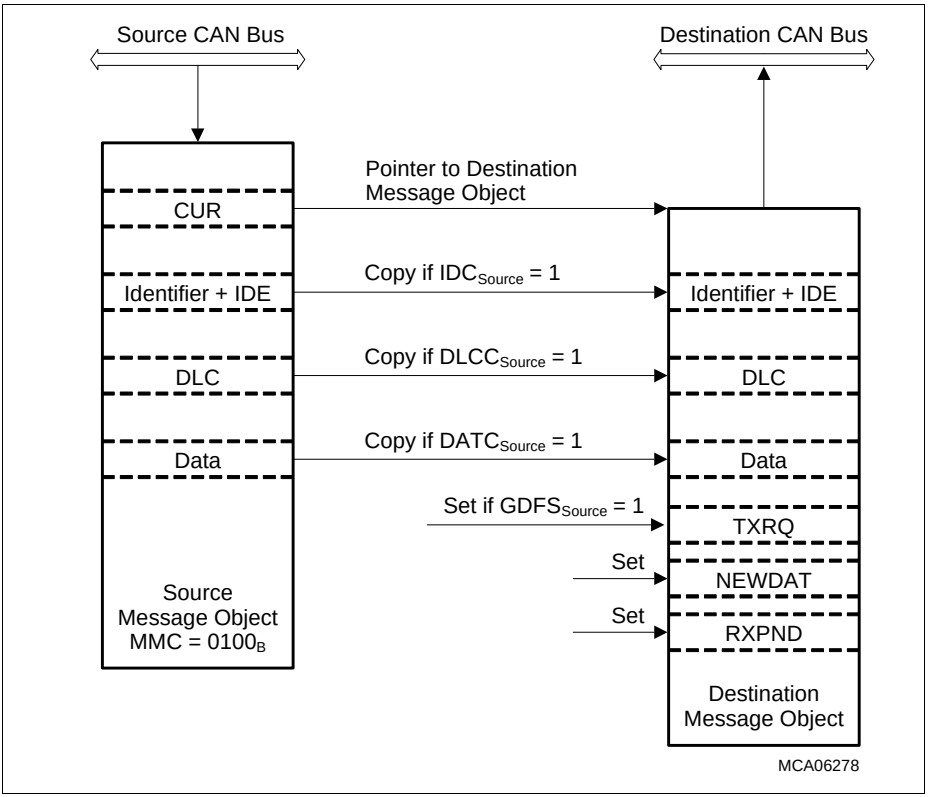

Figure 21-25 Gateway Transfer from Source to Destination

21.4.12.9 Foreign Remote Requests

When a Remote Frame has been received on a CAN node and is stored in a message object, a transmit request is set to trigger the answer (transmission of a Data Frame) to the request or to automatically issue a secondary request. If the Foreign Remote Request Enable bit MOFCRn.FRREN is cleared in the message object in which the remote request is stored, MOSTATn.TXRQ is set in the same message object.

If bit FRREN is set (FRREN = 1: foreign remote request enabled), TXRQ is set in the message object that is referenced by pointer MOFGPRn.CUR. The value of CUR is, however, not changed by this feature.

Although the foreign remote request feature works independently of the selected message mode, it is especially useful for gateways to issue a remote request on the source bus of a gateway after the reception of a remote request on the gateway destination bus. According to the setting of FRREN in the gateway destination object, there are two capabilities to handle remote requests that appear on the destination side (assuming that the source object is a receive object and the destination is a transmit object, i.e. DIR_{source} = 0 and $DIR_{destination}$ = 1):

FRREN = 0 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway destination object.
3. A Data Frame with the current data stored in the destination object is transmitted on the destination bus.

FRREN = 1 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway source object (must be referenced by CUR pointer of the destination object).
3. A remote request is transmitted by the source object (which is a receive object) on the source CAN bus.
4. The receiver of the remote request responds with a Data Frame on the source bus.
5. The Data Frame is stored in the source object.
6. The Data Frame is copied to the destination object (gateway action).
7. TXRQ is set in the destination object (assuming $GDFS_{source}$ = 1).
8. The new data stored in the destination object is transmitted on the destination bus, in response to the initial remote request on the destination bus.

21.4.12.10CAN FD - 64 byte Messages

In order to support higher than 8 data bytes payload (e.g 64bytes data payload) using current message object structure the data byte buffer (MODATALn and MODATAHn) has to be extended.

Thus an additional CAN FD 64 bytes message mode, MOFCR.MMC=5 is added. When CAN FD 64 bytes message mode is selected, additional message objects are used to store the extra data bytes.

The additional message objects used are specified by the pointer on MOFGPR.BOT and MOFGPR.TOP register bits. (i.e those message object registers (MOFCR, MOFGPR, MOIPR, MOAMR, MODATAL, MODATAH and MOAR) are used to store the extra data bytes with their alternate register view on EMOzDATAn at the same address location. MOCTR is the only register that is not used for data storage it retains its original function.

As an example for a 64 byte message, data bytes 0-7 are stored in the message object, similar to a standard message object, data bytes 8-35 are stored in the message object to which MOFGPR.BOT refers to and data bytes 36-63 are stored in the message object to which MOFGPR.TOP refers to. Data byte 0 refers to the first byte transferred within a CAN frame. For shorter than 64 bytes messages, unused data bytes are padded upon reception and ignored upon transmission.

The additional message objects chosen to store the extra data bytes must not take part in CAN communication i.e either they are allocated to a list that does not belong to an active CAN node or have that particular message object MOCTR register bits MOCTRn.RXEN, MOCTRn.TXEN0 (and/or TXEN1, TXRQ) cleared, i.e (RXEN=0, TXEN0=0, TXEN1=0 and TXRQ=0). MOCTR.MSGVAL remains the same, data is stored in the extra message objects when MSGVAL is set. When MSGVAL of the base object is cleared, an ongoing data transfer to TOP and BOT objects are aborted, thereby freeing objects BOT and TOP. Clearing MSGVAL bits of BOT, TOP objects and the extra message objects do not stop an ongoing data transfer and are not considered at all.

For optimum performance it is recommended to place the extra message objects outside active CAN node lists, so they do not take part in CAN acceptance filtering.

21.4.13 Measurement for Oscillator Calibration

The chip can be driven by an oscillator which is less accurate than required by the CAN specification, if it is possible to detect the deviation and to change the oscillator frequency during runtime. The MultiCAN module can measure the time interval between the start of a CAN frame and a certain edge on the bus. The timer hardware is accessed via Measurement Control Register MECR (see **Page 21-92**) and Measurement Status Register MESTAT (see **Page 21-94**).

A 16-bit timer is cleared and started by the first falling (dominant) edge of a CAN frame on the input line of the CAN node (selected by MECR.NODE). The timer is incremented by the module control clock f_{CLC}. The timer content is captured when an edge specified by MECR.ANYED is detected on the input line of the CAN node. However, the timer must have reached threshold MECR.TH before; so edges occurring earlier cannot cause a capture. Only the first edge after threshold is considered, and the node itself may not be sending. Bit field CAPT in the status register contains the captured timer value, and bit CAPRED indicates the type of edge that caused the capture. On a capture event, bit

CAPE in the same register will be set. If bit MECR.CAPEIE = 1, a node interrupt will be generated. With the starting edge of the following CAN frame, a new measurement cycle begins. To avoid an overflow on the measurement and to get a measurement result MESTAT.CAPE bit has to be cleared before the measurement end condition occurs.

To avoid wrong capture results due to timer overflow, the timer will be stopped when $FFFF_H$ is reached. If MECR.TH = 0000_H, the timer is always stopped and the capture function is disabled.

Some important issues should be mentioned:

- The timing of the measured CAN frame should be as exact as possible.
- No unadjusted CAN stations - including the selected MultiCAN node - should participate actively in the communication. The selected node can be set to Analyzer Mode.
- When setting the timer threshold and evaluating the capture result, the tolerances including the oscillator deviation must be considered.
- It may not be possible to use a well-defined CAN message for measurement. Then worst-case-scenarios according to the CAN protocol must be observed. E.g. in a data or remote frame, the first rising (recessive) edge might occur after five bit times, and the next falling one after additional five bit times.
- Also error and overload frames which may lead to unexpected capture results should be taken into account.
- Edges occurring a considerable time after the start of a CAN frame will yield good resolution but may produce ambiguous results if the oscillator is not yet sufficiently adjusted. Therefore, only one step for measurement and calibration may not be sufficient.
- As there is only one oscillator on the chip, its calibration influences the timing of the whole system and particularly the timing of other CAN nodes.

21.4.14 Debug Over CAN

The MultiCAN+ controller supports debugging[1)] using CAN tool access in parallel to regular CAN bus traffic. This is achieved by transmitting DAP telegrams and replies as regular CAN messages (DXCM DAP over CAN Messages). DXCM uses the two highest message objects and it is strongly recommended to use also the same CAN pins as for DXCPL (DAP over CAN Physical Layer). DXCM is enabled with the MCR.DXCM bit. Please refer to the OCDS chapter for more information about DAP, DXCM and DXCPL.

1) Debug over CAN feature is available through CAN module only and not available on CAN1 module.

21.5 Use Case Example MultiCAN+

This section explains the core functionality of the MultiCAN+ module with a code example. The example realizes sending a CAN message via internal CAN-bus from node 0 to node 1.

The MultiCAN+ module for the TC21x/TC22x/TC23x consists of 2[1)] modules (i.e MultiCAN with 3 CAN nodes and MultiCAN1 with 3 CAN Nodes), representing 6[2)] serial communication interfaces. Each CAN node can either be connected to a port or to the internal CAN bus (see). So a maximum of 6[2)] CAN channels can be realized with the MultiCAN+ module (For more information and further functions see **Section 21.2**).

All CAN nodes share a common set of 128/128 message objects. A message object function like a container for a specific CAN message; both transmitting and receiving of CAN messages can be realized. The message objects are organized in double-chained lists, each list is dedicated to a certain CAN node (list 1 is node 0, list 2 is node 1, etc.). After a reset, all message objects are unallocated and therefore assigned to list 0, this list does not belong to a CAN node. During initialization it is possible to allocate the message objects individually to certain CAN node lists. Each allocated message object can be set up with all necessary information like the message ID etc. (see chapter 26.2 and following for further explanations of the CAN module).

In the use case example CAN node 0 will send a CAN message via internal CAN bus to CAN node 1. The transmitting message object (MO) will be MO 0 and the receiving message object will be MO 1. As soon as the CAN frame successfully receives at MO 1 a receive interrupt will occur. The initialization process follows the following order:

1. Load global MuliCAN+ module registers
2. Initialize the CAN nodes
3. Allocate the message objects to the CAN nodes
4. Initialize the message objects
5. Start the CAN nodes
6. Start transmit request for CAN message from node 0 to node 1.
7. Receive message at node 1, Rx interrupt occurs.

Step description to initialize the MultiCAN+ module:

(Line 1) reset ENDINIT to get access to ENDINIT protected registers. (see also ENDINIT protection chapter 8.9.3(LINK)).

(Line 2) enable control of the module, in clock control register CLC (**CLC**).

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

1) TC23x consists of 2 modules (MultiCAN and MultiCAN1), TC22x consists of 1 module (MultiCAN).

2) TC23x has 6 CAN serial communication interfaces, TC22x has 3 CAN communication interfaces.

(Line 4) load fractional divider to $f_{CAN} = f_{ASYN\_CAN}$ (see also 26.3.2 Clock Control (**Fractional Divider**), f_{ASYN_CAN} see **MCR**).

(Line 5) set ENDINIT to lock the protected register again.

(Line 6) set clk source to f_{ASYN_CAN} in module control register MCR(**MCR**).

Note: The reconfiguration of the clk source must be done by two writes and a certain delay between these. See MCR for more details.

(Line 7) The setting of protection CCE[6] and INIT[0] activates the initialization and configuration mode for CAN node 0. This is necessary for the upcoming changes in CAN node 0. (see also node configuration register NCRn (**CAN_NCRx (x = 0-2)**))

(Line 8) This example uses the internal loop-back mode, so this line connects CAN node 0 to the internal CAN Bus. (see also Figure 26-13(**Figure 21-17**) and node port control register NPCR(**CAN_NPCRx (x = 0-2)**))

(Line 9) The CAN bit time is subdivided into different segments. (see also 26.3.6.1 Bit Timing Unit(**Bit Timing Unit**)). Assuming f_{CAN} = 100MHz this line then sets the baudrate to 500kBaud and the sample point to 80% in the node bit timing register NBTR (**CAN_NBTRx (x = 0-2)**).

Note: The FM PLL should be off. Otherwise a stable CAN communication is not ensured

(Line 10 - 12) same as line 7 - 9 but with node 1.

(Line 13) The allocation of the message objects to certain CAN node lists function via a list command panel. The panel control register PANCTR(**PANCTR**) can only be written if both busy flags are reseted. Therefore this while loop waits until the register is ready.

(Line 14) This line allocates message object 0 to list 1 (belongs to CAN node 0).

(Line 15) see line 13.

(Line 16) This line allocates message object 1 to list 2 (belongs to CAN node 0).

(Line 17) Initialize MO 0 in the message object register MOCTR(**CAN_MOCTRz (z = 0-126)**) as transmit MO by setting bits [27:25]. Set also MSGVAL[21], that's the main switch bit of the MO.

(Line 18) this line sets the message data length of MO 0 to 8 bytes.(see also message object function control register MOFCR (**CAN_MOFCRn (n = 0-127)**)).

(Line 19) the message ID of MO 0 gets set to standard message (11 bit length) with a message ID of 0xFF in the Message object arbitration register MOAR (**CAN_MOARn (n = 0-127)**).

(Line 20) Initialize MO 1 in the message object register MOCTR as receive MO by setting bit RXEN[23]. Set also MSGVAL[21], that's the main switch bit of the MO.

(Line 21) the receive interrupt gets enabled in the message object function control register MOFCR .

(Line 22) same as Line 19 but for MO 1. The same message ID is necessary to receive CAN messages from the bus with this specific ID.

(Line 23) the Rx interrupt gets connected to the CAN interrupt output line 1.(see also MOIPR(**CAN_MOIPRn (n = 0-127)**))

(Line 24) This line enables the Rx interrupt in the service request control register SRC_CANINT1 and sets the interrupt priority to CAN_SR1INT (1...255)

(Line 25) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example (Chapter 17.10.1) for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority CAN_SRN1INT.

(Line 26) The 4 lower data bytes are getting loaded in the MODATAL(**CAN_MODATALn (n = 0-127)**) register. the data itself is here just an example.

(Line 27) The 4 higher data bytes are getting loaded in the MODATAH(**CAN_MODATAHn (n = 0-127)**) register. (just an data example as well)

(Line 28) This line resets INIT[0] and CCE[6] bit in the node control register from node 0. The node is now synchronizing itself to the bus.

(Line 29) same as line 28, but with node 1.

(Line 30) The NEWDATA bit gets set in the MOCTR register, this should always be done after a write process in the data registers from line 26/27. The transmit request bit TXRQ gets set, this starts the transmission of the CAN message. The RTSEL gets reset to ensure the transmission.

(Line 31) If the message is received the MOCTR.NEWDAT[19] bit in the receive MO 1 is set. This line just waits for the reception. The occurrence of the Rx interrupt can also be used as a proof that the message arrived.

Note: The Rx ISR function prototype would be: void CAN1_Rx_irq (void); here could be your ISR code;

Initialization of the MultiCAN+ module:

```
// Load global MultiCAN+ registers:
(1)  SCU_vResetENDINIT (0);     // enable ENDINIT reg
(2)  CAN_CLC = 0x000;           // disable module control
(3)  dummy = CAN_CLC;           //read to check the made changes
(4)  CAN_FDR = (1 << 14)| 0x3FF;     //DM=1,STEP=1023
(5)  SCU_vSetENDINIT (0);       // lock ENDINIT reg
(6)  CAN_MCR = 0x1;             // CLKSEL=1
//Init CAN nodes 0 and 1:
(7)  CAN_NCR0 = (1 << 6)| 1;    // CCE=1,INIT=1
```

```
(8)  CAN_NPCR0 = (1 << 8);      // LBM=1
(9)  CAN_NBTR0 = 0x3EC9;        //set bit segments
(10) CAN_NCR1 = (1 << 6)| 1;    // CCE=1,INIT=1
(11) CAN_NPCR1 = (1 << 8);      // LBM=1
(12) CAN_NBTR1 = 0x3EC9;        //set bit segments
//Allocate message objects to CAN nodes:
(13) while(CAN_PANCTR.U & (0x00000100 | 0x00000200)); // busy?
(14) CAN_PANCTR = (1 << 24)|(0 << 16)| 2; // MO 0 to list 1
(15) while(CAN_PANCTR.U & (0x00000100 | 0x00000200)); // busy?
(16) CAN_PANCTR = (2 << 24)|(1 << 16)| 2; // MO 1 to list 2
//Init MO_0 (list 1, node 0)
(17) CAN_MOCTR0 = (1<<27)|(1<<26)|(1<<25)|(1<<21); // set to Tx
(18) CAN_MOFCR0 = (8 << 24);              // DLC=8
(19) CAN_MOAR0 =  (1 << 30)|(0xFF << 18); // PRI=01,ID=0xFF
//Init MO_1 (list 2, node 1)
(20) CAN_MOCTR1 = (1 << 23)|(1 << 21);    // set to Rx
(21) CAN_MOFCR1 = (1 << 16);              // RXIE=1
(22) CAN_MOAR1 =  (1 << 30)|(0xFF << 18);  // PRI=01, ID=0xFF
(23) CAN_MOIPR1 = 0x1;          // RXINP=1 -> select INT_O1
(24) SRC_CANINT1 = (1 << 10) | CAN_SRN1INT; // enable INT_01
(25) interruptHandlerInstall (CAN_SRN1INT, & CAN1_Rx_irq);
// Load Data, Start CAN nodes
(26) CAN_MODATAL0 = 0x0D0D0D0D; // load data, lower 4 Bytes
(27) CAN_MODATAH0 = 0x0E0E0E0E; // load data, higher 4 Bytes
(28) CAN_NCR0 &= ~((1<<6)| 1);  // reset CCE and INIT
(29) CAN_NCR1 &= ~((1<<6)| 1);  // reset CCE and INIT
// set transmit request to send message
(30) CAN_MOCTR0 = (1<<24)|(1<<19)|(1<<6);//TXRQ=1,NEWDAT=1
(31) while((CAN_MOSTAT1.B.NEWDAT) != 1);       //check if Rx
```

Note: Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):

__enable();
to set this bit. (See also Architecture Manual for more details)

21.6 MultiCAN+ Kernel Registers

This section describes the kernel registers of the MultiCAN+ module. All MultiCAN+ kernel register names described in this section are also referenced in other parts of the TC21x/TC22x/TC23x User's Manual by the module name prefix "CAN_".

MultiCAN+ Kernel Register Overview

The MultiCAN+ Kernel include three blocks of registers:

- Global Module Registers
- Node Registers, for each CAN node x
- Message Object Registers, for each message object n

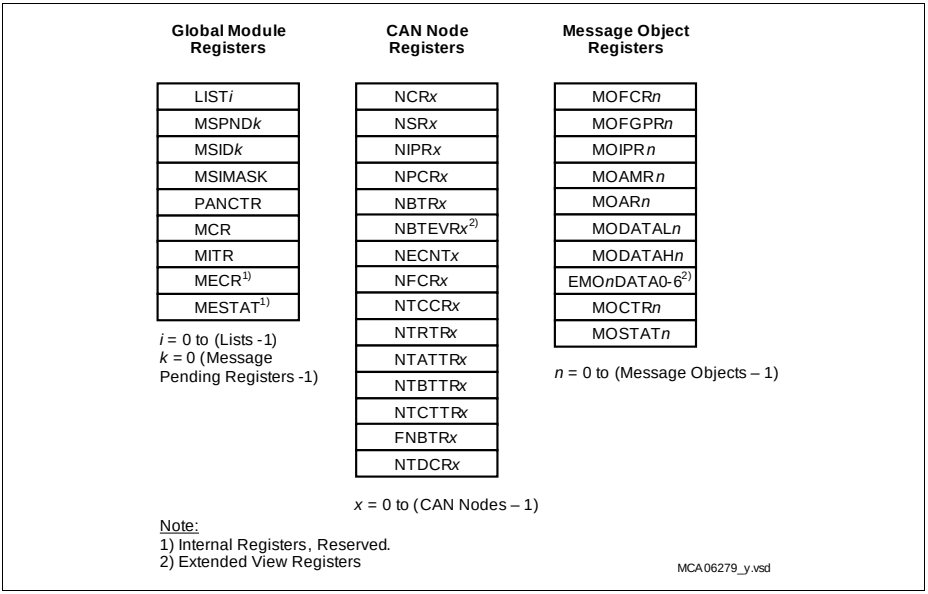

Figure 21-26 MultiCAN+ Kernel Registers

The registers of the MultiCAN+ module kernel are listed below.

Table 21-9 Registers Address Space - MultiCAN+ Kernel Registers

Module	Base Address	End Address	Note
CAN	$F001\ 8000_H$	$F001\ BFFF_H$	-
CAN1	$F002\ 8000_H$	$F002\ BFFF_H$	-

1) The absolute register address is calculated as follows:
Module Base Address (**Table 21-9**) + Offset Address (shown in this column)
Further, the following ranges for parameters i, k, x, and n are valid: i = 0-15, k = 0-7, x = 0-2, n = 0-127.

2) Accesses to empty addresses: nBE

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - Safety ENDINIT

Figure 21-27 shows the MultiCAN+ register address map.

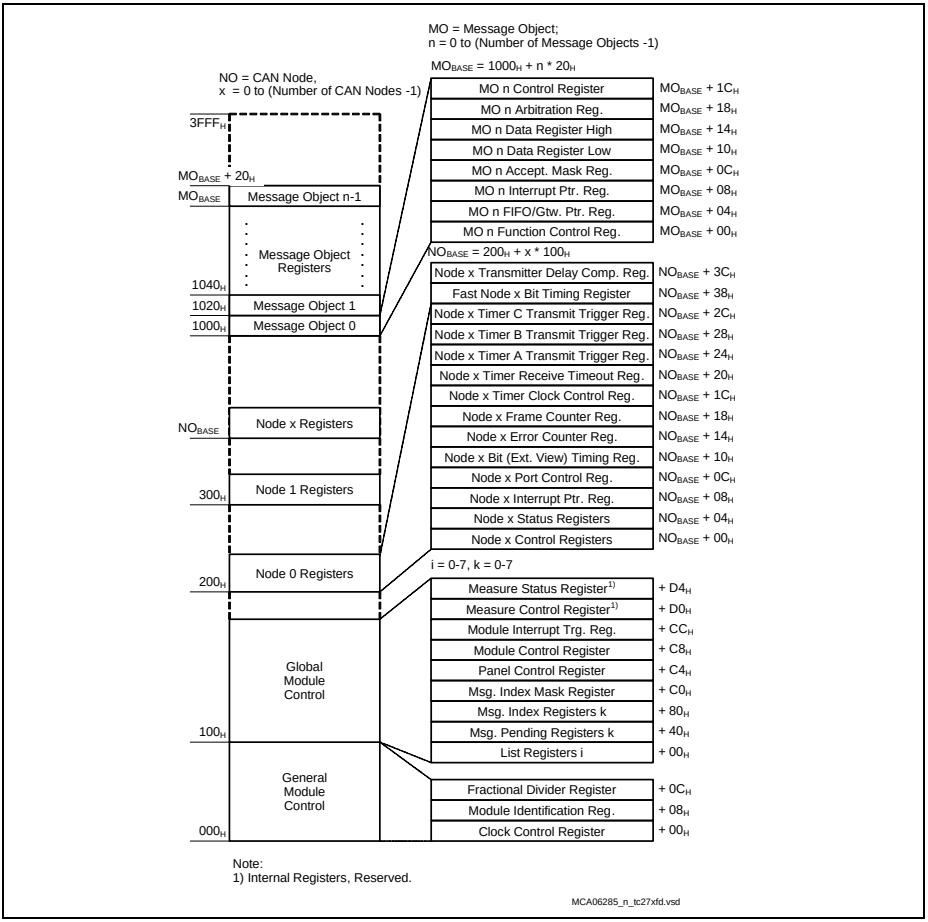

Figure 21-27 MultiCAN+ Register Address Map

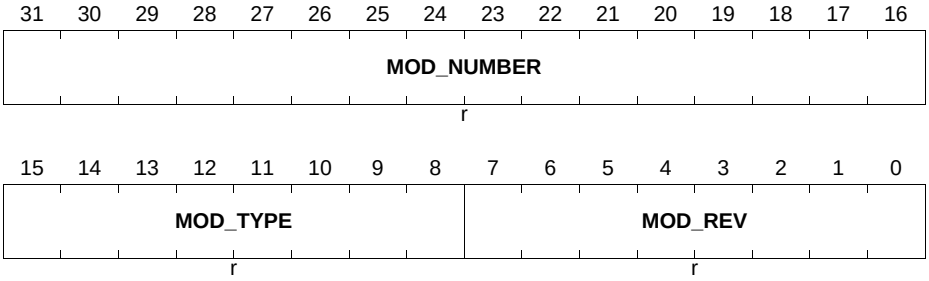
21.6.1 Global Module Registers

All list operations such as allocation, de-allocation and relocation of message objects within the list structure are performed via the Command Panel. It is not possible to modify the list structure directly by software by writing to the message objects and the LIST registers.

Module Identification Register.

ID

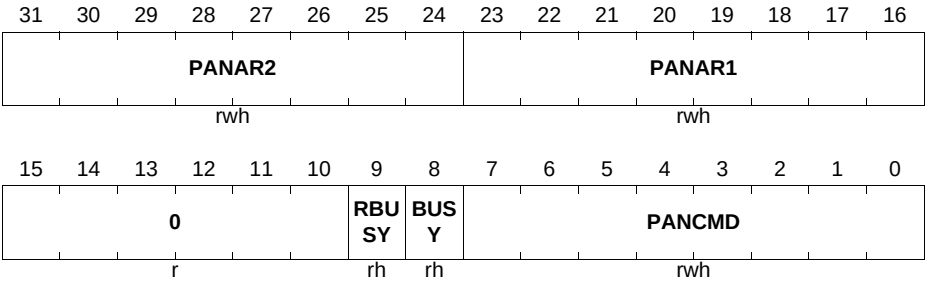
Module Identification Register (008$_H$) Reset Value: 00B5 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the revision number. The value of a module revision starts with 01$_H$ (first revision).
MOD_TYPE	[15:8]	r	**Module Type** C0$_H$ Define the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines the MultiCAN+ module identification number (=00B5H)

The Panel Control Register PANCTR is used to start a new command by writing the command arguments and the command code into its bit fields.

PANCTR
Panel Control Register **($1C4_H$)** **Reset Value: $0000\ 0301_H$**



Field	Bits	Type	Description
PANCMD	[7:0]	rwh	**Panel Command** This bit field is used to start a new command by writing a panel command code into it. At the end of a panel command, the NOP (no operation) command code is automatically written into PANCMD. The coding of PANCMD is defined in **Table 21-11**.
BUSY	8	rh	**Panel Busy Flag** 0_B Panel has finished command and is ready to accept a new command. 1_B Panel operation is in progress.
RBUSY	9	rh	**Result Busy Flag** 0_B No update of PANAR1 and PANAR2 is scheduled by the list controller. 1_B A list command is running (BUSY = 1) that will write results to PANAR1 and PANAR2, but the results are not yet available.
PANAR1	[23:16]	rwh	**Panel Argument 1** See **Table 21-11**.
PANAR2	[31:24]	rwh	**Panel Argument 2** See **Table 21-11**.
0	[15:10]	r	**Reserved** Read as 0; should be written with 0.

Panel Commands

A panel operation consists of a command code (PANCMD) and up to two panel arguments (PANAR1, PANAR2). Commands that have a return value deliver it to the PANAR1 bit field. Commands that return an error flag deliver it to bit 31 of the Panel Control Register, this means bit 7 of PANAR2.

Table 21-11 Panel Commands

PANCMD	PANAR2	PANAR1	Command Description
00_H	–	–	**No Operation** Writing 00_H to PANCMD has no effect. No new command is started.
01_H	**Result:** Bit 7: ERR Bit 6-0: undefined	–	**Initialize Lists** Run the initialization sequence to reset the CTRL and LIST fields of all message objects. List registers LIST[7:0] are set to their reset values. This results in the de-allocation of all message objects. The initialization command requires that bits NCRx.INIT and NCRx.CCE are set for all CAN nodes. Bit 7 of PANAR2 (ERR) reports the success of the operation: 0_B Initialization was successful 1_B Not all NCRx.INIT and NCRx.CCE bits are set. Therefore, no initialization is performed. The initialize lists command is automatically performed with each reset of the MultiCAN+ module, but with the exception that all message object registers are reset, too.
02_H	**Argument:** List Index	**Argument:** Message Object Number	**Static Allocate** Allocate message object to a list. The message object is removed from the list that it currently belongs to, and appended to the end of the list, given by PANAR2. This command is also used to deallocate a message object. In this case, the target list is the list of unallocated elements (PANAR2 = 0).

Table 21-11 Panel Commands (cont'd)

PANCMD	PANAR2	PANAR1	Command Description
03_H	**Argument:** List Index **Result:** Bit 7: ERR Bit 6-0: undefined	**Result:** Message Object Number	**Dynamic Allocate** Allocate the first message object of the list of unallocated objects to the selected list. The message object is appended to the end of the list. The message number of the message object is returned in PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0_B Success. 1_B The operation has not been performed because the list of unallocated elements was empty.
04_H	**Argument:** Destination Object Number	**Argument:** Source Object Number	**Static Insert Before** Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object. The source object thus becomes the predecessor of the destination object.
05_H	**Argument:** Destination Object Number **Result:** Bit 7: ERR Bit 6-0: undefined	**Result:** Object Number of inserted object	**Dynamic Insert Before** Insert a new message object before a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as a result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0_B Success. 1_B The operation has not been performed because the list of unallocated elements was empty.

Table 21-11 Panel Commands (cont'd)

PANCMD	PANAR2	PANAR1	Command Description
06_H	**Argument:** Destination Object Number	**Argument:** Source Object Number	**Static Insert Behind** Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object. The source object thus becomes the successor of the destination object.
07_H	**Argument:** Destination Object Number **Result:** Bit 7: ERR Bit 6-0: undefined	**Result:** Object Number of inserted object	**Dynamic Insert Behind** Insert a new message object behind a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0_B Success. 1_B The operation has not been performed because the list of unallocated elements was empty.
08_H - FF_H	–	–	**Reserved**

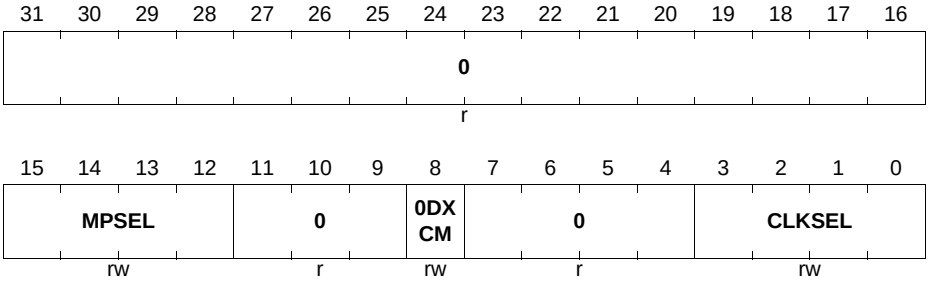
The Module Control Register MCR contains basic settings that determine the operation of the MultiCAN+ module.

The write access to the lowest byte of the MCR register is possible only if the CCE bits of all CAN nodes are set (NCRx.CCE bits). The NCRx.INIT bits will be automatically set when the lowest byte of the MCR register is written, independent of the setting of the CCE bits. The INIT bits have to be reset by software in order to activate the CAN nodes.

The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bit field, and then a second write defining the new clock source. Between the first and the second write a delay of 4 / f_A + 2 / f_{CAN} number of cycles must be inserted by software, where f_A is the frequency being switched off with the first write. Exception: in case that f_{ASYN_CAN} is selected as the baud rate logic clock (MCR.CLKSEL = 1), no delay cycles between the writes are necessary. In both cases, simply using one write defining the new clock source is not allowed.

Note: If the baud rate logic is supplied from an unstable clock source, or no clock at all, the CAN functionality is not guaranteed.

MCR
Module Control Register (1C8$_H$) Reset Value: 0000 0000$_H$

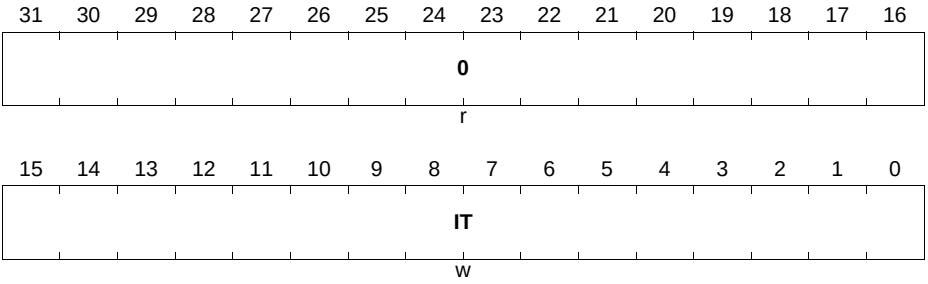


Field	Bits	Type	Description
CLKSEL	[3:0]	rw	**Baud Rate Logic Clock Select** 0000_B No clock supplied 0001_B f_{ASYN_CAN} 0010_B Oscillator Clock 0100_B E-Ray clock (f_{ERAY}) 1000_B hard wired to 0 $...{}_B$ not allowed

Field	Bits	Type	Description
DXCM	8	rw	**Debug Over CAN Messages Enable** This bit enables the debug over serial connections between DAP and CAN module. 0_B DXCM disabled 1_B DXCM enabled If enabled the highest two message objects are reserved for debugger communication. DXCM is described in detail in the OCDS chapter.
0	8	rw	**Reserved** Read as 0; should be written with 0.
MPSEL	[15:12]	rw	**Message Pending Selector** Bit field MPSEL makes it possible to select the bit position of the message pending bit after a message reception/transmission by a mixture of the MOIPRn register bit fields RXINP, TXINP, and MPN. Selection details are given in **Figure 21-21** on **Page 21-48**.
0	[31:16], [11:9], [7:4]	r	**Reserved** Read as 0; should be written with 0.

The Interrupt Trigger Register ITR is used to trigger interrupt requests on each interrupt output line by software.

MITR
Module Interrupt Trigger Register (1CC$_H$) **Reset Value: 0000 0000$_H$**



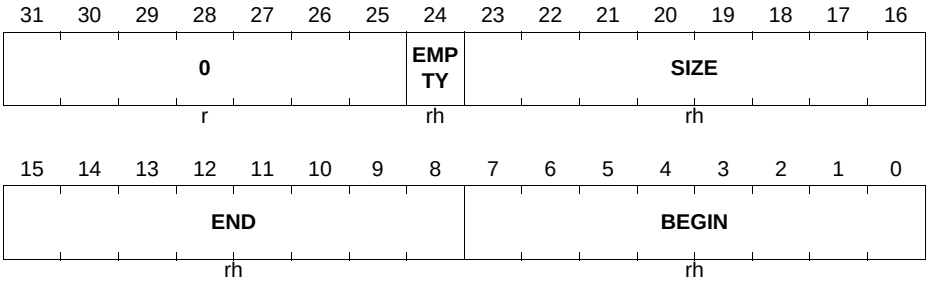
Field	Bits	Type	Description
IT	[15:0]	w	**Interrupt Trigger** Writing a 1 to IT[m] (m = 0-15) generates an interrupt request on interrupt output line INT_O[m]. Writing a 0 to IT[m] has no effect. Bit field IT is always read as 0. Multiple interrupt requests can be generated with a single write operation to MITR by writing a 1 to several bit positions of IT.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

List Pointer and List Register

Each CAN node has a list that determines the allocated message objects. Additionally, a list of all unallocated objects is available. Furthermore, general purpose lists are available which are not associated to a CAN node. The List Registers are assigned in the following way:

- LIST0 provides the list of all unallocated objects
- LIST1 provides the list for CAN node 0
- LIST2 provides the list for CAN node 1
- ...
- LIST3 provides the list for CAN node 2

LIST0
List Register 0 **(100_H)** **Reset Value: 007F 7F00$_H$**
LISTn (n = 1-15)
List Register n **(100_H+n*4$_H$)** **Reset Value: 0100 0000$_H$**



Field	Bits	Type	Description
BEGIN	[7:0]	rh	**List Begin** BEGIN indicates the number of the first message object in list i.
END	[15:8]	rh	**List End** END indicates the number of the last message object in list i.
SIZE	[23:16]	rh	**List Size** SIZE indicates the number of elements in the list i. SIZE = number of list elements - 1 SIZE = 0 indicates that list i is empty.

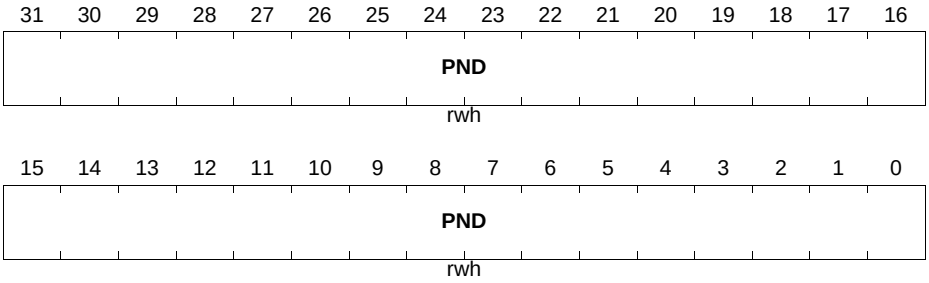
Field	Bits	Type	Description
EMPTY	24	rh	**List Empty Indication** 0_B At least one message object is allocated to list i. 1_B No message object is allocated to the list i. List i is empty.
0	[31:25]	r	**Reserved** Read as 0.

Message Notifications

When a message object n generates an interrupt request upon the transmission or reception of a message, then the request is routed to the interrupt output line selected by the bit field MOIPRn.TXINP or MOIPRn.RXINP of the message object n. As there are more message objects than interrupt output lines, an interrupt routine typically processes requests from more than one message object. Therefore, a priority selection mechanism is implemented in the MultiCAN+ module to select the highest priority object within a collection of message objects.

The Message Pending Register MSPNDk contains the pending interrupt notification of list i.

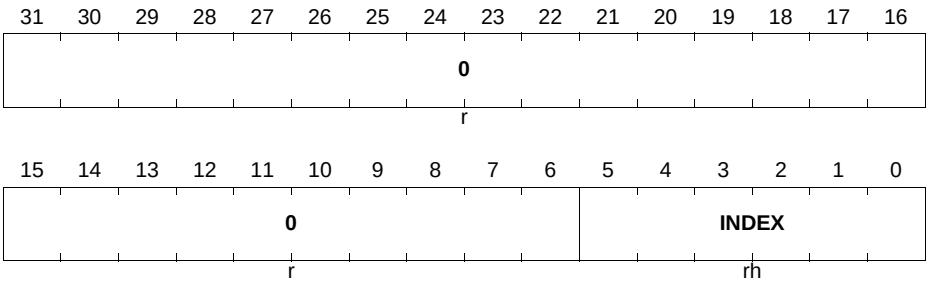
MSPNDk (k = 0-7)
Message Pending Register k **(140_H+k*4_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
PND	[31:0]	rwh	**Message Pending** When a message interrupt occurs, the message object sets a bit in one of the MSPND register, where the bit position is given by the MPN[4:0] field of the IPR register of the message object. The register selection n is given by the higher bits of MPN. The register bits can be cleared by software (write 0). Writing a 1 has no effect.

Each Message Pending Register has a Message Index Register MSIDk associated with it. The Message Index Register shows the active (set) pending bit with lowest bit position within groups of pending bits.

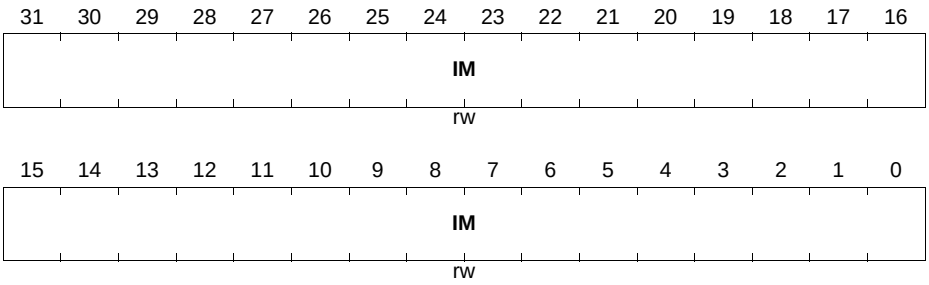
MSIDk (k = 0-7)
Message Index Register k **(180_H+k*4_H)** **Reset Value: 0000 0020_H**



Field	Bits	Type	Description
INDEX	[5:0]	rh	**Message Pending Index** The value of INDEX is given by the bit position i of the pending bit of MSPNDk with the following properties: 1. MSPNDk[i] & IM[i] = 1 2. i = 0 or MSPNDk[i-1:0] & IM[i-1:0] = 0 If no bit of MSPNDk satisfies these conditions then INDEX reads 100000_B. Thus INDEX shows the position of the first pending bit of MSPNDk, in which only those bits of MSPNDk that are selected in the Message Index Mask Register are taken into account.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

The Message Index Mask Register MSIMASK selects individual bits for the calculation of the Message Pending Index. The Message Index Mask Register is used commonly for all Message Pending registers and their associated Message Index registers.

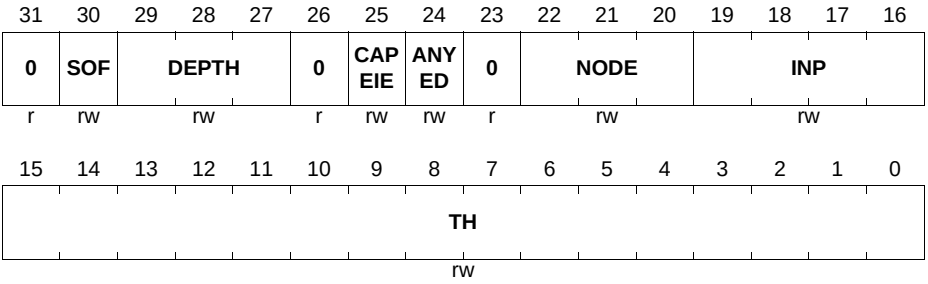
MSIMASK
Message Index Mask Register **($1C0_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
IM	[31:0]	rw	**Message Index Mask** Only those bits in MSPNDk for which the corresponding Index Mask bits are set contribute to the calculation of the Message Index.

The Measurement Control Register MECR controls the CAN edge timing measurement function for calibration purposes.

MECR
Measurement Control Register (1D0$_H$) Reset Value: 0000 0000$_H$

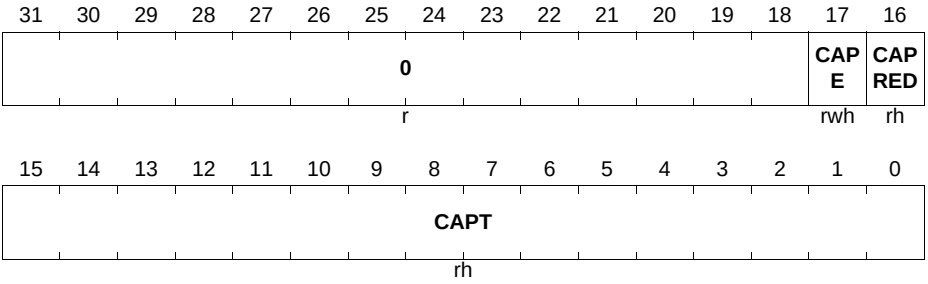


Field	Bits	Type	Description
TH	[15:0]	rw	**Threshold** This bit field contains the threshold value for the measurement timer. If TH = 0000$_H$, the timer is stopped and the capture function is disabled.
INP	[19:16]	rw	**Interrupt Node Pointer** INP selects the interrupt output line INT_Om (m = 0-15) for a capture event interrupt. 0000$_B$ Interrupt output line INT_O0 is selected. 0001$_B$ Interrupt output line INT_O1 is selected. …$_B$ … 1110$_B$ Interrupt output line INT_O14 is selected. 1111$_B$ Interrupt output line INT_O15 is selected.
NODE	[22:20]	rw	**Node** This bit field determines the CAN node x whose input line RXDCANx is used for start and capture of the measurement timer. 000$_B$ Node 0 001$_B$ Node 1 …$_B$ … 010$_B$ Node 2

Field	Bits	Type	Description
ANYED	24	rw	**Any Edge** This bit enables capture on any edge of CAN input line specified by NODE. 0_B Capture on falling (dominant) edge only 1_B Capture on rising (recessive) or falling (dominant) edge
CAPEIE	25	rw	**Capture Event Interrupt Enable** This bit enables the capture event interrupt. 0_B Capture event interrupt is disabled 1_B Capture event interrupt is enabled Bit field INP selects the interrupt output line which becomes activated at this type of interrupt.
DEPTH	[29:27]	rw	**Digital Glitch Filter Depth** DEPTH determines the number of input samples clocked with f_{CLC} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 000_B off, default 001_B Filter depth of 8 cycles 010_B Filter depth of 16 cycles 011_B Filter depth of 32 cycles 100_B Filter depth of 64 cycles 101_B Filter depth of 128 cycles 110_B Filter depth of 255 cycles 111_B not allowed, reserved
SOF	30	rw	**Start Of Frame** This bit selects falling edge or any edge as measurement for start of frame detection. 0_B Measurement starts with any falling edge 1_B Measurement starts with falling Start of Frame edge. i.e any falling edge that occurs while the CAN node is in idle state
0	23, 26, 31	r	**Reserved** Read as 0; should be written with 0.

The Measurement Status Register MESTAT contains the status information of the CAN edge timing measurement.

MESTAT
Measurement Status Register (1D4$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CAPT	[15:0]	rh	**Captured Timer** This bit field contains the captured measurement timer content. The timer itself is cleared and started by the first falling (dominant) edge of a CAN frame on the input line of the CAN node specified by MECR.NODE. The timer is incremented by the module control clock f_{CLC} and will be stopped when FFFF$_H$ is reached. If MECR.TH = 0000$_H$, the timer is always stopped. A capture will take place if all the following conditions are met: 1. MECR.TH > 0000$_H$ 2. Timer is cleared and started by new frame 3. Timer reaches MECR.TH 4. This node is not sending and first edge (as specified by MECR.ANYED) after 3. occurs on input line Capture will be repeated for the following CAN frames until MECR.TH is cleared.
CAPRED	16	rh	**Captured Rising Edge** This bit indicates the type of edge that caused the last capture event. 0_B Capture occurred on falling (dominant) edge 1_B Capture occurred on rising (recessive) edge

Field	Bits	Type	Description
CAPE	17	rwh	**Capture Event** This flag is set on a capture event. It must be reset by software. 0_B No capture event has occurred since last flag reset 1_B Capture event has occurred since last flag reset An interrupt request is generated if MECR.CAPEIE = 1. If CAPE=1 then no further measurement results are posted to MESTAT.CAPT and MESTAT.CAPRED. CAPE bit has to be cleared to re-enable update of MESTAT.CAPT and MESTAT.CAPRED.
0	[31:18]	r	**Reserved** Read as 0; should be written with 0.

21.6.2 CAN Node Registers

The CAN node registers are built in for each CAN node of the MultiCAN+ module. They contain information that is directly related to the operation of the CAN nodes and are shared among the nodes.

The Node Control Register contains basic settings that determine the operation of the CAN node.

CAN_NCRx (x = 0-2)
Node x Control Register **(200_H+x*100_H)** **Reset Value: 0000 0041_H**
CAN1_NCRy (y=0-2)
Node y Control Register **(200_H+y*100_H)** **Reset Value: 0000 0041_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						FDEN	SUSEN	CALM	CCE	TXDIS	CANDIS	ALIE	LECIE	TRIE	INIT
r						rw	rw	rw	rw	rw	rw	rw	rw	rw	rwh

Field	Bits	Type	Description
INIT	0	rwh	**Node Initialization** 0_B Resetting bit INIT enables the participation of the node in the CAN traffic. If the CAN node is in the bus-off state, the ongoing bus-off recovery (which does not depend on the INIT bit) is continued. With the end of the bus-off recovery sequence the CAN node is allowed to take part in the CAN traffic. If the CAN node is not in the bus-off state, a sequence of 11 consecutive recessive bits must be detected before the node is allowed to take part in the CAN traffic. 1_B Setting this bit terminates the participation of this node in the CAN traffic. Any ongoing frame transfer is cancelled and the transmit line goes recessive. If the CAN node is in the bus-off state, then the running bus-off recovery sequence is continued. If the INIT bit is still set after the successful completion of the bus-off recovery sequence, i.e. after detecting 128 sequences of 11 consecutive recessive bits (11×1), then the CAN node leaves the bus-off state but remains inactive as long as INIT remains set. Bit INIT is automatically set when the CAN node enters the bus-off state (see **Page 21-30**).
TRIE	1	rw	**Transfer Interrupt Enable** TRIE enables the transfer interrupt of CAN node x. This interrupt is generated after the successful reception or transmission of a CAN frame in node x. 0_B Transfer interrupt is disabled. 1_B Transfer interrupt is enabled. Bit field NIPRx.TRINP selects the interrupt output line which becomes activated at this type of interrupt.

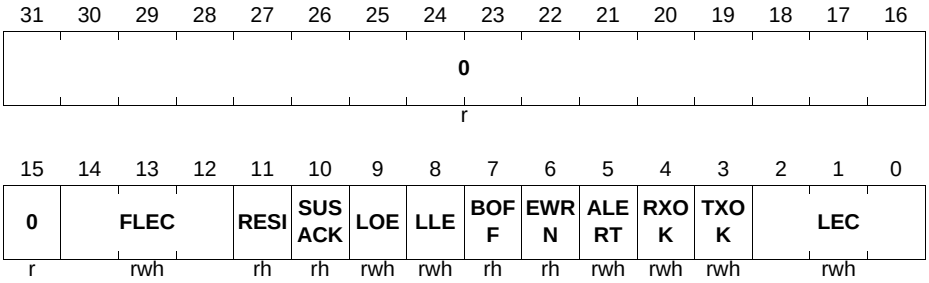
Field	Bits	Type	Description
LECIE	2	rw	**LEC Indicated Error Interrupt Enable** LECIE enables the last error code interrupt of CAN node x. This interrupt is generated with each hardware update of bit field NSRx.LEC with LEC > 0 (CAN protocol error). 0_B Last error code interrupt is disabled. 1_B Last error code interrupt is enabled. Bit field NIPRx.LECINP selects the interrupt output line which becomes activated at this type of interrupt.
ALIE	3	rw	**Alert Interrupt Enable** ALIE enables the alert interrupt of CAN node x. This interrupt is generated by any one of the following events: • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE 0_B Alert interrupt is disabled. 1_B Alert interrupt is enabled. Bit field NIPRx.ALINP selects the interrupt output line which becomes activated at this type of interrupt.
CANDIS	4	rw	**CAN Disable** Setting this bit disables the CAN node. The CAN node first waits until it is bus-idle or bus-off. Then bit NSRx.SUSACK and NCRx.INIT is automatically set, and an alert interrupt is generated if bit ALIE is set.
TXDIS	5	rw	**Transmit Disable** Setting this bit disables the transmission on CAN node x as soon as bus-idle is reached. Reception and bits in MOSTATn, e.g. TXRQ, will not be influenced.
CCE	6	rw	**Configuration Change Enable** 0_B The Bit Timing Register, the Port Control Register, Error Counter Register and NCRx.FDEN bit may only be read. All attempts to modify them are ignored. 1_B The Bit Timing Register, the Port Control Register, Error Counter Register and NCRx.FDEN bit may be read and written.

Field	Bits	Type	Description
CALM	7	rw	**CAN Analyzer Mode** If this bit is set, then the CAN node operates in Analyzer Mode. This means that messages may be received, but not transmitted. No acknowledge is sent on the CAN bus upon frame reception. Active-error flags are sent recessive instead of dominant. The transmit line is continuously held at recessive (1) level. Bit CALM can be written only while bit INIT is set.
SUSEN	8	rw	**Suspend Enable** This bit makes it possible to set the CAN node into Suspend Mode via OCDS (on chip debug support): 0_B An OCDS suspend trigger is ignored by the CAN node. 1_B An OCDS suspend trigger disables the CAN node: As soon as the CAN node becomes bus-idle or bus-off, bit INIT is internally forced to 1 to disable the CAN node. The actual value of bit INIT remains unchanged. Bit SUSEN is reset via OCDS Reset.
FDEN	9	rw	**CAN Flexible Data-Rate Enable** This bit enables the CAN FD feature: 0_B CAN FD disabled. Message transfer for CAN frames using classical CAN Format. 1_B CAN FD enabled. Message transfer for CAN frames using CAN FD Format[1)]. Bit FDEN is protected by CCE and INIT bit. Please see **Section 21.4.12.4** and **Table 21-18**
0	[31:10]	r	**Reserved** Read as 0; should be written with 0.

1) Message transmission in Classical CAN, Long Frame or Long + Fast CAN FD Frames. Message Reception according to CAN FD Protocol Specification, (i.e Able to Receive Classical CAN Format Frames ISO11898-1 Long Frame and Long + Fast CAN FD Frames)

The Node Status Register NSRx reports errors as well as successfully transferred CAN frames.

CAN_NSRx (x = 0-2)
Node x Status Register **(204_H+x*100_H)** **Reset Value: 0000 0000_H**
CAN1_NSRy (y=0-2)
Node y Status Register **(204_H+y*100_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
LEC	[2:0]	rwh	**Last Error Code** This bit field indicates the type of the last (most recent) CAN error. The encoding of this bit field is described in **Table 21-12**.
TXOK	3	rwh	**Message Transmitted Successfully** 0_B No successful transmission since last (most recent) flag reset. 1_B A message has been transmitted successfully (error-free and acknowledged by at least another node). TXOK must be reset by software (write 0). Writing 1 has no effect.
RXOK	4	rwh	**Message Received Successfully** 0_B No successful reception since last (most recent) flag reset. 1_B A message has been received successfully. RXOK must be reset by software (write 0). Writing 1 has no effect.

Field	Bits	Type	Description
ALERT	5	rwh	**Alert Warning** The ALERT bit is set upon the occurrence of one of the following events (the same events which also trigger an alert interrupt if ALIE is set): • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE ALERT must be reset by software (write 0). Writing 1 has no effect.
EWRN	6	rh	**Error Warning Status** 0_B No warning limit exceeded. 1_B One of the error counters REC or TEC reached the warning limit EWRNLVL.
BOFF	7	rh	**Bus-off Status** 0_B CAN controller is not in the bus-off state. 1_B CAN controller is in the bus-off state.
LLE	8	rwh	**List Length Error** 0_B No List Length Error since last (most recent) flag reset. 1_B A List Length Error has been detected during message acceptance filtering. The number of elements in the list that belongs to this CAN node differs from the list SIZE given in the list termination pointer. LLE must be reset by software (write 0). Writing 1 has no effect.
LOE	9	rwh	**List Object Error** 0_B No List Object Error since last (most recent) flag reset. 1_B A List Object Error has been detected during message acceptance filtering. A message object with wrong LIST index entry in the Message Object Status Register has been detected. LOE must be reset by software (write 0). Writing 1 has no effect.

Field	Bits	Type	Description
SUSACK	10	rh	**Suspend Acknowledge** 0_B The CAN node is not in Suspend Mode or a suspend request is pending, but the CAN node has not yet reached bus-idle or bus-off. 1_B The CAN node is in Suspend Mode: The CAN node is inactive (bit NCR.INIT internally forced to 1) due to an OCDS suspend request.
RESI	11	rh	**Received Error State Indicator Flag** This bit is an error flag that is set when the ESI flag in a received CAN FD frame is set. 0_B Last received CAN FD message did not have its ESI flag set. 1_B Last received CAN FD message had its ESI flag set.
FLEC	[14:12]	rwh	**Fast Last Error Code** This bit field indicates the type of the last (most recent) CAN error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. The encoding of this bit field is described in **Table 21-12**. This field will be cleared to zero when a CAN FD frame with its BRS flag set has been transferred (reception or transmission) without error.
0	[31:15]	r	**Reserved** Read as 0; should be written with 0.

Encoding of the LEC Bit field

Table 21-12 Encoding of the LEC Bit field

LEC Value	Signification
000_B	**No Error:** No error was detected for the last (most recent) message on the CAN bus.
001_B	**Stuff Error:** More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.
010_B	**Form Error:** A fixed format part of a received frame has the wrong format.

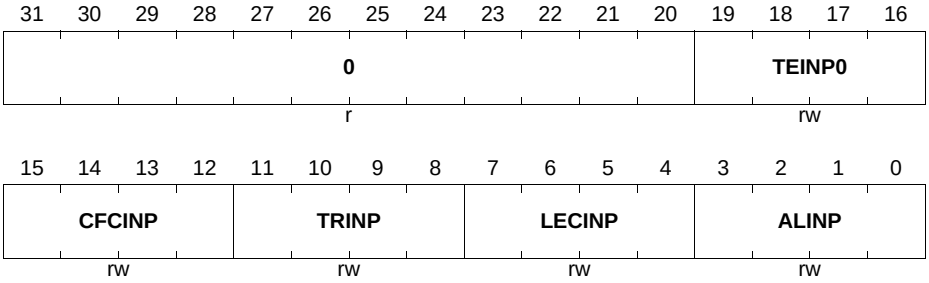
Table 21-12 Encoding of the LEC Bit field (cont'd)

LEC Value	Signification
011_B	**Ack Error:** The transmitted message was not acknowledged by another node.
100_B	**Bit1 Error:** During a message transmission, the CAN node tried to send a recessive level (1) outside the arbitration field and the acknowledge slot, but the monitored bus value was dominant.
101_B	**Bit0 Error:** Two different conditions are signaled by this code: 1. During transmission of a message (or acknowledge bit, active-error flag, overload flag), the CAN node tried to send a dominant level (0), but the monitored bus value was recessive. 2. During bus-off recovery, this code is set each time a sequence of 11 recessive bits has been monitored. The CPU may use this code as indication that the bus is not continuously disturbed.
110_B	**CRC Error:** The CRC checksum of the received message was incorrect.
111_B	**CPU write to LEC:** Whenever the CPU writes the value 111 to LEC, it takes the value 111. Whenever the CPU writes another value to LEC, the written LEC value is ignored.

Note: When a frame in CAN FD format reached data phase with BRS flag set, the next CAN event (error/valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of CAN FD CRC will be shown as Form and not Stuff Error. Correspondingly CAN event (error/valid frame) will be shown back at LEC after the first bit of the CRC delimiter when CAN FD switches from Data bit rate to Nominal bit rate.

The four five interrupt pointers in the Node Interrupt Pointer Register NIPRx select one out of the sixteen interrupt outputs individually for each type of CAN node interrupt. See also **Page 21-34** for more CAN node interrupt details.

CAN_NIPRx (x = 0-2)
Node x Interrupt Pointer Register (208_H+x*100_H) **Reset Value: 0000 0000_H**
CAN1_NIPRy (y=0-2)
Node y Interrupt Pointer Register (208_H+y*100_H) **Reset Value: 0000 0000_H**

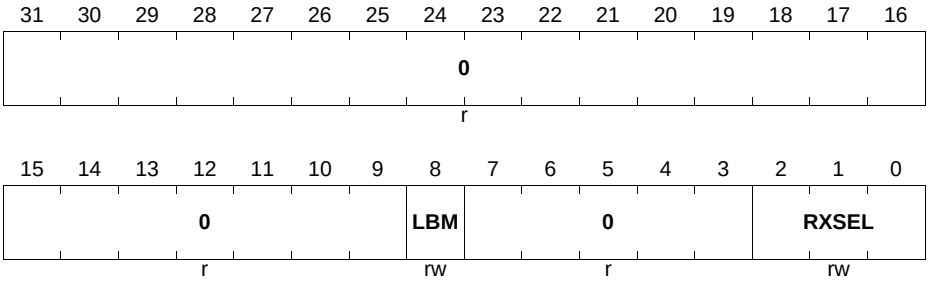


Field	Bits	Type	Description
ALINP	[3:0]	rw	**Alert Interrupt Node Pointer** ALINP selects the interrupt output line INT_Om (m = 0-15), CAN and (m = 0-7), CAN1 for an alert interrupt of CAN Node x. Option 1000_B to 1111_B is Reserved and not applicable for CAN1. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
LECINP	[7:4]	rw	**Last Error Code Interrupt Node Pointer** LECINP selects the interrupt output line INT_Om (m = 0-15), CAN and (m = 0-7), CAN1 for an LEC interrupt of CAN Node x. Option 1000_B to 1111_B is Reserved and not applicable for CAN1. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.

Field	Bits	Type	Description
TRINP	[11:8]	rw	**Transfer OK Interrupt Node Pointer** TRINP selects the interrupt output line INT_Om (m = 0-15), CAN and (m = 0-7), CAN1 for a transfer OK interrupt of CAN Node x. Option 1000_B to 1111_B is Reserved and not applicable for CAN1. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
CFCINP	[15:12]	rw	**Frame Counter Interrupt Node Pointer** CFCINP selects the interrupt output line INT_Om (m = 0-15), CAN and (m = 0-7), CAN1 for a frame counter overflow interrupt of CAN Node x. Option 1000_B to 1111_B is Reserved and not applicable for CAN1. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
TEINP	[19:16]	rw	**Timer Event Interrupt Node Pointer** TEINP selects the interrupt output line INT_Om (m = 0-15), CAN and (m = 0-7), CAN1 for a timer event interrupt of CAN Node x. Option 1000_B to 1111_B is Reserved and not applicable for CAN1. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
0	[31:20 16]	r	**Reserved** Read as 0; should be written with 0.

The Node Port Control Register NPCRx configures the CAN bus transmit/receive ports. NPCRx can be written only if bit NCRx.CCE is set.

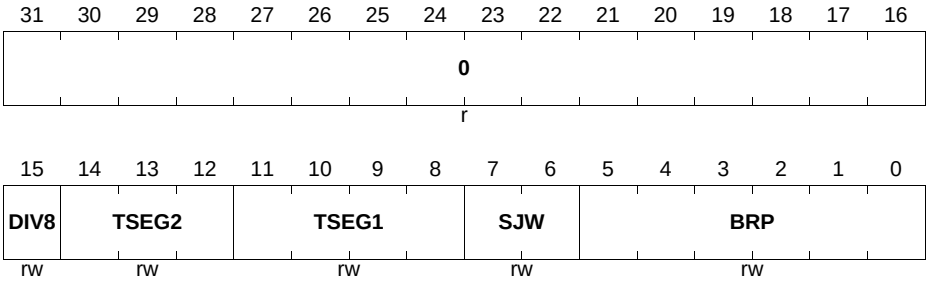
CAN_NPCRx (x = 0-2)
Node x Port Control Register **($20C_H$+x*100_H)** **Reset Value: 0000 0000_H**
CAN1_**NPCRy (y=0-2)**
Node y Port Control Register **($20C_H$+y*100_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RXSEL	[2:0]	rw	**Receive Select** RXSEL selects one out of 8 possible receive inputs. The CAN receive signal is performed only through the selected input. *Note: In TC21x/TC22x/TC23x, only specific combinations of RXSEL are available (see also **"Node Receive Input Selection" on Page 21-170** for description and the page before for RXSEL selections).*
LBM	8	rw	**Loop-Back Mode** 0_B Loop-Back Mode is disabled. 1_B Loop-Back Mode is enabled. This node is connected to an internal (virtual) loop-back CAN bus. All CAN nodes which are in Loop-Back Mode are connected to this virtual CAN bus so that they can communicate with each other internally. The external transmit line is forced recessive in Loop-Back Mode.
0	[7:3], [31:9]	r	**Reserved** Read as 0; should be written with 0.

The Node Bit Timing Register NBTRx contains all parameters to set up the bit timing for the CAN transfer. NBTRx can be written only if bit NCRx.CCE is set. Please note that NBTRx is a register with two views, depending on NCRx.FDEN settings different view applies. (i.e When NCRx.FDEN=0, CAN_NBTRx view applies and when NCRx.FDEN=1, CAN_NBTEVRx applies)

CAN_NBTRx (x = 0-2)
Node x Bit Timing Register **(210_H+x*100_H)** **Reset Value: 0000 0000_H**
CAN1_**NBTRy (y=0-2)**
Node y Bit Timing Register **(210_H+y*100_H)** **Reset Value: 0000 0000_H**

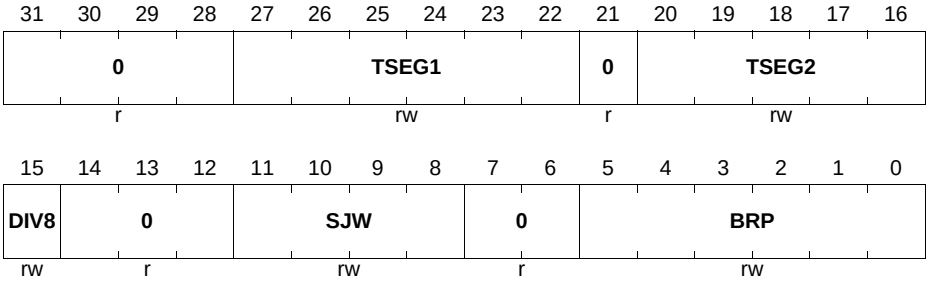


Field	Bits	Type	Description
BRP	[5:0]	rw	**Baud Rate Prescaler** The duration of one time quantum is given by (BRP + 1) clock cycles if DIV8 = 0. The duration of one time quantum is given by 8 × (BRP + 1) clock cycles if DIV8 = 1.
SJW	[7:6]	rw	**(Re) Synchronization Jump Width** (SJW + 1) time quanta are allowed for re-synchronization.
TSEG1	[11:8]	rw	**Time Segment Before Sample Point** (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization. Valid values for TSEG1 are 2 to 15.

Field	Bits	Type	Description
TSEG2	[14:12]	rw	**Time Segment After Sample Point** (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization. Valid values for TSEG2 are 1 to 7.
DIV8	15	rw	**Divide Prescaler Clock by 8** 0_B A time quantum lasts (BRP+1) clock cycles. 1_B A time quantum lasts 8 × (BRP+1) clock cycles.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Node Bit Timing Extended View Register NBTEVRx is applicable only when NCRx.FDEN=1 (CAN FD enabled). NBTEVRx contains all parameters to set up CAN bit timing for Nominal Bit Rate. NBTRx register can be written only if bit NCRx.CCE is set.

CAN_NBTEVRx (x = 0-2)
Node x Bit Timing Extended View Register(210_H+x*100_H) Reset Value: 0000 0000_H
CAN1_NBTEVRy (y = 0-2)
Node y Bit Timing Extended View Register(210_H+y*100_H) Reset Value: 0000 0000_H

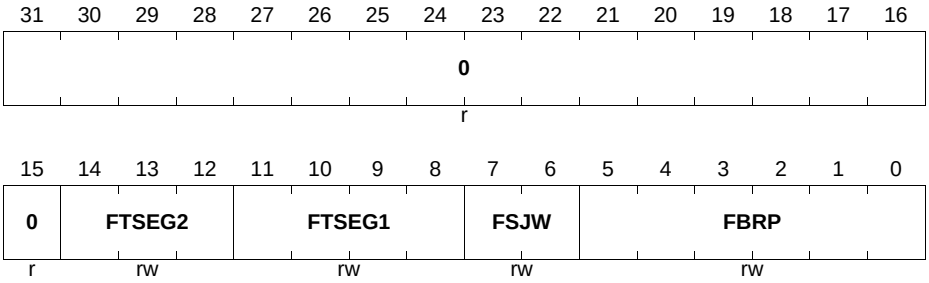


Field	Bits	Type	Description
BRP	[5:0]	rw	**Baud Rate Prescaler** The duration of one time quantum is given by (BRP + 1) clock cycles if DIV8 = 0. The duration of one time quantum is given by 8 × (BRP + 1) clock cycles if DIV8 = 1.
SJW	[11:8]	rw	**(Re) Synchronization Jump Width** (SJW + 1) time quanta are allowed for re-synchronization.
DIV8	15	rw	**Divide Prescaler Clock by 8** 0_B A time quantum lasts (BRP+1) clock cycles. 1_B A time quantum lasts 8 × (BRP+1) clock cycles.
TSEG2	[20:16]	rw	**Time Segment After Sample Point** (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization. Valid values for TSEG2 are 1 to 31.

Field	Bits	Type	Description
TSEG1	[27:22]	rw	**Time Segment Before Sample Point** (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization. Valid values for TSEG1 are 2 to 63.
0	[7:6], [14:12], 21, [31:28]	r	**Reserved** Read as 0; should be written with 0.

The Fast Node Bit Timing Register, FNBTRx contains all parameters to set up CAN bit timing for Data Bit Rate. FNBTRx can be written only if bit NCRx.CCE is set.

CAN_FNBTRx (x = 0-2)
Fast Node x Bit Timing Register (238_H+x*100_H) **Reset Value: 0000 0000_H**
CAN1_FNBTRy (y = 0-2)
Fast Node y Bit Timing Register (238_H+y*100_H) **Reset Value: 0000 0000_H**

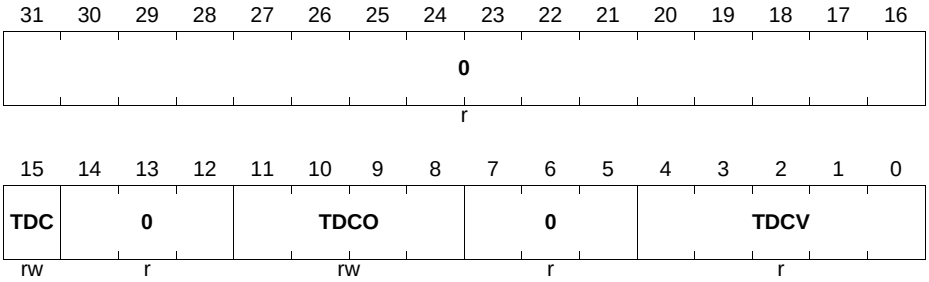


Field	Bits	Type	Description
FBRP	[5:0]	rw	**Fast Baud Rate Prescaler** The duration of one time quantum is given by (BRP + 1) clock cycles.
FSJW	[7:6]	rw	**Fast (Re) Synchronization Jump Width** (SJW + 1) time quanta are allowed for re-synchronization.
FTSEG1	[11:8]	rw	**Fast Time Segment Before Sample Point** (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization.
FTSEG2	[14:12]	rw	**Fast Time Segment After Sample Point** (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization.
0	[31:15]	r	**Reserved** Read as 0; should be written with 0.

The Transmitter Delay Compensation Register, TDCRx contains all parameters to setup the Transmitter Delay Compensation Feature and the corresponding status bits. NTDCRx register can be written only if bit NCRx.CCE is set.

CAN_NTDCRx (x = 0-2)
Node x Transmitter Delay Compensation Register
($23C_H$+x*100_H) **Reset Value: 0000 0000_H**

CAN1_NTDCRz (z = 0-2)
Node z Transmitter Delay Compensation Register
($23C_H$+z*100_H) **Reset Value: 0000 0000_H**

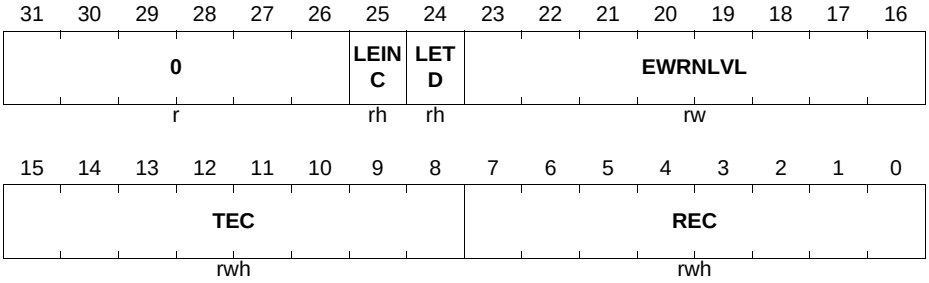


Field	Bits	Type	Description
TDCV	[4:0]	r	**Transmitter Delay Compensation Value** This bit field shows the secondary sample point which is the sum of the measured Transmitter Delay (from CAN Transmit to Receive) and Transmitter Delay compensation offset, NTDCRz.TDCO. Valid values for TDCV are 0 to 31 times of time quanta t_Q.
TDCO	[11:8]	rw	**Transmitter Delay Compensation Offset** This bit field defines the Transmitter Delay compensation offset that is added to the measured Transmitter Delay (from CAN Transmit to Receive) which forms the secondary sample point. Valid values for TDCO are 0 to 15 times of time quanta t_Q.

Field	Bits	Type	Description
TDC	15	rw	**Transmitter Delay Compensation Enable** This bit enables the Transmitter Delay Compensation feature: 0_B Transmitter Delay Compensation disabled. 1_B Transmitter Delay Compensation enabled.
0	[7:5], [14:12], [31:16]	r	**Reserved** Read as 0; should be written with 0.

The Node Error Counter Register NECNTx contains the CAN receive and transmit error counter as well as some additional bits to ease error analysis. NECNTx can be written only if bit NCRx.CCE is set.

CAN_NECNTx (x = 0-2)
Node x Error Counter Register **(214_H+x*100_H)** **Reset Value: 0060 0000$_H$**
CAN1_**NECNTy (y=0-2)**
Node y Error Counter Register **(214_H+y*100_H)** **Reset Value: 0060 0000$_H$**

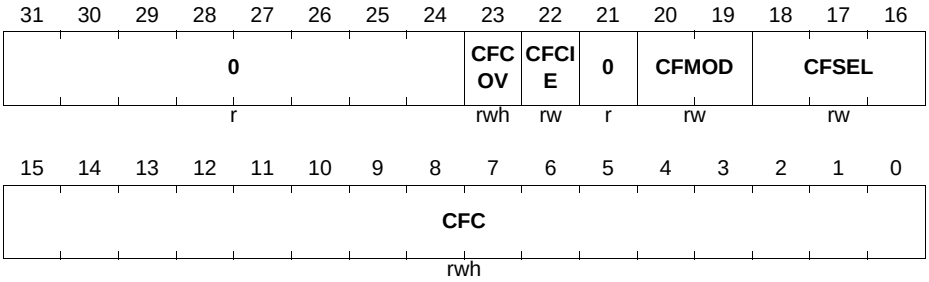


Field	Bits	Type	Description
REC	[7:0]	rwh	**Receive Error Counter** Bit field REC contains the value of the receive error counter of CAN node x.
TEC	[15:8]	rwh	**Transmit Error Counter** Bit field TEC contains the value of the transmit error counter of CAN node x.
EWRNLVL	[23:16]	rw	**Error Warning Level** Bit field EWRNLVL determines the threshold value (warning level, default 96) to be reached in order to set the corresponding error warning bit EWRN.
LETD	24	rh	**Last Error Transfer Direction** 0_B The last error occurred while the CAN node x was receiver (REC has been incremented). 1_B The last error occurred while the CAN node x was transmitter (TEC has been incremented).
LEINC	25	rh	**Last Error Increment** 0_B The last error led to an error counter increment of 1. 1_B The last error led to an error counter increment of 8.

Field	Bits	Type	Description
0	[31:26]	r	**Reserved** Read as 0; should be written with 0.

The Node Frame Counter Register NFCRx contains the actual value of the frame counter as well as control and status bits of the frame counter.

CAN_NFCRx (x = 0-2)
Node x Frame Counter Register ($218_H+x*100_H$) **Reset Value: 0000 0000$_H$**
CAN1_**NFCRy (y=0-2)**
Node y Frame Counter Register ($218_H+y*100_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CFC	[15:0]	rwh	**CAN Frame Counter** In Frame Count Mode (CFMOD = 00_B), this bit field contains the frame count value. In Time Stamp Mode (CFMOD = 01_B), this bit field contains the captured bit time count value, captured with the start of a new frame. In all Bit Timing Analysis Modes[1] (CFMOD = 10_B), CFC always displays the number of f_{CAN} clock cycles (measurement result) minus 1. Example: a CFC value of 34 in measurement mode CFSEL = 000_B means that 35 f_{CAN} clock cycles have been elapsed between the most recent two dominant edges on the receive input. In Error Count Mode (CFMOD = 11_B), this bit field contains the total amount of error frames received or error detected by the node.

Field	Bits	Type	Description
CFSEL	[18:16]	rw	**CAN Frame Count Selection** This bit field selects the function of the frame counter for the chosen frame count mode. **Frame Count Mode** Bit 0 If Bit 0 of CFSEL is set, then CFC is incremented each time a foreign frame (i.e. a frame not matching to a message object) has been received on the CAN bus. Bit 1 If Bit 1 of CFSEL is set, then CFC is incremented each time a frame matching to a message object has been received on the CAN bus. Bit 2 If Bit 2 of CFSEL is set, then CFC is incremented each time a frame has been transmitted successfully by the node. **Time Stamp Mode** The frame counter is incremented (internally) at the beginning of a new bit time. The value is sampled during the SOF bit of a new frame. The sampled value is visible in the CFC field. **Bit Timing Mode** The available bit timing measurement modes are shown in **Table 21-13**. If CFCIE is set, then an interrupt on request node x (where x is the CAN node number) is generated with a CFC update. **Error Count Mode** The frame counter is incremented when an error frame is received or an error is detected by the node. (001_B to 110_B) (see **Table 21-12** for **Encoding of the LEC Bit field**).
CFMOD	[20:19]	rw	**CAN Frame Counter Mode** This bit field determines the operation mode of the frame counter. 00_B Frame Count Mode: The frame counter is incremented upon the reception and transmission of frames. 01_B Time Stamp Mode: The frame counter is used to count bit times. 10_B Bit Timing Mode: The frame counter is used for analysis of the bit timing. 11_B Error Count Mode: The frame counter is used for counting when an error frame is received or an error is detected by the node.

Field	Bits	Type	Description
CFCIE	22	rw	**CAN Frame Count Interrupt Enable** CFCIE enables the CAN frame counter overflow interrupt of CAN node x. 0_B CAN frame counter overflow interrupt is disabled. 1_B CAN frame counter overflow interrupt is enabled. Bit field NIPRx.CFCINP selects the interrupt output line that is activated at this type of interrupt.
CFCOV	23	rwh	**CAN Frame Counter Overflow Flag** Flag CFCOV is set upon a frame counter overflow (transition from $FFFF_H$ to 0000_H). In bit timing analysis mode, CFCOV is set upon an update of CFC. An interrupt request is generated if CFCIE = 1. 0_B No overflow has occurred since last flag reset. 1_B An overflow has occurred since last flag reset. CFCOV must be reset by software.
0	21, [31:24]	r	**Reserved** Read as 0; should be written with 0.

1) The value of NFCRx.CFC is valid one module cycle later when NFCRx.CFCOV is set.

Bit Timing Analysis Modes

Table 21-13 Bit Timing Analysis Modes (CFMOD = 10)

CFSEL	Measurement
000_B	Whenever a dominant edge (transition from 1 to 0) is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC.
001_B	Whenever a recessive edge (transition from 0 to 1) is monitored on the receive input the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC.
010_B	Whenever a dominant edge is received as a result of a transmitted dominant edge, the time (clock cycles) between both edges is stored in CFC.
011_B	Whenever a recessive edge is received as a result of a transmitted recessive edge, the time (clock cycles) between both edges is stored in CFC.
100_B	Whenever a dominant edge that qualifies for synchronization is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent sample point is stored in CFC.

Table 21-13 Bit Timing Analysis Modes (CFMOD = 10) (cont'd)

CFSEL	Measurement
101_B	With each sample point, the time (measured in clock cycles) between the start of the new bit time and the start of the previous bit time is stored in CFC[11:0]. Additional information is written to CFC[15:12] at each sample point: CFC[15]: Transmit value of actual bit time CFC[14]: Receive sample value of actual bit time CFC[13:12]: CAN bus information (see **Table 21-14**)
110_B	Reserved, do not use this combination.
111_B	Reserved, do not use this combination.

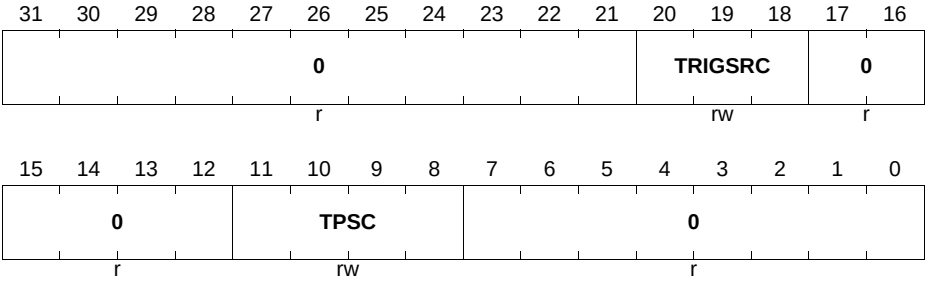
Table 21-14 CAN Bus State Information

CFC[13:12]	CAN Bus State
00_B	**NoBit** The CAN bus is idle, performs bit (de-) stuffing or is in one of the following frame segments: SOF, SRR, CRC, delimiters, first 6 EOF bits, IFS.
01_B	**NewBit** This code represents the first bit of a new frame segment. The current bit is the first bit in one of the following frame segments: Bit 10 (MSB) of standard ID (transmit only), RTR, reserved bits, IDE, DLC(MSB), bit 7 (MSB) in each data byte and the first bit of the ID extension.
10_B	**Bit** This code represents a bit inside a frame segment with a length of more than one bit (not the first bit of those frame segments that is indicated by NewBit). The current bit is processed within one of the following frame segments: ID bits (except first bit of standard ID for transmission and first bit of ID extension), DLC (3 LSB) and bits 6-0 in each data byte.
11_B	**Done** The current bit is in one of the following frame segments: Acknowledge slot, last bit of EOF, active/passive-error frame, overload frame. Two or more directly consecutive Done codes signal an Error Frame.

The Node x Timer Clock Control, Node x Timer Receive Timeout and Node x Timer A/B/C Transmit Trigger Registers offer additional timing functions for the node.

The Node x Timer Clock Control Register NTCCRx controls the functions of the node timer.

CAN_NTCCRx (x = 0-2)
Node x Timer Clock Control Register ($21C_H$+x*100_H) **Reset Value: 0000 0000$_H$**
CAN1_**NTCCRy (y=0-2)**
Node y Timer Clock Control Register ($21C_H$+y*100_H) **Reset Value: 0000 0000$_H$**

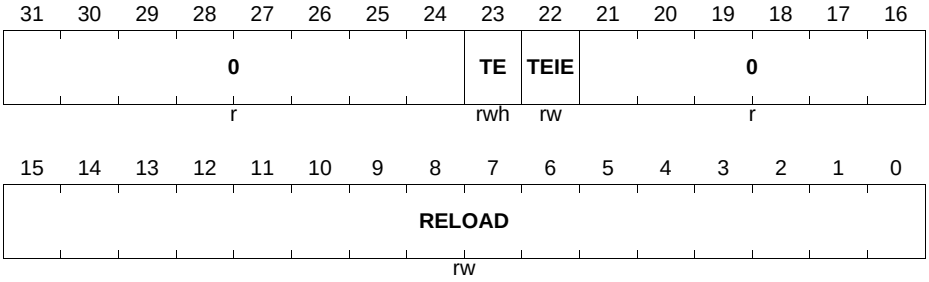


Field	Bits	Type	Description
0	[7:0]	r	**Reserved** Read as 0; should be written with 0.
TPSC	[11:8]	rw	**Timer Prescaler** The duration of one timer clock is given by (TPSC + 1) CAN bit times for all NTCCRx.TRIGSRC settings.
0	[17:12]	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
TRIGSRC	[20:18]	rw	**Trigger Source** This bit selects the trigger source for the different modes in the node timer. 000_B Node x Timer is decremented per f_{CLC} timing to 0. 001_B System Timer (STM) trigger event enabled. Node x Timer is decremented per STM trigger event prescaled by (TPSC + 1). 010_B General Timer (GTM) trigger event enabled. Node x Timer is decremented per GTM trigger event prescaled by (TPSC + 1). 011_B Reserved, do not use. $\ldots_B$ ... 111_B Reserved, do not use.
0	[31:21]	r	**Reserved** Read as 0; should be written with 0.

The Node x Timer Receive Timeout Register NTRTx controls the node timing functions for Receive Timeout Mode.

CAN_NTRTRx (x = 0-2)
Node x Timer Receive Timeout Register (220_H+x*100_H) **Reset Value: 0000 0000_H**
CAN1_**NTRTRy (y=0-2)**
Node y Timer Receive Timeout Register (220_H+y*100_H) **Reset Value: 0000 0000_H**

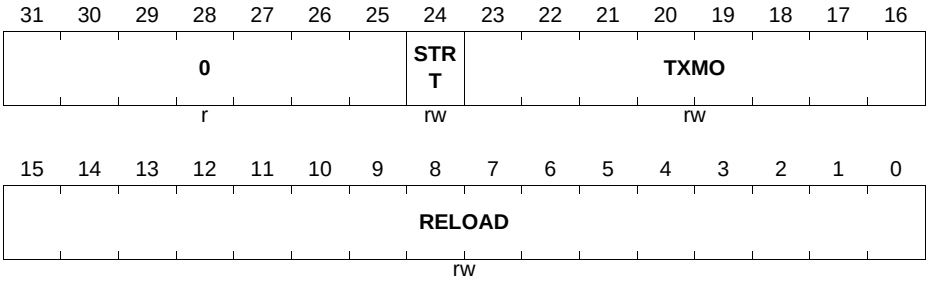


Field	Bits	Type	Description
RELOAD	[15:0]	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
0	[21:16]	r	**Reserved** Read as 0; should be written with 0.
TEIE	22	rw	**Timer Event Interrupt Enable** This bit enables the node timer event interrupt of CAN node x. 0_B Timer event interrupt is disabled 1_B Timer event interrupt is enabled Bit field NIPRx.TEINP selects the interrupt output line which becomes activated at this type of interrupt.
TE	23	rwh	**Timer Event** This flag is set on a node timer transition from 1 to 0 in Receive Timeout Mode. This bit must be reset (i.e Write to '0') by software, writing a '1' has no effect. 0_B No timer event has occurred since last flag reset 1_B Timer event has occurred since last flag reset An interrupt request is generated if TEIE = 1.

Field	Bits	Type	Description
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

The Node x Timer A Transmit Trigger Register NTATTx controls the node timing functions for Transmit Trigger Mode.

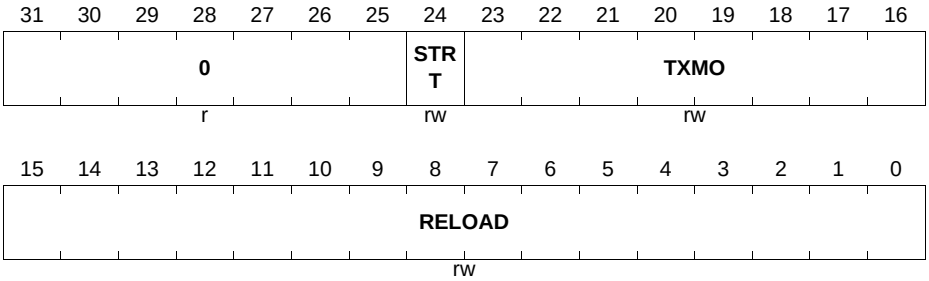
CAN_NTATTRx (x = 0-2)
Node x Timer A Transmit Trigger Register (224_H+x*100_H) Reset Value: 0000 0000_H
CAN1_**NTATTRy (y=0-2)**
Node y Timer A Transmit Trigger Register (224_H+y*100_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
RELOAD	[15:0]	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	[23:16]	rw	**Transmit Message Object** On a transmit trigger event selected by bit TRIGSRC, the transmit request bit MOSTATn.TXRQ of message object number n will be set. Note: The NTATTRx.STRT timer has to be stopped before a new value can be programmed into TXMO, i.e 1) Program NTATTR.STRT=0 2) Program NTATTR.TXMO with new value
STRT	24	rw	**Timer Start** This bit field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	[31:25]	r	**Reserved** Read as 0; should be written with 0.

The Node x Timer B Transmit Trigger Register NTBTTx controls the node timing functions for Transmit Trigger Mode.

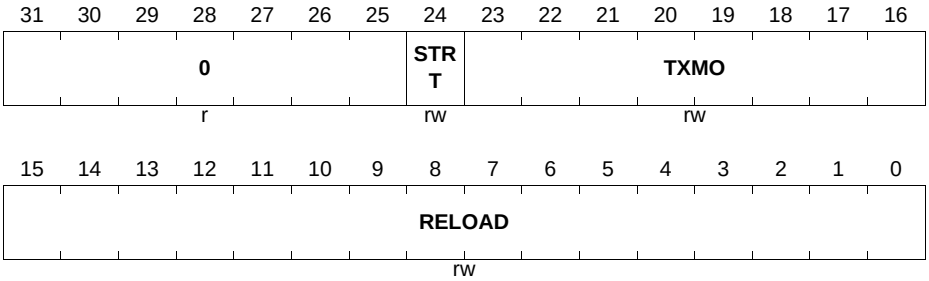
CAN_NTBTTRx (x = 0-2)
Node x Timer B Transmit Trigger Register (228_H+x*100_H) Reset Value: 0000 0000_H
CAN1_**NTBTTRy (y=0-2)**
Node y Timer B Transmit Trigger Register (228_H+y*100_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
RELOAD	[15:0]	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	[23:16]	rw	**Transmit Message Object** On a transmit trigger event selected by bit TRIGSRC, the transmit request bit MOSTATn.TXRQ of message object number n will be set. Note: The NTBTTRx.STRT timer has to be stopped before a new value can be programmed into TXMO, i.e 1) Program NTBTTR.STRT=0 2) Program NTBTTR.TXMO with new value
STRT	24	rw	**Timer Start** This bit field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	[31:25]	r	**Reserved** Read as 0; should be written with 0.

The Node x Timer C Transmit Trigger Register NTCTTx controls the node timing functions for Transmit Trigger Mode.

CAN_NTCTTRx (x = 0-2)
Node x Timer C Transmit Trigger Register ($22C_H$+x*100_H) Reset Value: 0000 0000_H
CAN1_**NTCTTRy (y=0-2)**
Node y Timer C Transmit Trigger Register ($22C_H$+y*100_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
RELOAD	[15:0]	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	[23:16]	rw	**Transmit Message Object** On a transmit trigger event selected by bit TRIGSRC, the transmit request bit MOSTATn.TXRQ of message object number n will be set. Note: The NTCTTRx.STRT timer has to be stopped before a new value can be programmed into TXMO, i.e 1) Program NTCTTR.STRT=0 2) Program NTCTTR.TXMO with new value
STRT	24	rw	**Timer Start** This bit field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	[31:25]	r	**Reserved** Read as 0; should be written with 0.

21.6.3 Message Object Registers

The Message Object Control Register MOCTRn and the Message Object Status Register MOSTATn are located at the same address offset within a message object address block (offset address $1C_H$). The MOCTRn is a write-only register that makes it possible to set/reset CAN transfer related control bits through software. Therefore the reset value is written as 0x0, even though the read part of the register has a different reset value.

CAN_MOCTRz (z = 0-126)
Message Object z Control Register($101C_H+z*20_H$) **Reset Value: 00000000_H**
CAN1_**MOCTRw (w=0-126)**
Message Object w Control Register($101C_H+w*20_H$) **Reset Value: 0000 0000_H**
CAN_MOCTR127
Message Object 127 Control Register($1FFC_H$) **Reset Value: 00000000_H**
CAN1_MOCTR127
Message Object 127 Control Register($1FFC_H$) **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				SET DIR	SET TXEN1	SET TXEN0	SET TXRQ	SET RXEN	SET RTSEL	SET MSGVAL	SET MSGLST	SET NEWDAT	SET RXUPD	SET TXPND	SET RXPND
w				w	w	w	w	w	w	w	w	w	w	w	w

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

w				w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
RESRXPND, SETRXPND	0, 16	w	**Reset/Set Receive Pending** These bits control the set/reset condition for RXPND (see **Table 21-15**).
RESTXPND, SETTXPND	1, 17	w	**Reset/Set Transmit Pending** These bits control the set/reset condition for TXPND (see **Table 21-15**).
RESRXUPD, SETRXUPD	2, 18	w	**Reset/Set Receive Updating** These bits control the set/reset condition for RXUPD (see **Table 21-15**).

Field	Bits	Type	Description
RESNEWDAT, SETNEWDAT	3, 19	w	**Reset/Set New Data** These bits control the set/reset condition for NEWDAT (see **Table 21-15**).
RESMSGLST, SETMSGLST	4, 20	w	**Reset/Set Message Lost** These bits control the set/reset condition for MSGLST (see **Table 21-15**).
RESMSGVAL, SETMSGVAL	5, 21	w	**Reset/Set Message Valid** These bits control the set/reset condition for MSGVAL (see **Table 21-15**).
RESRTSEL, SETRTSEL	6, 22	w	**Reset/Set Receive/Transmit Selected** These bits control the set/reset condition for RTSEL (see **Table 21-15**).
RESRXEN, SETRXEN	7, 23	w	**Reset/Set Receive Enable** These bits control the set/reset condition for RXEN (see **Table 21-15**).
RESTXRQ, SETTXRQ	8, 24	w	**Reset/Set Transmit Request** These bits control the set/reset condition for TXRQ (see **Table 21-15**).
RESTXEN0, SETTXEN0	9, 25	w	**Reset/Set Transmit Enable 0** These bits control the set/reset condition for TXEN0 (see **Table 21-15**).
RESTXEN1, SETTXEN1	10, 26	w	**Reset/Set Transmit Enable 1** These bits control the set/reset condition for TXEN1 (see **Table 21-15**).
RESDIR, SETDIR	11, 27	w	**Reset/Set Message Direction** These bits control the set/reset condition for DIR (see **Table 21-15**).
0	[15:12], [31:28]	w	**Reserved** Should be written with 0.

Table 21-15 Reset/Set Conditions for Bits in Register MOCTRn

RESy Bit[1)]	SETy Bit	Action on Write
Write 0	Write 0	Leave element unchanged
	No write	
No write	Write 0	
Write 1	Write 1	
Write 1	Write 0	Reset element
	No write	
Write 0	Write 1	Set element
No write		

1) The parameter “y” stands for the second part of the bit name (“RXPND”, “TXPND”, … up to “DIR”).

The MOSTATn is a read-only register that indicates message object list status information such as the number of the current message object predecessor and successor message object, as well as the list number to which the message object is assigned.

CAN_MOSTAT0
Message Object 0 Status Register ($101C_H$) Reset Value: 0100 0000_H
CAN1_**MOSTAT0**
Message Object 0 Status Register ($101C_H$) Reset Value: 0100 0000_H
CAN_MOSTATn (n = 1-126)
Message Object n Status Register($101C_H$+n*20_H)
Reset Value: ((n+1)*01000000_H)+((n-1)*00010000_H)
CAN1_**MOSTATw (w = 1-126)**
Message Object w Status Register($101C_H$+w*20_H)
Reset Value: ((w+1)*01000000_H)+((w-1)*00010000_H)
CAN_MOSTAT127
Message Object 127 Status Register ($1FFC_H$) Reset Value: 7F7E 0000_H
CAN1_**MOSTAT127**
Message Object 127 Status Register ($1FFC_H$) Reset Value: 7F7E 0000_H

rh				rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RXPND	0	rh	**Receive Pending** 0_B No CAN message has been received. 1_B A CAN message has been received by the message object n, either directly or via gateway copy action. RXPND is set by hardware and must be reset by software.

Field	Bits	Type	Description
TXPND	1	rh	**Transmit Pending** 0_B No CAN message has been transmitted. 1_B A CAN message from message object n has been transmitted successfully over the CAN bus. TXPND is set by hardware and must be reset by software.
RXUPD	2	rh	**Receive Updating** 0_B No receive update ongoing. 1_B Message identifier, DLC, and data of the message object are currently updated.
NEWDAT	3	rh	**New Data** 0_B No update of the message object n since last flag reset. 1_B Message object n has been updated. NEWDAT is set by hardware after a received CAN frame has been stored in message object n. NEWDAT is cleared by hardware when a CAN transmission of message object n has been started. NEWDAT should be set by software after the new transmit data has been stored in message object n to prevent the automatic reset of TXRQ at the end of an ongoing transmission.
MSGLST	4	rh	**Message Lost** 0_B No CAN message is lost. 1_B A CAN message is lost because NEWDAT has become set again when it has already been set.
MSGVAL	5	rh	**Message Valid** 0_B Message object n is not valid. 1_B Message object n is valid. Only a valid message object takes part in CAN transfers.

Field	Bits	Type	Description
RTSEL	6	rh	**Receive/Transmit Selected** 0_B Message object n is not selected for receive or transmit operation. 1_B Message object n is selected for receive or transmit operation. **Frame Reception:** RTSEL is set by hardware when message object n has been identified for storage of a CAN frame that is currently received. Before a received frame becomes finally stored in message object n, a check is performed to determine if RTSEL is set. Thus the CPU can suppress a scheduled frame delivery to this message object n by clearing RTSEL by software. **Frame Transmission:** RTSEL is set by hardware when message object n has been identified to be transmitted next. A check is performed to determine if RTSEL is still set before message object n is actually set up for transmission and bit NEWDAT is cleared. It is also checked that RTSEL is still set before its message object n is verified due to the successful transmission of a frame. RTSEL needs to be checked only when the context of message object n changes, and a conflict with an ongoing frame transfer shall be avoided. In all other cases, RTSEL can be ignored. RTSEL has no impact on message acceptance filtering. RTSEL is not cleared by hardware.
RXEN	7	rh	**Receive Enable** 0_B Message object n is not enabled for frame reception. 1_B Message object n is enabled for frame reception. RXEN is evaluated for receive acceptance filtering only.

Field	Bits	Type	Description
TXRQ	8	rh	**Transmit Request** 0_B No transmission of message object n is requested. 1_B Transmission of message object n on the CAN bus is requested. The transmit request becomes valid only if TXRQ, TXEN0, TXEN1 and MSGVAL are set. TXRQ is set by hardware if a matching Remote Frame has been received correctly. TXRQ is reset by hardware if message object n has been transmitted successfully and NEWDAT is not set again by software.
TXEN0	9	rh	**Transmit Enable 0** 0_B Message object n is not enabled for frame transmission. 1_B Message object n is enabled for frame transmission. Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set. The user may clear TXEN0 in order to inhibit the transmission of a message that is currently updated, or to disable automatic response of Remote Frames.
TXEN1	10	rh	**Transmit Enable 1** 0_B Message object n is not enabled for frame transmission. 1_B Message object n is enabled for frame transmission. Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set. TXEN1 is used by the MultiCAN+ module for selecting the active message object in the Transmit FIFOs.

Field	Bits	Type	Description
DIR	11	rh	**Message Direction** 0_B Receive Object selected: With TXRQ = 1, a Remote Frame with the identifier of message object n is scheduled for transmission. On reception of a Data Frame with matching identifier, the message is stored in message object n. 1_B Transmit Object selected: If TXRQ = 1, message object n is scheduled for transmission of a Data Frame. On reception of a Remote Frame with matching identifier, bit TXRQ is set.
LIST	[15:12]	rh	**List Allocation** LIST indicates the number of the message list to which message object n is allocated. LIST is updated by hardware when the list allocation of the object is modified by a panel command.
PPREV	[23:16]	rh	**Pointer to Previous Message Object** PPREV holds the message object number of the previous message object in a message list structure.
PNEXT	[31:24]	rh	**Pointer to Next Message Object** PNEXT holds the message object number of the next message object in a message list structure.

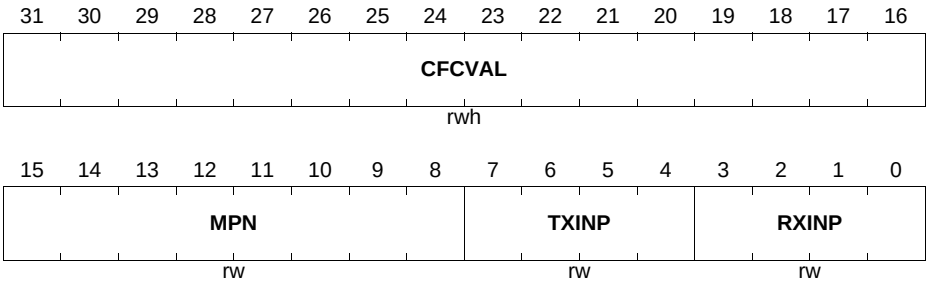
Table 21-16 MOSTATn Reset Values

Message Object	PNEXT	PPREV	Reset Value
0	1	0	$0100\ 0000_H$
1	2	0	$0200\ 0000_H$
2	3	1	$0301\ 0000_H$
3	4	2	$0402\ 0000_H$
…	…	…	…
127	127	126	$7F7E\ 0000_H$

The Message Object Interrupt Pointer Register MOIPRn holds the message interrupt pointers, the message pending number, and the frame counter value of message object n.

CAN_MOIPRn (n = 0-127)
Message Object n Interrupt Pointer Register
(1008_H+n*20_H) **Reset Value: 0000 0000_H**

CAN1_**MOIPRw (w = 0 - 127)**
Message Object w Interrupt Pointer Register
(1008_H+w*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RXINP	[3:0]	rw	**Receive Interrupt Node Pointer** RXINP selects the interrupt output line INT_Om (m = 0-15), CAN and (m = 0-7), CAN1 for a receive interrupt event of message object n. RXINP can also be taken for message pending bit selection (see **Page 21-48**). Option 1000_B to 1111_B is Reserved and not applicable for CAN1**.** 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\cdots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.

Field	Bits	Type	Description
TXINP	[7:4]	rw	**Transmit Interrupt Node Pointer** TXINP selects the interrupt output line INT_Om (m = 0-15), CAN and (m = 0-7), CAN1 for a transmit interrupt event of message object n. TXINP can also be taken for message pending bit selection (see **Page 21-48**). Option 1000_B to 1111_B is Reserved and not applicable for CAN1**.** 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
MPN	[15:8]	rw	**Message Pending Number** This bit field selects the bit position of the bit in the Message Pending Register that is set upon a message object n receive/transmit interrupt.
CFCVAL	[31:16]	rwh	**CAN Frame Counter Value** When a message is stored in message object n or message object n has been successfully transmitted, the CAN frame counter value NFCRx.CFC is then copied to CFCVAL.

The Message Object Function Control Register MOFCRn contains bits that select and configure the function of the message object. It also holds the CAN data length code.

CAN_MOFCRn (n = 0-127)
Message Object n Function Control Register
(1000_H+n*20_H) **Reset Value: 0000 0000_H**

CAN1_**MOFCRw (w = 0 - 127)**
Message Object w Function Control Register
(1000_H+w*20_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
MMC	[3:0]	rw	**Message Mode Control** MMC controls the message mode of message object n. 0000_B Standard Message Object 0001_B Receive FIFO Base Object 0010_B Transmit FIFO Base Object 0011_B Transmit FIFO Slave Object 0100_B Gateway Source Object 0101_B CANFD 64 bytes Message Mode $\ldots_B$ ... 1111_B Do not use

Field	Bits	Type	Description
RXTOE	4	rw	**Receive Time-Out Enable** RXTOE enables participation of message in receive time-out check which is performed via a Timer controlled by the register NTRTR of the corresponding node. 0_B Message does not take part in receive time-out check 1_B Message takes part in receive time-out check Applicable to receive messages and to transmit messages waiting for remote frames.
BRS	5	rwh	**Bit Rate Switch** 0_B Message Object transmission/reception without bit rate switching. 1_B Message Object transmission/reception with bit rate switching. Please see **Section 21.4.12.4** and **Table 21-18**
FDF	6	rwh	**CAN FD Frame Format** 0_B Message Object transmission/reception in Classical CAN Frame Format. 1_B Message Object transmission/reception in CAN FD Format (new DLC coding and CRC) Please see **Section 21.4.12.4** and **Table 21-18**
GDFS	8	rw	**Gateway Data Frame Send** 0_B TXRQ is unchanged in the destination object. 1_B TXRQ is set in the gateway destination object after the internal transfer from the gateway source to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.
IDC	9	rw	**Identifier Copy** 0_B The identifier of the gateway source object is not copied. 1_B The identifier of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.

Field	Bits	Type	Description
DLCC	10	rw	**Data Length Code Copy** 0_B Data length code is not copied. 1_B Data length code of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.
DATC	11	rw	**Data Copy** 0_B Data fields are not copied. 1_B Data fields in registers MODATALn and MODATAHn of the gateway source object (after storing the received frame in the source) are copied to the gateway destination. Applicable only to a gateway source object; ignored in other nodes.
RXIE	16	rw	**Receive Interrupt Enable** RXIE enables the message receive interrupt of message object n. This interrupt is generated after reception of a CAN message (independent of whether the CAN message is received directly or indirectly via a gateway action). 0_B Message receive interrupt is disabled. 1_B Message receive interrupt is enabled. Bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt.
TXIE	17	rw	**Transmit Interrupt Enable** TXIE enables the message transmit interrupt of message object n. This interrupt is generated after the transmission of a CAN message. 0_B Message transmit interrupt is disabled. 1_B Message transmit interrupt is enabled. Bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt.

Field	Bits	Type	Description
OVIE	18	rw	**Overflow Interrupt Enable** OVIE enables the FIFO full interrupt of message object n. This interrupt is generated when the pointer to the current message object (CUR) reaches the value of SEL in the FIFO/Gateway Pointer Register. 0_B FIFO full interrupt is disabled. 1_B FIFO full interrupt is enabled. If message object n is a Receive FIFO base object, bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt. If message object n is a Transmit FIFO base object, bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt. For all other message object modes, bit OVIE has no effect.
FRREN	20	rw	**Foreign Remote Request Enable** Specifies whether the TXRQ bit is set in message object n or in a foreign message object referenced by the pointer CUR. 0_B TXRQ of message object n is set on reception of a matching Remote Frame. 1_B TXRQ of the message object referenced by the pointer CUR is set on reception of a matching Remote Frame.
RMM	21	rw	**Transmit Object Remote Monitoring** 0_B Remote monitoring is disabled: Identifier, IDE bit, and DLC of message object n remain unchanged upon the reception of a matching Remote Frame. 1_B Remote monitoring is enabled: Identifier, IDE bit, and DLC of a matching Remote Frame are copied to transmit object n in order to monitor incoming Remote Frames. Bit RMM applies only to transmit objects and has no effect on receive objects.

Field	Bits	Type	Description
SDT	22	rw	**Single Data Transfer** If SDT = 1 and message object n is not a FIFO base object, then MSGVAL is reset when this object has taken part in a successful data transfer (receive or transmit). If SDT = 1 and message object n is a FIFO base object, then MSGVAL is reset when the pointer to the current object CUR reaches the value of SEL in the FIFO/Gateway Pointer Register. With SDT = 0, bit MSGVAL is not affected.
STT	23	rw	**Single Transmit Trial** If this bit is set, then TXRQ is cleared on transmission start of message object n. Thus, no transmission retry is performed in case of transmission failure.
DLC	[27:24]	rwh	**Data Length Code** Bit field determines the number of data bytes for message object n. In Classical CAN Format: A value of DLC > 8 results in a data length of 8 data bytes. If a frame with DLC > 8 is received, the received value is stored in the message object. In CAN FD format, valid values for DLC are 0 to 15. See **Table 21-17**
0	7, [15:12], 19, [31:28]	rw	**Reserved** Read as 0 after reset; value last written is read back; should be written with 0.

Coding of DLC in CAN FD

Table 21-17 Coding of DLC in CAN FD

DLC Value	Description
0000_B	0 Data Byte for Message Object n.
$\cdots_B$	...
1000_B	8 Data Byte for Message Object n.
1001_B	12 Data Byte for Message Object n.
1010_B	16 Data Byte for Message Object n.

Table 21-17 Coding of DLC in CAN FD (cont'd)

DLC Value	Description
1011_B	20 Data Byte for Message Object n.
1100_B	24 Data Byte for Message Object n.
1101_B	32 Data Byte for Message Object n.
1110_B	48 Data Byte for Message Object n.
1111_B	64 Data Byte for Message Object n.

CAN FD Transmit And Receive Behavior

Message transmission and reception behavior of CAN data frames is summarized at **Table 21-18** below.

Table 21-18 CAN FD Transmit And Receive Behavior

FDEN	FDF[1)]	BRS[1)]	Transmit Behavior
0_B	0_B	0_B	Classical CAN Frames (ISO 11898-1)
0_B	0_B	1_B	Classical CAN Frames (ISO 11898-1)
0_B	1_B	0_B	Transmission Cancelled[2)] (i.e TXRQ bit cleared)
0_B	1_B	1_B	Transmission Cancelled[2)] (i.e TXRQ bit cleared)
1_B	0_B	0_B	Classical CAN Frames (ISO 11898-1)
1_B	0_B	1_B	Classical CAN Frames (ISO 11898-1)
1_B	1_B	0_B	Long Frame (i.e CAN FD frame with BRS = 0, whole frame transmitted with slow baudrate)
1_B	1_B	1_B	Long + Fast Frame (i.e CAN FD frame with BRS = 1, switching fast baudrate for dataphase)
FDEN	**FDF[3)]**	**BRS[3)]**	**Receive Behavior[4)]**
0_B	$0/1_B$	$0/1_B$	- Classical CAN Frames
1_B	$0/1_B$	$0/1_B$	- Classical CAN Frames - Long Frames - Long + Fast Frames

1) User writes

2) TXRQ in message object is cleared upon transmit setup and transmit setup cancelled. CAN node is not blocked and able to transmit other message objects.

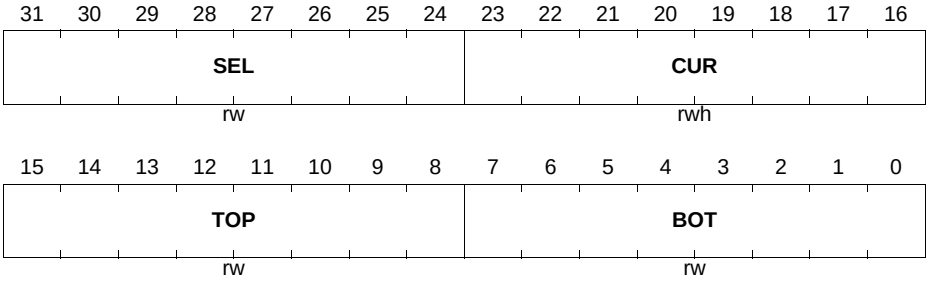
3) Hardware writes

4) Please note that Remote Frames Request do not change BRS and FDF bits.

The Message Object FIFO/Gateway Pointer register MOFGPRn contains a set of message object link pointers that are used for FIFO and gateway operations.

CAN_MOFGPRn (n = 0-127)
Message Object n FIFO/Gateway Pointer Register
(1004_H+n*20_H) **Reset Value: 0000 0000_H**

CAN1_**MOFGPRw (w = 0 - 127)**
Message Object n FIFO/Gateway Pointer Register
(1004_H+w*20_H) **Reset Value: 0000 0000_H**



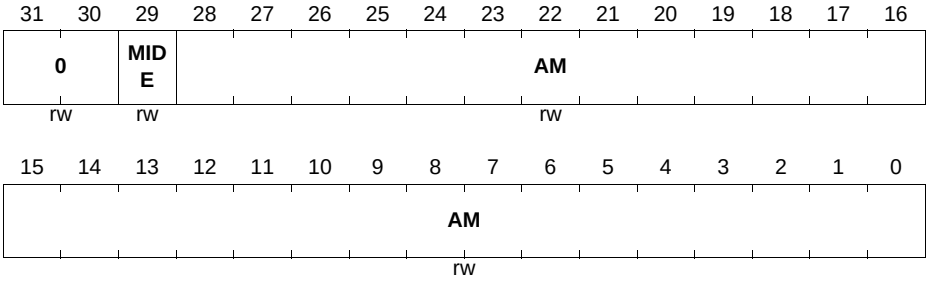
Field	Bits	Type	Description
BOT	[7:0]	rw	**Bottom Pointer** Bit field BOT points to the first element in a FIFO structure. Or in the case when MOFCR.MMC=5, CAN FD 64 bytes message mode, BOT points to where Data bytes 8-35 are stored in the message object.
TOP	[15:8]	rw	**Top Pointer** Bit field TOP points to the last element in a FIFO structure. Or in the case when MOFCR.MMC=5, CAN FD 64 bytes message mode, BOT points to where Data bytes 36-63 are stored in the message object.
CUR	[23:16]	rwh	**Current Object Pointer** Bit field CUR points to the actual target object within a FIFO/Gateway structure. After a FIFO/gateway operation CUR is updated with the message number of the next message object in the list structure (given by PNEXT of the Message Object Status Register) until it reaches the FIFO top element (given by TOP) when it is reset to the bottom element (given by BOT).

Field	Bits	Type	Description
SEL	[31:24]	rw	**Object Select Pointer** Bit field SEL is the second (software) pointer to complement the hardware pointer CUR in the FIFO structure. SEL is used for monitoring purposes (FIFO interrupt generation).

Message Object n Acceptance Mask Register MOAMRn contains the mask bits for the acceptance filtering of the message object n.

CAN_MOAMRn (n = 0-127)
Message Object n Acceptance Mask Register
($100C_H+n*20_H$) **Reset Value: 3FFF FFFF$_H$**

CAN1_**MOAMRw (w = 0 - 127)**
Message Object w Acceptance Mask Register
($100C_H+w*20_H$) **Reset Value: 3FFF FFFF$_H$**

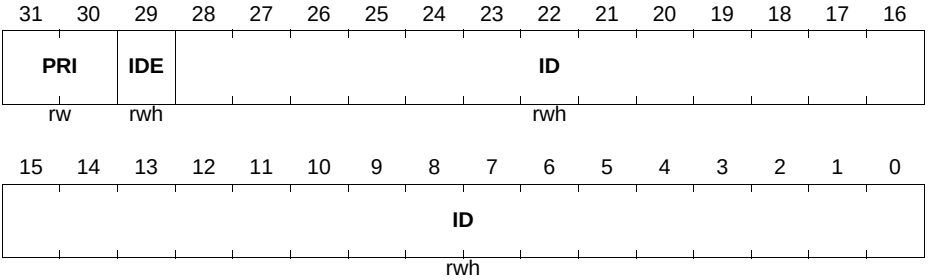


Field	Bits	Type	Description
AM	[28:0]	rw	**Acceptance Mask for Message Identifier** Bit field AM is the 29-bit mask for filtering incoming messages with standard identifiers (AM[28:18]) or extended identifiers (AM[28:0]). For standard identifiers, bits AM[17:0] are “don’t care”.
MIDE	29	rw	**Acceptance Mask Bit for Message IDE Bit** 0_B Message object n accepts the reception of both, standard and extended frames. 1_B Message object n receives frames only with matching IDE bit.
0	[31:30]	rw	**Reserved** Read as 0 after reset; value last written is read back; should be written with 0.

Message Object n Arbitration Register MOARn contains the CAN identifier of the message object.

CAN_MOARn (n = 0-127)
Message Object n Arbitration Register
(1018_H+n*20_H) **Reset Value: 0000 0000_H**

CAN1_**MOARw (w = 0 - 127)**
Message Object w Arbitration Register
(1018_H+w*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
ID	[28:0]	rwh	**CAN Identifier of Message Object n** Identifier of a standard message (ID[28:18]) or an extended message (ID[28:0]). For standard identifiers, bits ID[17:0] are “don’t care”.
IDE	29	rwh	**Identifier Extension Bit of Message Object n** 0_B Message object n handles standard frames with 11-bit identifier. 1_B Message object n handles extended frames with 29-bit identifier.

Field	Bits	Type	Description
PRI	[31:30]	rw	**Priority Class** PRI assigns one of the four priority classes 0, 1, 2, 3 to message object n. A lower PRI number defines a higher priority. Message objects with lower PRI value always win acceptance filtering for frame reception and transmission over message objects with higher PRI value. Acceptance filtering based on identifier/mask and list position is performed only between message objects of the same priority class. PRI also determines the acceptance filtering method for transmission: 00_B Reserved. 01_B Transmit acceptance filtering is based on the list order. This means that message object n is considered for transmission only if there is no other message object with valid transmit request (MSGVAL & TXEN0 & TXEN1 = 1) somewhere before this object in the list. 10_B Transmit acceptance filtering is based on the CAN identifier. This means, message object n is considered for transmission only if there is no other message object with higher priority identifier + IDE + DIR (with respect to CAN arbitration rules) somewhere in the list (see **Table 21-19**). 11_B Transmit acceptance filtering is based on the list order (as PRI = 01_B).

Transmit Priority of Msg. Objects based on CAN Arbitration Rules

Table 21-19 Transmit Priority of Msg. Objects Based on CAN Arbitration Rules

Settings of Arbitrarily Chosen Message Objects A and B, (A has higher transmit priority than B)	Comment
A.MOAR[28:18] < B.MOAR[28:18] (11-bit standard identifier of A less than 11-bit standard identifier of B)	Messages with lower standard identifier have higher priority than messages with higher standard identifier. MOAR[28] is the most significant bit (MSB) of the standard identifier. MOAR[18] is the least significant bit of the standard identifier.
A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = 0 (send Standard Frame) B.MOAR.IDE = 1 (send Extended Frame)	Standard Frames have higher transmit priority than Extended Frames with equal standard identifier.
A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = B.MOAR.IDE = 0 A.MOSTAT.DIR = 1 (send Data Frame) B.MOSTAT.DIR = 0 (send Remote Fame)	Standard Data Frames have higher transmit priority than standard Remote Frames with equal identifier.
A.MOAR[28:0] = B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 A.MOSTAT.DIR = 1 (send Data Frame) B.MOSTAT.DIR = 0 (send Remote Frame)	Extended Data Frames have higher transmit priority than Extended Remote Frames with equal identifier.
A.MOAR[28:0] < B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 (29-bit identifier)	Extended Frames with lower identifier have higher transmit priority than Extended Frames with higher identifier. MOAR[28] is the most significant bit (MSB) of the overall identifier (standard identifier MOAR[28:18] and identifier extension MOAR[17:0]). MOAR[0] is the least significant bit (LSB) of the overall identifier.

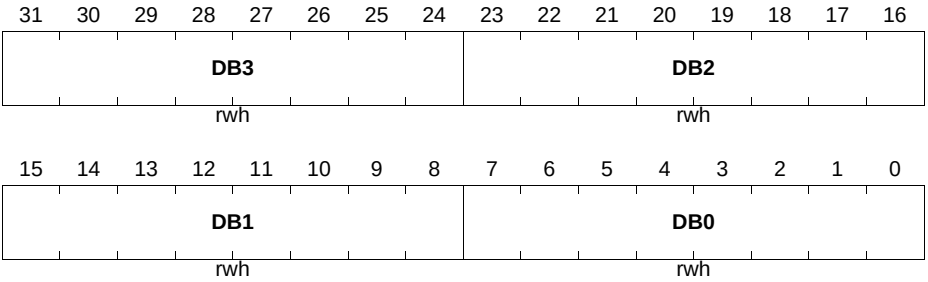
Message Object n Data Register Low MODATALn contains the lowest four data bytes of message object n. Unused data bytes are set to zero upon reception and ignored for transmission.

CAN_MODATALn (n = 0-127)
Message Object n Data Register Low

(1010_H+n*20_H) **Reset Value: 0000 0000_H**

CAN1_**MODATALw (w = 0 - 127)**
Message Object w Data Register Low

(1010_H+w*20_H) **Reset Value: 0000 0000_H**

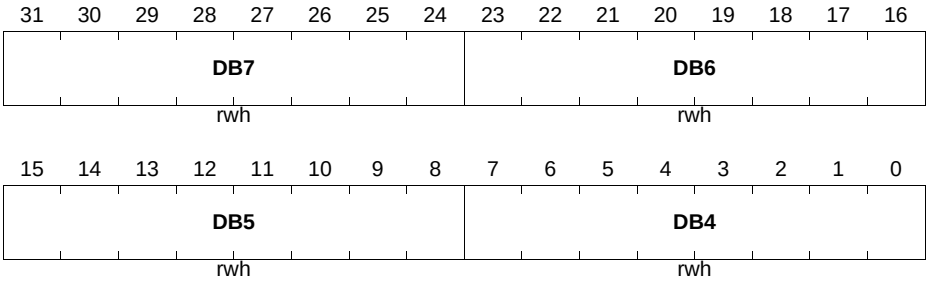


Field	Bits	Type	Description
DB0	[7:0]	rwh	**Data Byte 0 of Message Object n**
DB1	[15:8]	rwh	**Data Byte 1 of Message Object n**
DB2	[23:16]	rwh	**Data Byte 2 of Message Object n**
DB3	[31:24]	rwh	**Data Byte 3 of Message Object n**

Message Object n Data Register High MODATAH contains the highest four data bytes of message object n. Unused data bytes are set to zero upon reception and ignored for transmission.

CAN_MODATAHn (n = 0-127)
Message Object n Data Register High
(1014_H+n*20_H) **Reset Value: 0000 0000_H**

CAN1_**MODATAHw (w = 0 - 127)**
Message Object w Data Register High
(1014_H+w*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DB4	[7:0]	rwh	**Data Byte 4 of Message Object n**
DB5	[15:8]	rwh	**Data Byte 5 of Message Object n**
DB6	[23:16]	rwh	**Data Byte 6 of Message Object n**
DB7	[31:24]	rwh	**Data Byte 7 of Message Object n**

Extended Message Object n Data Register represents the alternate register view for MOFCR, MOFGPR, MOIPR, MOAMR, MODATAL, MODATAH and MOAR registers as pointed using (MOFGPR.TOP, MOFGPR.BOT) on the message object with message mode chosen in CAN FD 64 bytes message mode, (i.e MOFCR.MMC = 5). (See **Section 21.4.12.10**)

CAN_EMOzDATA0 (z = 0-127)
Extended Message Object z Data 0 Register
(1000_H+z*20_H) **Reset Value: 0000 0000_H**

CAN_EMOzDATA1 (z = 0-127)
Extended Message Object z Data 1 Register
(1004_H+z*20_H) **Reset Value: 0000 0000_H**

CAN_EMOzDATA2 (z = 0-127)
Extended Message Object z Data 2 Register
(1008_H+z*20_H) **Reset Value: 0000 0000_H**

CAN_EMOzDATA3 (z = 0-127)
Extended Message Object z Data 3 Register
($100C_H$+z*20_H) **Reset Value: 0000 0000_H**

CAN_EMOzDATA4 (z = 0-127)
Extended Message Object z Data 4 Register
(1010_H+z*20_H) **Reset Value: 0000 0000_H**

CAN_EMOzDATA5 (z = 0-127)
Extended Message Object z Data 5 Register
(1014_H+z*20_H) **Reset Value: 0000 0000_H**

CAN_EMOzDATA6 (z = 0-127)
Extended Message Object z Data 6 Register

21.7 MultiCAN+ Module Implementation

This section describes CAN module interfaces with the clock control, port connections, interrupt control, and address decoding.

21.7.1 Interfaces of the MultiCAN+ Module

Figure 21-28 shows the TC21x/TC22x/TC23x specific implementation details and interconnections of the MultiCAN+ module. The I/O lines of the MultiCAN+ module (two I/O lines of each CAN node) are connected to the Ports listed in**Table 21-22**. The MultiCAN+ module is also supplied by clock control, interrupt control, and address decoding logic. MultiCAN+ interrupts can be directed to the DMA, CPU, GTM modules which are able to trigger DMA transfers and GTM, CPU operations.

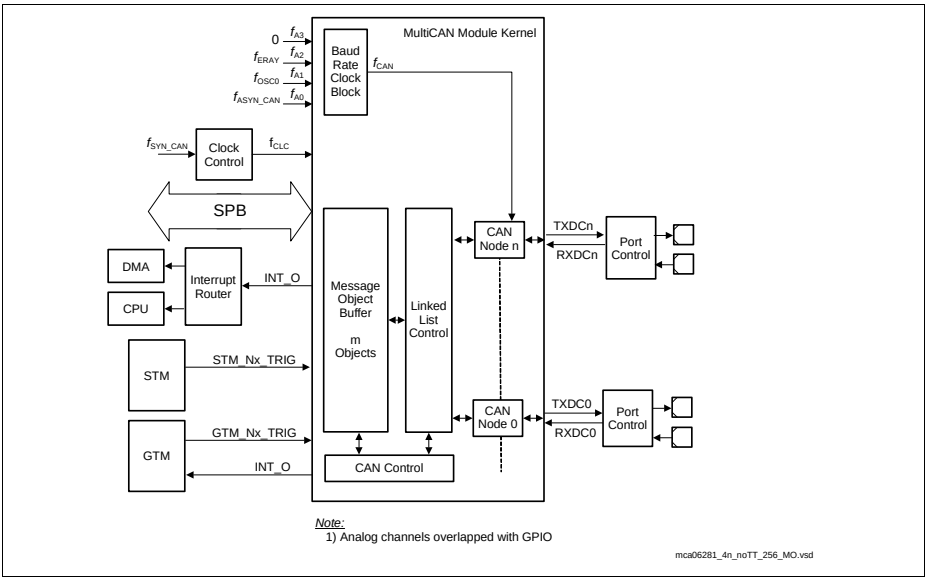

Figure 21-28 MultiCAN+ Module Implementation and Interconnections with n := 3 and m := 128 for AURIX
MultiCAN1 Module Implementation and Interconnections with n := 3 and n := 128 for AURIX

21.7.2 MultiCAN+ Module External Registers

The registers listed in **Figure 21-29** are not included in the MultiCAN+ module kernel, some registers must be programmed for proper operation of the MultiCAN+ module.

21.7.2.1 System Registers

OCDS Trigger Bus (OTGB)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status **($0E8_H$)** **Reset Value: $0000\ 0000_H$**

0	[23:4], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B,.. ,EN31 -> TAG ID 011111_B.

ACCEN0
Access Enable Register 0 ($0FC_H$) Reset Value: FFFF FFFF$_H$

ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

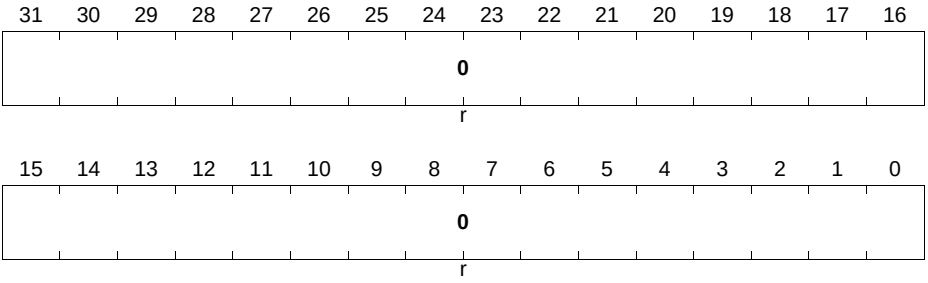
Access Enable Register 1

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN0 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... ,EN31 -> TAG ID 111111B.

ACCEN1

Access Enable Register 1 **($0F8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1).The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing to it with ´1´.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($0F4_H$)** **Reset Value: $0000\ 0000_H$**

r														rh	rwh

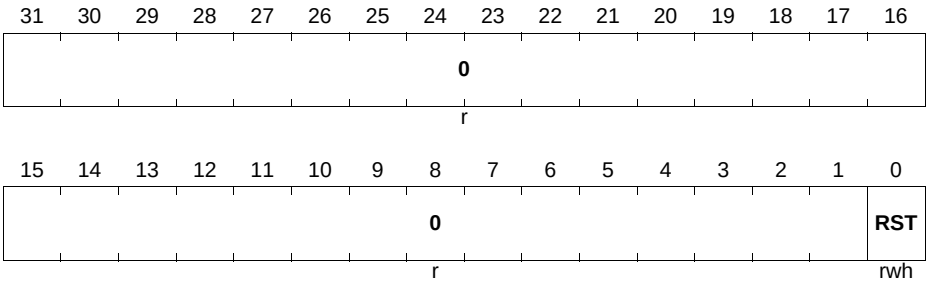
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.

Field	Bits	Type	Description
RSTSTAT	1	rw	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (CAN_KRSTx1.RST and CAN_KRSTx0.RST) related to the module kernel that should be reset (kernel 0 or kernel 1). The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($0F0_H$)** **Reset Value: $0000\ 0000_H$**

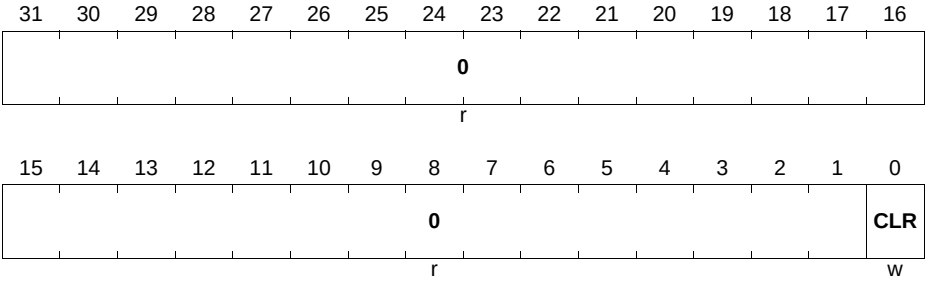


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Clear Register

The Kernel Reset Clear Register is used to clear the Kernel Reset Status bit (CAN_KRST0.RSTSTAT).

KRSTCLR
Kernel Reset Status Clear Register (0EC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

21.7.3 MultiCAN+ Clock Interconnects With SCU

The MultiCAN+ module clock inputs are connected to System Control Unit (SCU) clock control unit (CCU) as shown in **Figure 21-30** and **Table 21-21** below.

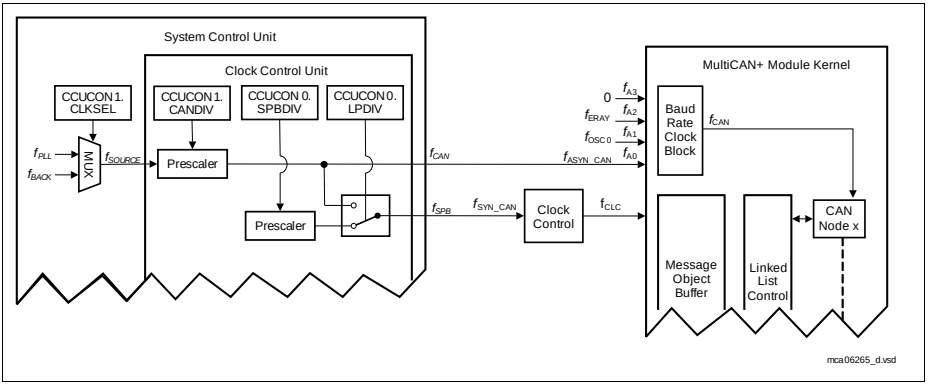


Figure 21-30 MultiCAN+ Clock Interconnects with SCU

Table 21-21 MultiCAN+ Clock Interconnects

CAN Clock Inputs	Connected to	Description
f_{ASYN_CAN}	SCU	f_{ASYN_CAN} of the MultiCAN+ module is one of the clock inputs of the Baud Rate Clock Block, providing the MultiCAN+ module timer clock f_{CAN}. f_{ASYN_CAN} connects to SCU CCU f_{CAN} and is controlled by CCUCON1.CANDIV. The CCUCON1.CANDIV is able to select different values of prescalers based on a selectable f_{PLL} or f_{BACK} source.
f_{SYN_CAN}	SCU	f_{SYN_CAN} of the MultiCAN+ module is the clock input of the Clock Control Register Block, providing the main kernel clock f_{CLC}. f_{SYN_CAN} connects to SCU CCU and is multiplexed between f_{SPB} and f_{CAN}. In normal mode, f_{SYN_CAN} is connected to f_{SPB} where else in pretended networking mode (CCUCON0.LPDIV >0), f_{SYN_CAN} connects to f_{CAN} of SCU CCU.

Note: The f_{CAN} mentioned on the SCU chapter does not refer to the same f_{CAN} that is mentioned on the MultiCAN+ chapter.

9. *The f_{CAN} mentioned on the SCU chapter refers in general to connection for MultiCAN+ clocking inputs f_{ASYN_CAN} and f_{SYN_CAN}. Depending on the settings of CCUCON1.CANDIV and CCUCON0.LPDIV different clock sources are connected (See **Table 21-21**).*
10. *The f_{CAN} mentioned on the MultiCAN+ chapter refers to the module timer clock (See **Section 21.7.4.2**).*

21.7.4 Module Clock Generation

This chapter describes the way the module get's its clock.

21.7.4.1 Clock Selection

The bit timing machine and the rest of the MultiCAN+ module are separate frequency domains and can be driven by separate independent frequencies. The bit timing unit can be driven by the SPB bus clock or with the direct oscillator clock, and the rest of the chip is driven only by the SPB bus clock.

The purpose of supplying the bit timing unit with a direct oscillator clock is to avoid the clock jitter added by the PLL, necessary when the chip is driven by a low cost ceramic resonator instead of by high precision quartz crystal.

Selecting the clock source for the bit timing unit is done by programming the bit-field MCR.CLKSEL.

Enabling and disabling the clock of the module by using CLC.DISR affects always both frequency domains, so that when f_{CLC} is switched off, f_A is also switched off.

21.7.4.2 Fractional Divider

As shown in **Figure 21-31**, the clock signals for the MultiCAN+ module are generated and controlled by a clock control unit. This clock generation unit is responsible for the enable/disable control, the clock frequency adjustment, and the debug clock control. This unit includes two registers:

- CAN_CLC: generation of the module control clock f_{CLC}
- CAN_FDR: frequency control of the module timer clock f_{CAN}

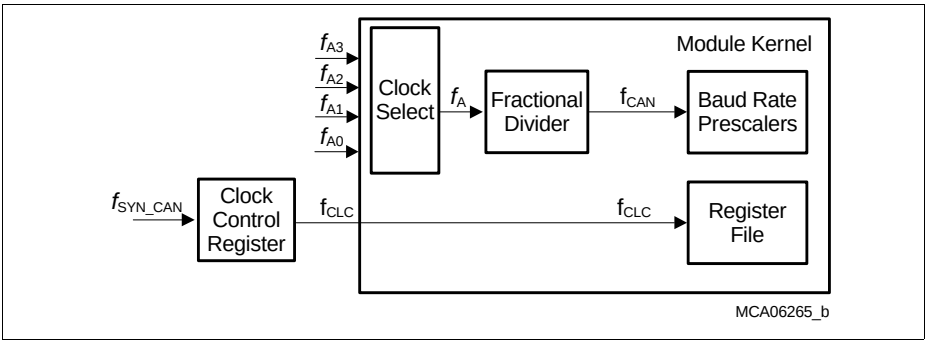

Figure 21-31 MultiCAN+ Module Clock Generation

The f_{SYN_CAN} is identical to f_{SPB}.

The module control clock f_{CLC} is used inside the MultiCAN+ module for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is identical to the system clock frequency f_{SPB}. The clock control register CAN_CLC makes it possible to enable/disable f_{CLC} under certain conditions.

The module timer clock f_{CAN} is used inside the MultiCAN+ module as input clock for all timing relevant operations (e.g. bit timing). The settings in the CAN_FDR register determine the frequency of the module timer clock f_{CAN} according the following two formulas:

$$f_{CAN} = f_A \times \frac{1}{n} \quad \text{with n = 1024 - CAN\_FDR.STEP} \tag{21.2}$$

$$f_{CAN} = f_A \times \frac{n}{1024} \quad \text{with n = 0-1023} \tag{21.3}$$

Equation (21.2) applies to normal divider mode (CAN_FDR.DM = 01_B) of the fractional divider. **Equation (21.3)** applies to fractional divider mode (CAN_FDR.DM = 10_B).

Note: The CAN module is disabled after reset. In general, after reset, the module control clock f_{CLC} must be switched on (writing to register CAN_CLC) before the frequency of the module timer clock f_{CAN} is defined (writing to register CAN_FDR).

CAN Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{CAN} module clock signal, sleep mode and fast shut-off mode for the module.

CLC
CAN Clock Control Register (000_H) Reset Value: 0000 0003$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

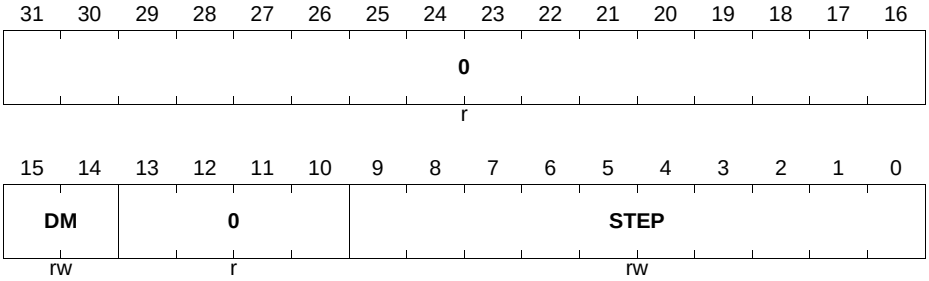
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. Note that no register access is possible to any register while module is disabled.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
0	[31:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency.

The fractional divider register allows the programmer to control the clock rate of the module timer clock f_{CAN}.

FDR

CAN Fractional Divider Register ($00C_H$) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for the result.
DM	[15:14]	rw	**Divider Mode** This bit field selects normal divider mode, fractional divider mode, and off-state.
0	[13:10], [31:16]	r	**Reserved** Read as 0; should be written with 0.

21.7.5 Port and I/O Line Control

The interconnections between the MultiCAN+ module and the port I/O lines are controlled in the port logic. Additionally to the port input selection, the following port control operations must be executed:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

21.7.5.1 Input/Output Function Selection in Ports

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections. The I/O lines for the MultiCAN+ module are controlled by the port input/output control registers, which are described in the port chapter. In case of discrepancies between port chapter and CAN chapter, the description in the port chapter is correct.

Table 21-22 shows the corresponding pins, sorted by node. Even though the table is pair wise, it is possible to select a different pairing for RXD and TXD. In addition the RXSEL value to be programmed for the Receive Pins is part of this table. For more information on RXSEL please see **Chapter 21.7.5.2**.

1) These ports are using fast pads and are suitable for TxD outputs with CAN FD at higher baud rates.

21.7.5.2 Node Receive Input Selection

Additionally to the I/O control selection, as defined in the port chapter, the selection of a CAN node's receive input line requires that bit field RXSEL in its node port control register NPCRx must be set according to **Table 21-22**. Values for NPCRx.RXSEL other than those of the table mentioned above will result in a recessive receive input for node x. As a hint A results in 0x0, B in 0x1 until H resulting in the value of 0x7.

This feature allows, for example, a CAN node which operates in analyzer mode to monitor the receive operations of its neighbor CAN node.

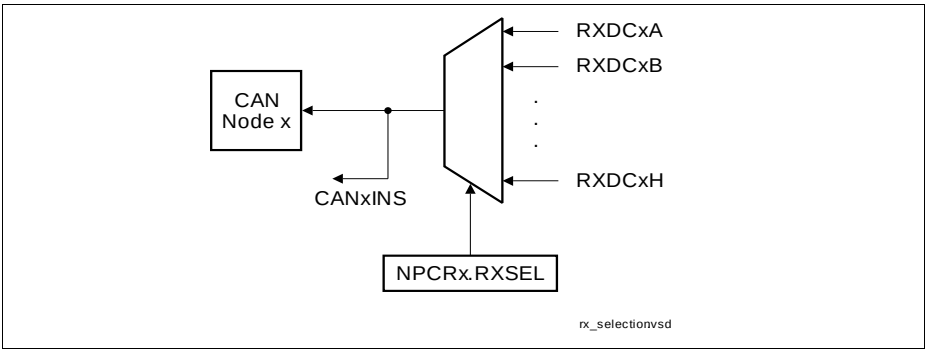

Figure 21-32 CAN Module Receive Input Selection

21.7.5.3 CAN Transmit Trigger Inputs

The CAN transmit trigger inputs of MultiCAN and MultiCAN1 are used to trigger for transmission of a message. In the TC21x/TC22x/TC23x, these input lines are connected as shown in **Table 21-23**.

Table 21-23 CAN Transmit Trigger Inputs

Timer input (gtm.tim_0_muxin_2_i(13))	INT_O13 (mcan0.int_req_o(13))
Timer input (gtm.tim_0_muxin_3_i(13))	INT_O14 (mcan0.int_req_o(14))
Timer input (gtm.tim_0_muxin_4_i(13))	INT_O15 (mcan0.int_req_o(15))

21.7.6 Interrupt Control

The interrupt control logic in the MultiCAN+ module uses an interrupt compressing scheme that allows high flexibility in interrupt processing. There are hardware and software interrupt sources available:

- CAN node interrupts:
  - Five different interrupt sources for each of the 3 CAN nodes = 5 * 3 interrupt sources (CAN) or 3 CAN nodes = 5 * 3 interrupt sources (CAN1)
- Message object interrupts:
  - Two interrupt source for each message object = 2 * 128 interrupt sources (CAN) or 2 * 128 interrupt sources (CAN1)
- One register (MITR) to initiate 16 (CAN) or 8 (CAN1) interrupts via software

Each of the hardware initiated interrupt sources is controlled by a 4-bit interrupt pointer that directs the interrupt source to one of the 16 (CAN) or 8 (CAN1) interrupt outputs INT_Om (m = 0-15), INT_Om(m=0-8). This makes it possible to connect more than one interrupt source (between one and all) to one interrupt output line. The interrupt wiring matrix shown in **Figure 21-33** is built up according to the following rules:

- Each output of the 4-bit interrupt pointer demultiplexer is connected to exactly one OR-gate input of the INT_Om line. The number “m” of the corresponding selected INT_Om interrupt output line is defined by the interrupt pointer value.
- Each INT_Om output line has an input OR gate which is connected to all interrupt pointer demultiplexer outputs which are selected by an identical 4-bit pointer value.

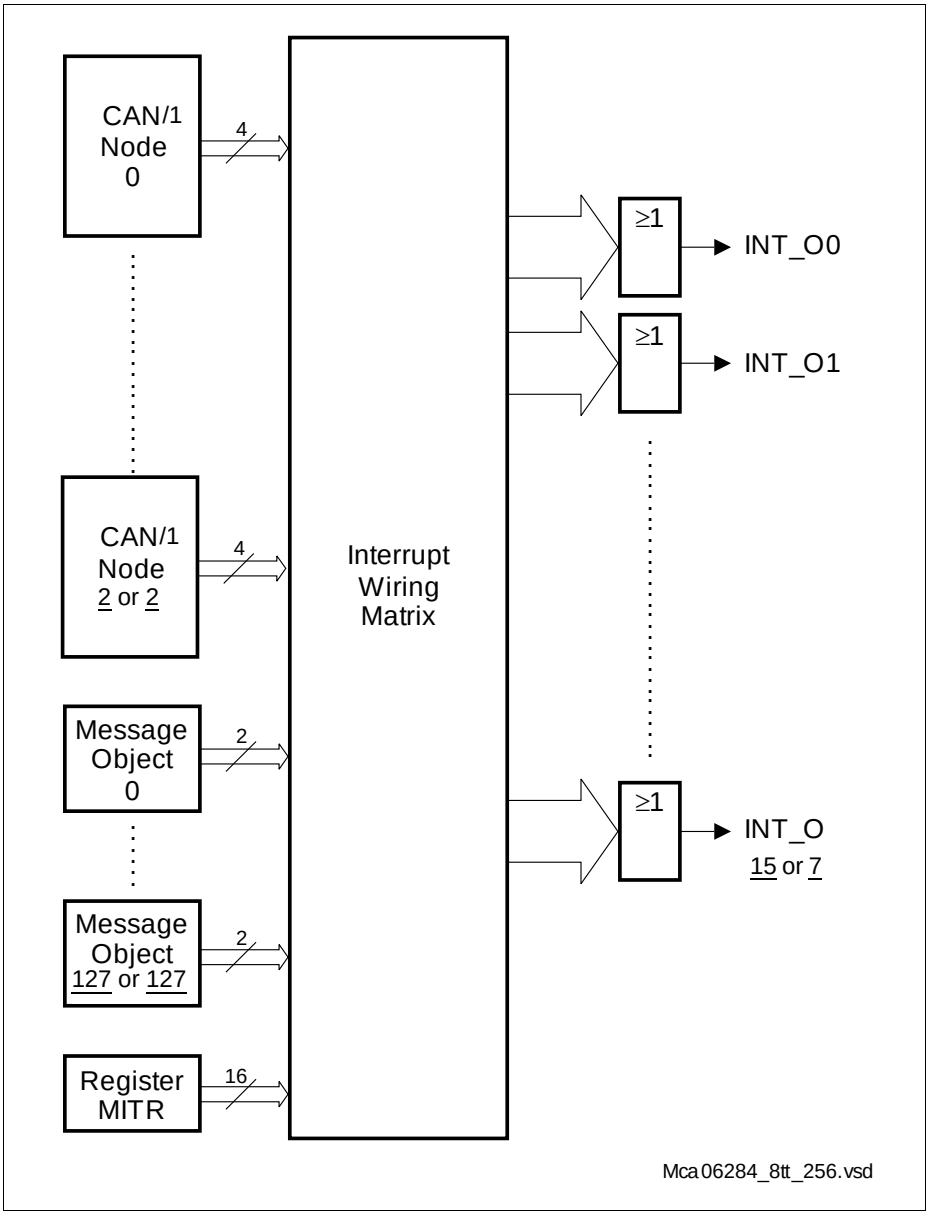

Figure 21-33 Interrupt Compressor

21.7.7 MultiCAN+ Module Register Address Map

The complete MultiCAN+ module register address map of **Figure 21-34** also shows the general implementation-specific registers for clock control, module identification, interrupt service request control and the absolute address information.

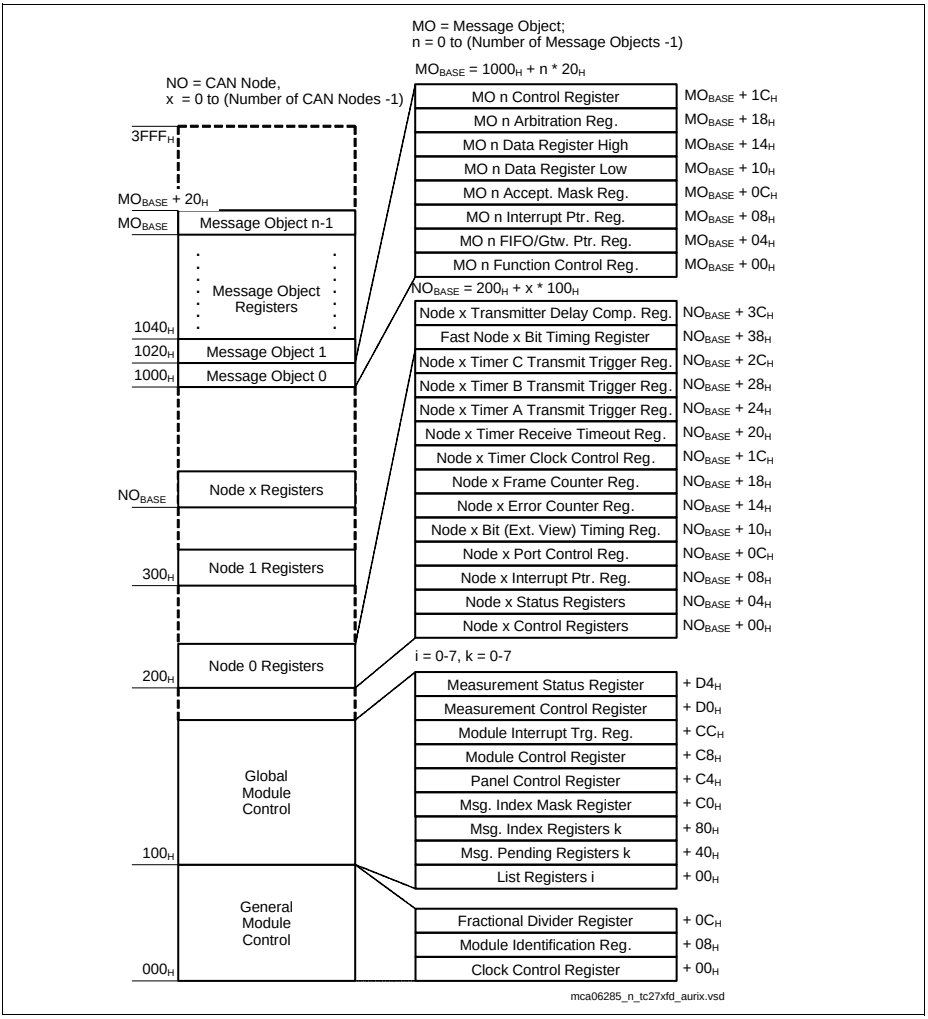

Figure 21-34 MultiCAN+ Register Address Map including CAN FD

21.8 Revision history

External revision history only shows major changes of MultiCAN+ module versions.

External Revision History (from MultiCAN+ v3.0 to MultiCAN+ v3.1)

- As per review meeting on 4Sep12 with designer, Removed for below:
  - Section 1.1.3.5 on Intermission removed as same as CAN V2.0B Bosch specs, under Section 9.1 Protocol Modifications, point 2.
  - Section 1.1.3.5 on Suspend transmission removed as same as CAN V2.0B Bosch specs, under Section 3.1.5 Interframe Spacing, Suspend Transmission.
  - Section 1.1.4.1 on Resynchronization removed as same as CAN V2.0B Bosch specs, under Section 8 Bit timing requirements, Resynchronization.
  - Section 1.1.4.1 on Synchronization rules, removed point 1,2 and 4. Point 3 and 5 are kept as new requirements in CAN FD.
  - Section 1.5.2 on Integrating mode, removed as same as CAN V2.0B Bosch specs, under Section 2 Sleep Mode / Wake-up.
- As per review meeting on 4Sep12 with designer, Added for below:
  - Additional text under MOFCRn.DLC, “Also if DLC>8 is programmed for message transmission, message transmit will be disabled.”
- As per review meeting on 4Sep12 with designer, Modified on Section 1.6.14 Debug over CAN with additional information.
- Added at Section 1.6.4 OCDS suspend, Note on “During suspend mode, kernel registers may be accessed only when the kernel clock is running”

External Revision History (from MultiCAN+ v3.1 to MultiCAN+ v3.2)

- As per AURIX JF on 1oct12, after bosch meeting on discussion of baudrates, request for below:
  - Modified on Section 1.1.3.1 on Fig1-2 CAN FD data frames changed to 64 data bytes and removed footnote on “Current design supports up to 8 data bytes payload only”
  - Removed on Section 1.3.1 footnote on “supports message transfer of data length code 0 to 8 data bytes with no Transmitter Delay compensation”
  - Removed on Section 1.5 “8 data bytes, no Transmitter Delay compensation “
  - Modified on Section 1.5.1, table 1-3, point 4 on Transmitter Delay compensation from “not implemented” to “implemented”
  - Removed on Section 1.6.8.1 on CAN Restricted operation mode.
  - Modified on MOFCR.DLC bit to support for more than 8 data bytes, have included 12, 16, 20, 24, 32, 48, 64 data bytes option.
  - Added Section 1.5.2 Transmitter Delay Compensation and FNBTRx.TDC, FNBTRx.TDCO, FNBSTATx.TDCV.
- As per EMail on DXCM DXCM_DAP_over_CAN_messages_120822.pdf, added for below:

- Modified MCR.DXCEN to MCR.DXCM, DAP Over CAN Message Enable
- Added to bit description “If enabled the highest two message objects are reserved for debugger communication. DXCM is described in detail in the OCDS chapter”
- Modified conditional text settings for DAP over CAN to “Has_DXCM”.

External Revision History (from MultiCAN+ v3.2 to MultiCAN+ v3.3)

- Modified MultiCAN+ clocking from SCU for below
  - Various diagrams and text that refers “$f_{MULTICAN}$” to “f_{ASYN_CAN}” and “f_{SYN_CAN}”. Also added Section 1.13.3 MultiCAN+ Clock Interconnects with SCU
  - Section 1.6.2 Table 1-5 footnote changed from “To guarantee the minimum operating frequencies when low power mode is enabled, fCLC is switched in fMULTICAN to a operating clock source, when SCU register CCUCON.” to “To guarantee the minimum operating frequencies when low power mode (pretended networking mode) is enabled (i.e when frequency of fSPB is reduced), fSYN_CAN and fCLC are switched from fSPB to fCAN when SCU register CCUCON0.LPDIV>0.”
- Renamed Fast Node x Bit Timing Status Register to Node x Transmitter Delay Compensation Register and moved FNBTRx.TDC, FNBTRx.TDCO to NTDCRx.TDC, NTDCRx.TDCO.

External Revision History (from MultiCAN+ v3.3 to MultiCAN+ v3.4)

- As per mail on “Widening of NBTR register field while maintaining compatibility and more” modified for below:
-
  - Rearranged FNBTRx register bits to use same layout as NBTRx for lowest 16bits and empty for upper 32bits
  - Changed address of FNBTRx to 0x0238 and NTDCRx to 0x23C
  - Swapped on NTDCRx register bits on TDC =Bit 15 and TDCO= Bits 11-8
  - Added NBTEVRx, Node Bit Timing Extended View Register. NBTEVRx view applies when NCRx.FDEN=1 and NBTRx view applies when NCRx.FDEN=0.
  - NBTEVRx. TSEG1 is 6 bits, valid values from 2 to 63
  - NBTEVRx. TSEG2 is 4 bits, valid values are 1 to 15
  - NBTEVRx.SJW is 4 bits, valid values are 1 to 15

External Revision History (from MultiCAN+ v3.4 to MultiCAN+ v3.5)

- As per review feedback on V3.3 CANFD specs review modified for below:
  - Removed on Section1.1.3.1 text on point 2e “In current CAN FD implementation, up to 8 data bytes payload are supported only”
  - Added on Table1-4 Minimum Operating Frequencies, footnote “To guarantee the minimum operating frequencies when low power mode.”
  - Removed on Section 1.4.12.4 “vice versa”

  - Update of Table 1-24 MultiCAN+ Clock Interconnects
- Additional modifications for below:
  - Added on NCRx.FDEN footnote on “Message transmission in Long & Fast CAN FD Frames. Message Reception according to CAN FD Protocol Specification, (i.e Able to Receive Classical CAN Format Frames ISO11898-1 and Long + Fast CAN FD Frames)”
  - Added on Table 1-8 Coding of DLC in CAN FD and MOFCRx.DLC
  - Added MOFCR.FDF, MOFCR.BRS bit to indicate message format reception when MOFCRx.MOFM =1 (CAN FD enabled) (i.e received frame in classical CAN or CAN FD format)
  - Added on NSRx.FLEC, fast last error code to indicate the error code during the fast bit rate.
  - Added note on Table 1-13 Encoding of LEC bit field, “When a frame in CAN FD format reached data phase with BRS flag set, the next CAN event (error/valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of CAN FD CRC will be shown as Form and not Stuff Error.”
- As per review feedback on V3.3 CANFD specs review modified for below:
  - Added description of message object used for DXCM RX and TX.
  - Used DXCM ITS text for DXCM message data description.

External Revision History (from MultiCAN+ v3.5 to MultiCAN+ v3.6)

- As per mail “C3 preparation for MultiCAN+” modified for Section 1.6.14 Debug Over CAN, to a summarized short version.
- As per mail “MultiCAN ITS problem DXCM bit position” modified for MCR.DXCM to bit 8.

External Revision History (from MultiCAN+ v3.6 to MultiCAN+ v3.7)

- As per mail on “Message Mode proposal for CAN FD 64 data bytes” modified for below.
  - Added **Section 21.4.12.10** on CAN FD 64 byte Message Mode
  - Added **CAN_EMOzDATA0 (z = 0-127)** Extended Message Object Data Register and on Table 1-11
  - Modified on MOFCR.MMC bit 101 to CAN FD 64 bytes message mode.
- As per TC24x_tag_coverage.xls added tags AURIX_GEN1:5246, 5396, 5373, 5374:
- As per AI124647 added additional CAN1 (3nodes/128MO) on module base address, modified Fig1-49 CAN Module Implementation and Interconnections and various places for additional CAN1 node.
- As per CAN FD weekly meeting on 21Nov12, modified for MOFCR.BRS and MOFCR.FDF bit from rh to rwh.

External Revision History (from MultiCAN+ v3.7 to MultiCAN+ v3.8)

- Added note on **Section 21.4.6.5** “The transmit request bits (i.e NTATTx.TXMO / NTBTTx.TXMO / NTCTTx.TXMO) in the timer control register of a node is able to trigger transmit request (MOSTATn.TXRQ) of message object in a list belonging to any other CAN nodes”.
- As per MultiCAN+ V3.7 feedback review
  – Modified on CAN_NBTEVRx text to “NBTEVRx contains all parameters to setup CAN bit timing for Nominal Bit Rate”.
  – Modified on CAN_FNBTRx text to “FNBTRx contains all parameters to setup CAN bit timing for Data Bit Rate”.
  – Modified on CAN_FNBTRx register bits name to FTSEG1, FTSEG2, FSJW and FBRP.
  – Modified on CAN_NBTEVRx.TSEG2 to 5bits, bit20 to bit16.

External Revision History (from MultiCAN+ v3.8 to MultiCAN+ v3.9)

- As per MultiCAN+ V3.7 feedback review.
  – As per mail “CCE protection of register tdcr” added on CAN_NTDCR register “NTDCRx register can be written only if bit NCRx.CCE is set.”. Removed on NTDCR.TDC text on “this bit is CCE and INIT protected”.
  – Added on soft configuration section a footnote on CAN FD “When CAN FD is disabled by PRDCFG, access to CAN FD registers do not generate a bus error. To verify CAN FD is disabled, try to set NCRx.FDEN bit and read back the NCRx register values, the NCRx.FDEN bits remain cleared.”
  – Modified on NTDCR.TDCV text from fcan/fclc to time quanta “Valid values for TDCV are 0 to 31 times of time quanta t_Q”
  – Modified on NTDCR.TDCO text from facn/fclc to time quanta “Valid values for TDCO are 0 to 15 times of time quanta t_Q.”
  – Added text under Section CAN FD 64 bytes Message Mode “When MSGVAL of the base object is cleared, an ongoing data transfer to TOP and BOT objects are aborted, thereby freeing objects BOT and TOP. Clearing MSGVAL bits of BOT, TOP objects and the extra message objects do not stop an ongoing data transfer and are not considered at all.”
  – Added text on NCRx.FDEN, MOFCR.MOFM, MOFCR.BRS and MOFCR.FDF bits “Please see Table 1-19 CAN FD Transmit and Receive Behavior.

External Revision History (from MultiCAN+ v3.9 to MultiCAN+ v3.10)

- As per MultiCAN+ V3.7 feedback review
  – Updated Table 1-19 CAN FD Transmit and Receive Behavior, corrected for transmit behavior “Classical CAN Frames” FDEN from 0_B to X_B.

External Revision History (from MultiCAN+ v3.10 to MultiCAN+ v3.11)

- As per MultiCAN+ V3.7 feedback review
  - Updated Table 1-30 MultiCAN+ I/O control Selection and Setup and Table 1-36 Receive Input Selection
  - Added Footnote on Table 1-30 “These ports are using A1+ pads and are suitable for TxD outputs with CAN FD at higher baud rates.”
  - Added Table 1-9 “Minimum Operating Frequencies for CAN FD [MHz]”
- This bulleted point is not applicable to TC23x.
- Updated on Section 1.6.2 Clock Control on example of equation 1.1 to “As an example, when f_{CLC} = 10MHz, f_{CAN} = 20MHz, No of active CAN nodes =2, Baudratemax=[(8x50ns) + (8x100ns) + (4x2x100ns)] = 2000ns = 500 KBaud
- Updated for TC23x Section 1.13.5.1 Input / Output Function Selection in Ports, Section 1.13.5.2 Node Receive Input Selection, Section 1.13.5.4 CAN Transmit Trigger Inputs, Fig 1-49 CAN Module Implementation and Interconnections.

External Revision History (from MultiCAN+ v3.11 to MultiCAN+ v3.12)

- Updated for TC23x on MOFCR register corrected BRS to bit5, FDF to bit6 and MOFM to bit 7.
- Modified on Section 1.1.3.2 Remote Frames, paragraph from “Remote frames is only defined in CAN format, Remote frames and RTR bit do not exist for CAN FD format. ~~In a CAN FD node, Remote frames request are always replied back in CAN format and will never receive replies in CAN FD format.~~” to “Remote frames is only defined in CAN format, Remote frames and RTR bit do not exist for CAN FD format. Remote frame requests do not change the format of the preconfigured reply data frames (i.e FDF and BRS bits of preconfigured data frames are not changed on remote frame requests, reply data frames may be in CAN base/extended or CAN FD base/extended).”
- Modified on Table 1-20 CAN FD Transmit and Receive Behavior on receive behavior to FDEN=0, MOFM=X, BRS=0/1, FDF=0/1- Classical CAN Frames, FDEN=1, MOFM=X, BRS=0/1, FDF=0/1- Classical CAN Frames, Long Frames, Long + Fast Frames.
- Added on Table 1-20 CAN FD Transmit and Receive Behavior, footnote on receive behavior “Please note that Remote Request Frames do not change BRS and FDF bits.”

External Revision History (from MultiCAN+ v3.12 to MultiCAN+ v3.13)

- Modified for below
  - Removed from Table 1-31 MultiCAN+ I/O Control Selection and Setup, incorrect RXDCAN1E-P20.9.
  - Added on MCR.CLKSEL bit option 0100_B E-Ray clock “(Feray)”.

  - Added Fig1-52 MultiCAN+ Interconnects with SCU on section 1.13.3 MultiCAN+ Clock Interconnects With SCU.
  - Corrected on Fig 19-27 CAN Module Implementation and Interconnections, change to 128 MO, Feray, corrected STM_Nx_TRIG and GTM_Nx_TRIG to CAN and CAN1 module.
- This bulleted point is not applicable to TC23x.

External Revision History (from MultiCAN+ v3.13 to MultiCAN+ v3.14)

- Removed NSRx.RESI bit would generate interrupt on NSRx.ALERT and NCRx.ALIE. Also modified NSRx.RESI bit to 'rh' changed description to "This bit is an error flag that is set when the ESI flag in a received CAN FD frame is set." and "0_b-Last received CAN FD message did not have its ESI flag set. 1_b-Last received CAN FD message had its ESI flag set."
- Addition to note on Table 1-13 Encoding of LEC bit field, "Correspondingly CAN event (error/valid frame) will be shown back at LEC after the first bit of the CRC delimiter when CAN FD switches from Data bit rate to Nominal bit rate".

External Revision History (from MultiCAN+ v3.14 to MultiCAN+ v3.15)

- Removal of MOFCR.MOFM bit. Update of Table 1-20 CAN FD Transmit and Receive Behaviour.
- Update of Table 1-5 Minimum Operating Frequencies for CAN FD [MHz].
  - Addition of Acceleration Factor rows for values from 1 to 8
  - Modified on Footnote 3) with addition of Base Nominal Bit Rate is 1Mbit/s and addition "when several nodes operate at different acceleration factor A.F, only the node operating the highest acceleration factor need to be considered for the required minimum operating frequency requirement."

External Revision History (from MultiCAN+ v3.15 to MultiCAN+ v3.16)

- Section 1.6.12.4 Message Object Format updated with removal of MOFCR.MOFM and replaced with description of NCRx.FDEN and MOFCRn.FDF, MOFCRn.BRS bits.
- CAN FD feature added for TC27x C-step, TC26x B-step, TC29x B-step.
- Updated on features list, with bullet item "Supports an acceleration factor of 8 when operating in CAN FD mode per Bosch CAN FD V1.0 April17th 2012"
- Debug over CAN feature removed for TC27x C-step, TC26x B-step, TC29x B-step.

External Revision History (from MultiCAN+ v3.16 to MultiCAN+ v3.17)

- Added on section 1.4.14 Debug over CAN and under features list for item on Debug over CAN, footnote "Debug over CAN feature is available through CAN module only and not available on CAN1 module."

- Updated Table 1-5 Minimum Operating Frequencies for CAN FD [MHz], with corrected values from multican_performance_canfd_16apr13.xls
  – Modified Acceleration Factor rows for values from 1 to 5 and at various places that mentions AF to 1 to 5.

External Revision History (from MultiCAN+ v3.17 to MultiCAN+ v3.18)

- Added additional text on Section 1.5.2 Transmitter Delay Compensation to describe more details on secondary sample point implementation.
- Added on footnote of Table 1-5 Minimum Operating Frequencies for CAN FD “When message objects are configured as transmit or receive FIFO structures i.e MOFCRn.MMC = 0001/0010, only the base object of 1 is counted towards the minimum frequency requirement, all other slave objects on the FIFO do not count towards the minimum frequency requirement. See Section 1.6.12.5.
- Relabel tags CAN_NUMBER_NODES to CAN1_NUMBER_NODES on Table1-2.

External Revision History (from MultiCAN+ v3.18 to MultiCAN+ v3.19)

- Text enhancements below:
  – Under Section 1.1.3.1, abbreviation added for FDF, BRS, ESI bit
  – Under Section 1.1.3.3, amended from “shall switch back” to “will switch back”
  – Under Section 1.3, amended from “on every nodes” to “on all nodes”
  – Under Section 1.3.1, amended from “measured Transmitter Delay” to measured loop delay”
  – Under CAN_MOFCR on CAN FD Transmit and Receive Behavior, added text “Message transmission and reception behavior of CAN data frames is summarized at Table 1-20 below.”
  – Under CAN_MOFGPR.TOP/BOT added text MOFGPR.BOT points to data byte 8-35 and MOFGPR.TOP points to 36-63.

External Revision History (from MultiCAN+ v3.19 to MultiCAN+ v3.20)

- All reference to EDL is renamed to FDF, register bit MOFCR.EDL is renamed to MOFCR.FDF, functionality remains the same.

External Revision History (from MultiCAN+ v3.20 to MultiCAN+ v3.21)

- This bulleted point is not applicable to TC23x.

External Revision History (from MultiCAN+ v3.21 to MultiCAN+ v3.22)

- Changed CAN FD descriptions to customer relevant information.

External Revision History (from MultiCAN+ v3.22 to MultiCAN+ v3.23)

- Corrected spelling bugs

External Revision History (from MultiCAN+ v3.23 to MultiCAN+ v3.24)

- Changes for XMC device frequencies, not applying for AURIX devices

External Revision History (from MultiCAN+ v3.24 to MultiCAN+ v3.25)

- Changes for XMC port naming. Correcting XMC specification by removing AURIX relevant issues.

External Revision History (from MultiCAN+ v3.25 to MultiCAN+ v3.26)

- Corrected memory space for XCM1000.
- Fixed pad naming for all devices.
- Corrected Safety tagging for AURIX
- CLC and FDR are existing on all modules, which are existent in one microcontroller.

External Revision History (from MultiCAN+ v3.26 to MultiCAN+ v3.27)

- Corrected interrupt mapping for XCM1000.

External Revision History (from MultiCAN+ v3.27 to MultiCAN+ v3.28)

- CRC issue of CAN FD documented.

External Revision History (from MultiCAN+ v3.28 to MultiCAN+ v3.29)

- MCR register, formula for clock switching mathematically not correct. As no clock cycles were calculated. Exchanged to clock cycles..

22 Single Edge Nibble Transmission (SENT)

This chapter describes the SENT Interface of the TC21x/TC22x/TC23x. It contains the following sections:

- Functional description of the SENT kernel (see **"Overview" on Page 22-3**)
- SENT kernel register descriptions (see **"SENT Kernel Registers" on Page 22-23**)
- TC21x/TC22x/TC23x implementation-specific details and registers of the SENT module (port connections and control, interrupt control, address decoding, and clock control,
  see **"SENT Module Implementation" on Page 22-71**

22.1 SENT Kernel Description

Figure 22-1 shows a global view of the SENT interface.

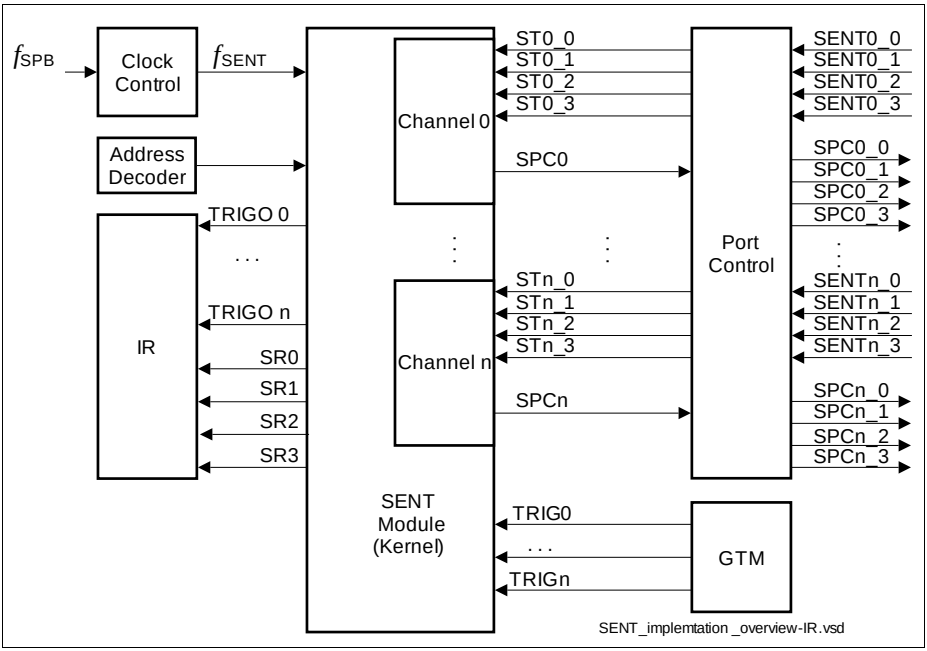

Figure 22-1 General Block Diagram of the SENT Interface

The SENT module communicates with the external world via one I/O line for each channel. The STx lines are the receive data input signals. They can overlay ADC inputs. If the optional SPC mode is used, they can be used on a port configured with an open drain transistor. This way the optional SPC data can be transmitted and the line is used

bidirectionally. In case of an external transceiver, receive and transmit path can be routed to two different ports.

22.1.1 Overview

The SENT interface provides a serial communication link typically used to connect sensors or other peripheral devices.

Clock control, address decoding, and service request control are managed by the SENT module kernel.

The SENT IP-module performs communication according to the SENT specification J2716 JAN2010.
While staying compliant to this standard, it is able to cover as well the Short PWM Code (SPC) protocol extensions. This enhances the standardized SENT protocol defined by J2716 JAN2010. SPC enables the use of enhanced protocol functionality like “synchronous”, “range selection” and “ID selection” protocol mode.

Receive data on a SENT channel can be set up according to the underlying application. In particular the number of nibbles forming one value is configurable.

The message storage consists of two 32-bit registers for each channel, representing a flexible double buffer system.

In SPC mode, maintaining the sample and transmission schedule as well as providing message status information is support.

The register set of the SENT module can be accessed directly by the CPU for configuration, data read out and status query.

The SENT IP-module supports the following features:

Features

- Conformance with SENT protocol specification J2716 JAN2010
- Data rates of up to 65,8 kbit/s at 3 µs tick length and 6 data nibbles on each channel
- Support of standard tick times (3 µs through 90 µs) and
- Message tick time programmable between 0.2 µs and 90 µs
- 4 SENT channels working independently in parallel
- Status nibble optionally included in the checksum (default not included)
- Sticky interrupt flags, error interrupt optional (default disabled)
- Configurable frame length (default is 24 bit), max data size is 32 bits
- Serial data processing optional (default: disabled)
- Option for bigger frame lengths (must still be fix for each application)
- transparent mode (nibble CRCs are written to the receive control register for SW processing)
- Support of SPC
- Support of trailing Pause Nibble of any length (even longer than 70 ticks)
- Indication of system status: STOP, INITIALIZED, RUNNING, SYNCHRONIZED
- The receiver module will monitor the message for the following error conditions:
  - Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
  - Too many or too few nibbles between calibration pulses.
  - Checksum error.
  - Successive calibration pulse differ by more than 1.5625%
  - Any nibble data values measured as < 0 or >15.
- When any of those errors is detected, the receiver module shall declare that a message error has occurred and ignore the entire message.
- Any of those errors shall cause the receiver to begin searching for a valid calibration pulse to re synchronize.
- Option to enable/disable the check of the next calibration pulse before validation of received data
- Digital Glitch filter suppressing noise
- Buffer overrun detection
- Optional output inversion for use of external open drain transistor
- Optional input inversion for use of external open transistor for level shifting
- Interrupt on status nibble violation
- Programmable Nibble sorting to support LSN or HSN first and relief CPU
- Time stamp generation
- Watch Dog on incoming frames

22.1.2 General Operation

The Single Edge Nibble Transmission encoding scheme (SENT) is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 22-3 shows a typical TC21x/TC22x/TC23x application in which a SENT interface reads a sensor device.

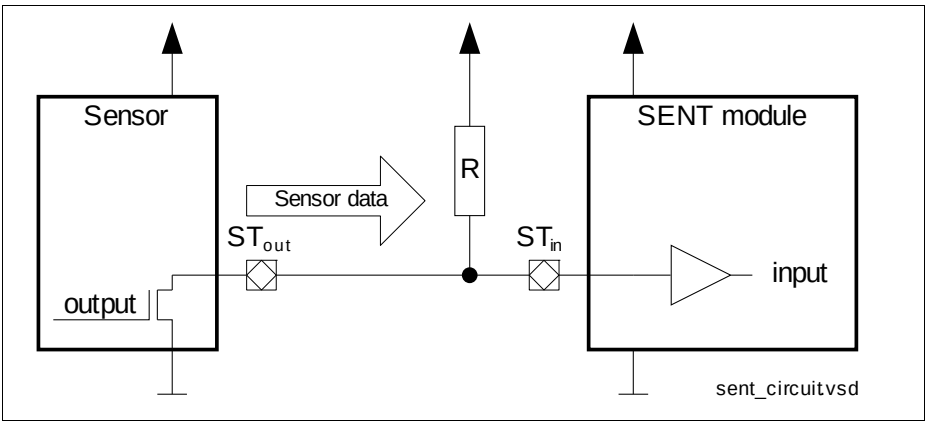

Figure 22-2 SENT to External Device Connection

SENT communication is unidirectional from sensor to controller without any synchronization. The sensor signal is transmitted as a series of PWM blocks measured as falling to falling edge times.

The Short PWM Code (SPC) extension overcomes the drawback of unidirectionality as said above while keeping conformance to the standard.

Figure 22-3 shows a typical TC21x/TC22x/TC23x application in which an SPC enabled SENT ECU reads an SPC enabled SENT sensor device.

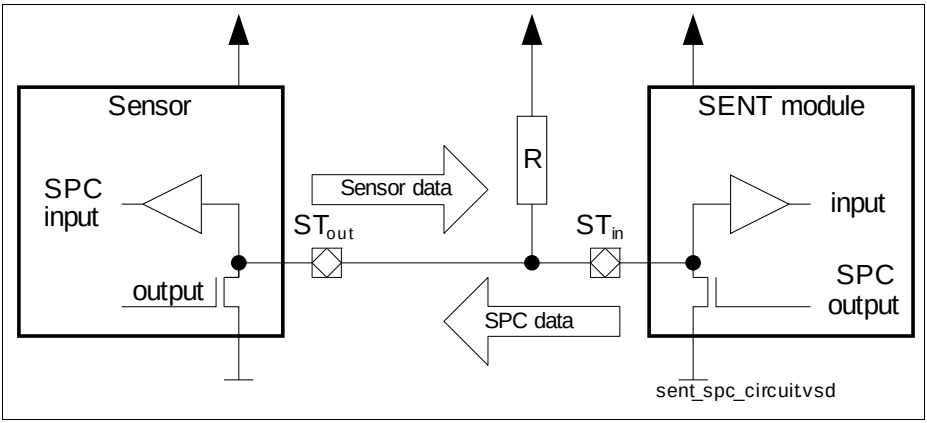

Figure 22-3 SENT SPC to External Device Connection

Some applications are:

- Read out of the external throttle position sensor (e.g. SENT enabled linear hall sensor)
- Receiving pedal position
- Synchronize sampling and read out of up to four sensors on one single line (SPC)
- Selection of 1 out of 4 sensors connected to a single SENT channel.
- Serial connections of the TC21x/TC22x/TC23x to other peripheral devices

22.1.2.1 Definitions

SENT: Single Edge Nibble Transmission

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

SPC: Short PWM Code

PWM: Pulse Width Modulation

ASIC: Application Specific Integrated Circuit

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

ECU: Electronic Control Unit

FSM: Finite State Machine

22.1.3 Standard SENT Operation

Standard SENT Mode supports communication fully compliant to J2716 JAN2010, in which only the external device is sending and the ECU is receiving. In this unidirectional communication, both transmitter and receiver use the same data frame format and have the same baud rate. These settings are defined at system integration time and do not change for a given application. Data is received on pin ST. **Figure 22-4** shows the block diagram of the SENT Module when operating in Standard SENT Mode.

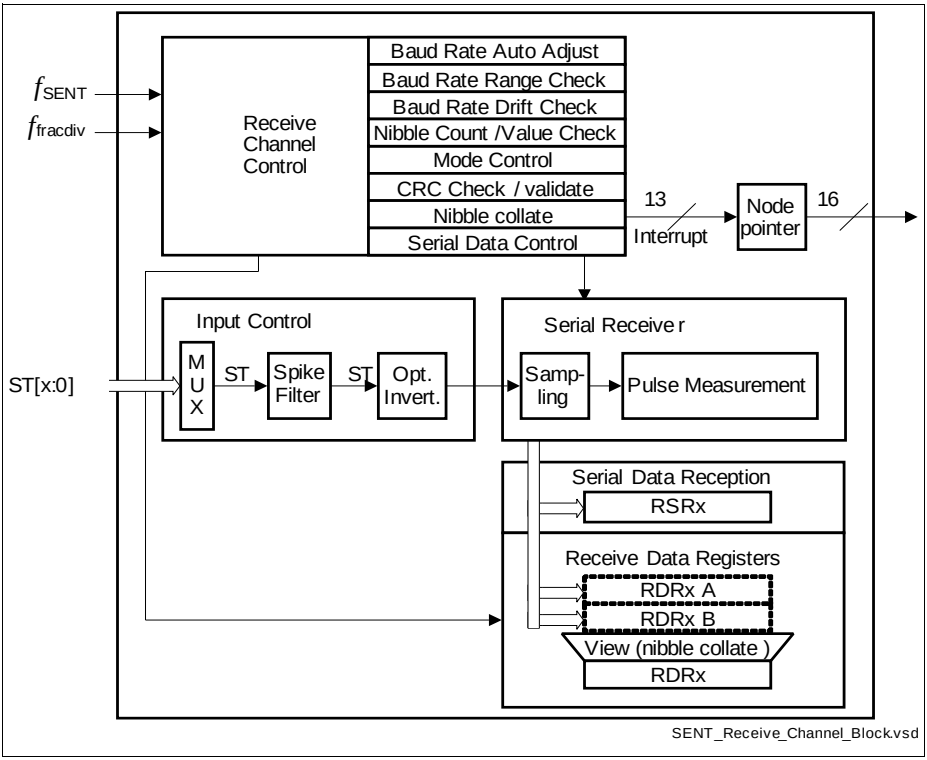

Figure 22-4 Standard SENT Mode Operation

22.1.3.1 Frame Formats and Definitions

This section describes the frame formats and definitions of the SENT protocol.

Basic Definitions

Figure 22-5 shows the layout and definitions of a standard SENT frame. Note that the SENT standard does not specify whether the most significant nibble or the least significant nibble is sent out first.

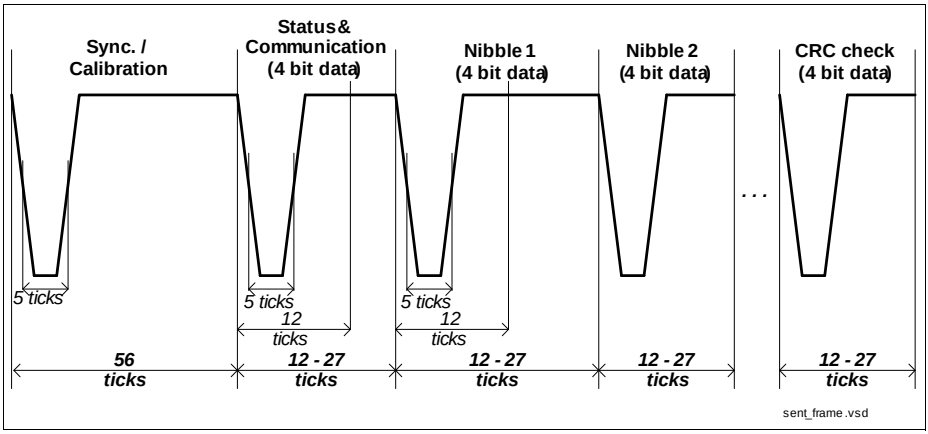

Figure 22-5 Standard Encoding Frame

Serial Data Encoding in Status and Communication Nibble

The Status and Communication nibble is used by sensors that transmit extra serial data such as part numbers or diagnostic information. Data bits from this nibble are constructed across multiple SENT messages to form a Short Serial Message or an Enhanced Serial Message. These messages are alternately referred to as “Slow Channel” data in the J2716 specification.

Table 22-1 Short Serial Data Encoding

Bit Number	Bit Function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = 1, otherwise = 0

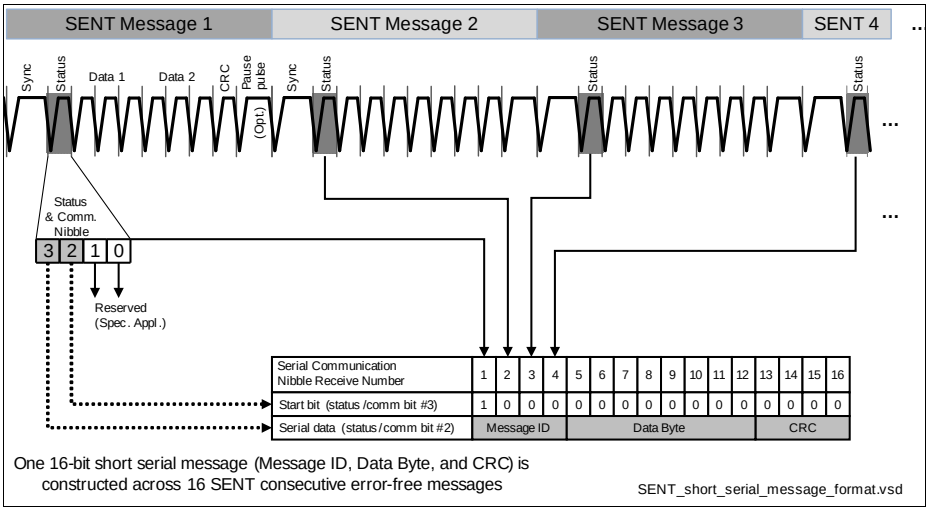

Figure 22-6 Short Serial Message, Serial Data Encoding over 16 messages

Short Serial Message Format

The SENT kernel supports the Short Serial Message Format defined in the J2716 specification. The Short Serial Message Format provides 16 bits of data, constructed across 16 SENT messages. Each of the 16 messages contains one bit of Short Serial Message data in Status and Communication nibble bit 2.

Serial data is communicated in a 16-bit sequence as shown in **Table 22-2**. The start of a Short Serial Message is indicated by a 1 in bit 3 of the Status and Communication nibble. That SENT message and the next 15 must be successfully received (no errors) for the Short Serial Message data to be received. The CRC generation is identical to the CRC generation on the data nibbles. Short Serial Message data is provided in the SDSx register.

Table 22-2 Short Serial Message Format

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Startbit (bit # 3)	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Serial Data (bit # 2)	Message ID				Data Byte								CRC			

CRC Calculation

SENT signal data and Short Serial Message data is secured with a 4 bit CRC. The standard CRC calculation method is defined in the J2716 JAN2010 specification.

RCR.CRZ defines, if a zero nibble is added for calculation or not.

The alternative checksum nibble is a 4-bit CRC of the data nibbles (including the status nibble if RCR.SNI is set, as used in sensor TLE4998). The CRC is calculated using a polynomial x^4 +x^3 + x^2 + 1 with a seed value of 0101.

In order to facilitate CRC implementations and to avoid ambiguities, an example implementation of the alternative 4-bit CRC is given below. This is used e.g. in the sensor TLE4998 for the signal data. See **Figure 22-7** for details.

```
// Fast way for any µC with low memory and compute capabilities
// contains input data (status nibble, 6 data nibble, CRC)
char Data[8] = {…};
// required variables and LUT
char CheckSum, i;
char CrcLookup[16] = {0, 13, 7, 10, 14, 3, 9, 4, 1, 12, 6, 11, 15,
2, 8, 5};
CheckSum= 5; // initialize checksum with seed “0101”
for (i=0; i<7; i++) {
     CheckSum = CheckSum ^ Data[i];
     CheckSum = CrcLookup[CheckSum];
};
// finally check if Data[7] is equal to CheckSum
```

Note: For the “Enhanced Serial Message Frame Format”, an own 6-bit CRC calculation method is defined by the standard.

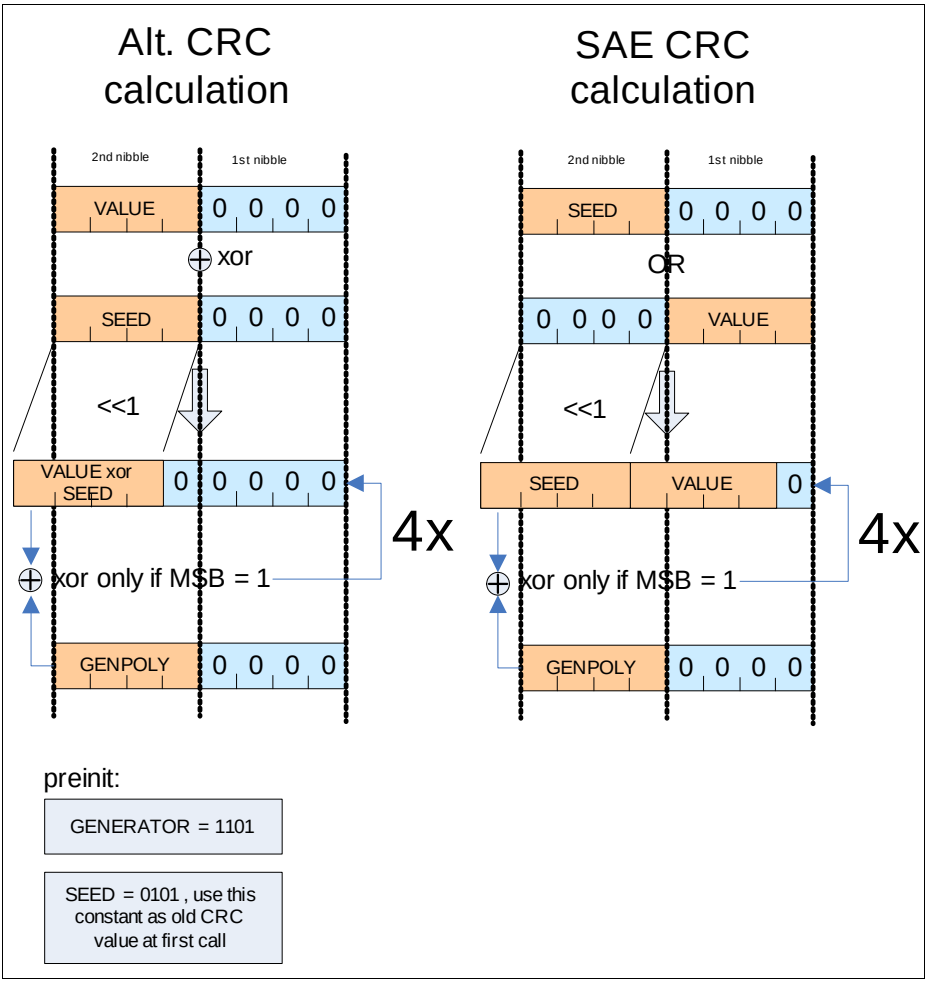

Figure 22-7 Alternate vs. SAE CRC Calculation

Enhanced Serial Message Format

The SENT kernel supports the Enhanced Serial Message Format defined in the J2716 specification. The Enhanced Serial Message Format provides 21 bits of message data and a 6-bit CRC, constructed across 18 SENT messages.The serial data is transmitted bit wise per frame in bits [3:2] of the Status and Communication nibbles of 18 consecutive messages from the transmitter.

Table 22-3 Enhanced Serial Data Encoding

Bit Number	Bit Function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = **1** 1 1 1 1 1 0

Enhanced Serial Message Frame

Serial data is communicated in an 18 frame sequence as shown in **Table 22-4**. The start of an Enhanced Serial Message is indicated by the unique pattern “1111110” in bit #3 of the status and communication nibble, constructed across 7 SENT messages. In message 1 - 6 they are set to “1”. In message 7, 13 and 18 they are set to “0”. 18 consecutive SENT messages must be successfully received (no errors) for the Enhanced Serial Message data to be received. The 6-bit Enhanced Serial Message CRC is different from the 4-bit CRC on SENT (fast channel) messages. (See SENT Standard)

An Enhanced Serial Message contains 21 bits of message data and a 6-bit frame-check sequence. A configuration bit (serial data bit #3 of the 8th SENT message's Serial Communication Nibble) determines how the SENT module interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID, see **Table 22-5**
- Configuration bit = 1: 16-bit data and 4-bit message ID, see **Table 22-6**

Enhanced Serial Message data is provided in the SDSx register.

Table 22-4 Enhanced Serial Data Frame

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	C	8-bit ID (7-4)				0	8-bit ID (3-0) or 4-bit data				0
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

Note:

11. *Message 8 Status Nibble bit # 3 is Configuration Bit C that defines the Enhanced Serial Data format:*
    *0: 12-bit data, 8-bit ID, see **Table 22-5***
    *1: 16-bit data, 4-bit ID, see **Table 22-6***
12. *Messages 17-14 Status Nibble bit # 3 contain either the lower 4 bits (Bit 3-0) of 8bit ID or 4 additional data bits.*

Table 22-5 shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 0.

Table 22-5 Configuration Bit = 0

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	0	8-bit ID (7-4)				0	8-bit ID (3-0)				0
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

Table 22-6 shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 1.

Table 22-6 Configuration Bit = 1

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	1	4-bit ID (3-0)				0	4-bit data (15-12)				0
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

22.1.4 SPC Operation

The module supports a SPC (Short PWM Code) protocol, which enhances the standardized SENT protocol (Single Edge Nibble Transmission) defined by J2716 JAN2010. SPC enables the use of enhanced protocol functionality due to the ability to select between “synchronous”, “range selection” and “ID selection” protocol mode or even “bidirectional transmit mode”.

22.1.4.1 Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a low pulse is forced by the master on the OUT pin. This means that the data line is bidirectional - an open drain output of the micro controller (master) sends the trigger pulse. The sensor then initiates a sync pulse and starts to calculate the new output data value. After the synchronization period, the data follows in form of a standard SENT frame, starting with the status, data and CRC nibbles. At the end, an end pulse allows the CRC nibble decoding and indicates that the data line is idle again. The timing diagram in **Figure 22-8** visualizes a synchronous transmission

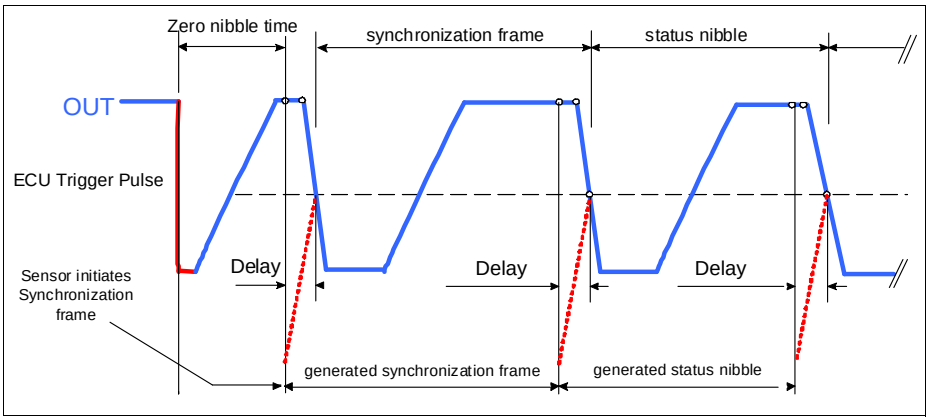

Figure 22-8 Synchronous Transmission (SPC)

22.1.4.2 Range Selection

The low time duration of the master can be used to select the range of the sensor in SPC dynamic range selection mode.

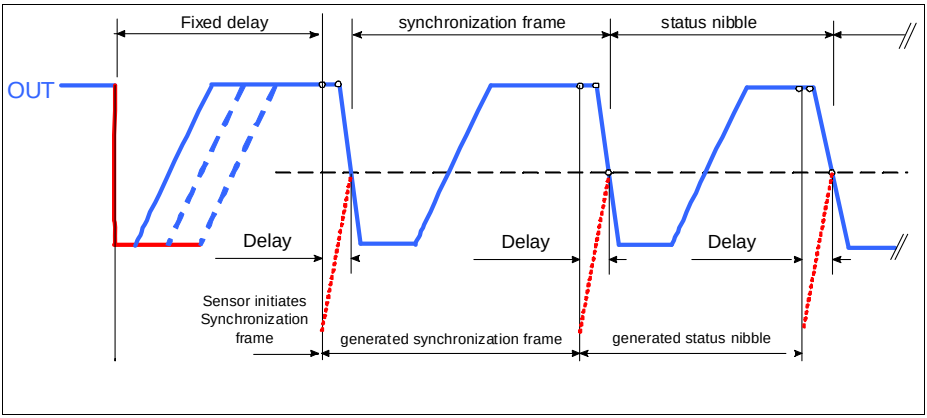

Figure 22-9 Range (SPC)

22.1.4.3 ID Selection

This functionality is similar to the previous mode, but instead of switching the range of one sensor, one of up to four sensors are selectable on a bus (bus mode, 1 master with up to 4 slaves). This allows parallel connection of up to 4 sensors using only three lines (VDD, GND, OUT), as illustrated in **Figure 22-10**.

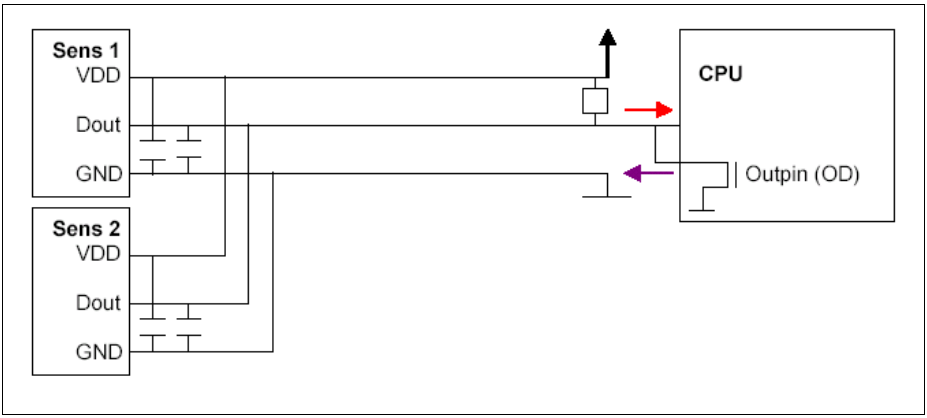

Figure 22-10 ID Selection (SPC)

22.1.4.4 Bidirectional Transmit Mode

After addressing the sensor the ECU interrupts the sensor sync pulse by pulling down the line. The ECU starts to transmit own nibbles on the time base of the selected sensor. The ECU has to adapt the sensors timing from an earlier received cycle.

The sensor detects the falling edge that infringes the protocol and switches to receive mode as illustrated in **Figure 22-11**.

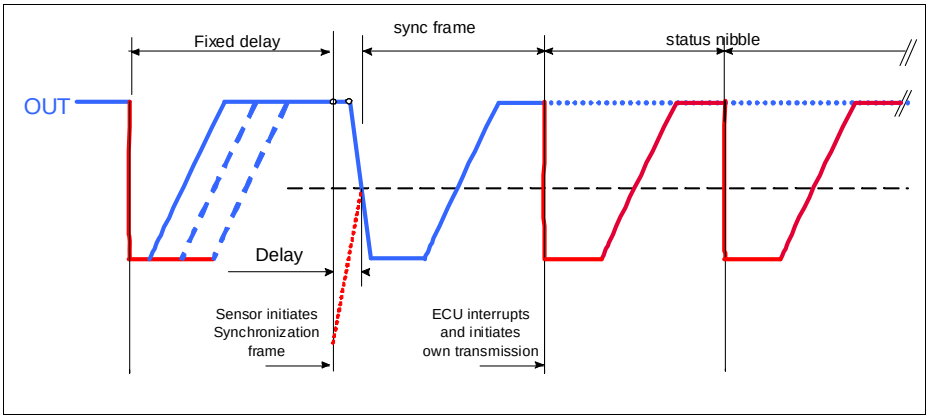

Figure 22-11 Bidirectional Transmit Mode (SPC)

22.1.4.5 SPC Timing

An SPC transmission is initiated by a Master pulse on the OUT pin. To detect a low level on the OUT pin, the voltage must be below a threshold Vthf. The sensor detects that the OUT line has been released as soon as Vthr is crossed. **Figure 22-12** shows the timing definitions for the master pulse. The master low time tmlow as well as the total trigger time tmtr are individual for the different SPC modes and are given in the sensors specifications.It is recommended to chose the typical master low time exactly between the minimum and the maximum possible time given by the connected sensor: tmlow,typ = (tmlow,min + tmlow,max) / 2.

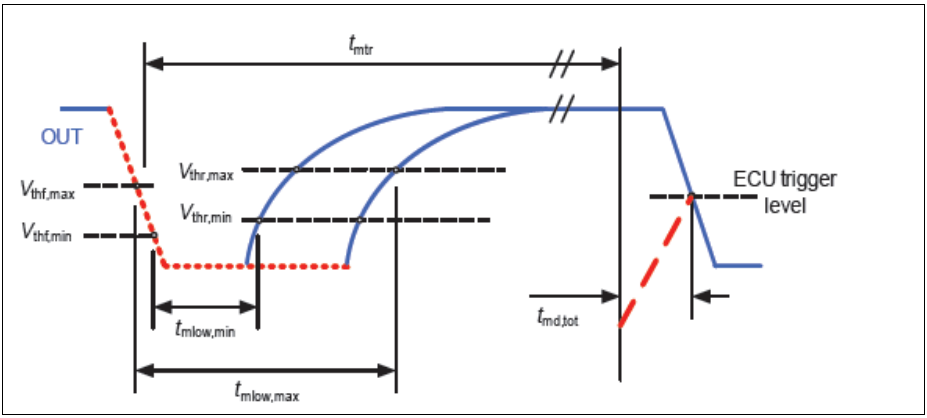

Figure 22-12 Timing (SPC)

22.1.4.6 Abort of Frames

Only a reset condition of the device, a hard suspend or choosing Mode 0 by clearing bit field SCRx.TRIG can abort a current SPC transmission immediately. During hard suspend, the port output drives its current value until suspend is terminated. If the receive channel becomes disabled, the soft suspend mode is requested, or the sleep mode is entered, the SENT module still does start a new frame transmission. If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no frame finished interrupt is generated any more.

Note: Received frames are aborted immediately on a disable, suspend or sleep request.

22.1.5 Baud Rate Generation

The nominal baud rate of each channel is individually adjustable. This is required as it is depending from the connected sensor and its current deviation from nominal frequency.

The actual baud rate of the channel follows automatically the baud rate of the connected device and its current deviation from nominal frequency. The adaptation range is +- 25% as specified in J2716 JAN2010.

Chapter 22.1.5 shows in detail how the baud rate for each channel is adjusted. 1 / f_{tick_x} defines the resulting tick length.

In the first stage, a global fractional divider serves as pre divider. Its intermediate frequency $f_{fracdiv}$ can be set up so that it is handy as input frequency for the different SENT channels. The clock signal f_{pdiv} of a channel must always be at least 20 times the nominal tick frequency of the channel. This is to allow for the highly flexible and big tolerance of +-25% versus the sending device. In addition the module must be able to detect a deviation in the length of 2 consecutive Synchronization / Calibration pulses of 1.5625% (1/64) and adapt the own baud rate. The tick time is typically 3 µs but can vary by standard and take values up to 10 µs. Future application might require even shorter tick times for higher repetition rates. This is why this implementation allows for an even extended range of 0.2 … 90 µs. To achieve this each channel has its own fractional divider. This allows to downscale the frequency of f_{tick} precisely to the required tick frequency. For details on the principles of a fractional divider, please refer to the SCU chapter of TC21x/TC22x/TC23x section “Clock Control”.

The SENT module provides two clock signals to the channels (**Figure 22-13**):

- f_{SENT}
  This is the module clock that is used inside the SENT kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{SENT} is always identical to the system clock frequency f_{SYS}. The clock control register SENT_CLC makes it possible to enable/disable f_{SENT} under certain conditions.
- $f_{fracdiv}$
  This clock is the module clock that is used inside the SENT kernel for baud rate generation of the serial channels. The fractional divider register SENT_FDR controls the frequency of $f_{fracdiv}$. Usually not required and set to 1.

The channels generate two local clock signals:

- f_{pdiv_x}
  This clock is the channel clock that is used inside the SENT channel x for baud rate generation of the serial channel. The divider register SENT_CPDRx controls the frequency of f_{pdiv_x}.
- f_{tick_x}
  This clock is the channel clock that is used inside the SENT channel as the baud rate frequency. The fractional divider register SENT_CFDRx controls the frequency of

f_{tick_x}.The higher the value of DIV the higher the precision with which the Synchronization / Calibration pulse and the deviation in the length of 2 consecutive Synchronization / Calibration pulses (drift) can be measured.
DIV must be set in an interval of [560, 3276].

Each time a Synchronization / Calibration pulse starts DIVM is measured. DIVM is the result of measuring the calibration pulse duration with f_{pdiv_x}. At the end of the Synchronization / Calibration pulse this value is taken as new divider of the CFDR.

Each time a pulse starts, the internal accumulator of the CFDR is preset with DIVM / 2. This is required to center the data eye and to make the margin symmetrical.

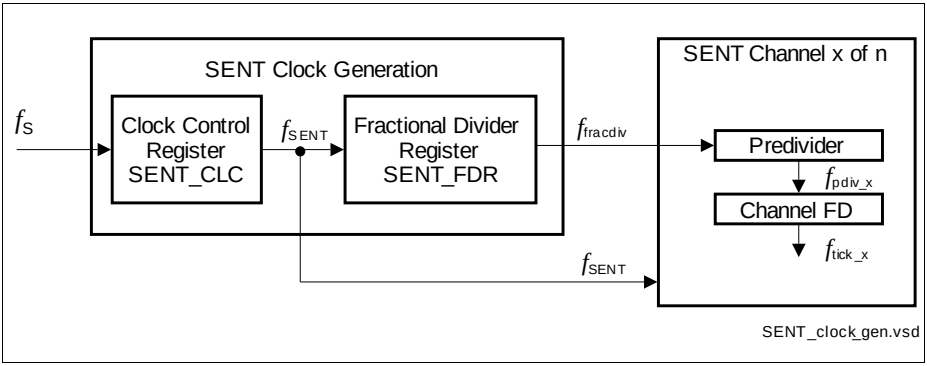

Figure 22-13 SENT Module Clock Generation

The following two formulas define the frequency of $f_{fracdiv}$:

$f_{fracdiv} = f_{SENT}$ / (1024 - SENT_FDR.STEP); FDR.DM = 01_B (22.1)

$f_{fracdiv} = f_{SENT}$ x SENT_FDR.STEP / 1024 with STEP = 0 … 1023; FDR.DM = 10_B (22.2)

The following formula defines the frequency of f_{pdiv_x}:

$f_{pdiv\_x} = f_{fracdiv}$ / (SENT_CPDRx.PDIV + 1) (22.3)

The following formula defines the nominal frequency of f_{tick_x}. For the actual frequency of f_{tick_x} DIV is replaced by DIVM after the current sensor frequency was validly measured.

$f_{tick\_x} = f_{pdiv\_x}$ x 56 / SENT_CFDRx.DIV with DIV = 560 … 3276 (22.4)

22.1.6 Error Detection Capabilities

Each SENT channel can detect and signal the following error conditions:

Protocol Level:

- Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
- Too many or too few nibbles between calibration pulses
- Checksum error
- Successive calibration pulse differ by more than 1.5625%
- Any nibble data values measured as < 0 or >15
- Wrong Status and Communication nibbles
- Serial Communication CRC error

Transfer Management Level:

- Receive Data Buffer Overrun
- SPC Data Buffer Underrun

22.1.7 Digital Glitch Filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter similar to a Filter and Prescaler Cell (FPC) in Delayed Debounce Filter Mode with up and down (no reset).

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. Thus it helps to find the exact pulse length for said slow slopes in noisy environment.

The glitch filter is clocked with f_{pdiv}. If the state of the input sample differs from the current output signal value, the internal counter is incremented by one. When the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one. When the timer matches the compare value stored in IOCRx.DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again.

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{pdiv} is sufficient. By default it is cleared. If IOCRx.DEPTH is cleared the filter is inactive. Nevertheless, the input signal is sampled with f_{pdiv}.

The internal signal after the filter will change value not before the new value was sampled DEPTH times. If during this period a spike occurs, it takes 2 x T_{pdiv} times longer for the internal signal to change value. The filters principal implies a delay of the signal by (DEPTH x T_{pdiv}).

Upon detection of glitch during rising or falling edge, IOCRx.REG or IOCRx.FEG is set. The rising / falling edge glitch flags must be reset by software.

Figure 22-14 shows the digital glitch filter:

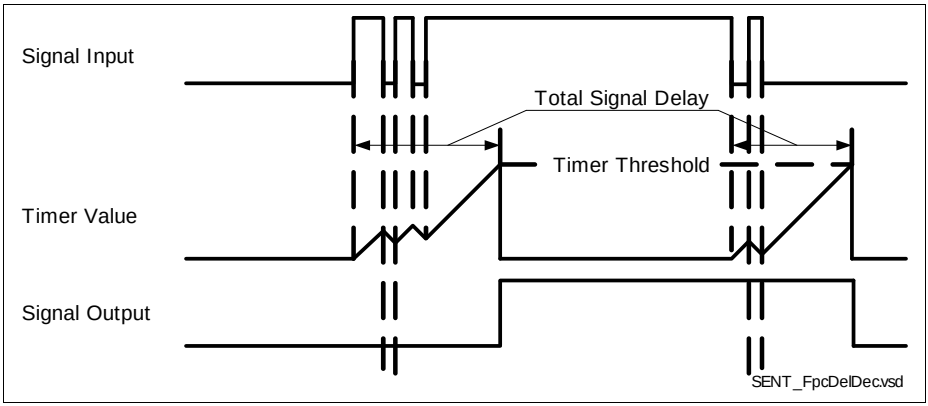

Figure 22-14 Digital Glitch Filter

22.1.8 Interrupts

4 Interrupt request lines are available for the SENT module.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to a Receive Data Register RDR. RSI indicates a receive frame success interrupt, i.e. the CRC was successful. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct. RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (“overwrite”), i.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. TDI indicates a transmit interrupt. It is activated when data is moved from a SCR to a transmit shift register. TBI indicates a transfer buffer under run interrupt. It is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. In addition the protocol error interrupts are available: FRI, FDI, NNI, NVI, CRCI. If one of the protocol interrupts is activated, data is to be treated as invalid according to J2716 JAN2010. WSI, SDI SCRI treat the interrupts referring to the Status and Communication nibble. WDI is the Watch Dog Error Interrupt. It is issued if the time between two frames is too long.

For acceleration of the interrupt service routine, a Register INTOV is implemented that holds a flag for each channel. This flag is automatically set if there is an interrupt pending for the channel which is enabled. It is automatically reset, if no more enabled interrupt is pending for this channel.

The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR.
If more than one interrupt source is connected to the same interrupt node pointer (in register INPx), the requests are combined to one common line.

22.1.9 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to a IR input. See **Table 22-9 “Service Request Lines of SENT” on Page 22-72**.

22.2 SENT Kernel Registers

This section describes the kernel registers of the SENT module. All SENT kernel register names described in this section will be referenced in other parts of the TC21x/TC22x/TC23x User's Manual by the module name prefix "SENT_" for the SENT interface.

All registers in the SENT address spaces are reset with the application reset (definition see SCU section "Reset Operation").

SENT Kernel Register Overview

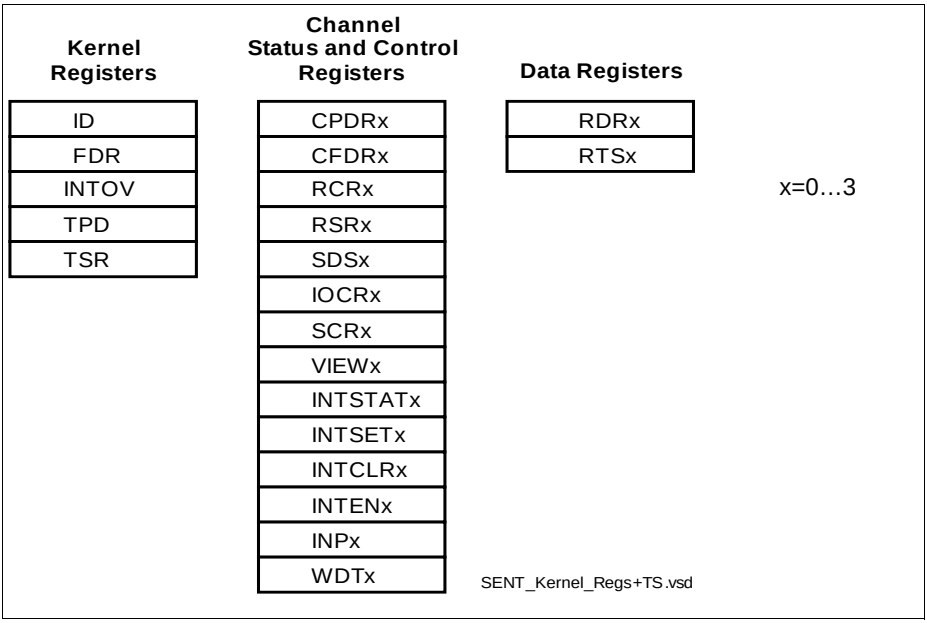

Figure 22-15 SENT Kernel Registers

The complete and detailed address map of the SENT module is described in **Table 22-7** on **Page 22-23**.

Note: x can take the values 0 … 3

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

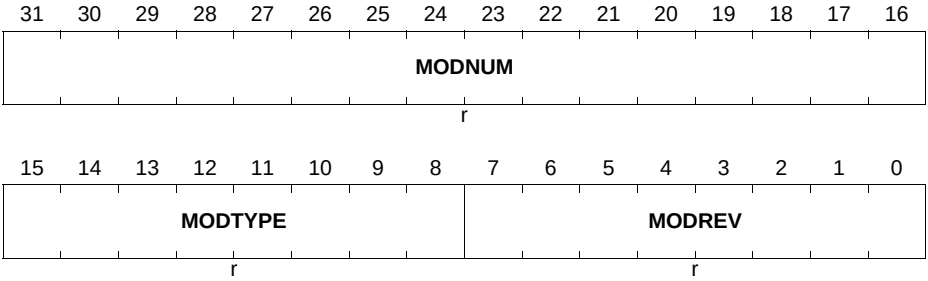
SE - Safety ENDINIT

22.2.1 Module Control

Module Identification Register

The SENT Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register (08$_H$) Reset Value: 0080 C0XX$_H$

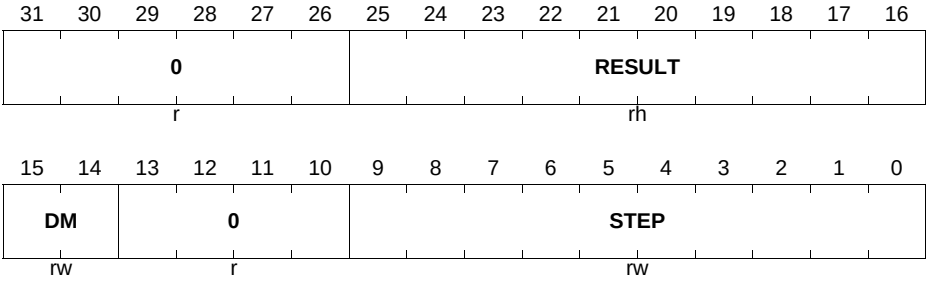


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: C0$_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the SENT: 0080$_H$

Fractional Divider Register

The Fractional Divider Register controls the input clock $f_{fracdiv}$ of all SENT channels.

SENT_FDR
SENT Fractional Divider Register ($0C_H$) Reset Value: 0000 0000$_H$

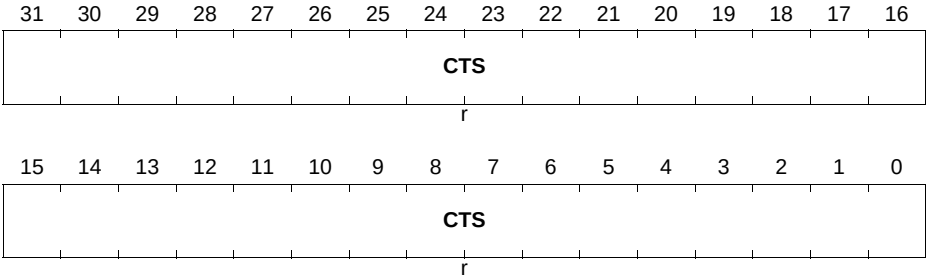


Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
0	[13:10], [31:26]	r	**Reserved** Read as 0; should be written with 0.

Module Time Stamp Register

The SENT Module Time Stamp Register contains read-only information about the current time given in clock cycles generated from TPD since last reset while module was clocked. Writing to TPD clears this register.

TSR
Time Stamp Register **(18_H)** **Reset Value: $0000\ 0000_H$**

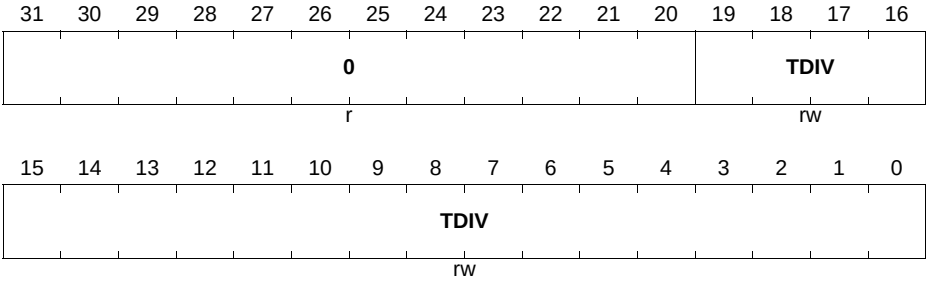


Field	Bits	Type	Description
CTS	[31:0]	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.

Module Time Stamp Pre Divider Register

The SENT Module Time Stamp Predivider Register contains the pre divider that defines the time resolution of TSR. Writing to TPD clears register TSR.

TPD
Time Stamp Predivider Register ($1C_H$) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
TDIV	[19:0]	rw	**Divider Factor of Pre Divider for TSR** Divides $f_{fracdiv}$ by (TDIV + 1) and drives TSR.
0	[31:20]	r	**Reserved** Read as 0; should be written with 0.

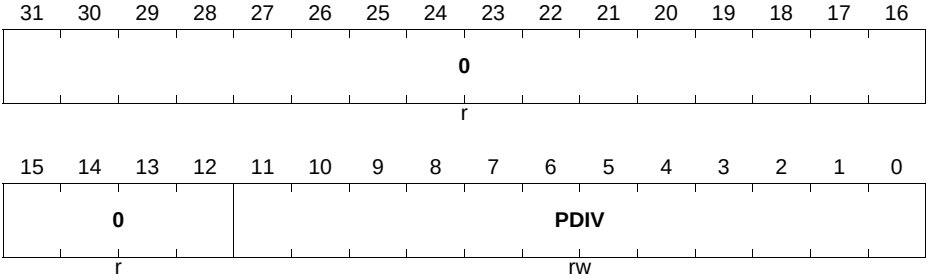
22.2.2 Channel Baud Rate Registers

Channel Pre Divider Register

The Channel Pre Divider Register CPDRx contains the pre divider that is related to the SENT channel baud rate.

See **Equation (22.3)**

CPDRx (x = 0-3)
Channel Pre Divider Register x **(100_H+40_H*x)** **Reset Value: 0000 0000_H**



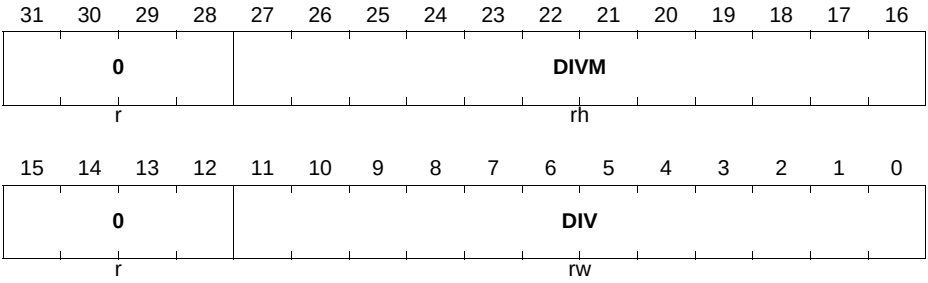
Field	Bits	Type	Description
PDIV	[11:0]	rw	**Divider Factor of Pre Divider for Channel x** Divides $f_{fracdiv}$ by (PDIV + 1) and delivers f_{pdiv_x} to the Channel Fractional Divider. RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
0	[31:12]	r	**Reserved** Read as 0; should be written with 0.

Channel Fractional Divider Register

The Channel Fractional Divider Register CFDRx contains control bits/bit fields that are related to the SENT channel baud rate.

See **Equation (22.4)** in **Chapter 22.1.5** for a detailed description.

CFDRx (x = 0-3)
Channel Fractional Divider Register x(104_H+40_H*x) **Reset Value: 0000 0000_H**



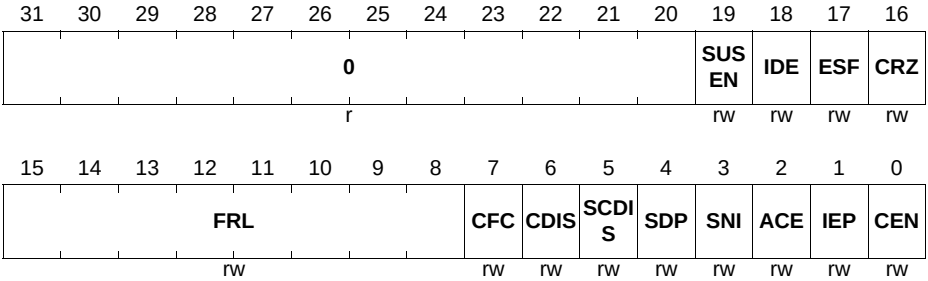
Field	Bits	Type	Description
DIV	[11:0]	rw	**Divider Value** Initial and reference divider value for the CFDR. DIV must be programmed > 0. If cleared, DIV becomes 1. If written, DIVM is updated automatically with the same value.RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
DIVM	[27:16]	rh	**Measured Divider Value** DIVM is automatically updated by HW to adjust the receiver frequency to the current sender frequency. This value is kept automatically in the range of 75% DIV < DIVM < 125% DIV Write data is ignored.
0	[15:12], [31:28]	r	**Reserved** Read as 0; should be written with 0.

22.2.3 Receiver Control and Status Registers

Receiver Control Register

The Receiver Control Register RCRx contains control bits/bit fields that are related to the SENT receiver operation.

RCRx (x = 0-3)
Receiver Control Register x **(108_H+40_H*x)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CEN	0	rw	**Channel Enable** When CEN is set, the receiver of channel x is enabled. The internal receiver state machine can be initialized by switching the channel off and on. This does not change the current register content. 0_B channel x disabled (default) 1_B channel x enabled
IEP	1	rw	**Ignore End Pulse** When IEP is set, an end pulse is ignored. An end pulse can be generated in SPC mode or as pause pulse. 0_B End Pulse not ignored (default) 1_B End Pulse ignored For systems with an end pulse, during synchronize or re-synchronize of reception, if calibration pulses are detected one immediately following the other, the first calibration pulse shall be ignored as it may be a pause pulse with duration matching the calibration pulse range.

Field	Bits	Type	Description
ACE	2	rw	**Alternative CRC Mode Enable** When ACE is set, the CRC is calculated in an alternative way for both: fast (signal) and slow (serial message) data path. *Note: If ESF is set, the standard 6 bit CRC is always used for the serial message and ACE is ignored.* 0_B Serial CRC calculation as specified in J2716 JAN2010 (default) 1_B Alternative: 4 bit in parallel CRC calculation as used e.g. in hall sensor TLE4998C.
SNI	3	rw	**Status Nibble Included in CRC** When SNI is set, the status Nibble is included in (signal data) CRC. 0_B Status Nibble not included in CRC (default) 1_B Status Nibble included in CRC (as used e.g. in hall sensor TLE4998C).
SDP	4	rw	**Serial Data Processing Mode** This bit switches automatic serial data processing on. 0_B Automatic Serial Data Processing is disabled. Status and Communication nibble can be read from RSRx for SW processing. (default) 1_B Automatic Serial Data Processing is enabled. Status and Communication nibble can be read from RSRx; Message ID, Serial Data and SCRC can be read from SDSx after serial data interrupt SDI is activated.
SCDIS	5	rw	**CRC for Serial Data Disabled Mode** This bit selects the CRC disabled mode. 00_B CRC is enabled (default) 01_B CRC is disabled CRC nibble can be read from SDSx. The CPU must perform the CRC on the current data by SW.

Field	Bits	Type	Description
CDIS	6	rw	**CRC Disabled Mode** This bit selects the CRC disabled mode. 00_B CRC is enabled (default) 01_B CRC is disabled CRC nibble can be read from RSRx. The CPU must perform the CRC on the current data by SW.

Field	Bits	Type	Description
CFC	7	rw	**Consecutive Frame Check** This bit determines the way the most recently received frame buffer is indicated as valid. 0_B **Check against Past Sync Pulse** The current Synchronization / Calibration Pulse is compared to the Synchronization / Calibration Pulse received immediately before. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the Synchronization / Calibration Pulse before by more than 1.5625%. In this case of error, its length is not used as new reference. In case the check passes and no other error occurs the Frame Buffer is indicated valid immediately after CRC calculation result is correct. Resynchronization: On the third successive calibration pulse error, the current calibration pulse value is considered as valid and the message accepted unless the message frame contains other errors. In both cases a receive data interrupt (RDI), or a referring error interrupt is issued. 1_B **Check against Future Sync Pulse** The current Synchronization / Calibration Pulse is compared with the Synchronization / Calibration Pulse received immediately after the current frame. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the following Synchronization / Calibration Pulse by more than 1.5625%. Resynchronization: In this case of error, the current length is used as new reference. Note: The whole frame can be indicated valid only after additionally measuring the Synchronization / Calibration Pulse of the successive frame.

Field	Bits	Type	Description
FRL	[15:8]	rw	**Frame Length** FRL determines the number of data nibbles per frame that the SENT channel x is setup for. Note that FRL does not include the Synchronization / Calibration Pulse, the Status and Communication nibble, the CRC nibble nor the additional zero length nibble that might be introduced by use of SPC. 00000000_B No data nibble 00000001_B 1 data nibble 00000010_B 2 data nibbles 00000011_B 3 nibbles ... ... 00001000_B 8 nibbles Maximum in normal length mode ... ... 11111111_B 255 nibbles If more than 8 nibbles are configured, please note: In addition to the receive success interrupt RSI at the successfully received end of a frame, a receive data interrupt RDI is issued each time 8 nibbles have been transferred to the Receive Data Register RDRx. At the end of a frame, RDI is issued if RSI is issued. If an error occurred, RDI is not set at the end of a frame. If no CRC has been received at the point in time where RDI is issued, the receive data interrupt is no indication whether or not the transfer was successful so far. A CRC Error Interrupt is issued at the end of the frame if Automatic CRC check is enabled and the CRC is wrong.

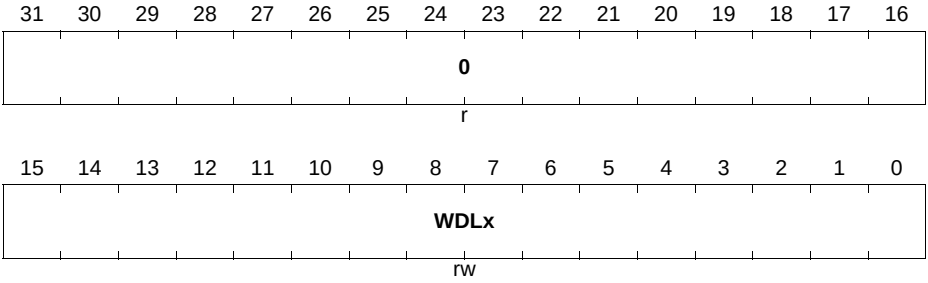
Field	Bits	Type	Description
CRZ	16	rw	**CRC with Zero Nibble for Serial Data** This bit selects the CRC method. If CRZ is cleared, augmentation is selected, (i.e a ZERO NIBBLE is added at the end of CRC calculation (only in calculation)). E.g. as 7th nibble (in case of 6 data nibbles) 00_B Augmentation is selected for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames) (default) 01_B Augmentation is switched off for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames). The enhanced serial message (18 Frames, 6-bit CRC) is not controlled by CRZ but the 6-bit CRC is always augmented according to standard.
ESF	17	rw	**Enhanced Serial Frame Mode** This bit selects the serial frame structure. 0_B short (16 frames, 4 bit ID, 8 bit data, 4 bit CRC) 1_B enhanced (18 frames, 4 or 8 bit ID, 12 or 16 bit data, 6 bit CRC)
IDE	18	rw	**Ignore Drift Error Mode** This bit selects if drift errors lead to frame rejection and if an interrupt (INTSTAT.FDI) is generated. Used, if sensors are triggered by SPC. During a long pause period the accumulated drift could be more than 1.5625%. In this special case setting IDE is useful. 0_B Drift Errors enabled (default) 1_B Drift Errors disabled
SUSEN	19	rw	**Suspend Enable** This bit makes it possible to set the SENT channel into Suspend Mode via OCDS (on chip debug support): 0_B An OCDS suspend trigger is ignored by this SENT channel. 1_B An OCDS suspend trigger disables the SENT channel: As soon as the SPC sender logic of the SENT channel becomes idle, the module is stopped while all registers of the channel stay readable. The receiver is stopped unconditionally. A partly received frame is discarded. Bit SUSEN is reset via OCDS Reset.

Field	Bits	Type	Description
0	[31:20]	r	**Reserved** Read as 0; should be written with 0.

Watch Dog Timer Register

The Watch Dog Timer Register WDTx contains the time out value for channel x.
The internal Watch Dog timer is cleared and started automatically each time an RDI (Receive Data Interrupt Request Flag) is set in the INTSTAT of the referring channel and also on any write to WDL that sets WDL>0. The value entered here defines the time in multiples of T_{tick_x} (defined in CFDR) from the last RDI on channel x.
The internal Watch Dog Timer is compared to WDLx.
A match triggers interrupt WDI and stops the internal Watch Dog Counter x.
After such a match, the Watch Dog Timer will be cleared and started automatically with clearing bit WDI (by setting INTCLR.WDI). I.e. the Watch Dog Counter is running only if interrupt flag WDI is cleared.
If WDL is cleared, the WDTx is stopped/disabled.

WDTx (x = 0-3)
Watch Dog Timer Register x **(134_H + x * 40_H)** **Reset Value: 0000 0000_H**

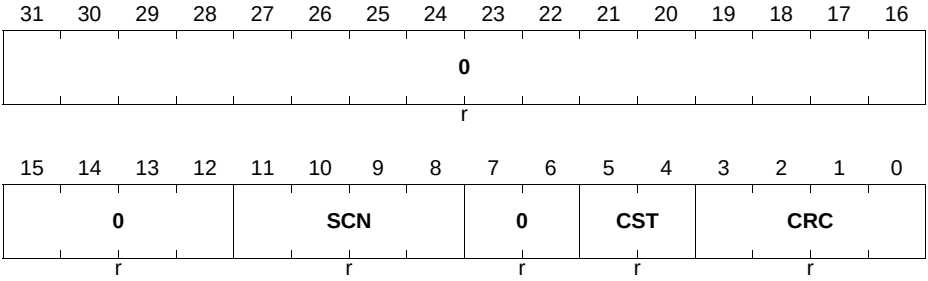


Field	Bits	Type	Description
WDLx	[15:0]	rw	**Watch Dog Timer Limit** for channel x .
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Receiver Status Register

The Receive Status Register provides the status information of channel x.

RSRx (x = 0-3)
Receive Status Register x **($10C_H+40_H*x$)** **Reset Value: 0000 0000_H**

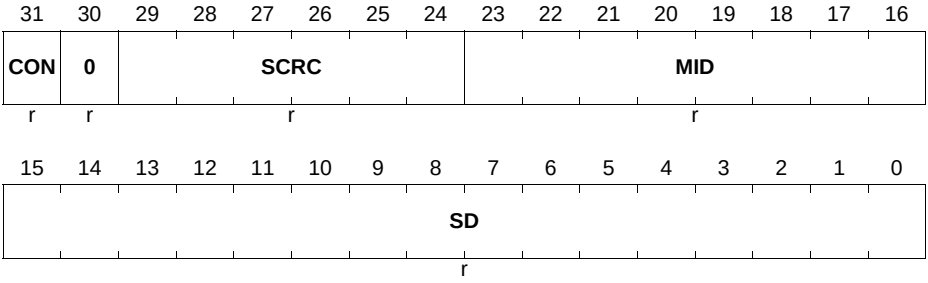


Field	Bits	Type	Description
CRC	[3:0]	r	**CRC** of last frame. CRC_0 is on bit position 0.
CST	[5:4]	r	**Channel Status** CST shows the current status of channel x. 00_B STOP Channel is disabled and can be configured 01_B INITIALIZED Channel is configured and enabled and no Synchronization / Calibration Pulse was received since last enable. 10_B RUNNING one or more Synchronization / Calibration Pulses were received and Frequency Range or Frequency Drift not or no longer in range. Fallback status from SYNCHRONIZED. 11_B SYNCHRONIZED Frequency Range and Frequency Drift in range
SCN	[11:8]	r	**Status and Communication Nibble** of last frame. SCN_0 is on bit position 8.
0	[7:6], [31:12]	r	**Reserved** Read as 0; should be written with 0.

Serial Data and Status Register

The Serial (Receive) Data and Status Register provides the data and status information of channel x.

SDSx (x = 0-3)
Serial Data and Status Register x (110_H+40_H*x) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SD	[15:0]	r	**Serial Data** of last serial data frame. SD_0 is on bit position 0. If RCR.ESF is cleared 8 bits of data are available and bits [15:8] are zero. If RCR.ESF is set and if SDS.CON is cleared 12 bits of data are available and bits [15:12] are zero.
MID	[23:16]	r	**Message ID** of last serial data frame. ID_0 is on bit position 16. If RCR.ESF is cleared, or if SDS.CON is set, bits [23:20] are zero.
SCRC	[29:24]	r	**SCRC** CRC of last serial data frame. CRC_0 is on position 24. If RCR.ESF is cleared, bits [29:28] are always zero.
CON	31	r	**Configuration bit** of last serial frame. 0_B 12-bit data and 8-bit message ID 1_B 16-bit data and 4-bit message ID
0	30	r	**Reserved** Read as 0; should be written with 0.

22.2.4 Input and Output Control

Input and Output Control Register Functions

The Input and Output Control Register IOCRx determines for the SENT channel x:

for the receiver:

- the alternate input
- the filter depth
- the input signal polarity

for the SPC Unit

- the trigger source
- the output signal polarity

IOCRx (x = 0-3)
Input and Output Control Register x(114_H+40_H*x) **Reset Value: X000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rh	rh	r	w	rw	rw	rw				r		rw	

Field	Bits	Type	Description
ALTI	[1:0]	rw	**Alternate Input Select** Selects the alternate input for channel y: 0000_B Alternate Input 0 selected 0001_B Alternate Input 1 selected $…_B$ … 0011_B Alternate Input 3 selected

Field	Bits	Type	Description
DEPTH	[7:4]	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with f_{pdiv} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 0000_B off, default 0001_B 1 T_{pdiv} 0010_B 2 0011_B 3 $\cdots_B$ … 1111_B 15
OIE	8	rw	**Output Inverter Enable Channel x** Selects the Pulse Polarity of the output of channel x 0_B Pulse polarity is active low 1_B Pulse polarity is active high
IIE	9	rw	**Input Inverter Enable Channel x** Selects the Pulse Polarity of the input of channel x 0_B Pulse polarity is active low 1_B Pulse polarity is active high
CEC	10	w	**Clear Edge Counter** If this bit is set, IOCR.EC is cleared. Always reads back as ‘0’.
REG	12	rh	**Rising Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x 0_B No Glitch detected on rising edge 1_B Glitch detected on rising edge REG is cleared by setting CREG.
FEG	13	rh	**Falling Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x 0_B No Glitch detected on falling edge 1_B Glitch detected on falling edge FEG is cleared by setting CFEG.
CREG	14	rw	**Clear Rising Edge Glitch Flag for Channel x** Clears the status flag REG 0_B REG is not cleared 1_B REG is cleared CREG always read zero.

Field	Bits	Type	Description
CFEG	15	rw	**Clear Falling Edge Glitch Flag for Channel x** Clears the status flag FEG 0_B FEG is not cleared 1_B FEG is cleared CFEG always read zero.
ETS	[19:16]	rw	**External Trigger Select** Selects the external trigger line if SCRx.TRIG is programmed to 11_B. 0000_BTRIG0 0001_BTRIG1 ... ... 3_D TRIG3 ... ... 1111_Breserved
EC	[27:20]	rh	**Edge Counter** This bit field contains a counter with saturation (stops at 0xFF). It is incremented with any falling edge that appears on the input pin selected by IOCR.ALTI. Note that this holds true in all states (STOP, INITIALIZED, RUNNING, SYNCHRONIZED). It is intended for debugging, in particular to find a bubbling idiot that sends before enabling the module.
CTR	28	rw	**Clear Trigger Monitor Flag for Channel x** Clears the status flag TRM 0_B TRM is not cleared 1_B TRM is cleared CTR always read zero. Reset value of CTR is 0.
TRM	29	rh	**Trigger Monitor Flag for Channel x** Shows the status of the trigger detection of channel x 0_B No Trigger detected 1_B Trigger detected (one or several) TRM is cleared by setting CTR. Reset value of TRM is 0.
RXM	30	rh	**Receive Monitor for Channel x** Shows the status of the receive signal of channel x after glitch filtering and inverted as specified by IIE. 0_B Current signal is low. 1_B Current signal is high. Reset value of RXM is X.

Field	Bits	Type	Description
TXM	31	rh	**Transmit Monitor for Channel x** Shows the status of the transmit signal of channel x inverted as specified by OIE. 0_B Current signal is low. 1_B Current signal is high. Reset value of TXM is X.
0	[3:2], 11	r	**Reserved** Read as 0; should be written with 0.

22.2.5 Receive Data Registers

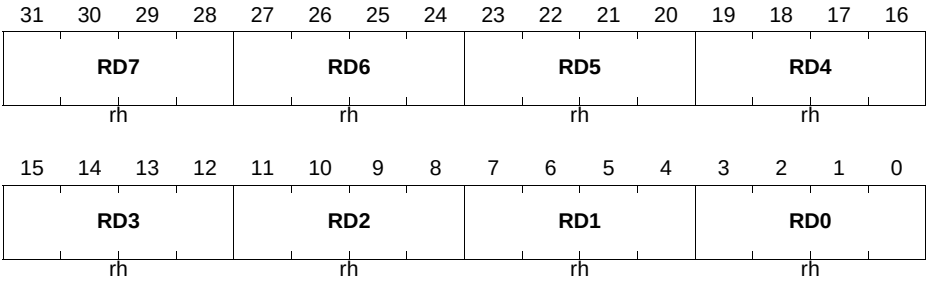
Receive Data Registers RDRx

The Receive Data Registers RDRx for channel x shows the data content of a received data frame. Register VIEWx is used to sort the nibbles.

Note: Register VIEW must be set up correctly to see all data nibbles of the frame! By default the application software set VIEW to 7654 3210$_H$.

Note: The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused nibbles are always read as zero.

RDRx (x = 0-3)
Receive Data Register x **(80_H+x*4_H)** **Reset Value: 0000 0000_H**

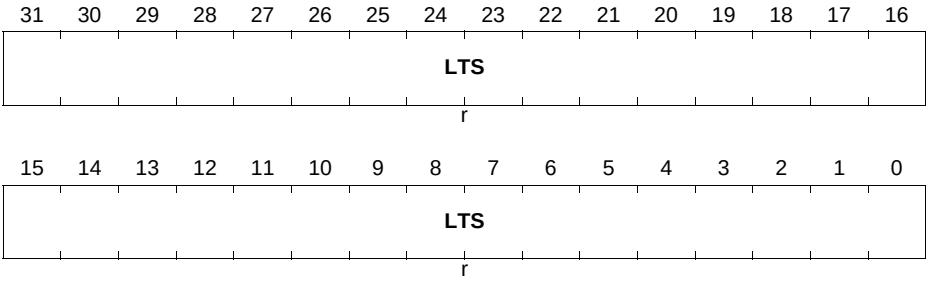


Field	Bits	Type	Description
RDy (y = 0-7)	[4*y+3 :4*y]	rh	**Receive Data Nibble y** RDy shows the nibble from the received frame that is sorted to this position. It can be selected by any of VIEWx.RDNPy (y = 0-7). By default all nibbles are sorted to RD0 as the reset value of VIEW is 0x0000 0000_H. I.e. at the end of frame reception RD0 contains the last data nibble of the frame.

Channel Receive Time Stamp Register

The SENT Channel x Receive Time Stamp Register contains read-only information about the time the last frame for channel x was received. Time is captured with the second falling edge, i.e. at the Status/Communication data pulse.

RTSx (x=0-3)
Receive Time Stamp Register x (A80$_H$+x*4$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
LTS	[31:0]	r	**Last Receive Time Stamp for Channel x** This bit field shows the time stamp of the last frame on channel x.

Receive Data View Register VIEWx

The Receive Data View Registers VIEWx stores the nibble pointers. They determine the sequence in which the received data nibbles are presented to the host. This reduces the SW effort to sort the nibbles.
The data nibble that is received first in the received frame is moved to the location given in register VIEW.RDNP0, the second to VIEW.RDNP1 and so on until VIEW.RDNP7.
If more than one VIEW.RDNPx point to a certain location in RDR, the last one will overwrite the previous ones.
Example: two 12 bit values are transmitted. One with highest significant nibble first and one with lowest significant nibble first. The frame looks like this: 456321$_H$. Note that the 1 is received as first data nibble and the 4 comes in as last data nibble.
The actual signal values are 0x123$_H$ and 0x456$_H$. By using VIEWx this can be sorted out into two 16bit values by HW. In the example VIEWx would be set to: 73 654 012$_H$. 73 is a dummy value and is not regarded if not more than 6 nibbles are received in a frame. The Register RDRx looks like this: 0x0456 0123$_H$ to the host.

In the example RDR nibbles 3 and 7 contain 0x0000$_B$ as the Receive Buffer is always cleared (0x0000 0000$_H$) before new data is received.

If a frame contains more than eight nibbles and the sorting can not be specified statically, VIEW can be set to e.g. 7654 3210_H.

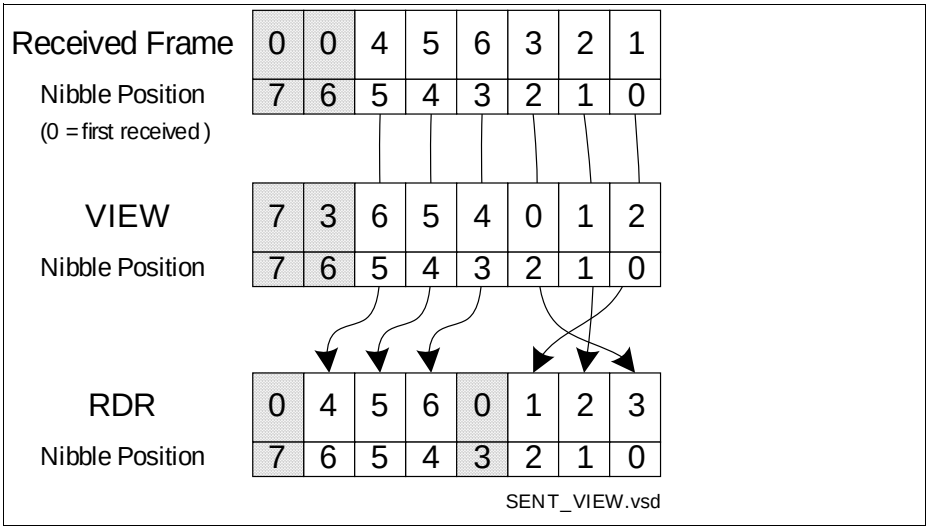


Figure 22-16 Functionality of VIEW Register

VIEWx (x = 0-3)

Receive Data View Register x ($11C_H$+40_H*x) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RDNPy (y = 0-7)	[4*y+2 :4*y]	rw	**Receive Data Target Nibble Pointer y** RDNPy points to the Nibble in Receive Data Register RDRx where the nibble y from the received frame is sorted to. Nibble 0 is the first data nibble in the frame. It gets moved to the position defined in RDNP0. And on. 000_B Nibble 0 selected 001_B Nibble 1 selected $\ldots_B$ … 111_B Nibble 7 selected *Note: RDNPy must be written before first frame reception. All RDNPy must have different values. (Higher RDNPy overwrite lower RDNPy.)*
0	3, 7, 11, 15, 19, 23, 27, 31	r	**Reserved** Read as 0; should be written with 0.

22.2.6 SPC Control

SPC Control Registers SCRx

The SPC Control Register SCR contains data to be transmitted during the sync pulse of the data frames. It contains as well the trigger control bits required for sending nibbles from the SENT module to the sensor / external SENT device.

The SPC Control Register is used to control the trigger mode and time base of the SPC channel transmission.

Data and the control bits are collected in this single register to ease transfer of multiple pulses in cases where dynamic switching of the trigger condition is required.

The SPC Control Register is build to control single pulse transfers only.

Thus it is possible to change the control settings of an individual channel from pulse to pulse as it is required in SPC mode “Bidirectional transmit”. Here it might be considered useful to change trigger mode between Mode 1 (immediately) and Mode 2 (falling edge of next Synchronization / Calibration Pulse with programmable delay).

In addition repeating transfers with the same control settings are supported. For a pulse transfer to be initiated a synchronization signal can be sufficient and no further SW intervention is required. Here the data can be changed (“ID-Selection” Mode) or simply left constant (“Sync” Mode). Only a HW trigger needs to be set up.

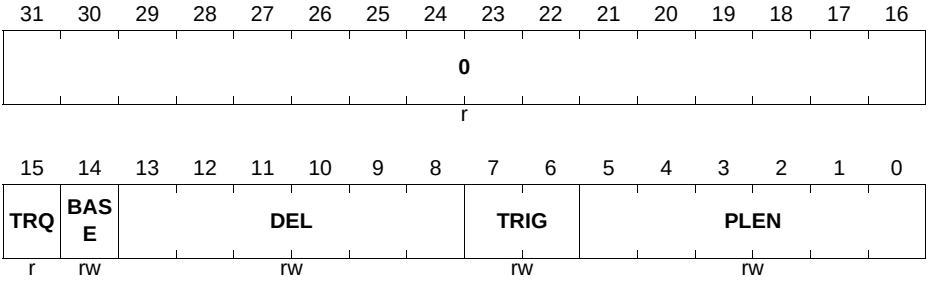
In Mode 0, SPC is deactivated for this channel. A write access to SCRx does not initiate an SPC pulse transmission. All state transmitter machines are initialized.

In Mode 1, an SPC pulse is sent, each time SPC Control Register SCRx is written to. If a transfer is ongoing, the channel waits automatically until the internal transmission register is ready. Transmit Buffer Underflow bit TBIx is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. After the data was transferred to the internal transmission register, interrupt TDIx signals that a new value can be written. INTSTATx.TDIx must be cleared by SW. Independently from this interrupt pending bit, a new interrupt pulse is generated on each transfer of an SPC pulse.
This mode is important for back to back transfers of several nibbles as in bidirectional SPC mode.

In Mode 2, an SPC pulse is sent, each time the first falling edge of any Synchronization / Calibration Pulse is received. In this mode, the programmable delay DEL is most useful. In SPC mode “Bidirectional Transmit” this mode is useful to synchronize the transmission. TDIx and TBIx work as in Mode 1.

In Mode 3, an SPC pulse is sent (with current DEL and PLEN) after each external trigger event (defined by IOCRx.ETS). This is most useful in SPC “sync” mode. TDIx and TBIx work as in Mode 1.

SCRx (x = 0-3)
SPC Control Register x **(118_H+40_H*x)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
PLEN	[5:0]	rw	**Pulse Length** Defines the length of the pulse in tick times. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 000000_B Pulse length is 0 ticks 000001_B Pulse length is 1 tick ... ... 111111_B Pulse length is 63 ticks

Field	Bits	Type	Description
TRIG	[7:6]	rw	**Trigger Source and Mode Selection** Selects the Trigger Source and Mode. The internal sender state machine can be initialized by switching the channel off (TRIG is cleared) and on. This does not change the current register content. 00_B No Pulse is generated, OFF When cleared, an ongoing transfer is stopped immediately and the transmit output is driven recessive. 01_B Pulse starts immediately (no auto repetition) 10_B Pulse starts each time the first falling edge of any Synchronization / Calibration Pulse is received (auto repetition on next Sync. / Cal. Pulses) 11_B Pulse starts after each external trigger event. (auto repetition on next trigger) IOCRx.ETS selects the source of this event.
DEL	[13:8]	rw	**Delay Length** Selects how long the SPC pulse is delayed after the trigger condition. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 000000_B Pulse is not delayed 000001_B Pulse is delayed by 1 tick ... ... 111111_B Pulse is delayed by 63 ticks
BASE	14	rw	**Time Base** Selects the Pulse Time Base 0_B Pulse is based on measured frequency of last Synchronization/Calibration Pulse 1_B Pulse is based on nominal frequency
TRQ	15	r	**Transfer Request in Progress** While an SPC Pulse is being sent this bit is set. Write access is ignored.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

22.2.7 Interrupt Control Registers

INTOV
Interrupt Overview Register **(14_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r						rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
IPCy (y = 0-3)	y	rh	**Interrupt Pending on Channel y** If any interrupt requested flag is set for channel y in register INTSTATy AND the referring interrupt is enabled in INTENx then IPCy is set. It is automatically reset if all flags in INTSTATy are cleared for which the referring interrupt is enabled in INTENx. *Note: Not all IPC0-9 are available, the number of Interrupt Pending on Channel is equivalent to the SENT channels available, e.g 4 SENT channels has 4 Interrupt Pending IPC0-3 and vice versa.*
0	[31:4]	r	**Reserved** Read as 0.

Interrupt Status Register

The Interrupt Status Register INTSTATx contains status bits that show the status of any interrupt of SENT channel x.

Note: The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATx (x = 0-3)
Interrupt Status Register x **(120_H+40_H*x)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		WDI	SCRI	SDI	WSI	CRCI	NVI	NNI	FDI	FRI	TBI	TDI	RBI	RDI	RSI
r		rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. Depending on bit RCRx.CDIS this indicates a successful check of the CRC. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.RSI. This bit can be set by bit INTSETx.RSI. This bit is set independently from INTENx.

Field	Bits	Type	Description
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDR. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct or not checked (if RCRx.CDIS is cleared). 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.RDI. This bit can be set by bit INTSETx.RDI. This bit is set independently from INTENx.
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDRx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set.The old data is overwritten by the new data. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by reading RDRx. This bit can be cleared by bit INTCLRx.RBI. This bit can be set by bit INTSETx.RBI. This bit is set independently from INTENx.
TDI	3	rh	**Transfer Data Interrupt Request Flag** This bit is set after the trigger condition was detected. Data to be transferred has been moved internally. Thus a new value can be written to SCRx. This can be used for back to back transfers. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is automatically cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TDI. This bit can be set by bit INTSETx.TDI. This bit is set independently from INTENx.

Field	Bits	Type	Description
TBI	4	rh	**Transmit Buffer Underflow Interrupt Request Flag** This bit is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TBI. This bit can be set by bit INTSETx.TBI. This bit is set independently from INTENx.
FRI	5	rh	**Frequency Range Interrupt Request Flag** This bit is set after a Synchronization / Calibration pulse was received that deviates more than +- 25% from the nominal value. The referring data is ignored. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.FRI. This bit can be set by bit INTSETx.FRI. This bit is set independently from INTENx.
FDI	6	rh	**Frequency Drift Interrupt Request Flag** This bit is set after a subsequent Synchronization / Calibration pulse was received that deviates more than 1.5625% (1/64) from its predecessor. (See RCR.CFC) 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.FDI. This bit can be set by bit INTSETx.FDI. This bit is set independently from INTENx.

Field	Bits	Type	Description
NNI	7	rh	**Number of Nibbles Wrong Request Flag** This bit is set after a more nibbles have been received than expected or a Synchronization / Calibration Pulse is received too early thus too few nibbles have been received. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.NNI. This bit can be set by bit INTSETx.NNI. This bit is set independently from INTENx.
NVI	8	rh	**Nibbles Value out of Range Request Flag** This bit is set after a too long or too short nibble pulse has been received. I.e. value < 0 or value > 15. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.NVI. This bit can be set by bit INTSETx.NVI. This bit is set independently from INTENx.
CRCI	9	rh	**CRC Error Request Flag** This bit is set if the CRC fails. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.CRCI. This bit can be set by bit INTSETx.CRCI. This bit is set independently from INTENx.

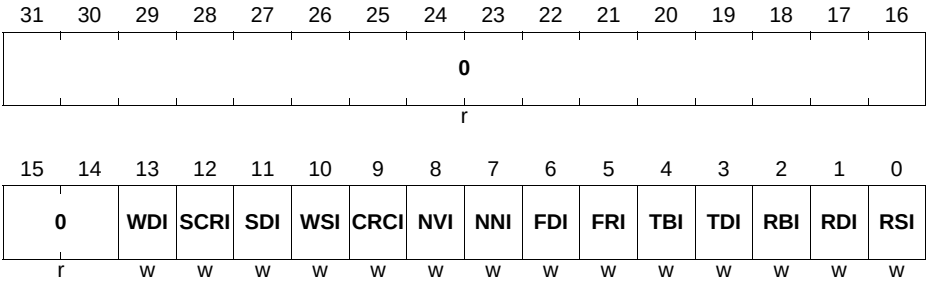
Field	Bits	Type	Description
WSI	10	rh	**Wrong Status and Communication Nibble Error Request Flag** In Short Serial Frame Mode (RCR.ESF is cleared), this bit is set if the Status and Communication nibble shows a start bit in a frame other than frame number n x 16. In Enhanced Serial Frame Mode this bit is without function. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.WSI. This bit can be set by bit INTSETx.WSI. This bit is set independently from INTENx.
SDI	11	rh	**Serial Data Receive Interrupt Request Flag** This bit is set after all serial data bits have been received via the Status and Communication nibble. Depending on bit RCRx.SCDIS this indicates a successful check of the CRC. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.SDI. This bit can be set by bit INTSETx.SDI. This bit is set independently from INTENx.
SCRI	12	rh	**Serial Data CRC Error Request Flag** This bit is set if the CRC of the serial message fails. In Enhanced Serial Message Format, this includes a check of the Serial Communication Nibble for correct 0 values of bit 3 in frames 7, 13 and 18. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.SCRI. This bit can be set by bit INTSETx.SCRI. This bit is set independently from INTENx.

Field	Bits	Type	Description
WDI	13	rh	**Watch Dog Error Request Flag** This bit is set if the Watch Dog Timer of the channel x expires. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.WDI. This bit can be set by bit INTSETx.WDI. This bit is set independently from INTENx.
0	[31:14]	r	**Reserved** Read as 0.

Interrupt Set Register

The Interrupt Set Register INTSETx contains control bits that trigger an interrupt pulse for any interrupt of SENT channel x.

INTSETx (x = 0-3)
Interrupt Set Register x **(124_H+40_H*x)** **Reset Value: 0000 0000_H**



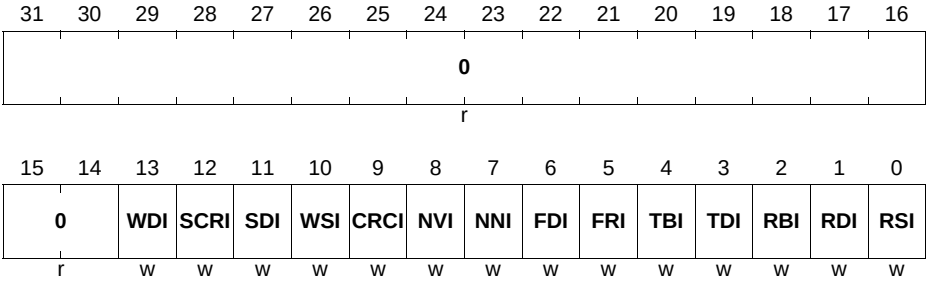
Field	Bits	Type	Description
RSI	0	w	**Set Interrupt Request Flag RSI** Setting this bit set bit INTSTATx.RSI. Clearing this bit has no effect. Reading this bit returns always zero.
RDI	1	w	**Set Interrupt Request Flag RDI** Setting this bit set bit INTSTATx.RDI. Clearing this bit has no effect. Reading this bit returns always zero.
RBI	2	w	**Set Interrupt Request Flag RBI** Setting this bit set bit INTSTATx.RBI. Clearing this bit has no effect. Reading this bit returns always zero.
TDI	3	w	**Set Interrupt Request Flag TDI** Setting this bit set bit INTSTATx.TDI. Clearing this bit has no effect. Reading this bit returns always zero.
TBI	4	w	**Set Interrupt Request Flag TBI** Setting this bit set bit INTSTATx.TBI. Clearing this bit has no effect. Reading this bit returns always zero.

Field	Bits	Type	Description
FRI	5	w	**Set Interrupt Request Flag FRI** Setting this bit set bit INTSTATx.FRI. Clearing this bit has no effect. Reading this bit returns always zero.
FDI	6	w	**Set Interrupt Request Flag FDI** Setting this bit set bit INTSTATx.FDI. Clearing this bit has no effect. Reading this bit returns always zero.
NNI	7	w	**Set Interrupt Request Flag NNI** Setting this bit set bit INTSTATx.NNI. Clearing this bit has no effect. Reading this bit returns always zero.
NVI	8	w	**Set Interrupt Request Flag NVI** Setting this bit set bit INTSTATx.NVI. Clearing this bit has no effect. Reading this bit returns always zero.
CRCI	9	w	**Set Interrupt Request Flag CRCI** Setting this bit set bit INTSTATx.CRCI. Clearing this bit has no effect. Reading this bit returns always zero.
WSI	10	w	**Set Interrupt Request Flag WSI** Setting this bit set bit INTSTATx.WSI. Clearing this bit has no effect. Reading this bit returns always zero.
SDI	11	w	**Set Interrupt Request Flag SDI** Setting this bit set bit INTSTATx.SDI. Clearing this bit has no effect. Reading this bit returns always zero.
SCRI	12	w	**Set Interrupt Request Flag SCRI** Setting this bit set bit INTSTATx.SCRI. Clearing this bit has no effect. Reading this bit returns always zero.
WDI	13	w	**Set Interrupt Request Flag WDI** Setting this bit set bit INTSTATx.WDI. Clearing this bit has no effect. Reading this bit returns always zero.
0	[31:14]	r	**Reserved** Read as 0; should be written with 0.

Interrupt Clear Register

The Interrupt Clear Register INTCLRx contains control bits that clear the status of any interrupt of SENT channel x.

INTCLRx (x = 0-3)
Interrupt Clear Register x **(128_H+40_H*x)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RSI	0	w	**Clear Interrupt Request Flag RSI** Setting this bit clears bit INTSTATx.RSI. Clearing this bit has no effect. Reading this bit returns always zero.
RDI	1	w	**Clear Interrupt Request Flag RDI** Setting this bit clears bit INTSTATx.RDI. Clearing this bit has no effect. Reading this bit returns always zero.
RBI	2	w	**Clear Interrupt Request Flag RBI** Setting this bit clears bit INTSTATx.RBI. Clearing this bit has no effect. Reading this bit returns always zero.
TDI	3	w	**Clear Interrupt Request Flag TDI** Setting this bit clears bit INTSTATx.TDI. Clearing this bit has no effect. Reading this bit returns always zero.
TBI	4	w	**Clear Interrupt Request Flag TBI** Setting this bit clears bit INTSTATx.TBI. Clearing this bit has no effect. Reading this bit returns always zero.

Field	Bits	Type	Description
FRI	5	w	**Clear Interrupt Request Flag FRI** Setting this bit clears bit INTSTATx.FRI. Clearing this bit has no effect. Reading this bit returns always zero.
FDI	6	w	**Clear Interrupt Request Flag FDI** Setting this bit clears bit INTSTATx.FDI. Clearing this bit has no effect. Reading this bit returns always zero.
NNI	7	w	**Clear Interrupt Request Flag NNI** Setting this bit clears bit INTSTATx.NNI. Clearing this bit has no effect. Reading this bit returns always zero.
NVI	8	w	**Clear Interrupt Request Flag NVI** Setting this bit clears bit INTSTATx.NVI. Clearing this bit has no effect. Reading this bit returns always zero.
CRCI	9	w	**Clear Interrupt Request Flag CRCI** Setting this bit clears bit INTSTATx.CRCI. Clearing this bit has no effect. Reading this bit returns always zero.
WSI	10	w	**Clear Interrupt Request Flag WSI** Setting this bit clears bit INTSTATx.WSI. Clearing this bit has no effect. Reading this bit returns always zero.
SDI	11	w	**Clear Interrupt Request Flag SDI** Setting this bit clears bit INTSTATx.SDI. Clearing this bit has no effect. Reading this bit returns always zero.
SCRI	12	w	**Clear Interrupt Request Flag SCRI** Setting this bit clears bit INTSTATx.SCRI. Clearing this bit has no effect. Reading this bit returns always zero.
WDI	13	w	**Clear Interrupt Request Flag WDI** Setting this bit clears bit INTSTATx.WDI. Clearing this bit has no effect. Reading this bit returns always zero.
0	[31:14]	r	**Reserved** Read as 0; should be written with 0.

Interrupt Enable Register

The Interrupt Enable Register INTENx contains control bits that enable the interrupt source of any interrupt of SENT channel x.

Note: The Interrupt Status bits in register INTSTATx are set independently from the Interrupt Enable in Register INTENx.

INTENx (x = 0-3)
Interrupt Enable Register x **($12C_H$+40_H*x)** **Reset Value: 0000 0000_H**

0	[31:14]	r	**Reserved** Read as 0; should be written with 0.

Interrupt Node Pointer Register

The Interrupt Node Pointer Register INPx contains the node pointers of SENT channel x.

Note: Node Pointer ERRI is one single node pointer for the following error interrupts:

- FRI
- FDI
- NNI
- NVI
- CRCI
- WSI
- SCRI

INPx (x = 0-3)

Interrupt Node Pointer Register x (130_H+40_H*x) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
RDI	[7:4]	rw	**Interrupt Node Pointer for Interrupt RDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RDI (if enabled by bit INTENx.RDI). For bit field definition, see RSI.
RBI	[11:8]	rw	**Interrupt Node Pointer for Interrupt RBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RBI (if enabled by bit INTENx.RBI). For bit field definition, see RSI.
TDI	[15:12]	rw	**Interrupt Node Pointer for Interrupt TDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TDI (if enabled by bit INTENx.TDI). For bit field definition, see RSI.
TBI	[19:16]	rw	**Interrupt Node Pointer for Interrupt TBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TBI (if enabled by bit INTENx.TBI). For bit field definition, see RSI.
ERRI	[23:20]	rw	**Interrupt Node Pointer for Interrupt FRI, FDI, NNI, NVI, CRCI, WSI, SCRI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.FRI (if enabled by bit INTENx.FRI) or INTSTATx.FDI (if enabled by bit INTENx.FDI) or INTSTATx.NNI (if enabled by bit INTENx.NNI) or INTSTATx.NVI (if enabled by bit INTENx.NVI) or INTSTATx.CRCI (if enabled by bit INTENx.CRCI) or INTSTATx.WSI (if enabled by bit INTENx.WSI) or INTSTATx.SCRI (if enabled by bit INTENx.SCRI) For bit field definition, see RSI.
SDI	[27:24]	rw	**Interrupt Node Pointer for Interrupt SDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.SDI (if enabled by bit INTENx.SDI). For bit field definition, see RSI.

Field	Bits	Type	Description
WDI	[31:28]	rw	**Interrupt Node Pointer for Interrupt WDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.WDI (if enabled by bit INTENx.WDI). For bit field definition, see RSI.

22.3 SENT Module Implementation

This section describes the SENT module interface as it is implemented in the TC21x/TC22x/TC23x. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

22.3.1 Interface Connections of the SENT Module

Figure 22-17 shows the TC21x/TC22x/TC23x-specific implementation details and interconnections of the SENT module.

The SENT module is supplied with a separate clock control, address decoding, and interrupt control logic. Outputs of the GTM module are connected to the 4 timer inputs.

The serial data inputs of the receive channels of the SENT module as well as the SPC outputs (SPCn) are connected to GPIO lines. If SPC outputs are used, they are usually mapped to the same port pin like the referring SENT data input line as this minimizes the pin count requirement.

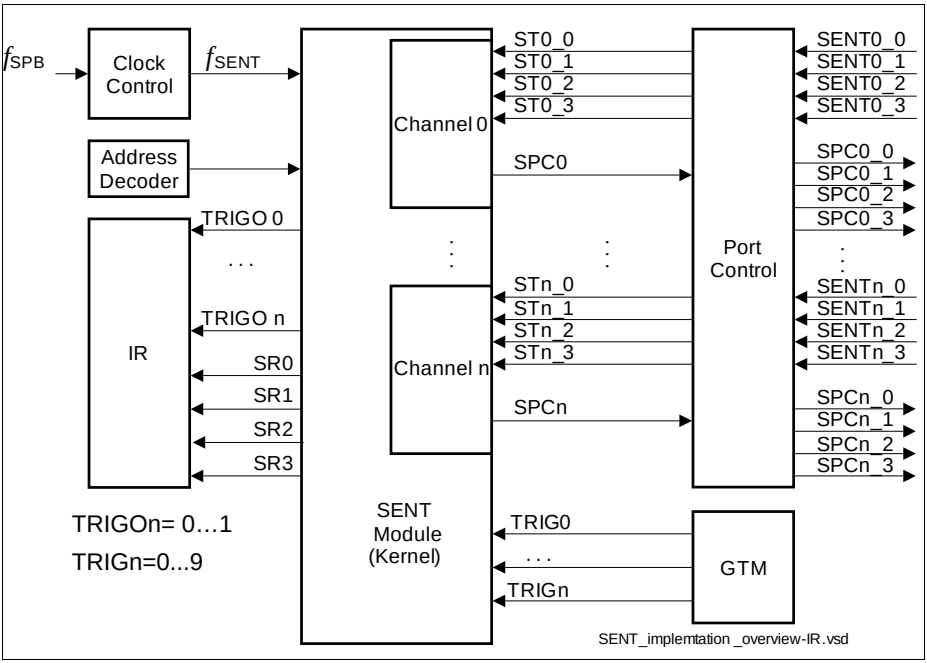

Figure 22-17 SENT Module Implementation and Interconnections

22.3.1.1 On-Chip Connections

This section describes the on-chip connections of the SENT module.

22.3.1.2 Interrupt and DMA Controller Service Requests

The trigger outputs of the SENT module are connected via the Interrupt router. The request lines are connected as shown in **Table 22-9**.

Table 22-9 Service Request Lines of SENT

INP value	Request Line	Connected to	Description
0000_b	SR0	SRC_SENT0	Interrupt Router SENT Request 0
0001_b	SR1	SRC_SENT1	Interrupt Router SENT Request 1
0010_b	SR2	SRC_SENT2	Interrupt Router SENT Request 2
0011_b	SR3	SRC_SENT3	Interrupt Router SENT Request 3
0100_b	TRIGO0	SRC_SENT4	Not Connected
0101_b	TRIGO1	SRC_SENT5	Not Connected
0110_b	TRIGO2	SRC_SENT6	Not Connected
0111_b	TRIGO3	SRC_SENT7	Not Connected
1000_b	TRIGO4	SRC_SENT8	Not Connected
1001_b	TRIGO5	SRC_SENT9	Not Connected
1010_b	TRIGO6	SRC_SENT10	Not Connected
...	...	...	...
1111_b	TRIGO11	SRC_SENT15	Not Connected

Trigger Inputs

The module has 4 Sent Channels and the same number of trigger inputs which can be randomly chosen by programming IOCRx.ETS. The trigger inputs (TRIG[3:0]) of the SENT module are connected to the GTM as shown in **Table 22-10**. n = [0 .. 3]

Table 22-10 Trigger Input Lines of SENT

Request Line	Connected to	Description
TRIG0	TRIG0	GTM.ADC_0_TRIG_0
TRIG1	TRIG1	GTM.ADC_1_TRIG_0
...	...	...

Table 22-10 Trigger Input Lines of SENT

Request Line	Connected to	Description
TRIG2	TRIG2	GTM.ADC_2_TRIG_0[1)]
TRIG3	TRIG3	GTM.ADC_3_TRIG_0[1)]

1) These connections are not available on TC23x PD and are available on TC23x ED only, as TC23x PD has only ADC 0/1 while TC23x ED has ADC0/1/2/3.

22.3.2 SENT Module-Related External Registers

The registers listed in **Figure 22-18** are external of the SENT module kernel but must be programmed for proper operation of the SENT module.

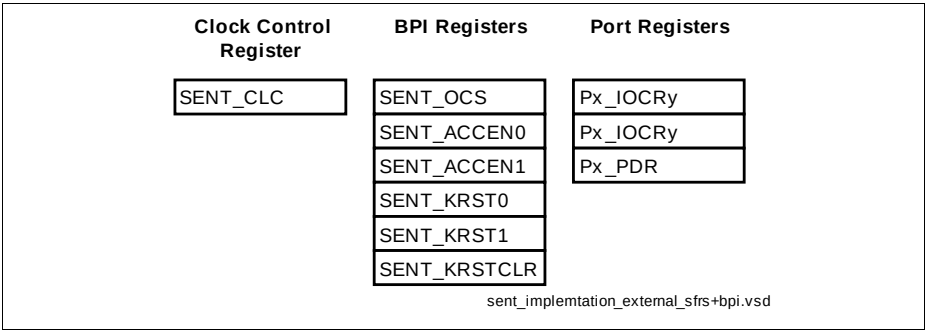

Figure 22-18 SENT Implementation-specific Special Function Registers

22.3.2.1 Port Control

The SENT input channels are overlaid with standard ADC channels as they are replacing former analog signals. Each channel is connected to two ADC channels that can be chosen alternatively. In addition each channel is connected to general purpose I//O lines as well. Each channel is connected to two different general purpose I/O lines that can be chosen alternatively. The selection from on of these 4 alternatives is done by application SW by programming SENT_IOCRx.ALTI respectively.

The SPC output lines are connected to the same I/O ports as the referring input channel. The ADC channels do not provide output functionality. The SPC I/O ports are controlled in the port logic (see also **Figure 22-17**). The following port control operations and selections must be executed for these I/O lines:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Input/Output Function Selection

SENT can be used in three different ways:

- ADC input (dedicated for ADC) overlaid with SENT digital input and no output option on this pin.
- SENT configured digital I/O lines (open drain, no push/pull, uses SDIR, single pin hardware direction control HW_DIR, SDIR is controlled by the data value: 0 = active out, 1 = passive/open drain, input)

- Standard general purpose input/output function on two lines for each channel (input on ADC alternative 1 or 2, or on I/O port alternative 1 while the output is chosen to be on I/O ports alternative 2.

The SENT module overlays dedicated analog to digital converter (ADC) pins as digital input port.

SENT physical layer uses 5V signal voltage levels. All SENT inputs are mapped to 5V compatible ADC pads. Vddm must be supplied with 5V for SENT operation.

The SENT module can be configured to use input/output ports configured for use with SENT. These control settings for the port pins differ from the standard general purpose I/O lines in so far as

- they are controlled by the SENT module output data via their HW_DIR line
- they are configured to use no push/pull devices and to work in open drain mode if the output function is selected by the HW_DIR line of the port

The SENT module can be configured to use standard (push pull) general purpose I/O lines as well. Different port pins can be selected for input and for output. This allows the use of external transceiver devices.

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as port direction (input/output) with alternate output selection, pull-up/down devices, and open-drain selections. The I/O lines for the SENT module are controlled by the Port input/output control registers shown below.

Table 22-11 shows an overview how bits and bit fields must be programmed for the required I/O functionality of the SENT I/O lines.

Table 22-11 SENT I/O Control Selection and Setup

SENT Channel	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
0	SENT0A / P40.11	SENT_IOCR0.ALTI = 0000_B	P40_PDISC.PDIS11 = 0_B	I
	SENT0B / P00.1	SENT_IOCR0.ALTI = 0001_B	P00_IOCR0.PC1 = $0XXXX_B$	I
	SENT0C / P02.8	SENT_IOCR0.ALTI = 0010_B	P02_IOCR8.PC8 = $0XXXX_B$	I
		SENT_IOCR0.ALTI = 0001_B		O

Table 22-11 SENT I/O Control Selection and Setup (cont'd)

SENT Channel	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
1	SENT1A / P41.0	SENT_IOCR1.ALTI = 0000_B	P41_PDISC.PDIS0 = 0_B	I
	SENT1B / P00.2	SENT_IOCR1.ALTI = 0001_B	P00_IOCR0.PC2 = 0XXXX$_B$	I

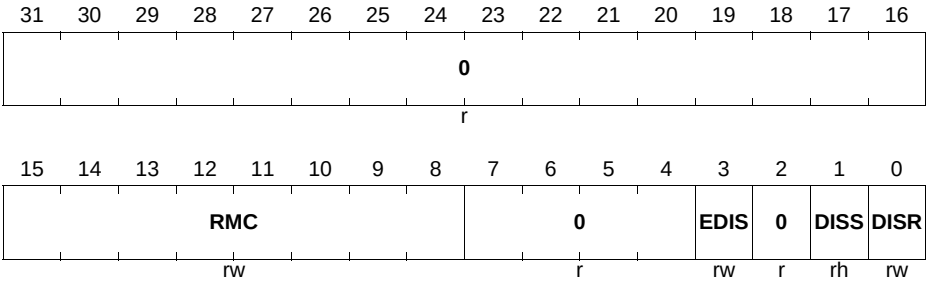
		SENT_IOCR1.ALTI = 0010_B		O
2	SENT2A / P41.2	SENT_IOCR2.ALTI = 0000_B	P41_PDISC.PDIS2 = 0_B	I
	SENT2B / P00.3	SENT_IOCR2.ALTI = 0001_B	P00_IOCR0.PC3 = 0XXXX$_B$	I
	SENT2C / P02.6	SENT_IOCR2.ALTI = 0010_B	P02_IOCR4.PC6 = 0XXXX$_B$	I
		SENT_IOCR2.ALTI = 0001_B		O
3	SENT3A / P41.3	SENT_IOCR3.ALTI = 0000_B	P41_PDISC.PDIS3 = 0_B	I
	SENT3B / P00.4	SENT_IOCR3.ALTI = 0001_B	P00_IOCR4.PC4 = 0XXXX$_B$	I
	SENT3C / P02.5	SENT_IOCR3.ALTI = 0010_B	P02_IOCR4.PC5 = 0XXXX$_B$	I
		SENT_IOCR3.ALTI = 0001_B		O

22.3.3 BPI_FPI Module Registers

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

SENT_CLC
Clock Control Register (00_H) Reset Value: $0000\ 0003_H$



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
RMC	[15:8]	rw	**8-bit Clock Divider Value in RUN Mode**
0	[31:16], [7:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

13. *After a hardware reset operation, the f_{SENT} and $f_{fracdiv}$ clocks are switched off and the SENT module is disabled (DISS set).*

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status (E8$_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. (SPC low pulse breaks immediately, Port Pin keeps the last value if suspend state is entered) 2_H Soft suspend (SPC low pulse will be finished before suspend state is entered) **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0
Access Enable Register 0 (FC_H) Reset Value: FFFF FFFF$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

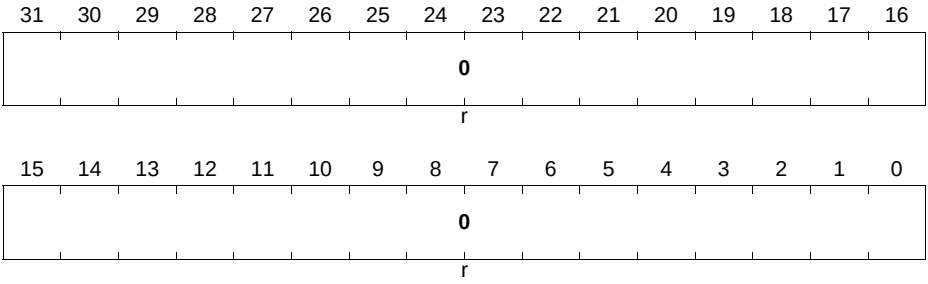
Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

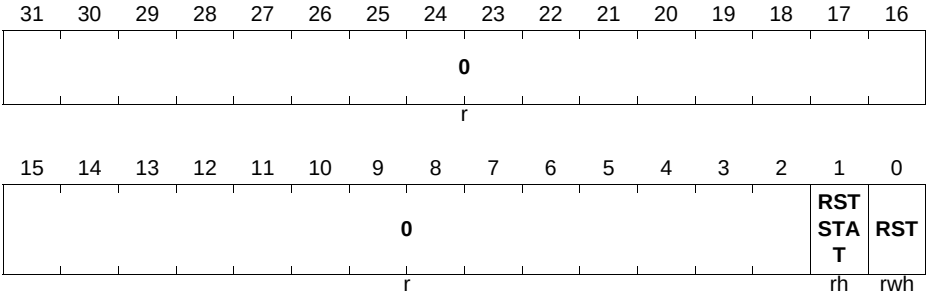
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**

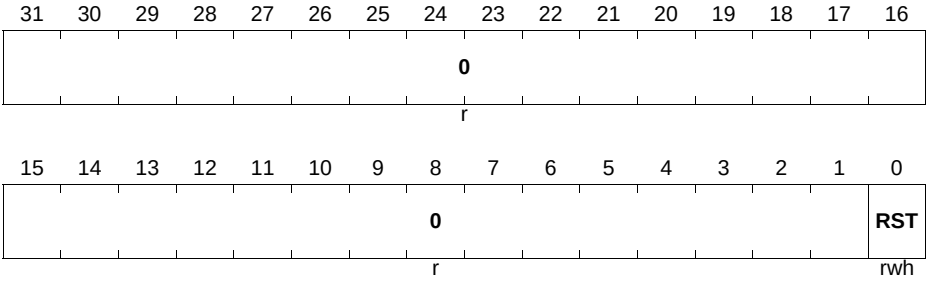


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: 0000 0000$_H$**



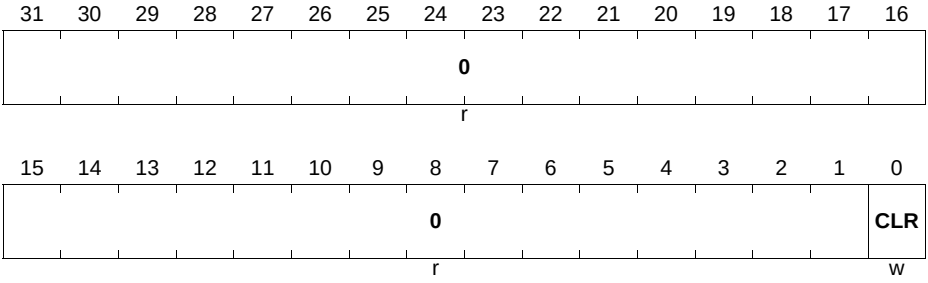
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

22.4 Revision History

This User's Manual is based on: SAE Standard "SENT **Revision J2716 JAN2010**".

Table 22-12 Revision History

Version Number	Changes to Previous Version
Rev_0.1D	First Draft (Bullet Points ++)
Rev_0.2D	Second Draft (Bullet Points ++)
Rev_0.3D	First Review Version
Rev_0.4D	• RCRx.NINT removed as unnecessary FIFO support • Spelling Checked • Renamed INTNP to INP (request DE) • One common error node pointer in INP for FRI, FDI, NNI, NVI, CRCI, WSI, SCRI (reduce DE effort) • Interrupt Node Pointer in INPx increased from 2 bit to 4 bit • Renamed PVAL to PDIV in register CPDRx • RCRx.ASP "Additional Sync/Cal Pulse expected" deleted, not required • RCRx.ACE "Alternate CRC Mode" added, request customer • cleanup Register SCR • ISR0 (Input select register) deleted • AltIn and Filter DEPTH moved to IOCRx • SCRx.DEL moved to SDRx • SCRx deleted, BASE and TRQ moved to SDR • Restructured Chapters (interrupts after functional registers, implementation chapter cleaned up) • Simplified Baud rate generation (Fdtick removed)
Rev_0.5D	• Clean up Glitch filter Chapter • Detailed Baud Rate Generation • Added Address overview table

Table 22-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_0.6D	• Channel **Fractional Divider with variable divider** instead of variable dividend • Glitch filter based on F_pdiv and no longer on F_sent • Glitch detection added • Pre divider = PDIV and no longer PDIV + 1 • Compressed address overview table • Interrupt generation updated with figure • Trigger outputs renamed (RSI and SDI, no more TRIGO) and completed • RDI simplified - now independent from RSI • ETS wording corrected • INTOV now only updated for enabled interrupts (before: any change) • Renamed "SPC Data Register SDR" to "SPC Control Register SCR", it contains both data and control information • TDI wording optimized • External Registers Overview corrected • KSCFG removed
Rev_1.0D	First complete revision (To be done)
Rev_1.1D	• Moved Base Address to F032_1000 - F032_19FF (10x256 bytes) • Serial message ID added. SDSx.SCN moved to [19:16], SDSx.SCRC moved to [15:12], SDSx.MID placed at [11:8]. • RSI and TDI as trigger outputs replaced by 8 Trigger Outputs programmable in the INPs. • implemented first port mapping proposal from product
Rev_1.2	• Added hint to RCR.CEN that FSMs are initialized during enable • Port mapping updated to latest changes of CW08/47

Table 22-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.3	• Fixed INTENx Bit descriptions: all bits are rw and high active (typo) • added to feature list: "Programmable Nibble sorting to support LSN or HSN first and relief CPU" (was missing) • SENT_FDR.DM[1:0] added description of all 4 states of this bit field. (same as system level) • IOCR.DEPTH corrected f_{SENT} sent to f_{pdiv} (longer glitch tolerance) • Add Freeze-Disable Bit [10] to SENT_FDR (system requirement) • Pre divider factor is (PDIV + 1) and no longer PDIV (ease design) • Resulting Channel Fractional Divider is (DIV + 1) and no longer DIV • Add IOCR.TXM, RXM and TRM monitor bits (ease of validation) • RDRx added explanation: unused nibbles are shown as '0' (for clarity) • RDI and RSI: Read clears these bits NOT (request from AE) • Renamed Transmit Buffer Overflow to UNDER-Flow with change to respective functionality (data completely transmitted without new write) • RCRx.CFC: Wording improved and details added
Rev_1.4	• Added column Access Modes to Register Table • Updated **Figure 22-2**, **Figure 22-3**, **Figure 22-4** (beautification) • The clock signal f_{pdiv} of a channel must always be at least 20 (old value 10) times the nominal tick frequency, to cater for worst case. • INPx: Added reserved values • Corrected interrupt structure figure, no more separate DMA TRIGO lines. • RCRx, VIEWx and CFDRx Reset value corrected to 0x0000 0000 hex • Added explanations to RDRx and VIEWx • AI00050230 - SENT_FDR register located at "unusual" address: Moved CLC to offset 0x0Ch for consistency with other modules • Reduced ETS to 3 bit and ALTI to 2 bit width • "Zero Nibble Insertion in CRC" covered. See RCR.CRZ. • UTP AI00050205 - "Extended Serial Frame" covered. Added description of extended serial frame. SDS.SCN moved to RSR.SCN (Allows for an aligned representation of ID and Data as well as a fixed position for SCN) SDS.SD, SDS.MID, SDS.SCRC enlarged (to 16, 8 and 6 bit width) SDS.CON and RCR.ESF added • Resulting Channel Fractional Divider is DIV and no longer (DIV + 1)

Table 22-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.5	• Corrected TBIx description on Page 50. • SCR.TRQ corrected (deleted "Reads back zero") • Added hint to definition of Alternate CRC Mode (ACE) • Detailed RBI behavior. It is set if kernel wants to set RSI or RDI and finds RSI or RDI already set. • Detailed that RCR.CEN resets the receiver state machines only while SCR.TRIG resets the sender state machines. • RCR.WSI updated wrt. the special case "extended serial frame" (2009-06-24) • INSTAT.SCRI detailed wrt.: CRC check must include check for correct 0 values in Extended Serial Frame Format (2009-06-24) • Message tick time prolonged to 90 µs according to new standard (2009-06-24) • RCR.CFC (successive calibration pulse detection) adopted to new standard. (2009-06-24) • Updated INTSTAT.FDI wrt.: new additional error diagnostics (total frame length variation and ration calibration pulse/total frame length) in new standard. (2009-06-24)
Rev_1.6	• Added bit RCR.IDE (Ignore Drift Error) to cater for rare triggers by SPC. • Removed SV protection from SENT_FDR. • VIEW.RDNP must be set before reception. • SCR.TRQ spec' ed not active from request to pulse start. • Added "alternative CRC" spec from TLE4998 . • Changed wording for RBI. • New additional error diagnostics (total frame length variation and ration calibration pulse/total frame length) removed.
Rev_1.7	• Added note: RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV. • SCRI typo: frame 8, not 7 contains a zero value. • **Chapter 22.1.5** typo corrected: replaced f_{SENT} with $f_{fracdiv}$ • **Chapter 22.1.3.1** note added on *RCR.CRZ.* • Added hint to Chapter "Module Clock Generation" for details on CLC. • Updated Port connections and Trigger Output connections
Rev_1.8	• Changed functionality of VIEW. • Changed functionality of WSI.
Rev_1.9	
Rev_1.10

Table 22-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.33	• Modified for below: – Added Note on INTOV, Interrupt Overview Register "Not all IPC0-9 are available, the number of Interrupt Pending on Channel is equivalent to the SENT channels available, e.g 4 SENT channels has 4 Interrupt Pending IPC0-3 and vice versa." – Replaced "Fig 1-7 Standard Serial Data Encoding" in .emf with same "Table 1-1 Standard Serial Data Encoding" as framemaker table. – Replaced "Fig 1-8 Serial Data Frame" in .emf with same "Table 1-2 "Serial Data Frame" as framemaker table. – Replaced "Fig 1-9 Extended Serial Data Encoding" in .emf with same "Table 1-3 Extended Serial Data Encoding" as framemaker table. – Replaced "Fig1-11 Extended Serial Data Frame" in .emf with same "Table 1-4 Extended Serial Data Frame" – Replaced "Fig 1-12 Configuration Bit = 0" in .emf with same "Table 1-5 Configuration Bit = 0" – Replaced "Fig 1-13 Configuration Bit = 1" in .emf with same "Table 1-6 Configuration Bit = 1" – Updated for Table 1-11 SENT I/O Control Selection and Setup aligned to TC23x V2.1 ITS/TS chapter 14 GPIO – Replaced on Table 1-5 Trigger Input Lines of SENT for TRIG3 from "GTM.DSADC_0_TRIG0" to "GTM.ADC_3_TRIG_0" – Added footnote on Table 1-5 Trigger Input Lines of SENT for TRIG 2 and TRIG 3 "These connections are not available on TC23x PD and are available on TC23x ED only, as TC23x PD has only ADC 0/1 while TC23x ED has ADC0/1/2/3."
Rev_1.34	Changed minimum tick timer to 0.2 µs For TC29x only: • Removed SENT2D from P40.6 • Moved SENT5A from P40.9 to P40.5 and SENT4A from P40.8 to P40.4 where available in product
Rev_1.34a	Updated Serial Message Frame Chapter

23 FlexRay™ Protocol Controller (E-Ray)

The E-Ray IP-module performs communication according to the FlexRay™ [1] protocol specification v2.1, developed for automotive applications. With maximum specified clock the bitrate can be programmed to values up to 10 Mbit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

23.1 E-Ray Kernel Description

Figure 23-1 shows a global view of the E-Ray interface.

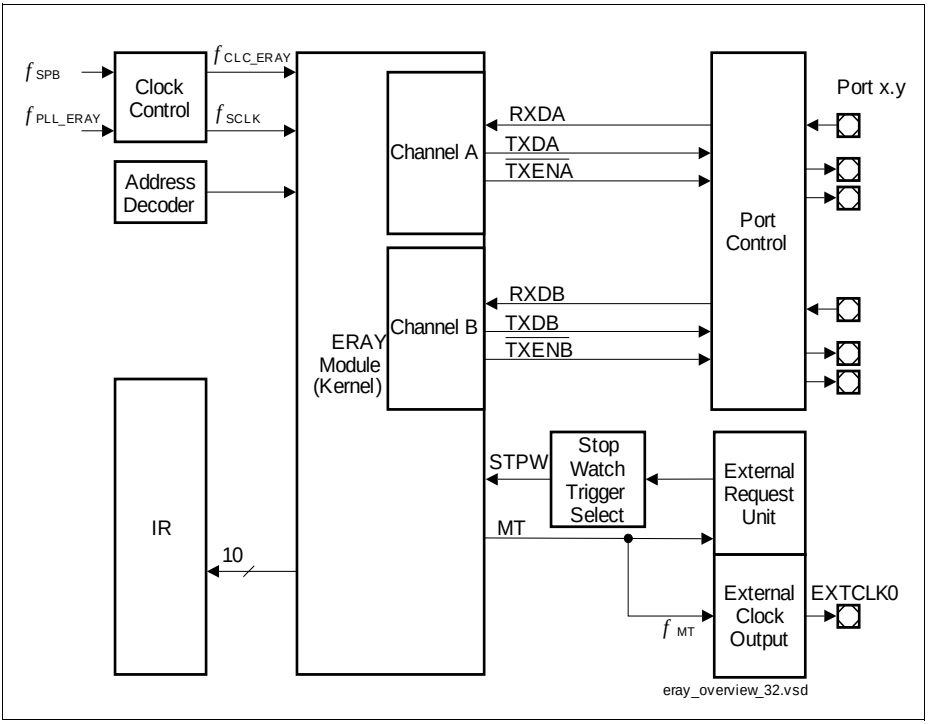

Figure 23-1 General Block Diagram of the E-Ray Interface

The E-Ray module communicates with the external world via three I/O lines each channel. The RXDAx and RXDBx lines are the receive data input signals, TXDA and

1) *Infineon®, Infineon Technologies®, are trademarks of Infineon Technologies AG. FlexRay™* is a trademark of FlexRay Consortium.

TXDB lines are the transmit output signals, $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ the transmit enable signals.

Clock control, address decoding, and service request control are managed outside the E-Ray module kernel.

23.2 Overview

For communication on a FlexRay™ network, individual Message Buffers with up to 254 data byte are configurable. The message storage consists of a single-ported Message RAM that holds up to 128 Message Buffers. All functions concerning the handling of messages are implemented in the Message Handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay™ Channel Protocol Controllers and the Message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the E-Ray IP-module can be accessed directly by an external Host via the module's Host interface. These registers are used to control/configure/monitor the FlexRay™ Channel Protocol Controllers, Message Handler, Global Time Unit, System Universal Control, Frame and Symbol Processing, Network Management, Service Request Control, and to access the Message RAM via Input / Output Buffer.

The E-Ray IP-module supports the following features:

- Conformance with FlexRay™ protocol specification v2.1
- Data rates of up to 10 Mbit/s on each channel
- Up to 128 Message Buffers configurable
- 8 Kbyte of Message RAM for storage of e.g. 128 Message Buffers with max. 48 byte data field or up to 30 Message Buffers with 254 byte Data Sections
- Configuration of Message Buffers with different payload lengths possible
- One configurable receive FIFO
- Each Message Buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
- Host access to Message Buffers via Input and Output Buffer.
  Input Buffer: Holds message to be transferred to the Message RAM
  Output Buffer: Holds message read from the Message RAM
- Filtering for slot counter, cycle counter, and channel
- Maskable module service requests
- Network Management supported
- Four service request lines
- Automatic delayed read access to Output Command Request Register (OBCR) if a data transfer from Message RAM to Output Shadow Buffer (initiated by a previous write access to the OBCR) is ongoing.
- Automatic delayed read access to Input Command Request Register (IBCR) if a data transfer from Input Shadow Buffer to Message RAM to (initiated by a previous write access to the IBCR) is ongoing.

- Four Input Buffer for building up transmission Frames in parallel.
- Flag indicating which Input Buffer is currently accessible by the host.

23.3 Definitions

FlexRay™ Frame: Header Segment + Payload Segment

Message Buffer: Header Section + Data Section

Message RAM: Header Partition + Data Partition

Data Frame: FlexRay™ Frame that is not a NULL Frame

23.4 Block Diagram

The E-Ray is built up by the following main submodules:

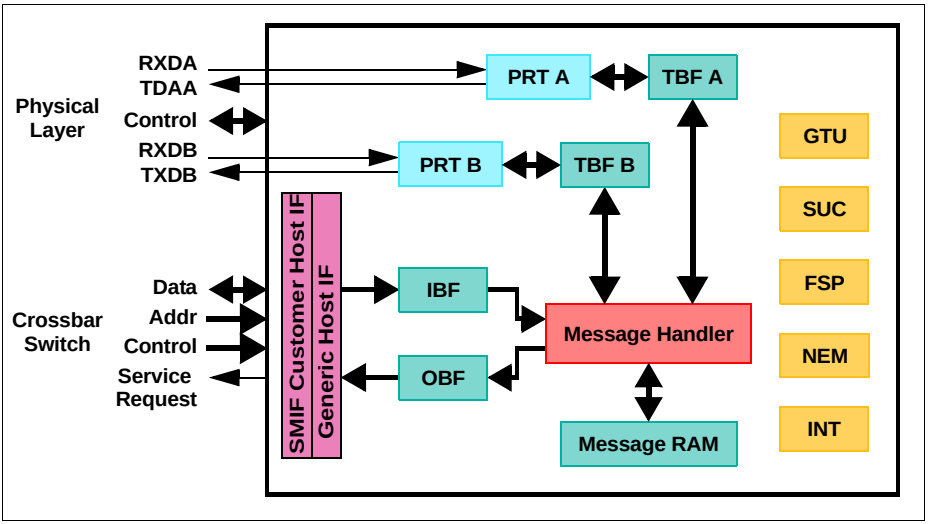

Figure 23-2 E-Ray Block Diagram

Customer Host Interface (CIF)

Connects the FPI Bus to the E-Ray IP-module via the Generic Host Interface.

Generic Host Interface (GIF)

The E-Ray IP-module is provided with an 8/16/32-bit Generic Host Interface prepared for the connection to a wide range of customer-specific Hosts. Configuration registers, status registers, and service request registers are attached to the respective blocks and can be accessed via the Generic Host Interface.

Input Buffer (IBF)

For write access to the Message Buffers configured in the Message RAM, the Host can write the Header and Data Section for a specific Message Buffer to the Input Buffer. The Message Handler then transfers the data from the Input Buffer to the selected Message Buffer in the Message RAM.

Because the Input Buffer (IBF) Scheme does only allow to write the entire Message Frame, not only parts of it, the number of IBF has been increased from originally 2 to 4. This enables to fill the buffer partly and at the end request transfer into Message RAM. Therefore 2 extra bits allow to switch between the two banks of IBF and one status bit signals the IBF currently active for Host writes.

Output Buffer (OBF)

For read access to a Message Buffer configured in the Message RAM the Message Handler transfers the selected Message Buffer to the Output Buffer. After the transfer has completed, the Host can read the Header and Data Section of the transferred Message Buffer from the Output Buffer.

Message Handler (MHD)

The E-Ray Message Handler controls data transfers between the following components:

- Input / Output Buffer and Message RAM
- Transient Buffer RAMs of the two FlexRay™ Protocol Controllers and Message RAM

Message RAM (MRAM)

The Message RAM consists of a single-ported RAM that stores up to 128 FlexRay™ Message Buffers together with the related configuration data (Header and Data Partition).

Transient Buffer RAM (TBF 1/2)

Stores the Data Section of two complete messages.

FlexRay™ Channel Protocol Controller (PRT A/B)

The FlexRay™ Channel Protocol Controllers consist of shift register and FlexRay™ protocol FSM. They are connected to the Transient Buffer RAMs for intermediate message storage and to the physical layer via bus driver BD.

They perform the following functionality:

- Control and check of bit timing
- Reception and transmission of FlexRay™ Frames and symbols
- Check of Header CRC
- Generation / check of Frame CRC

- Interfacing to bus driver

The FlexRay™ Channel Protocol Controllers have interfaces to:

- Physical Layer (bus driver)
- Transient Buffer RAM
- Message Handler
- Global Time Unit
- System Universal Control
- Frame and Symbol Processing
- Network Management
- Service Request Control

Global Time Unit (GTU)

The Global Time Unit performs the following functions:

- Generation of Microtick
- Generation of Macrotick
- Fault tolerant clock synchronization by FTM algorithm
  - Rate correction
  - Offset correction
- Cycle counter
- Timing control of static segment
- Timing control of dynamic segment (minislotting)
- Support of external clock correction

System Universal Control (SUC)

The System Universal Control controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal Operation
- Passive Operation
- Monitor Mode

Frame and Symbol Processing (FSP)

The Frame and Symbol Processing controls the following functions:

- Checks the correct timing of Frames and symbols
- Tests the syntactical and semantical correctness of received Frames
- Sets the slot status flags

Network Management (NEM)

Handles of the Network Management vector

Service Request Control (INT)

The Service Request Controller performs the following functions:

- Provides error and status service request flags
- Enables and disables service request sources
- Assignment of service request sources to one of the two module service request lines
- Enables and disables module service request lines
- Manages the two service request timers
- Stop watch time capturing

23.5 Programmer's Model

The programmer's model of the E-Ray module follows the principle of memory mapped peripheral. Some portion of the memory follows the principle of segmented/paged memory organization.

23.5.1 Register Map

The E-Ray module allocates an address space of 4 Kbyte (000_H to $FFFF_H$). The registers are organized as 32-bit registers. 8/16-bit accesses are also supported. Host access to the Message RAM is done via the Input and Output Buffers. They buffer data to be transferred to and from the Message RAM under control of the Message Handler, avoiding conflicts between Host accesses and message reception / transmission. Addresses 0004_H - $000F_H$,$03C8_H$ - $03EC_H$ and 0800_H - $0FFF_H$ are reserved for customer specific purposes. All functions related to these addresses are located in the Customer Host Interface. The test registers located on address 0010_H and 0014_H are writable only under the conditions described in **"Special Registers" on Page 23-22**.

The assignment of the Message Buffers is done according to the scheme shown in **Table 23-1** below. The number N of available Message Buffers depends on the payload length of the configured Message Buffers. The maximum number of Message Buffers is 128. The maximum payload length supported is 254 byte.

The Message Buffers are separated into three consecutive groups:

- Static Buffers: Transmit / Receive Buffers assigned to static segment
- Static and Dynamic Buffers: Transmit / Receive Buffers assigned to static or dynamic segment
- FIFO- Receive FIFO

The Message Buffer separation configuration can be changed only in "DEFAULT_CONFIG" or "CONFIG" state only by programming the Message RAM Configuration register (MRC).

The first group starts with Message Buffer 0 and consists of static Message Buffers only. Message Buffer 0 is dedicated to hold the startup / SYNC Frame or the single slot Frame, if node transmit one, as configured by SUCC1.TXST, SUCC1.TXSY, and SUCC1.TSM

in the SUC Configuration Register 1 (SUCC1). In addition, Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames or single-slot Frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1 and Message Buffers 0 and 1 have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only.

The second group consists of Message Buffers assigned to the static or to the dynamic segment. Message Buffers belonging to this group may be reconfigured during run time from dynamic to static or vice versa depending on the state of MRC.SEC.

The Message Buffers belonging to the third group are concatenated to a single receive FIFO.

Table 23-1 Assignment of Message Buffers

Message Buffer 0	⇓ Static Buffers	
Message Buffer 1		
…		
	⇓ Static + Dynamic Buffers	⇐ **FDB**
	⇓ FIFO	⇐ **FFB**
Message Buffer N-1		
Message Buffer N		⇐ **LCB**

23.5.2 E-Ray Kernel Registers

This chapter describes all registers of the E-Ray kernel.

All registers in the E-Ray address spaces are reset with the application reset with one exception: OCS is reset with debug reset only. (Definition see SCU section “Reset Operation”)

Table 23-2 Registers Address Space E-Ray Kernel Register Address Space

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

Note: Registers covered by the ACCENx write protection mechanism are marked with ´P´ in Access Mode, Write.

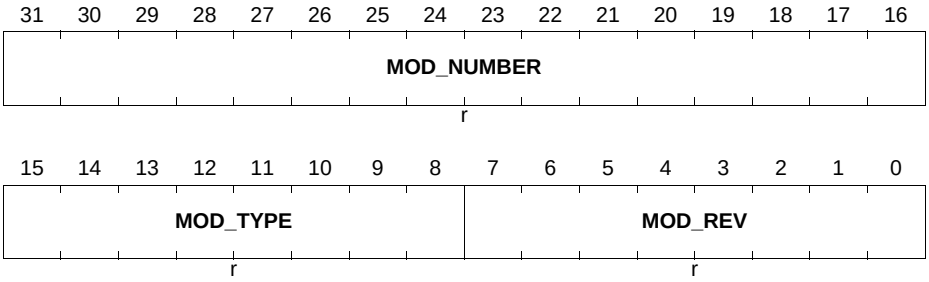
23.5.2.1 Customer Registers

The addresses 0004_H - $000F_H$,$03C8_H$ - $03EC_H$ and 0800_H - $0FFF_H$ are reserved for customer-specific registers.

Module Identification Register (ID)

This register contains bit fields identifying the E-Ray module in Infineons Module portfolio and is read only.

ID
Module Identification Register (0008_H) Reset Value: 0044 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The value of this bit field is $C0_H$. It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. For the E-Ray module the module identification number is 44_H.

Busy Control Register (CUST1)

The Busy Control Register enables the automatic delay scheme. Furthermore it signals a time-out service request for the automatic delay scheme. IBFS changes 2 clock cycles after any reset to ‘1’. Thus the application will read this bit as ‘1’ already at first access after any reset.

CUST1

Busy and Input Buffer Control Register

(0004_H) **Reset Value: $0000\ 0000_H$**

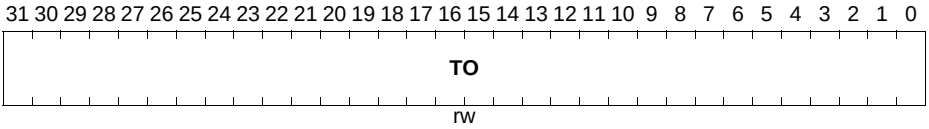
0	[6:5], [9:8], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Customer Interface Time-out Counter Register (CUST3)

The Time-out Counter Register is realizing the time-out counter reload (startup) value for the automatic delay scheme (not the time-out down counter itself).

CUST3
Customer Interface Timeout Counter ($000C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TO	[31:0]	rw	**CIF Timeout Reload Value** The 32-bit down counter reload (start-up) value must be setup for the automatic delay scheme.

Automatic Delayed Write Access to OBCR and IBCR

Write and read accesses to the Output Buffer Control Register (OBCR) can be automatically stalled due to a ongoing transfer from the Message Buffer to the Output Buffer. Also write and read accesses to the Input Buffer Control Register (IBCR) may be automatically delayed due to a ongoing transfer from the Input Buffer to the Message Buffer.

This delay scheme can be controlled (enabled or disabled) by CUST1.IEN and CUST1.OEN. The maximum time to stall a write or read access is determined by a single time-out counter preluded with the 32-bit value specified in the bit field CUST3.TO. If the time-out counter counts down to zero before the transfer to/from the Message Buffer is completed, the access (read or write) will be canceled and a service request will be generated. A canceled read access provides a 0 value. A canceled write access does not modify any bits in the OBCR or IBCR. In addition the bit CUST1.INT0 of the service request status register will be set and must be reset by the host to disable the service request line.

The read and write access to the Output Buffer Control Register (OBCR) may be configured without automatic delay by clearing CUST1.OEN. Setting OBCR.REQ and immediately afterwards reading or writing OBCR, e.g. to set OBCR.VIEW will lead to a canceled read or write operation, e.g. OBCR.VIEW remains cleared, and an error is signalled by a set EIR.IOBA. Besides canceling the erroneous read or write operation, and setting the error bit, no further state change happens. So full operation is granted. OBCR remains read and write inaccessible until the transfer of data from the Message Buffer to the Output Buffer (MBF⇒OBF) is completed. During this time span all read and

write accesses to the Output Buffer Control Register (OBCR) are canceled. The transfer is completed when OBCR.OBSYS is cleared. Additionally signal TOBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Output Buffer Control Register (OBCR) may be configured to be automatic delayed by setting CUST1.OEN and configuring CUST3.TO to the maximum stall time acceptable to the system. If setting OBCR.REQ and immediately afterwards reading or writing to OBCR, e.g. to set the OBCR.VIEW bit, this read or write will be stalled until either the maximum delay time elapsed (in this case the read or write operation is cancelled after the stall time, e.g. OBCR.VIEW remains cleared, and an error is signalled by setting EIR.IOBA) or the read or write completes normally, e.g. set OBCR.VIEW after the transfer of data from the Message Buffer to the Output Buffer (MBF⇒OBF) is finalized. During this time the bus is locked and no further access to the E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TOBC or due to other not processed read or write accesses to the E-Ray module.

The read and write access to the Input Buffer Control Register (IBCR) may also be configured without automatic delay by clearing CUST1.IEN. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF is copied into the MBF (IBF⇒MBF), and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remained set (previously initiated copy process IBF⇒MBF ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. This will set the signal IBUSY. A third access, read or write, to IBCR while IBCR.IBSYH remains set will cancel this third access and an error is signalled by setting EIR.IIBA. Besides canceling this last access to IBCR and setting the error bit, no further state change happens. So full operation is granted. IBCR remains read and write inaccessible until the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF⇒MBF) is completed and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time span all read and write accesses to the Input Buffer Control Register (IBCR) are canceled. The transfer is completed when IBCR.IBSYH is cleared. Additionally signal TIBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Input Buffer Control Register (IBCR) may be configured for being automatically delayed by setting CUST1.IEN and configuring CUST3.TO to the maximum stall time acceptable to the system. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF copied into the MBF, and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remains set (previously initiated copy process ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. A third access to IBCR while IBCR.IBSYH remains set will stall this read or write until either the maximum delay

time elapsed (in this case the read or write operation is cancelled after the stall time and an error is signalled by setting EIR.IOBA) or the read or write completes normally, after the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF⇒MBF) is finalized and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time the bus is locked and no further access to E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TIBC or due to other not processed read or write accesses to the E-Ray module.

So setting CUST3.TO = $FFFFFFFF_H$, CUST1.IEN = 1, and CUST1.OEN = 1 will always grant a consistent data access of the host to the Output and Input Buffers without the need of reading and taking into account the status of OBCR.OBSYS or IBCR.IBSYH. But this simplified access may cause system latencies and system performance loss.

23.5.2.2 Special Registers

Test Register 1 (TEST1)

The Test Register 1 holds the control bits to configure the test modes of the E-Ray module. Write access to these bits is only possible if bit TEST1.WRTEN is set.

The Test Register 1 bits therefore can be used to test the interface to the physical layer (connectivity test) by driving / reading the respective pins.

When the E-Ray IP is operated in one of its test modes that requires TEST1.WRTEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available.

The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the E-Ray module. Therefore normal operation as specified outside this chapter and as required by the FlexRay™ protocol specification and the FlexRay™ conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay™ protocol functions.

The test mode features are intended for hardware testing or for FlexRay™ bus analyzer tools. They are not intended to be used in FlexRay™ applications

TEST1
Test Register 1 **(0010_H)** **Reset Value: $0000\ 0300_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0						AOB	AOA	0		TMC		0		ELBE	WRTEN
r						rh	rh	r		rw		r		rw	rw

Field	Bits	Type	Description
WRTEN	0	rw	**Write Test Register Enable** Enables write access to the test registers. To set the bit from 0 to 1 the test mode key has to be written as defined on **"Lock Register (LCK)" on Page 23-30**. The unlock sequence is not required when TEST1.WRTEN is kept at 1 while other bits of the register are changed. The bit can be reset to 0 at any time. 0_B Write access to test registers disabled. 1_B Write access to test registers enabled.

Field	Bits	Type	Description
ELBE	1	rw	**External Loop Back Enable** There are two possibilities to perform a loop back test. External loop back via physical layer or internal loop back for in-system self-test (default). In case of an internal loop back pins TXENA and TXENB are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDA and RXDB are not evaluated. Bit ELBE is evaluated only when POC is in loop back mode and test multiplexer control is in non multiplexed mode TMC = 00. 0_B Internal loop back (default) 1_B External loop back
TMC	[5:4]	rw	**Test Multiplexer Control** 00_B Normal signal path (default). 01_B RAM Test Mode: Internal busses are multiplexed to make all RAM blocks of the E-Ray module directly accessible by the Host. This mode is intended to enable testing of the embedded RAM blocks during production testing. 10_B I/O Test Mode: Output pins are driven to the values defined by bits TXA, TXB, TXENA, TXENB. The values applied to the input pins can be read from register bits RXA and RXB. 11_B Reserved; should not be used.
AOA	8	rh	**Activity on A** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel A idle 1_B Activity detected, channel A not idle
AOB	9	rh	**Activity on B** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel B idle 1_B Activity detected, channel B not idle
RXA	16	rh	**Read Channel A Receive Pin** 0_B RXDA = 0 1_B RXDA = 1

Field	Bits	Type	Description
RXB	17	rh	**Read Channel B Receive Pin** 0_B RXDB = 0 1_B RXDB = 1
TXA	18	rwh	**Read or Write to Channel A Transmit Pin** 0_B TXDA = 0 1_B TXDA = 1
TXB	19	rwh	**Read or Write to Channel B Transmit Pin** 0_B TXDB = 0 1_B TXDB = 1
TXENA	20	rwh	**Read or Write to Channel A Transmit Enable Pin** 0_B $\overline{\text{TXENA}}$= 0 1_B $\overline{\text{TXENA}}$= 1
TXENB	21	rwh	**Read or Write to Channel B Transmit Enable Pin** 0_B $\overline{\text{TXENB}}$ = 0 1_B $\overline{\text{TXENB}}$= 1
CERA	[27:24]	rh	**Coding Error Report Channel A[1)]** Set when a coding error is detected on channel A. Reset to zero when register TEST1 is read or written. Once the CERA is set it will remain unchanged until the Host accesses the TEST1 register. 0000_B No coding error detected 0001_B Header CRC error detected 0010_B Frame CRC error detected 0011_B Frame Start Sequence FSS too long 0100_B First bit of Byte Start Sequence BSS seen LOW 0101_B Second bit of Byte Start Sequence BSS seen HIGH 0110_B First bit of Frame End Sequence FES seen HIGH 0111_B Second bit of Frame End Sequence FES seen LOW 1000_B CAS / MTS symbol seen too short 1001_B CAS / MTS symbol seen too long Other combinations are reserved.

Field	Bits	Type	Description
CERB	[31:28]	rh	**Coding Error Report Channel B[1)]** Set when a coding error is detected on channel B. Reset to zero when register TEST1 is read or written. Once the CERB is set it will remain unchanged until the Host accesses the TEST1 register. 0000_B No coding error detected 0001_B Header CRC error detected 0010_B Frame CRC error detected 0011_B Frame Start Sequence FSS too long 0100_B First bit of Byte Start Sequence BSS seen LOW 0101_B Second bit of Byte Start Sequence BSS seen HIGH 0110_B First bit of Frame End Sequence FES seen HIGH 0111_B Second bit of Frame End Sequence FES seen LOW 1000_B CAS / MTS symbol seen too short 1001_B CAS / MTS symbol seen too long Other combinations are reserved.
0	[3:2], [7:6], [15:10], [23:22]	r	**Reserved** Returns 0 if read; should be written with 0.

1) Coding errors are also signalled when the Communication Controller is in “MONITOR_MODE”. The error codes regarding CAS / MTS symbols concern only the monitored bit pattern, irrelevant whether those bit patterns are seen in the symbol window or elsewhere.

Asynchronous Transmit Mode (ATM)

The asynchronous transmit mode is entered by writing 1110_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: ATM) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will return 1110_B while the E-Ray module is in ATM mode. Asynchronous Transmit mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

In ATM mode transmission of a FlexRay™ Frame is triggered by writing the number of the respective Message Buffer to the Input Buffer Command Request register (IBCR.IBRH) while bit IBCM.STXRS in the Input Buffer Command Mask register is set to 1. In this mode wake-up, startup, and clock synchronization are bypassed. The CHI command SEND_MTS results in the immediate transmission of an MTS symbol.

The cycle counter value of Frames send in ATM mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Loop Back Mode

The loop back mode is entered by writing 1111_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: LOOP_BACK) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will show 0000 1101_H while the E-Ray module is in loop back mode.

Loop Back mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

The loop back test mode is intended to check the module’s internal data paths. Normal, time triggered operation is not possible in loop back mode.

There are two possibilities to perform a loop back test. External loop back via physical layer (TEST1.ELBE = 1) or internal loop back for in-system self-test (TEST1.ELBE = 0). In case of an internal loop back pins $\overline{\text{TXENA}}$, $\overline{\text{TXENB}}$ are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDAn and RXDBn are not evaluated.

When the Communication Controller is in loop back mode, a loop back test is started by the Host writing a message to the Input Buffer and requesting the transmission by writing to the Input Buffer Command Request register IBCR. The Message Handler will transfer the message into the Message RAM and then into the Transient Buffer of the selected channel. The Channel Protocol Controller (PRT) will read (in 32-bit words) the message from the transmit part of the Transient Buffer and load it into its Rx / Tx shift register. The serial transmission is looped back into the shift register; its content is written into the receive part of the channels’s Transient Buffer before the next word is loaded.

The PRT and the Message Handler will then treat this transmitted message like a received message, perform an acceptance filtering on Frame ID and receive channel, and store the message into the Message RAM if it passed acceptance filtering. The loop back test ends with the Host requesting this received message from the Message RAM and then checking the contents of the Output Buffer.

Each FlexRay™ channel is tested separately. The E-Ray cannot receive messages from the FlexRay™ bus while it is in the loop back mode.

The cycle counter value of Frames used in loop back mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Note that in case of an odd payload the last two bytes of the looped-back payload will be shifted by 16 bits to the right inside the last 32-bit data word.

Test Register 2 (TEST2)

The Test Register 2 holds all bits required for the RAM test of the seven embedded RAM blocks of the E-Ray module. Write access to this register is only possible when TEST1.WRTEN in the Test Register 1 is set to 1.

TEST2
Test Register 2 **(0014_H)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
SSEL	[6:4]	rw	**Segment Select** To enable access to the complete Message RAM (8192 byte addresses) the Message RAM is segmented. 000_B access to RAM byte 0000_H to $03FF_H$ enabled 001_B access to RAM byte 0400_H to $07FF_H$ enabled 010_B access to RAM byte 0800_H to $0BFF_H$ enabled 011_B access to RAM byte $0C00_H$ to $0FFF_H$ enabled 100_B access to RAM byte 1000_H to $11FF_H$ enabled 101_B access to RAM byte 1400_H to $17FF_H$ enabled 110_B access to RAM byte 1800_H to $1BFF_H$ enabled 111_B access to RAM byte $1C00_H$ to $1FFF_H$ enabled
WR ECC	14	rw	**Write ECC Data Enable** Content of ECCW is transferred to the RAM: 0_B disabled 1_B enabled *Note: Test mode must be entered. See* ***"Test Register 1 (TEST1)" on Page 23-22***
0	3, [13:7], 15, [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

RAM Test Mode

In RAM test mode (TEST1.TMC = 1), one of the seven RAM blocks can be selected for direct RD/WR access by programming TEST2.RS.

For external access the selected RAM block is mapped to address space 400_H to $7FF_H$ (1024 byte addresses or 256 word addresses).

Because the length of the Message RAM exceeds the available address space, the Message RAM is segmented into segments of 1024 byte. The segments can be selected by programming TEST2.SSEL in the Test Register 2.

In RAM test mode the memory must be accessed with 32Bit accesses only.

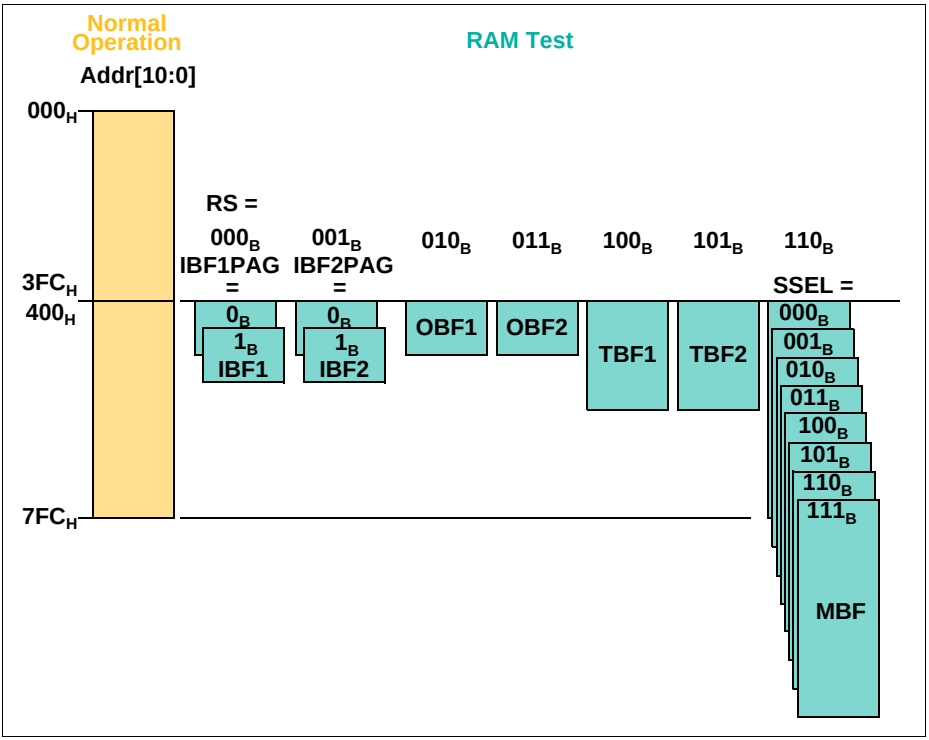

Figure 23-3 RAM test mode Access to E-Ray RAM Blocks

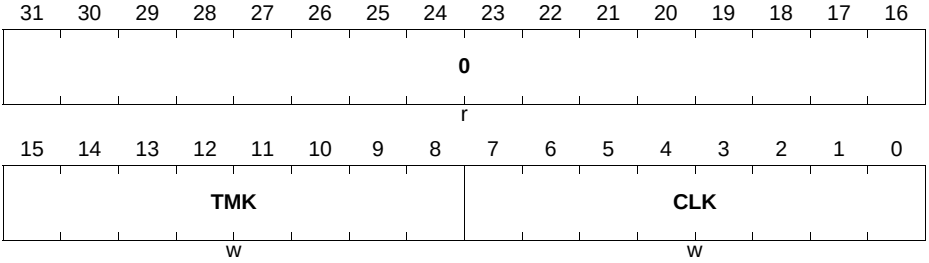
Lock Register (LCK)

The Lock Register is write-only. Reading the register will return 0000 0000_H.

LCK
Lock Register **($001C_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CLK	[7:0]	w	**Configuration Lock Key** To leave “CONFIG” state by writing to SUCC1.CMD commands READY, MONITOR_MODE, ATM, LOOP_BACK) in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the Communication Controller remains in “CONFIG” state and the sequence has to be repeated. First write: LCK.CLK = CE_H = 1100 1110_B Second write: LCK.CLK = 31_H = 0011 0001_B Third write: SUCC1.CMD Returns 0 if read

Field	Bits	Type	Description
TMK	[15:8]	w	**Test Mode Key** To set bit TEST1.WRTEN the write operation has to be directly preceded by two consecutive write accesses to the Test Mode Key. If the write sequence is interrupted by other write accesses between the second write to the Test Mode Key and the write access to the Test1 register, bit TEST1.WRTEN is not set to 1 and the sequence has to be repeated. First write: LCK.TMK = 75_H = 0111 0101_B Second write: LCK.TMK = $8A_H$ = 1000 1010_B Second write: TEST1.WRTEN = 1 Returns 0 if read
0	[31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no "dummy accesses" e.g. to the remaining register bytes / words are inserted by the compiler.

To exit "CONFIG" state by writing to SUCC1.CMD in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key. If this write sequence is service requested by read accesses or write accesses to other locations, the Communication Controller remains in "CONFIG" state and the sequence has to be repeated.

First write: LCK.CLK = CE_H = 1100 1110_B

Second write: LCK.CLK = 31_H = 0011 0001_B

23.5.2.3 Service Request Registers

The address space from 0020_H to $007F_H$ is reserved for service request registers.

Error Service Request Select (EIR)

The flags are set when the Communication Controller detects one of the listed error conditions. They remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

EIR
Error Service Request Register (0020_H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r				rwh	rwh	rwh	rwh	rh	rh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
PEMC	0	rwh	**POC Error Mode Changed** This flag is set whenever the error mode signalled by CCEV.ERRM in the Communication Controller Error Vector register has changed. 0_B Error mode has not changed 1_B Error mode has changed This flag is cleared by writing a 1.
CNA	1	rwh	**Command Not Accepted** The flag signals that the write access to the CHI command vector SUCC1.CMD in the SUC Configuration Register 1 was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (CCL = 1). 0_B CHI command accepted 1_B CHI command not accepted This flag is cleared by writing a 1.

Field	Bits	Type	Description
SFBM	2	rwh	**SYNC Frames Below Minimum** This flag signals that the number of SYNC Frames received during the last communication cycle was below the limit required by the FlexRay™ protocol. May be set during startup and therefore should be cleared by the Host after the Communication Controller entered “NORMAL_ACTIVE” state. 0_B Sync node: 1 or more SYNC Frames received Non-sync node: 2 or more SYNC Frames received 1_B Less than the required minimum of SYNC Frames received This flag is cleared by writing a 1.
SFO	3	rwh	**SYNC Frame Overflow** Set when either the number of SYNC Frames received during the last communication cycle or the total number of SYNC Frames received during the last double cycle exceeds the maximum number of SYNC Frames as defined by GTUC02.SNM in the GTU Configuration Register 2. 0_B Number of received SYNC Frames ≤ GTUC02.SNM 1_B More SYNC Frames received than configured by GTUC02.SNM This flag is cleared by writing a 1.
CCF	4	rwh	**Clock Correction Failure** This flag is set at the end of the cycle whenever one of the following errors occurred: • Missing offset and / or rate correction • Clock Correction limit reached The clock correction status is monitored in registers CCEV and SFS. A failure may occur during startup, therefore bit CCF should be cleared by the Host after the Communication Controller entered “NORMAL_ACTIVE” state. 0_B Clock correction successful so far 1_B Clock correction failed This flag is cleared by writing a 1.

Field	Bits	Type	Description
CCL	5	rwh	**CHI Command Locked** The flag signals that the write access to the CHI command vector SUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed. In this case bit EIR.CNA is also set to 1. 0_B CHI command accepted 1_B CHI command not accepted This flag is cleared by writing a 1.
EERR	6	rh	**ECC Error** The flag signals an ECC error to the Host. It is set whenever one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1. See also **“Message Handler Status (MHDS)” on Page 23-136**. This bit must be cleared at initialization of the module! 0_B No error detected 1_B Error detected
RFO	7	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FSR. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected
EFA	8	rwh	**Empty FIFO Access** This flag is set by the Communication Controller when the Host requests the transfer of a message from the receive FIFO via Output Buffer while the receive FIFO is empty. 0_B No Host access to empty FIFO occurred 1_B Host access to empty FIFO occurred

Field	Bits	Type	Description
IIBA	9	rwh	**Illegal Input Buffer Access** This flag is set by the Communication Controller when the Host wants to modify a Message Buffer via Input Buffer while the Communication Controller is not in “CONFIG” or “DEFAULT_CONFIG” state and one of the following conditions applies: 1. The Host writes to the Input Buffer Command Request register to modify the: a) Header Section of Message Buffer 0, 1 if configured for transmission in key slot b) Header Section of static Message Buffers with buffer number < MRC.FDB while MRC.SEC = 01_B c) Header Section of any static or dynamic Message Buffer while MRC.SEC = $1x_B$ d) Header and / or Data Section of any message buffer belonging to the receive FIFO 2. The Host writes to any register of the Input Buffer while IBCR.IBSYS is set. 0_B No illegal Host access to Input Buffer occurred 1_B Illegal Host access to Input Buffer occurred
IOBA	10	rwh	**Illegal Output Buffer Access** This flag is set by the Communication Controller when the Host requests the transfer of a Message Buffer from the Message RAM to the Output Buffer while OBCR.OBSYS is set to 1. 0_B No illegal Host access to Output Buffer occurred 1_B Illegal Host access to Output Buffer occurred
MHF	11	rwh	**Message Handler Constraints Flag** The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB, MHDF.TBFA, MHDF.TBFB, MHDF.TNSA, MHDF.TNSB, MHDF.WAHP changes from 0 to 1. 0_B No Message Handler failure detected 1_B Message Handler failure detected

Field	Bits	Type	Description
EDA	16	rwh	**Error Detected on Channel A** This bit is set whenever one of the flags ACS.SEDA, ACS.CEDA, ACS.CIA, ACS.SBVA changes from 0 to 1. 0_B No error detected on channel A 1_B Error detected on channel A This flag is cleared by writing a 1.
LTVA	17	rwh	**Latest Transmit Violation Channel A** The flag signals a latest transmit violation on channel A to the Host. 0_B No latest transmit violation detected on channel A 1_B Latest transmit violation detected on channel A This flag is cleared by writing a 1.
TABA	18	rwh	**Transmission Across Boundary Channel A** The flag signals to the Host that a transmission across a slot boundary occurred for channel A. 0_B No transmission across slot boundary detected on channel A 1_B Transmission across slot boundary detected on channel A This flag is cleared by writing a 1.
EDB	24	rwh	**Error Detected on Channel B** This bit is set whenever one of the flags ACS.SEDB, ACS.CEDB, ACS.CIB, ACS.SBVB changes from 0 to 1. 0_B No error detected on channel B 1_B Error detected on channel B This flag is cleared by writing a 1.
LTVB	25	rwh	**Latest Transmit Violation Channel B** The flag signals a latest transmit violation on channel B to the Host. 0_B No latest transmit violation detected on channel B 1_B Latest transmit violation detected on channel B This flag is cleared by writing a 1.

Field	Bits	Type	Description
TABB	26	rwh	**Transmission Across Boundary Channel B** The flag signals to the Host that a transmission across a slot boundary occurred for channel B. 0_B No transmission across slot boundary detected on channel B 1_B Transmission across slot boundary detected on channel B This flag is cleared by writing a 1.
0	[15:12], [23:19], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

Status Service Request Register (SIR)

The flags are set whenever the Communication Controller detects one of the listed events. The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

SIR
Status Service Request Register (0024$_H$) Reset Value: 0000 0000$_H$

Field	Bits	Type	Description
WST	0	rwh	**Wakeup Status** This flag is set when the wakeup status vector CCSV.WSV in the Communication Controller Status Vector register changes to a value other than UNDEFINED. 0_B Wake-up status unmodified 1_B Wake-up status modified (and not UNDEFINED) This flag is cleared by writing a 1.
CAS	1	rwh	**Collision Avoidance Symbol** This flag is set by the Communication Controller during STARTUP state when a CAS or potential CAS was received. 0_B No bit pattern matching the CAS symbol received 1_B Bit pattern matching the CAS symbol received This flag is cleared by writing a 1.
CYCS	2	rwh	**Cycle Start Service Request** This flag is set by the Communication Controller when a communication cycle starts 0_B No communication cycle started 1_B Communication cycle started This flag is cleared by writing a 1.

Field	Bits	Type	Description
TXI	3	rwh	**Transmit Service Request** This flag is set by the Communication Controller at the end of Frame transmission if bit WRHS1.MBI in the respective Message Buffer is set (see **Table 23-24**). 0_B No Frame transmitted from a transmit buffer with WRHS1.MBI = 1 1_B At least one Frame was transmitted from a transmit buffer with WRHS1.MBI = 1 This flag is cleared by writing a 1.
RXI	4	rwh	**Receive Service Request** This flag is set by the Communication Controller whenever the set condition of a Message Buffer ND flag is fulfilled and if bit WRHS1.MBI of that Message Buffer is set to 1(see **Table 23-24**). 0_B No ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1 1_B At least one ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1 This flag is cleared by writing a 1.
RFNE	5	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame was stored into the empty receive FIFO.m The actual state of the receive FIFO is monitored in register FSR 0_B Receive FIFO is empty 1_B Receive FIFO is not empty
RFCL	6	rh	**Receive FIFO Critical Level** This flag is set when a valid receive FIFO fill level FSR.RFFL is equal or greater than the critical level as configured by FCL.CL. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached
NMVC	7	rwh	**Network Management Vector Changed** This service request flag signals a change in the Network Management Vector visible to the Host. 0_B No change in the Network Management vector 1_B Network Management vector changed This flag is cleared by writing a 1.

Field	Bits	Type	Description
TI0	8	rwh	**Timer Service Request 0** This flag is set whenever timer 0 matches the conditions configured in the Timer Service Request 0 Configuration Register T0C. A Timer Service Request 0 is also signalled by TINT0SRC . 0_B No Timer Service Request 0 1_B Timer Service Request 0 occurred This flag is cleared by writing a 1.
TI1	9	rwh	**Timer Service Request 1** This flag is set whenever the conditions programmed in the Timer Service Request 1 Configuration Register T1C are met. A Timer Service Request 1 is also signalled by TINT1SRC. 0_B No Timer Service Request 1 1_B Timer Service Request 1 occurred This flag is cleared by writing a 1.
TIBC	10	rwh	**Transfer Input Buffer Completed** This flag is set whenever a transfer from Input Buffer to the Message RAM has completed and bit IBCR.IBSYS in the Input Buffer Command Request register has been reset by the Message Handler. 0_B No transfer completed 1_B Transfer between Input Buffer and Message RAM completed This flag is cleared by writing a 1.
TOBC	11	rwh	**Transfer Output Buffer Completed** This flag is set whenever a transfer from Message RAM to the Output Buffer has completed and bit OBCR.OBSYS in the Output Buffer Command Request register has been reset by the Message Handler. 0_B No transfer completed 1_B Transfer between Message RAM and the Output Buffer completed This flag is cleared by writing a 1.
SWE	12	rwh	**Stop Watch Event** This flag is set after a stop watch activation when the current cycle counter and Macrotick value are stored in the Stop Watch Register 1 (STPW1). 0_B No Stop Watch Event 1_B Stop Watch Event occurred This flag is cleared by writing a 1.

Field	Bits	Type	Description
SUCS	13	rwh	**Startup Completed Successfully** This flag is set whenever a startup completed successfully and the Communication Controller entered “NORMAL_ACTIVE” state. 0_B No startup completed successfully 1_B Startup completed successfully This flag is cleared by writing a 1.
MBSI	14	rwh	**Message Buffer Status Service Request** This flag is set by the Communication Controller when the Message Buffer status MBS has changed and if bit RDHS1.MBI of that Message Buffer is set (see **Table 23-24**). 0_B No Message Buffer status change of Message Buffer with RDHS1.MBI= 1 has changed 1_B Message Buffer status of at least one Message Buffer with RDHS1.MBI= 1 has changed This flag is cleared by writing a 1.
SDS	15	rwh	**Start of Dynamic Segment** This flag is set by the Communication Controller when the dynamic segment starts. 0_B Dynamic segment not yet started 1_B Dynamic segment started
WUPA	16	rwh	**Wakeup Pattern Channel A** This flag is set by the Communication Controller when a wakeup pattern was received on channel A. Only set when the Communication Controller is in “WAKEUP”, “READY”, or “STARTUP” state, or when in Monitor mode. 0_B No wake-up pattern received on channel A 1_B Wake-up pattern received on channel A This flag is cleared by writing a 1.
MTSA	17	rwh	**MTS Received on Channel A** (vSS!ValidMTSA) Media Access Test symbol received on channel A during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. 0_B No MTS symbol received on channel A 1_B MTS symbol received on channel A This flag is cleared by writing a 1.

Field	Bits	Type	Description
WUPB	24	rwh	**Wakeup Pattern Channel B** This flag is set by the Communication Controller when a wakeup pattern was received on channel B. Only set when the Communication Controller is in “WAKEUP”, “READY”, or “STARTUP” state, or when in Monitor mode. 0_B No wake-up pattern received on channel B 1_B Wake-up pattern received on channel B This flag is cleared by writing a 1.
MTSB	25	rwh	**MTS Received on Channel B** (vSS!ValidMTSB) Media Access Test symbol received on channel B during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. 0_B No MTS symbol received on channel B 1_B MTS symbol received on channel B This flag is cleared by writing a 1.
0	[23:18], [31:26]	r	**Reserved** Returns 0 if read; should be written with 0.

Error Service Request Line Select (EILS)

The Error Service Request Line Select register assigns a service request generated by a specific error service request flag from register EIR to one of the two module service request lines INT0SRC or INT1SRC:

0 = Interrupt assigned to interrupt line (INT0SRC)

1 = Interrupt assigned to interrupt line (INT1SRC)

Field	Bits	Type	Description
0	[23:18], [31:26]	r	**Reserved** Returns 0 if read; should be written with 0.

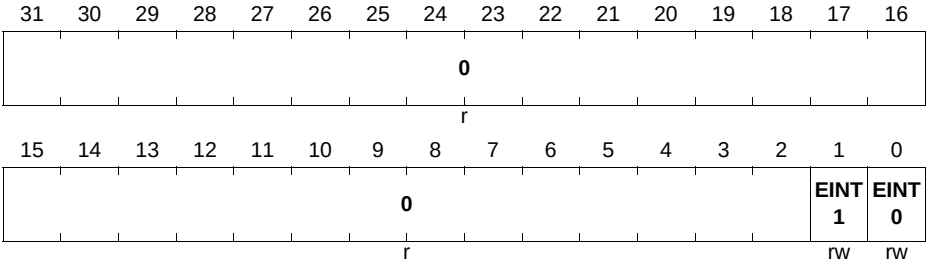
Service Request Line Enable (ILE)

Each of the two service request lines to the Host INT0SRC, INT1SRC can be enabled / disabled separately by programming bit EINT0 and EINT1.

ILE
Service Request Line Enable **(0040_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
EINT0	0	rw	**Enable Service Request Line 0** (INT0SRC) 0_B Service Request line disabled 1_B Service Request line enabled
EINT1	1	rw	**Enable Service Request Line 1** (INT1SRC) 0_B Service Request line disabled 1_B Service Request line enabled
0	[31:2]	r	**Reserved** Returns 0 if read; should be written with 0.

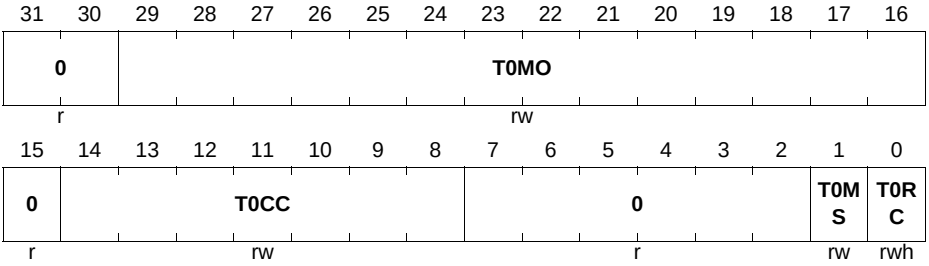
Timer 0 Configuration (T0C)

Absolute timer. Specifies in terms of cycle count and Macrotick the point in time when the timer 0 service request occurs. When the timer 0 service request is asserted, output signal TINT0SR is set to 1 for the duration of one Macrotick and SIR.TI0 is set to 1.

Timer 0 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 0 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit T0RC.

T0C
Timer 0 Configuration **(0044_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
T0RC	0	rwh	**Timer 0 Run Control** 0_B Timer 0 halted 1_B Timer 0 running
T0MS	1	rw	**Timer 0 Mode Select** 0_B Single-shot mode 1_B Continuous mode
T0CC	[14:8]	rw	**Timer 0 Cycle Code** The 7-bit timer 0 cycle code determines the cycle set used for generation of the timer 0 service request. For details about the configuration of the cycle code see **“Cycle Counter Filtering” on Page 23-215**.
T0MO	[29:16]	rw	**Timer 0 Macrotick Offset** Configures the Macrotick offset from the beginning of the cycle where the service request is to occur. The Timer 0 Service Request occurs at this offset for each cycle of the cycle set.

Field	Bits	Type	Description
0	[7:2], 15, [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The configuration of timer 0 is compared against the Macrotick counter value, there is no separate counter for timer 0. In case the Communication Controller leaves “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state, or if timer 0 is halted by Host command, output signal TINT0SR *is reset to 0 immediately.*

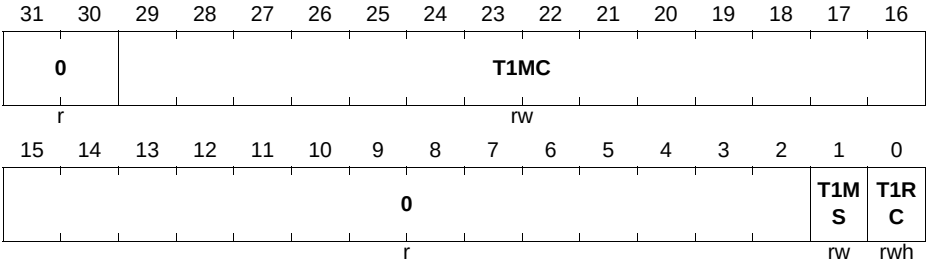
Timer 1 Configuration (T1C)

Relative timer. After the specified number of Macroticks has expired, the timer 1 service request is asserted, output signal TINT1SR is set to 1 for the duration of one Macrotick and SIR.TI1 is set to 1.

Timer 1 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 1 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by resetting bit T1RC to 0.

T1C
Timer 1 Configuration **(0048_H)** **Reset Value: 0002 0000$_H$**



Field	Bits	Type	Description
T1RC	0	rwh	**Timer 1 Run Control** 0_B Timer 1 halted 1_B Timer 1 running
T1MS	1	rw	**Timer 1 Mode Select** 0_B Single-shot mode 1_B Continuous mode
T1MC	[29:16]	rw	**Timer 1 Macrotick Count** When the configured Macrotick count is reached the timer 1 service request is generated. Valid values are: 2_H …$3FFF_H$ Macroticks in continuous mode 1_H …$3FFF_H$ Macroticks in single-shot mode
0	[15:2], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case the Communication Controller leaves "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state, or if timer 1 is halted by Host command, output signal TINT1SR *is reset to 0 immediately.*

Stop Watch Register 1 (STPW1)

The stop watch is activated by a rising or falling edge on signal STPW, by a service request 0 or 1 event (rising edge on signal INT0SR or INT1SR) or by the Host by writing bit STPW1.SSWT to 1. With the Macrotick counter increment following next to the stop watch activation the actual cycle counter and Macrotick value are captured in the Stop Watch Register 1 STPW1 while the slot counter values for channel A and B are captured in the Stop Watch Register 2 STPW2.

STPW1
Stop Watch Register 1 **(004C$_H$)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								SMTV

0		SCCV						0	EINT1	EINT0	EETP	SSWT	EDGE	SWMS	ESWT
r		rh						r	rw	rw	rw	rwh	rw	rw	rwh

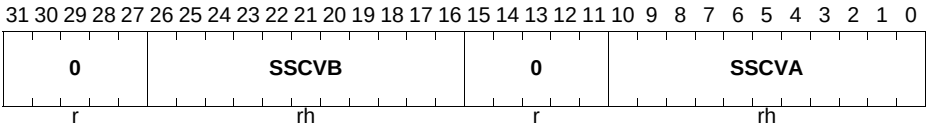
Field	Bits	Type	Description
ESWT	0	rwh	**Enable Stop Watch Trigger** If enabled an edge on input STPW or a service request 0 or 1 event (rising edge on signal INT0SR or INT1SR) activates the stop watch. In single-shot mode this bit is reset to 0 after the actual cycle counter and Macrotick value are stored in the Stop Watch register. 0_B Stop watch trigger disabled 1_B Stop watch trigger enabled
SWMS	1	rw	**Stop Watch Mode Select** It is not possible to change the Stop Watch Mode during enabled stop watch trigger (STPW1.ESWT) 0_B Single-shot mode 1_B Continuous mode
EDGE	2	rw	**Stop Watch Trigger Edge Select** 0_B Falling Edge 1_B Rising Edge

Field	Bits	Type	Description
SSWT	3	rwh	**Software Stop Watch Trigger** When the Host writes this bit to 1 the stop watch is activated. After the actual cycle counter and Macrotick value are stored in the Stop Watch register this bit is reset to 0. The bit is only writeable while ESWT = 0. 0_B Software trigger reset 1_B Stop watch activated by software trigger
EETP	4	rw	**Enable External Trigger Pin** Enables stop watch trigger event via signal STPW if ESWT = 1. 0_B Stop watch trigger via signal STPW disabled 1_B Edge on signal STPW triggers stop watch
EINT0	5	rw	**Enable Service Request 0 Trigger** Enables stop watch trigger by service request 0 event if ESWT = 1. 0_B Stop watch trigger by service request 0 disabled 1_B Service Request 0 event triggers stop watch
EINT1	6	rw	**Enable Service Request 1 Trigger** Enables stop watch trigger by service request 1 event if ESWT = 1. 0_B Stop watch trigger by service request 1 disabled 1_B Service Request 1 event triggers stop watch
SCCV	[13:8]	rh	**Stopped Cycle Counter Value** State of the cycle counter when the stop watch event occurred. Valid values are: $0…3F_H$ Valid Values
SMTV	[29:16]	rh	**Stopped Macrotick Value** State of the Macrotick counter when the stop watch event occurred. Valid values are: $0…3F_H$ Valid Values
0	7, [15:14], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: Bits ESWT and SSWT cannot be set to 1 simultaneously. In this case the write access is ignored, and both bits keep their previous values. Therefore either the external stop watch triggers or the software stop watch trigger may be used.

Stop Watch Register 2 (STPW2)

STPW2
Stop Watch Register 2 **(0050_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SSCVA	[10:0]	rh	**Stop Watch Captured Slot Counter Value Channel A** State of the slot counter for channel A when the stop watch event occurred. Valid values are 0 to 2047 (0_H to $7FF_H$).
SSCVB	[26:16]	rh	**Stop Watch Captured Slot Counter Value Channel B** State of the slot counter for channel B when the stop watch event occurred. Valid values are 0 to 2047 (0_H to $7FF_H$).
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

23.5.2.4 Communication Controller Control Registers

This section describes the registers provided by the Communication Controller to allow the Host to control the operation of the Communication Controller. The FlexRay™ protocol specification requires the Host to write application configuration data in “CONFIG” state only. Please consider that the configuration registers are not locked for writing in “DEFAULT_CONFIG” state.

The configuration data is reset when “DEFAULT_CONFIG” state is entered from application reset. To change POC state from “DEFAULT_CONFIG” to “CONFIG” state the Host has to apply CHI command “CONFIG”. If the Host wants the Communication Controller to leave “CONFIG” state, the Host has to proceed as described on **“Lock Register (LCK)” on Page 23-30**.

SUC Configuration Register 1 (SUCC1)

SUCC1
SUC Configuration Register 1 (0080_H) Reset Value: $0C40\ 1000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				CCHB	CCHA	MTSB	MTSA	HCSE	TSM	WUCS	PTA				
r				rw	rw	rw	rw	rw	rw	rw	rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSA					0	TXSY	TXST	PBSY	0			CMD			
rw					r	rw	rw	rh	r			rwh			

Field	Bits	Type	Description
CMD	[3:0]	rwh	**CHI Command Vector** The host may write any CHI command at any time, but certain commands are only enabled in specific POC states. A disabled command will not be executed, the CHI command vector CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”, and flag EIR.CNA in the Error Service Request register will be set to 1. In case the previous CHI command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, POC state change command applied while the Communication Controller is already in the requested POC state will be ignored. 0000_B COMMAND_NOT_ACCEPTED” 0001_B CONFIG 0010_B READY 0011_B WAKEUP 0100_B RUN 0101_B ALL_SLOTS 0110_B HALT 0111_B FREEZE 1000_B SEND_MTS 1001_B ALLOW_COLDSTART 1010_B RESET_STATUS_INDICATORS 1011_B MONITOR_MODE 1100_B CLEAR_RAMS 1101_B Reserved 1110_B Reserved 1111_B Reserved Reading SUCC1.CMD shows whether the last CHI command was accepted. CCSV.POCS monitors the actual POC state. The reserved CHI commands code hardware test functions.
PBSY	7	rh	**POC Busy** Signals that the POC is busy and cannot accept a command from the Host. SUCC1.CMD is locked against write accesses. Set to 1 after hard reset during initialization of internal RAM blocks. 0_B POC not busy, SUCC1.CMD writable 1_B POC is busy, SUCC1.CMD locked

Field	Bits	Type	Description
TXST	8	rw	**Transmit Startup Frame in Key Slot**[1) 2)] (pKeySlotUsedForStartup) Defines whether the key slot is used to transmit startup Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B No Startup Frame transmission in key slot, node is non-coldstarter 1_B Key slot used to transmit startup Frame, node is leading or following coldstarter
TXSY	9	rw	**Transmit SYNC Frame in Key Slot**[1) 2)] (pKeySlotUsedForSync) Defines whether the key slot is used to transmit SYNC Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B No SYNC Frame transmission in key slot, node is neither sync nor coldstart node 1_B Key slot used to transmit SYNC Frames, node is sync node
CSA	[15:11]	rw	**Cold Start Attempts**[1)](gColdStartAttempts) Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Must be identical in all nodes of a cluster. Valid values are 2 to 31.
PTA	[20:16]	rw	**Passive to Active**[1)] (pAllowPassiveToActive) Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If set to 00000_B the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 31 even / odd cycle pairs.

Field	Bits	Type	Description
WUCS	21	rw	**Wakeup Channel Select**[1)] (pWakeupChannel) With this bit the Host selects the channel on which the Communication Controller sends the Wakeup pattern. The Communication Controller ignores any attempt to change the status of this bit when not in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Send wakeup pattern on channel A 1_B Send wakeup pattern on channel B
TSM	22	rw	**Transmission Slot Mode**[1)] (pSingleSlotEnabled) Selects the initial transmission slot mode. In SINGLE slot mode the Communication Controller may only transmit in the preconfigured key slot. The key slot ID is configured in the Header Section of Message Buffer 0 respectively Message Buffers 0 and 1 depending on bit MRC.SPLM. In case SUCC1.TSM = 1, Message Buffer 0 respectively Message Buffers 0,1 can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. In ALL slot mode the Communication Controller may transmit in all slots. The bit can be written in “DEFAULT_CONFIG” or “CONFIG” state only. The communication controller changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing SUCC1.CMD = 0101_B in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. The actual slot mode is monitored by CCSV.SLM. 0_B ALL Slot Mode 1_B SINGLE Slot Mode (default after application reset)
HCSE	23	rw	**Halt due to Clock Sync Error**[1)] (pAllowHaltDueToClock) Controls the transition to “HALT” state due to a clock synchronization error. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B Communication Controller will enter / remain in “NORMAL_PASSIVE” 1_B Communication Controller will enter “HALT” state
MTSA	24	rw	**Select Channel A for MTS Transmission**[1) 3)] The bit selects channel A for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Channel A disabled for MTS transmission 1_B Channel A selected for MTS transmission

Field	Bits	Type	Description
MTSB	25	rw	**Select Channel B for MTS Transmission[1) 3)]** The bit selects channel B for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Channel B disabled for MTS transmission 1_B Channel B selected for MTS transmission
CCHA	26	rw	**Connected to Channel A[1)]** (pChannels) Configures whether the node is connected to channel A. 0_B Not connected to channel A 1_B Node connected to channel A (default after application reset)
CCHB	27	rw	**Connected to Channel B[1)]** (pChannels) Configures whether the node is connected to channel B. 0_B Not connected to channel B 1_B Node connected to channel B (default after application reset)
0	[6:4], 10, [31:28]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

2) The protocol requires that both bits TXST and TXSY are set for coldstart nodes.

3) MTSA and MTSB may also be changed outside “DEFAULT_CONFIG” or “CONFIG” state when the write to SUCC1 register is directly preceded by the unlock sequence as described in Lock Register (LCK). This may be combined with CHI command “SEND_MTS”. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B.

COMMAND_NOT_ACCEPTED

SUCC1.CMD is reset to 0000_B due to one of the following conditions:

- Illegal command applied by the Host
- Host writes command_not_accepted
- Host applied new command while execution of the previous Host command has not completed

When SUCC1.CMD is reset to 0000_B, bit EIR.CNA in the Error Service Request register is set, and - if enabled - an service request is generated. Commands which are not accepted are not executed.

CONFIG

Go to POC state “CONFIG” when called in POC states “DEFAULT_CONFIG“, “READY“, or in “MONITOR_MODE“. When called in “HALT” state transits to POC state

“DEFAULT_CONFIG“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

READY

Go to POC state “READY” when called in POC states “CONFIG”, “NORMAL_ACTIVE”, “NORMAL_PASSIVE”, “STARTUP”, or “WAKEUP”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

WAKEUP

Go to POC state WAKEUP when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

RUN

Go to POC state “STARTUP” when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

ALL_SLOTS

Leave SINGLE slot mode after successful startup / integration at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. When called in any other state, SUCC1.CMD will be reset to
0000_B = “COMMAND_NOT_ACCEPTED”.

HALT

Set the halt request CCSV.HRQ bit in the Communication Controller Status Vector register and go to POC state “HALT” at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

FREEZE

Set the freeze status indicator CCSV.FSI and go to POC state “HALT” immediately. Can be called from any state.

SEND_MTS

Send single MTS symbol during the next following symbol window on the channel configured by SUCC1.MTSA, SUCC1.MTSB, when called in POC state “NORMAL_ACTIVE”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

ALLOW_COLDSTART

The command resets bit CCSV.CSI to enable the node to become cold starter. When called in states “DEFAULT_CONFIG“, “CONFIG”, “HALT”, or “MONITOR_MODE“. SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. To become leading coldstarter it is also required that both TXST and TXSY are set.

RESET_STATUS_INDICATORS

Resets status flags CCSV.CSNI, CCSV.CSAI, CCSV.WSV to their default values. May be called in POC state READY. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

MONITOR_MODE

Enter MONITOR_MODE when called in POC state CONFIG. In this mode the Communication Controller is able to receive FlexRay™ Frames and wakeup pattern. It is also able to detect coding errors. The temporal integrity of received Frames is not checked. This mode can be used for debugging purposes, e.g. in case that the startup of a FlexRay™ network fails. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. For details see **“MONITOR_MODE” on Page 23-199**.

CLEAR_RAMS

Sets bit MHDS.CRAM in the Message Handler Status register when called in “DEFAULT_CONFIG” or “CONFIG” state. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. By setting MHDS.CRAM all internal RAM blocks are initialized to zero. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required. During the initialization of the RAMs, SUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the E-Ray internal RAM blocks requires 2048 f_{CLC_ERAY} cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after application reset or after assertion of CHI command CLEAR_RAMS. Before asserting CHI command CLEAR_RAMS the Host should make sure that no transfer between Message RAM and IBF / OBF or the Transient Buffer RAMs is ongoing. This command also resets the Message Buffer Status registers MHDS, LDTS, FSR, MHDF, TXRQ1, TXRQ2, TXRQ3, TXRQ4, NDAT1, NDAT2, NDAT3, NDAT4, MBSC1, MBSC2, MBSC3, and MBSC4.

Note: All accepted commands with exception of CLEAR_RAMS and SEND_MTS will cause a change of register CCSV after at most 8 cycles of the slower of the two clocks f_{CLC_ERAY} and f_{SCLK}, assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time Frame. Reading register CCSV will show data that is delayed by synchronization from f_{SCLK} to f_{CLC_ERAY} domain and by the Host-specific CPU interface.

Table 23-4 below references the CHI commands from the FlexRay™ Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the E-Ray CHI command vector CMD.]

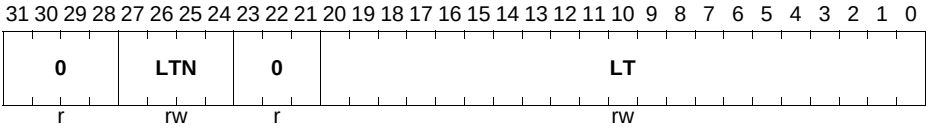
Table 23-4 Reference to CHI Host command summary from FlexRay™ protocol specification

CHI Command	Where processed (POC State)	CHI Command Vector CMD
ALL_SLOT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	ALL_SLOTS
ALLOW_COLDSTART	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:HALT	ALLOW_COLDSTART
CONFIG	POC:DEFAULT_CONFIG, POC:READY	CONFIG
CONFIG_COMPLETE	POC:CONFIG	Unlock sequence & READY
DEFAULT_CONFIG	POC:HALT	CONFIG
FREEZE	All	FREEZE
HALT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	HALT
READY	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:READY, POC:HALT	READY
RUN	POC:READY	RUN
WAKEUP	POC:READY	WAKEUP

SUC Configuration Register 2 (SUCC2)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

SUCC2
SUC Configuration Register 2 (0084_H) Reset Value: 0100 0504_H



Field	Bits	Type	Description
LT	[20:0]	rw	**Listen Timeout**[1] (pdListenTimeout) Configures wakeup / startup listen timeout in Microticks. The range for wakeup / startup listen timeout (pdListenTimeout) is 1284 to 1283846 (504_H to 139706_H) Microticks
LTN	[27:24]	rw	**Listen Time-out Noise**[1] (gListenNoise - 1) Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of the cluster constant pdListenTimeout. The range of pdListenTimeout 2 to 16. LTN must be configured identical in all nodes of a cluster. 1_H Listen Time-out Noise is equal 2 2_H Listen Time-out Noise is equal 3 $..._H$ ... F_H Listen Time-out Noise is equal 16
0	[23:21], [31:28]	r	**Reserved** Returns 0 if read; should be written with 0.

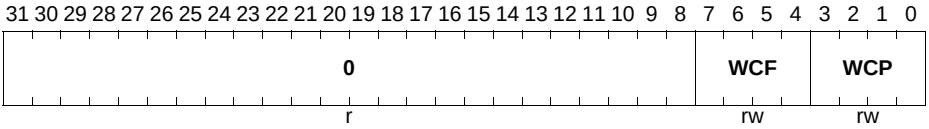
1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

Note: The wakeup / startup noise time-out is calculated as follows:
The wakeup / startup noise time-out = pdListenTimeout • gListenNoise
= LT • (LTN+ 1)

SUC Configuration Register 3 (SUCC3)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

SUCC3
SUC Configuration Register 3 (0088_H) Reset Value: $0000\ 0011_H$



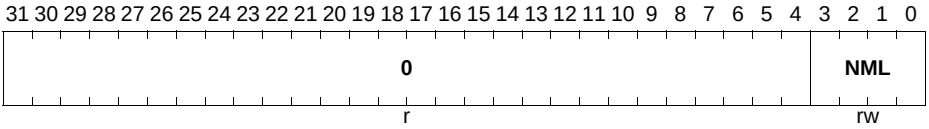
Field	Bits	Type	Description
WCP	[3:0]	rw	**Maximum Without Clock Correction Passive**[1)] (gMaxWithoutClockCorrectionPassive) Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H) cycle pairs.
WCF	[7:4]	rw	**Maximum Without Clock Correction Fatal**[1)] (gMaxWithoutClockCorrecti on Fatal) Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to “HALT” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H)cycle pairs.
0	[31:8]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

NEM Configuration Register (NEMC)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

NEMC
NEM Configuration Register (008C$_H$) **Reset Value: 0000 0000$_H$**



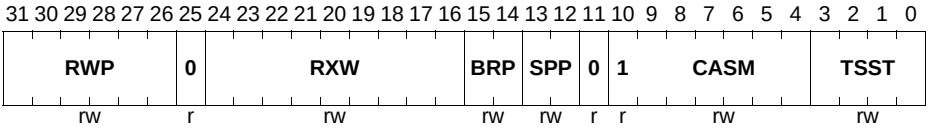
Field	Bits	Type	Description
NML	[3:0]	rw	**Network Management Vector Length**[1)] (gNetworkManagementVectorLength) These bits configure the length of the NM Vector. The configured length must be identical in all nodes of a cluster. Valid values are 0 to 12 (0_H to C_H) bytes.
0	[31:4]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

PRT Configuration Register 1 (PRTC1)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC1
PRT Configuration Register 1 (0090_H) Reset Value: $084C\ 0633_H$



Field	Bits	Type	Description
TSST	[3:0]	rw	**Transmission Start Sequence Transmitter**[1)] (gdTSSTransmitter) Configures the duration of the Transmission Start Sequence (TSS) in terms of Bit Times (1 bit time = 4 Microticks = 100ns at 10Mbps). Must be identical in all nodes of a cluster. Valid values are 3 to 15 (3_H to F_H) Bit Times.
CASM	[10:4]	rw	**Collision Avoidance Symbol Maximum**[1)] (gdCASRxLowMax) Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS). Valid values are 67 to 99 (43_H to 63_H). Most significant bit of CASM is hard wired to 1 and can not be modified.
SPP	[13:12]	rw	**Strobe Point Position**[1)] Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by SPP. 00_B Sample 5 (default) 01_B Sample 4 10_B Sample 6 11_B Reserved; should not be used. *Note: The current revision 2.1 of the FlexRay™ protocol requires that SPP = 00_B. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.*

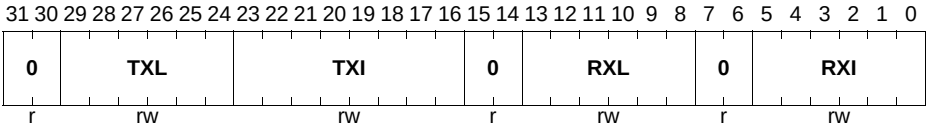
Field	Bits	Type	Description
BRP	[15:14]	rw	**Baud Rate Prescaler**[1] (gdSampleClockPeriod, pSamplePerMicrotick) The baud rate prescaler configures the baud rate on the FlexRay™ bus. The baud rates listed below are valid with a sample clock f_{SCLK}= 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate. 00_B 10 Mbit/s (1 Microtick= 25 ns; twice sampled with f_{SCLK}) gdSampleClockPeriod = 12.5 ns = 1 / f_{SCLK} pSamplesPerMicrotick = 2 01_B 5 Mbit/s (1 Microtick= 25ns; single sampled with f_{SCLK} / 2) gdSampleClockPeriod = 25 ns = 2 / f_{SCLK} pSamplesPerMicrotick = 1 10_B 2.5 Mbit/s (1 Microtick = 50ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / f_{SCLK} pSamplesPerMicrotick = 1 11_B Reserved; should not be used (2.5 Mbit/s (1 Microtick = 50 ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / f_{SCLK} pSamplesPerMicrotick = 1
RXW	[24:16]	rw	**Wakeup Symbol Receive Window Length**[1] (gdWakeupSymbolRxWindow**)** Configures the number of Bit Times used by the node to test the duration of the received wakeup pattern. Must be identical in all nodes of a cluster. Valid values are 76 to 301 ($4C_H$ to $12D_H$) Bit Times.
RWP	[31:26]	rw	**Repetitions of Tx Wakeup Pattern**[1] (pWakeupPattern) Configures the number of repetitions (sequences) of the Tx wakeup symbol. Valid values are 2 to 63 (2_H to $3F_H$).
0	11, 25	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

PRT Configuration Register 2 (PRTC2)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC2
PRT Configuration Register 2 (0094_H) Reset Value: $0F2D\ 0A0E_H$



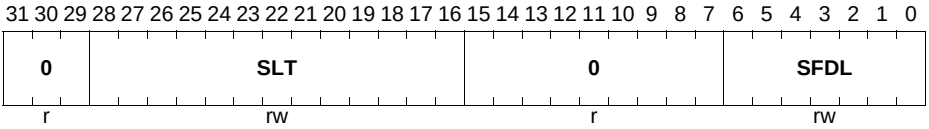
Field	Bits	Type	Description
RXI	[5:0]	rw	**Wakeup Symbol Receive Idle**[1)] (gdWakeupSymbolRxIdle) Configures the number of Bit Times used by the node to test the duration of the idle phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 14 to 59 (E_H to $3B_H$) Bit Times.
RXL	[13:8]	rw	**Wakeup Symbol Receive Low**[1)] (gdWakeupSymbolRxLow) Configures the number of Bit Times used by the node to test the duration of the low phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 10 to 55 (A_H to 37_H) Bit Times.
TXI	[23:16]	rw	**Wakeup Symbol Transmit Idle**[1)] (gdWakeupSymbolTxIdle) Configures the number of Bit Times used by the node to transmit the idle phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 45 to 180 ($2D_H$ to $B4_H$)Bit Times.
TXL	[29:24]	rw	**Wakeup Symbol Transmit Low**[1)] (gdWakeupSymbolTxLow) Configures the number of Bit Times used by the node to transmit the low phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 15 to 60 (F_H to $3C_H$) Bit Times.
0	[7:6], [15:14], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

MHD Configuration Register (MHDC)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

MHDC
MHD Configuration Register **(0098_H)** **Reset Value: $0000\ 0000_H$**



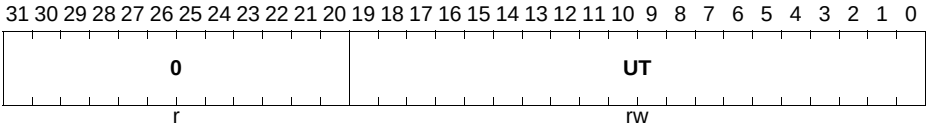
Field	Bits	Type	Description
SFDL	[6:0]	rw	**Static Frame Data Length** (gPayloadLengthStatic)[1)] Configures the cluster-wide payload length for all Frames sent in the static segment in double byte. The payload length must be identical in all nodes of a cluster. Valid values are 0 to 127 (0 to $7F_H$).
SLT	[28:16]	rw	**Start of Latest Transmit** (pLatestTx)[1)] Configures the maximum minislot value allowed before inhibiting Frame transmission in the dynamic segment of the cycle. There is no transmission dynamic segment if SLT is reset to zero. Valid values are 0 to 7981 (0 to $1F2D_H$) minislots.
0	[15:7], [31:29]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 1 (GTUC01)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC01
GTU Configuration Register 1 (00A0$_H$) **Reset Value: 0000 0280$_H$**



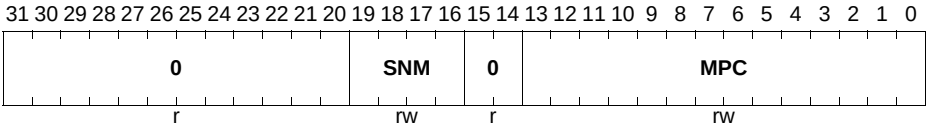
Field	Bits	Type	Description
UT	[19:0]	rw	**Microtick per Cycle** (pMicroPerCycle)[1)] Configures the duration of the communication cycle in Microticks. Valid values are 640 to 640000 (280$_H$ to 9C400$_H$) Microticks.
0	[31:20]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 2 (GTUC02)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC02
GTU Configuration Register 2 (00A4$_H$) **Reset Value: 0002 000A$_H$**



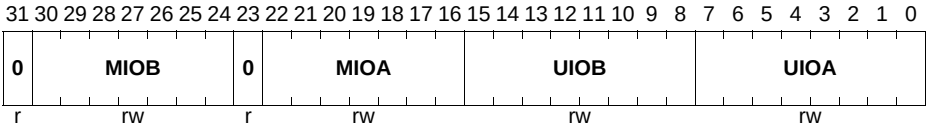
Field	Bits	Type	Description
MPC	[13:0]	rw	**Macrotick Per Cycle** (gMacroPerCycle)[1)] Configures the duration of one communication cycle in Macroticks. The cycle length must be identical in all nodes of a cluster. Valid values are 10 to 16000 (A_H to $3E80_H$) Macroticks.
SNM	[19:16]	rw	**Sync Node Max** (gSyncNodeMax)[1)] Maximum number of Frames within a cluster with SYNC Frame indicator bit SYN set to 1. Must be identical in all nodes of a cluster. Valid values are 2 to 15 (2_H to F_H).
0	[15:14], [31:20]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 3 (GTUC03)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC03
GTU Configuration Register 3 (00A8$_H$) Reset Value: 0202 0000$_H$



Field	Bits	Type	Description
UIOA	[7:0]	rw	**Microtick Initial Offset Channel A**[1)] (pMicroInitialOffset[A]) Configures the number of Microticks between the actual time reference point on channel A and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[A] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.
UIOB	[15:8]	rw	**Microtick Initial Offset Channel B**[1)] (pMicroInitialOffset[B]) Configures the number of Microticks between the actual time reference point on channel B and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[B] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.
MIOA	[22:16]	rw	**Macrotick Initial Offset Channel A** (gMacroInitialOffset[A])[1)] Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.
MIOB	[30:24]	rw	**Macrotick Initial Offset Channel B** (gMacroInitialOffset[B])[1)] Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.

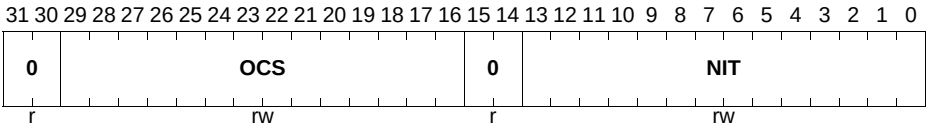
Field	Bits	Type	Description
0	23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 4 (GTUC04)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only. For details about configuration of NIT and OCS see **“Configuration of Network Idle Time (NIT) Start and Offset Correction Start” on Page 23-188**.

GTUC04
GTU Configuration Register 4 (00AC$_H$) Reset Value: 0008 0007$_H$



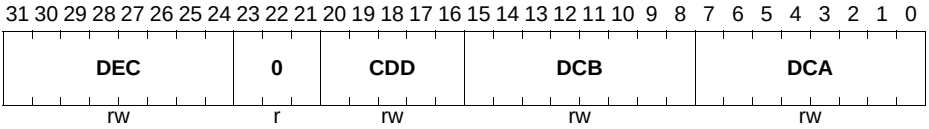
Field	Bits	Type	Description
NIT	[13:0]	rw	**Network Idle Time Start** [1)] (gMacroPerCycle - gdNIT - 1) Configures the starting point of the Network Idle Time (NIT) at the end of the communication cycle expressed in terms of Macroticks from the beginning of the cycle. The start of network idle time (NIT) is recognized if Macrotick = gMacroPerCycle - gdNIT -1 and the increment pulse of Macrotick is set. Must be identical in all nodes of a cluster. Valid values are 7 to 15997 (7_H to $3E7D_H$) Macroticks.
OCS	[29:16]	rw	**Offset Correction Start**[1)] (gOffsetCorrectionStart - 1) Determines the start of the offset correction within the network idle time (NIT) phase, calculated from start of cycle. Must be identical in all nodes of a cluster. For cluster consisting of E-Ray implementations only, it is sufficient to program OCS = NIT + 1. Valid values are 8 to 15998 (8_H to $3E7E_H$) Macroticks.
0	[15:14], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 5 (GTUC05)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC05
GTU Configuration Register 5 ($00B0_H$) Reset Value: $0E00\ 0000_H$



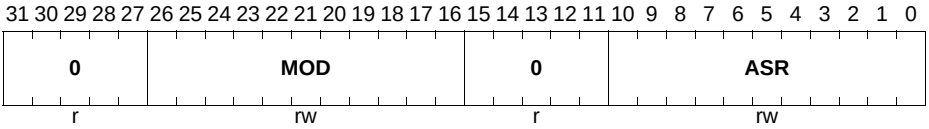
Field	Bits	Type	Description
DCA	[7:0]	rw	**Delay Compensation Channel A**[1)] (pDelayCompensation[A]) Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125µs to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
DCB	[15:8]	rw	**Delay Compensation Channel B**[1)] (pDelayCompensation[B]) Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
CDD	[20:16]	rw	**Cluster Drift Damping** (pClusterDriftDamping)[1)] Configures the cluster drift damping value used in clock synchronization to minimize accumulation of rounding errors. Valid values are 0 to 20 (0_H to 14_H) Microticks.
DEC	[31:24]	rw	**Decoding Correction** (pDecodingCorrection)[1)] Configures the decoding correction value used to determine the primary time reference point. Valid values are 14 to 143 (E_H to $8F_H$) Microticks.
0	[23:21]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 6 (GTUC06)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC06
GTU Configuration Register 6 (00B4$_H$) Reset Value: 0002 0000$_H$



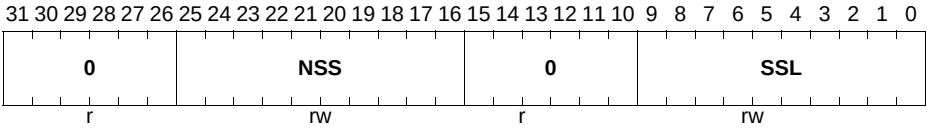
Field	Bits	Type	Description
ASR	[10:0]	rw	**Accepted Startup Range**[1] (pdAcceptedStartupRange) Number of Microticks constituting the expanded range of measured deviation for startup Frames during integration. Valid values are 0 to 1875 (0_H to 753_H) Microticks.
MOD	[26:16]	rw	**Maximum Oscillator Drift** (pdMaxDrift)[1] Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in Microticks. Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 7 (GTUC07)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC07
GTU Configuration Register 7 (00B8$_H$) **Reset Value: 0002 0004$_H$**



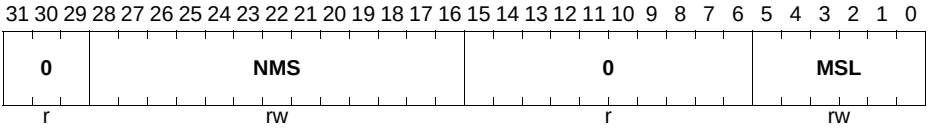
Field	Bits	Type	Description
SSL	[9:0]	rw	**Static Slot Length** (gdStaticSlot)[1)] Configures the duration of a static slot in Macroticks. The static slot length must be identical in all nodes of a cluster. Valid values are 4 to 659 (4_H to 293_H) Macroticks.
NSS	[25:16]	rw	**Number of Static Slots** (gNumberOfStaticSlots)[1)] Configures the number of static slots in a cycle. At least 2 coldstart nodes must be configured to startup a FlexRay™ network. The number of static slots must be identical in all nodes of a cluster. Valid values are 2 to 1023 (2_H to $3FF_H$).
0	[15:10], [31:26]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 8 (GTUC08)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC08
GTU Configuration Register 8 (00BC$_H$) Reset Value: 0000 0002$_H$



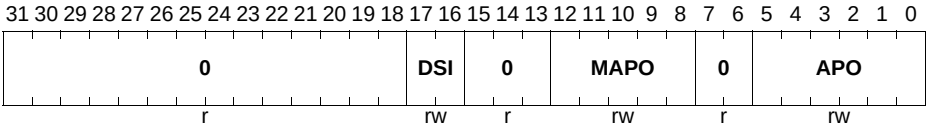
Field	Bits	Type	Description
MSL	[5:0]	rw	**Minislot Length** (gdMinislot)[1)] Configures the duration of a minislot in Macroticks. The minislot length must be identical in all nodes of a cluster. Valid values are 2 to 63 (2_H to $3F_H$) Macroticks.
NMS	[28:16]	rw	**Number of Minislots** (gNumberOfMinislots)[1)] Configures the number of minislots within the dynamic segment of a cycle. The number of minislots must be identical in all nodes of a cluster. Valid values are 0 to 7986 (0_H to $1F32_H$).
0	[15:6], [31:29]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 9 (GTUC09)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC09
GTU Configuration Register 9 ($00C0_H$) Reset Value: $0000\ 0101_H$



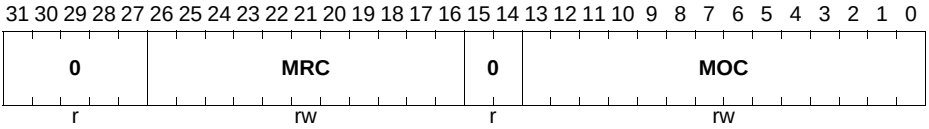
Field	Bits	Type	Description
APO	[5:0]	rw	**Action Point Offset** (gdActionPointOffset)[1)] Configures the action point offset in Macroticks within static slots and symbol window. Must be identical in all nodes of a cluster. Valid values are 1 to 63 (1_H to $3F_H$) Macroticks.
MAPO	[12:8]	rw	**Minislot Action Point Offset**[1)] (gd Minislot Action Point Offset) Configures the action point offset in Macroticks within the minislots of the dynamic segment. Must be identical in all nodes of a cluster. Valid values are 1 to 31 (1_H to $1F_H$) Macroticks.
DSI	[17:16]	rw	**Dynamic Slot Idle Phase**[1)] (gdDynamicSlotIdlePhase) The duration of the dynamic slot idle phase has to be greater or equal than the idle detection time. Must be identical in all nodes of a cluster. Valid values are 0 to 2 Minislot.
0	[7:6], [15:13], [31:18]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 10 (GTUC10)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC10
GTU Configuration Register 10 ($00C4_H$) Reset Value: $0002\ 0005_H$

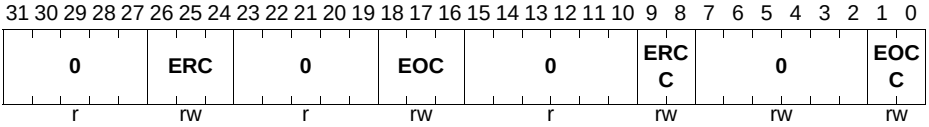


Field	Bits	Type	Description
MOC	[13:0]	rw	**Maximum Offset Correction**[1] (pOffsetCorrectionOut) Holds the maximum permitted offset correction value to be applied by the internal clock synchronization algorithm (absolute value). The Communication Controller checks only the internal offset correction value against the maximum offset correction value. Valid values are 5 to 15266 (5_H to $3BA2_H$) Microticks.
MRC	[26:16]	rw	**Maximum Rate Correction**[1] (pRateCorrectionOut) Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The communication controller checks only the internal rate correction value against the maximum rate correction value (absolute value). Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	[15:14], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 11 (GTUC11)

GTUC11
GTU Configuration Register 11 (00C8$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
EOCC	[1:0]	rw	**External Offset Correction Control** (pExternOffsetControl) By writing to EOCC the external offset correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external clock correction 01_B No external clock correction 10_B External offset correction value subtracted from calculated offset correction value 11_B External offset correction value added to calculated offset correction value
ERCC	[9:8]	rw	**External Rate Correction Control** (pExternRateControl) By writing to ERCC the external rate correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external rate correction 01_B No external rate correction 10_B External rate correction value subtracted from calculated rate correction value 11_B External rate correction value added to calculated rate correction value
EOC	[18:16]	rw	**External Offset Correction**[1)] (pExternOffsetCorrection) Holds the external clock offset correction value in Microticks to be applied by the internal synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during network idle time (NIT). May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.

Field	Bits	Type	Description
ERC	[26:24]	rw	**External Rate Correction**[1] (pExternRateCorrection) Holds the external rate correction value in Microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during network idle time (NIT). May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.
0	[7:2], [15:10], [23:19], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

23.5.2.5 Communication Controller Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the Communication Controller between two accesses (non-atomic read accesses). The status vector may change faster than the Host can poll the status vector, depending on f_{CLC_ERAY} frequency.

Communication Controller Status Vector (CCSV)

CCSV

Communication Controller Status Vector(0100_H) **Reset Value: $0010\ 4000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	CSI	CSAI	CSNI	0		SLM		HRQ	FSI	POCS					
r	rh	rh	rh	r		rh		rh	rh	rh					

Field	Bits	Type	Description
POCS	[5:0]	rh	**Protocol Operation Control Status** Indicates the actual state of operation of the Communication Controller Protocol Operation Control 000000_B “DEFAULT_CONFIG” state 000001_B “READY” state 000010_B “NORMAL_ACTIVE” state 000011_B “NORMAL_PASSIVE” state 000100_B “HALT” state 000101_B “MONITOR_MODE” state 000110_B … 001110_B are reserved. 001111_B “CONFIG” state Indicates the actual state of operation of the POC in the wakeup path 010000_B WAKEUP_STANDBY state 010001_B “WAKEUP_LISTEN” state 010010_B “WAKEUP_SEND” state 010011_B “WAKEUP_DETECT” state 010100_B … 011111_B are reserved. Indicates the actual state of operation of the POC in the startup path 100000_B “STARTUP_PREPARE” state 100001_B “COLDSTART_LISTEN” state 100010_B “COLDSTART_COLLISION_RESOLUTION state 100011_B “COLDSTART_CONSISTENCY_CHECK” state 100100_B “COLDSTART_GAP state 100101_B “COLDSTART_JOIN” State 100110_B “INTEGRATION_COLDSTART_CHECK” state 100111_B “INTEGRATION_LISTEN” state 101000_B “INTEGRATION_CONSISTENCY_CHECK” state 101001_B “INITIALIZE_SCHEDULE” state 101010_B “ABORT_STARTUP” state 101011_B “STARTUP_SUCCESS” state 101100_B … 111111_B are reserved.

Field	Bits	Type	Description
FSI	6	rh	**Freeze Status Indicator** (vPOC!Freeze**)** Indicates that the POC has entered the “HALT” state due to CHI command “FREEZE” or due to an error condition requiring an immediate POC halt. Reset by transition from “HALT” to “DEFAULT_CONFIG” state.
HRQ	7	rh	**Halt Request** (vPOC!CHIHaltRequest) Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle. Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.
SLM	[9:8]	rh	**Slot Mode** (vPOC!SlotMode) Indicates the actual slot mode of the POC in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE. Default is “SINGLE”. Changes to “ALL”, depending on configuration bit SUCC1.TSM. In “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the CHI command “ALL_SLOTS” will change the slot mode from “SINGLE” over “ALL_PENDING” to “ALL”. Set to SINGLE in all other states. 00_B SINGLE 01_B Reserved 10_B ALL_PENDING 11_B ALL
CSNI	12	rh	**Coldstart Noise Indicator** (vPOC!ColdstartNoise) Indicates that the cold start procedure occurred under noisy conditions. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.
CSAI	13	rh	**Coldstart Abort Indicator** Coldstart aborted. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.

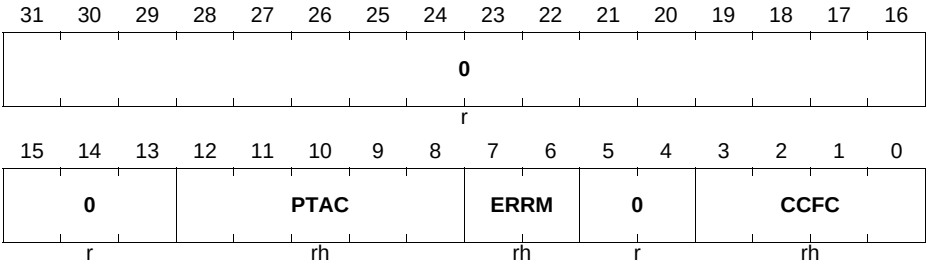
Field	Bits	Type	Description
CSI	14	rh	**Cold Start Inhibit** (vColdStartInhibit) Indicates that the node is disabled from cold starting. The flag is set whenever the POC enters “READY” state due to CHI command “READY”. The flag has to be reset under control of the Host by CHI command “ALLOW_COLDSTART” (SUCC1.CMD = 1001_B). 0_B Cold starting of node enabled 1_B Cold starting of node disabled
WSV	[18:16]	rh	**Wakeup Status** (vPOC!WakeupStatus) Indicates the status of the current wakeup attempt. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state. 000_B UNDEFINED. Wakeup not yet executed by the Communication Controller. 001_B RECEIVED_HEADER. Set when the Communication Controller finishes wakeup due to the reception of a Frame Header without coding violation on either channel in “WAKEUP_LISTEN” state. 010_B RECEIVED_WUP. Set when the Communication Controller finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in “WAKEUP_LISTEN” state. 011_B COLLISION_HEADER. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid Header on either channel. 100_B COLLISION_WUP. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel. 101_B COLLISION_UNKNOWN. Set when the Communication Controller stops wakeup by leaving “WAKEUP_DETECT” state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid Frame Header. 110_B TRANSMITTED. Set when the Communication Controller has successfully completed the transmission of the wakeup pattern. 111_B Reserved

Field	Bits	Type	Description
RCA	[23:19]	rh	**Remaining Coldstart Attempts** (vRemainingColdstartAttempts) Indicates the number of remaining coldstart attempts. The RUN command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA.
PSL	[29:24]	rh	**POC Status Log** Status of CCSV.POCS immediately before entering “HALT” state. Set when entering “HALT” state. Set to “HALT” when FREEZE command is applied during “HALT” state. Reset to 000000_B when leaving “HALT” state.
0	[11:10], 15, [31:30]	rh	**Reserved** Returns 0 if read; should be written with 0.

Communication Controller Error Vector (CCEV)

Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.

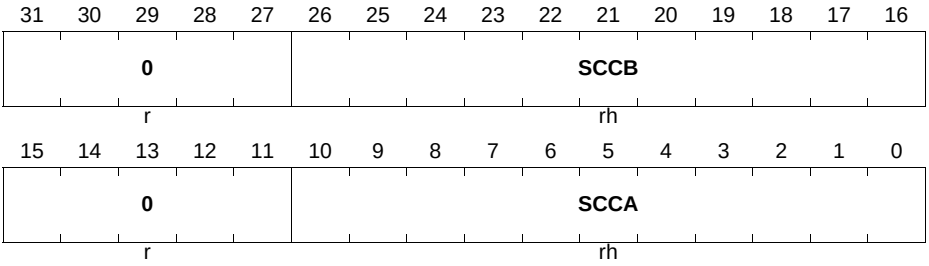
CCEV
Communication Controller Error Vector (0104_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CCFC	[3:0]	rh	**Clock Correction Failed Counter** (vClockCorrectionFailed) The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active. The Clock Correction Failed Counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active. The Clock Correction Failed Counter stops at 15.
ERRM	[7:6]	rh	**Error Mode** (vPOC!ErrorMode) Indicates the actual error mode of the POC. 00_B “ACTIVE” (green) 01_B “PASSIVE” (yellow) 10_B “COMM_HALT” (red) 11_B Reserved
PTAC	[12:8]	rh	**Passive to Active Count** (vAllowPassiveToActive) Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from “NORMAL_PASSIVE” state to “NORMAL_ACTIVE” state. The transition takes place when PTAC equals SUCC1.PTA.
0	[5:4], [31:13]	r	**Reserved** Returns 0 if read; should be written with 0.

Slot Counter Value (SCV)

SCV
Slot Counter Value **(0110_H)** **Reset Value: $0000\ 0000_H$**

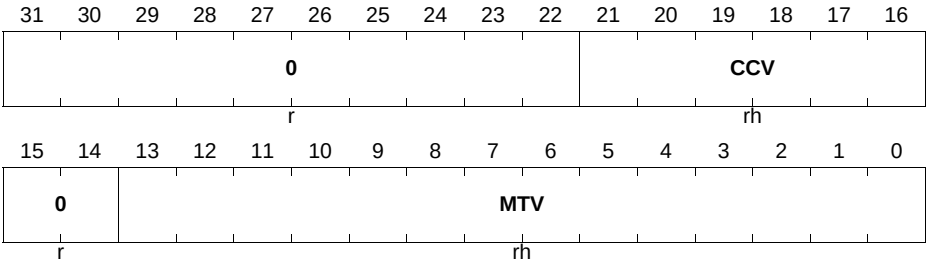


Field	Bits	Type	Description
SCCA	[10:0]	rh	**Slot Counter Channel A** (vSlotCounter[A]**)** Current slot counter value on channel A. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FD_H$).
SCCB	[26:16]	rh	**Slot Counter Channel B** (vSlotCounter[B]**)** Current slot counter value on channel B. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FD_H$).
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

Macrotick and Cycle Counter Value (MTCCV)

MTCCV

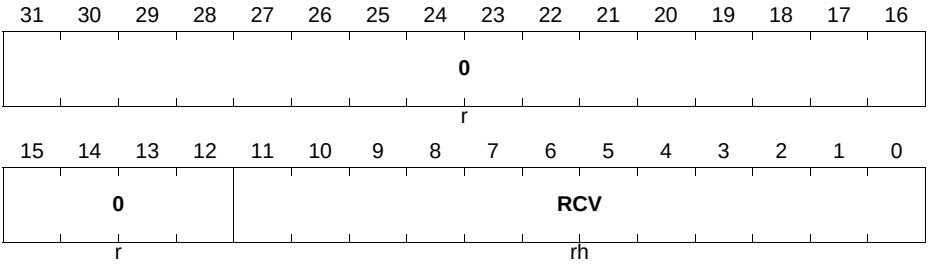
Macrotick and Cycle Counter Value (0114_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
MTV	[13:0]	rh	**Macrotick Value** (vMacrotick) Current Macrotick value. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 16000 (0_H to $3E80_H$).
CCV	[21:16]	rh	**Cycle Counter Value** (vCycleCounter) Current cycle counter value. The value is incremented by the Communication Controller at the start of a communication cycle. Valid values are 0 to 63 (0_H to $3F_H$).
0	[15:14], [31:22]	r	**Reserved** Returns 0 if read; should be written with 0.

Rate Correction Value (RCV)

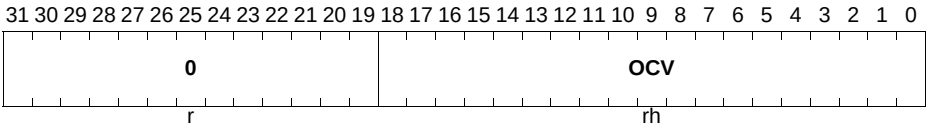
RCV
Rate Correction Value **(0118_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RCV	[11:0]	rh	**Rate Correction Value** (vRateCorrection) Rate correction value (two's complement). Calculated internal rate correction value before limitation. If the RCV value exceeds the limits defined by GTUC10.MRC, flag SFS.RCLR is set to 1.
0	[31:12]	r	**Reserved** Returns 0 if read; should be written with 0.

Offset Correction Value (OCV)

OCV
Offset Correction Value **($011C_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OCV	[18:0]	rh	**Offset Correction Value** (vOffsetCorrection) Offset correction value (two's complement). Calculated internal offset correction value before limitation. If the OCV value exceeds the limits defined by GTUC10.MOC flag SFS.OCLR is set to 1.
0	[31:19]	r	**Reserved** Returns 0 if read; should be written with 0.

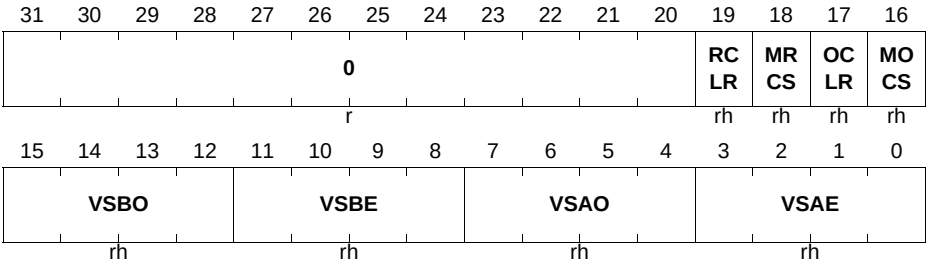
Note: The external rate / offset correction value is added to the limited rate / offset correction value.

SYNC Frame Status (SFS)

The maximum number of valid SYNC Frames in a communication cycle is 15.

SFS

SYNC Frame Status **(0120_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
VSAE	[3:0]	rh	**Valid SYNC Frames Channel A, even communication cycle** Holds the number of valid SYNC Frames received on channel A in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSAO	[7:4]	rh	**Valid SYNC Frames Channel A, odd communication cycle** Holds the number of valid SYNC Frames received on channel A in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSBE	[11:8]	rh	**Valid SYNC Frames Channel B, even communication cycle** Holds the number of valid SYNC Frames received on channel B in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.

Field	Bits	Type	Description
VSBO	[15:12]	rh	**Valid SYNC Frames Channel B, odd communication cycle** Holds the number of valid SYNC Frames received on channel B in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.
MOCS	16	rh	**Missing Offset Correction Signal** The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction signal valid 1_B Missing offset correction signal
OCLR	17	rh	**Offset Correction Limit Reached** The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by GTUC10.MOC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction below limit 1_B Offset correction limit reached
MRCS	18	rh	**Missing Rate Correction Signal** The Missing Rate Correction Flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction signal valid 1_B Missing rate correction signal
RCLR	19	rh	**Rate Correction Limit Reached** The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit.as defined by GTUC10.MRC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction below limit 1_B Rate correction limit reached
0	[31:20]	r	**Reserved** Returns 0 if read; should be written with 0.

Symbol Window and network idle time (NIT) Status (SWNIT)

Symbol window related status information. Updated by the Communication Controller at the end of the symbol window for each channel. During startup the status data is not updated.

Note: MTSA and MTSB may be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUC Configuration Register 1 (SUCC1) register is directly preceded by the unlock sequence as described in ***"Lock Register (LCK)" on Page 23-30****. This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B*

Updated by the Communication Controller for each channel at the end of the symbol window. When this bit is set to 1, also interrupt flag SIR.MTSA is set to 1. 0_B No MTS symbol received on channel A 1_B MTS symbol received on channel A
MTSB	7	rh	**MTS Received on Channel B** (vSS!ValidMTSB)[1)] Media Access Test symbol received on channel B during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. When this bit is set to 1, also interrupt flag SIR.MTSB is set to 1. 0_B No MTS symbol received on channel B 1_B MTS symbol received on channel B

Field	Bits	Type	Description
SENA	8	rh	**Syntax Error during network idle time (NIT) Channel A** (vSS!SyntaxErrorA) Updated by the Communication Controller channel A at the end of the NIT. 0_B No syntax error detected 1_B Syntax error during network idle time (NIT) detected on channel A
SBNA	9	rh	**Slot Boundary Violation during network idle time (NIT) Channel A** (vSS!BViolationA) Updated by the Communication Controller channel A at the end of the NIT. 0_B No slot boundary violation detected 1_B Slot boundary violation during network idle time (NIT) detected on channel A
SENB	10	rh	**Syntax Error during network idle time (NIT) Channel B** (vSS!SyntaxErrorB) Updated by the Communication Controller channel B at the end of the NIT. 0_B No syntax error detected 1_B Syntax error during network idle time (NIT) detected on channel B
SBNB	11	rh	**Slot Boundary Violation during network idle time (NIT) Channel B** (vSS!BViolationB) Updated by the Communication Controller channel B at the end of the NIT. 0_B No slot boundary violation detected 1_B Slot boundary violation during network idle time (NIT) detected on channel B
0	[31:12]	r	**Reserved** Returns 0 if read; should be written with 0.

1) MTSA and MTSB may also be changed outside “DEFAULT_CONFIG” or “CONFIG” state when the write to SUCC1 register is directly preceded by the unlock sequence as described in “Lock Register (LCK)”. This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B.

Aggregated Channel Status (ACS)

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception. The aggregated channel status also includes status data from the symbol window and the network idle time. The status data is updated (set) after each slot and aggregated until it is reset by the Host. During startup the status data is not updated. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

ACS
Aggregated Channel Status (0128$_H$) Reset Value: 0000 0000$_H$

CEDB	10	rwh	**Content Error Detected on Channel B** (vSS!ContentErrorB) One or more Frames with a content error were received on channel B in any static or dynamic slot during the observation period. 0_B No Frame with content error received 1_B Frame(s) with content error received on channel B

Field	Bits	Type	Description
CIB	11	rwh	**Communication Indicator Channel B** One or more valid Frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid Frame AND had any combination of either syntax error OR content error OR slot boundary violation. 0_B No valid Frame(s) received in slots containing any additional communication 1_B Valid Frame(s) received on channel B in slots containing any additional communication
SBVB	12	rwh	**Slot Boundary Violation on Channel B** (vSS!BViolationB) One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and network idle time NIT). 0_B No slot boundary violation observed 1_B Slot boundary violation(s) observed on channel B
0	[7:5], [31:13]	r	**Reserved** Returns 0 if read; should be written with 0.

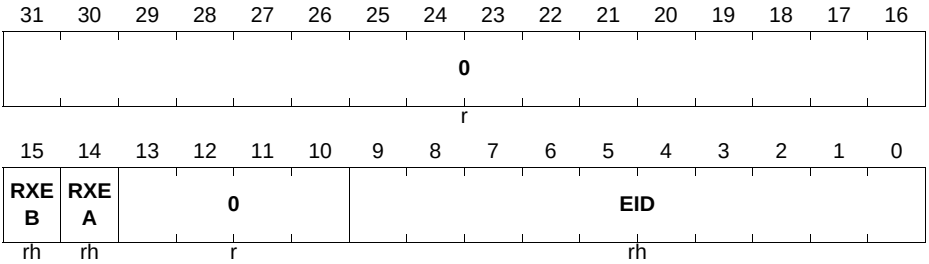
Note: The set condition of flags CIA and CIB is also fulfilled if there is only one single Frame in the slot and the slot boundary at the end of the slot is reached during the Frames channel idle recognition phase. When one of the flags SEDB, CEDB, CIB, SBVB changes from 0 to 1, service request flag EIR.EDB is set to 1.When one of the flags SEDA, CEDA, CIA, SBVA changes from 0 to 1, service request flag EIR.EDA is set to 1.

Even Sync ID [01…15] (ESIDnn)

Registers Even Sync ID nn (ESIDnn, nn=01-15) hold the Frame IDs of the SYNC Frames received in **even** communication cycles, sorted in ascending order, with register ESID01 holding the lowest received SYNC Frame ID. If the node itself transmits a SYNC Frame in an even communication cycle, register ESID01 holds the respective SYNC Frame ID as configured in Message Buffer 0 and the flags RXEA, RXEB are set. The value is updated during the network idle time (NIT) of each even communication cycle.

ESIDnn (nn = 01-15)
Even Sync ID Symbol Window nn

($012C_H$ + nn * 4) **Reset Value: 0000 0000_H**



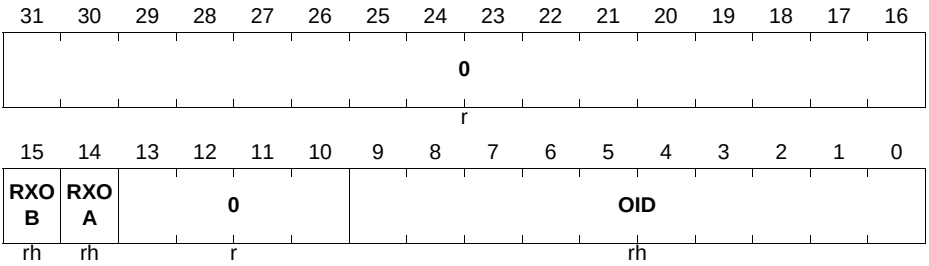
Field	Bits	Type	Description
EID	[9:0]	rh	**Even Sync ID** (vsSyncIDListA,B even) SYNC Frame ID even communication cycle.
RXEA	14	rh	**Received/Configured Even Sync ID on Channel A** Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0_B SYNC Frame not received on channel A / node configured to transmit SYNC Frames 1_B SYNC Frame received on channel A/ node not configured to transmit SYNC Frames
RXEB	15	rh	**Received/Configured Even Sync ID on Channel B** Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0_B SYNC Frame not received on channel B / node configured to transmit SYNC Frames 1_B SYNC Frame received on channel B / node not configured to transmit SYNC Frames

Field	Bits	Type	Description
0	[13:10], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Odd Sync ID [01…15] (OSIDnn)

he Odd Sync ID nn (OSIDnn, nn=01-15) hold the Frame IDs of the SYNC Frames received in **odd** communication cycles, sorted in ascending order, with register OSID01 holding the lowest received SYNC Frame ID. If the node itself transmits a SYNC Frame in an odd communication cycle, register OSID01 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXOA, RXOB are set. The value is updated during the network idle time (NIT) of each odd communication cycle.

OSIDnn (nn = 01-15)
Odd Sync ID Symbol Window nn ($016C_H$ + nn * 4) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OID	[9:0]	rh	**Odd Sync ID** (vsSyncIDListA,B odd) SYNC Frame ID even communication cycle.
RXOA	14	rh	**Received Odd Sync ID on Channel A** Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = OID (OSID1 only). 0_B SYNC Frame not received on channel A/ node configured to transmit SYNC Frames 1_B SYNC Frame received on channel A/ node not configured to transmit SYNC Frames
RXOB	15	rh	**Received Odd Sync ID on Channel B** Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = OID (OSID1 only) 0_B SYNC Frame not received on channel B/ node configured to transmit SYNC Frames 1_B SYNC Frame received on channel B/ node not configured to transmit SYNC Frames

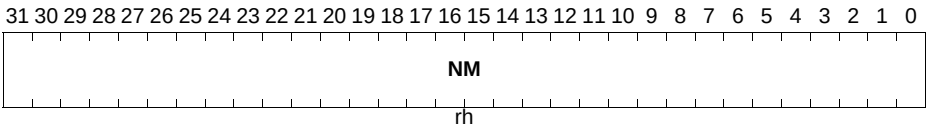
Field	Bits	Type	Description
0	[13:10], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Network Management Vector [1…3] (NMVx)

The three Network Management Vectors n (NMVx, x=1-3) registers hold the accrued Network Management (NM) vector (configurable 0 to 12 byte). The accrued Network Management (NM) vector is generated by the Communication Controller by bit-wise ORing each Network Management (NM) vector received (valid static Frames with PPI = 1) on each channel (see **"Network Management" on Page 23-213**). The Communication Controller updates the Network Management (NM) vector at the end of each communication cycle as long as the Communication Controller is either in "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state. NMVx-bytes exceeding the configured Network Management (NM) vector length are not valid.

NMVx (x = 1-3)
Network Management Vector x

($01AC_H$ + x * 4) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
NM	[31:0]	rh	**Network Management Vector**

Table 23-5 below shows the assignment of the received payload's data byte to the Network Management vector.

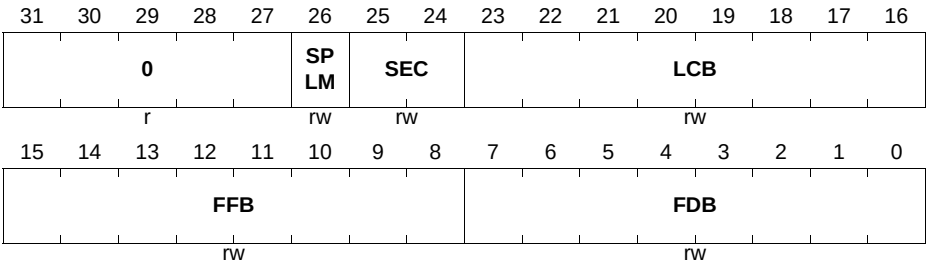
23.5.2.6 Message Buffer Control Registers

Message RAM Configuration (MRC)

The Message RAM Configuration register defines the number of Message Buffers assigned to the static segment, dynamic segment, and FIFO. The register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

MRC
Message RAM Configuration ((0300_H)) Reset Value: $0180\ 0000_H$



Field	Bits	Type	Description
FDB	[7:0]	rw	**First Dynamic Buffer** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H No group of Message Buffers exclusively for the static segment configured 01_H …$7F_H$ Message Buffers 0 to FDB-1 reserved for static segment 80_H …FF_H No dynamic Message Buffers configured
FFB	[15:8]	rw	**First Buffer of FIFO** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H …$7E_H$ Message Buffers from FFB to LCB assigned to the FIFO $7F_H$ All Message Buffers assigned to the FIFO 80_H …FF_H No Message Buffers assigned to the FIFO

Field	Bits	Type	Description
LCB	[23:16]	rw	**Last Configured Buffer** May be only modified in “DEFAULT_CONFIG” or “CONFIG” state. 01_H …$7F_H$ Number of Message Buffers is LCB + 1 80_H …FF_H No Message Buffer configured
SEC	[25:24]	rw	**Secure Buffers** Not evaluated when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For temporary unlocking see **“Host Handling of Errors” on Page 23-248**. 00_B Reconfiguration of Message Buffers enabled with numbers < FFB enabled. *Note: In nodes configured for SYNC Frame transmission or for single slot mode operation Message Buffer 0 (and if SPLM = 1, also Message Buffer 1) Reconfiguration of all Message Buffers is always locked* 01_B Reconfiguration of Message Buffers with numbers < FDB and with numbers ≥ FFB locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled 10_B Reconfiguration of all Message Buffers locked 11_B Reconfiguration of all Message Buffers locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled
SPLM	26	rw	**SYNC Frame Payload Multiplex** This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1). When this bit is set to 1 Message Buffers 0 and 1 are dedicated for SYNC Frame transmission with different payload data on channel A and B. When this bit is reset to 0, SYNC Frames are transmitted from Message Buffer 0 with the same payload data on both channels. Note that the channel filter configuration for Message Buffer 0 resp. Message Buffer 1 has to be chosen accordingly. 0_B Only Message Buffer 0 locked against reconfiguration 1_B Both Message Buffers 0 and 1 are locked against reconfiguration

Field	Bits	Type	Description
0	[31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

*Note: In case the node is configured as sync node (*SUCC1.*TXSY = 1) or for single slot mode operation (*SUCC1.*TSM = 1), Message Buffer 0 resp. 1 is reserved for SYNC Frames or single slot Frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation Message Buffer 0 resp. 1 is treated like all other Message Buffers.*

Table 23-6 Usage of the three Message Buffer Pointer

Message Buffer 0	⇓ Static Buffers		
Message Buffer 1			
	⇓ Static + Dynamic	⇐ **FDB**	
	Buffers		
…			FIFO configured: **FFB** > **FDB**
	⇓ FIFO	⇐ **FFB**	No FIFO configured: **FFB** ≥ 128
Message Buffer N-1			**LCB** ≥ **FDB**, **LCB** ≥ **FFB**
Message Buffer N		⇐ **LCB**	

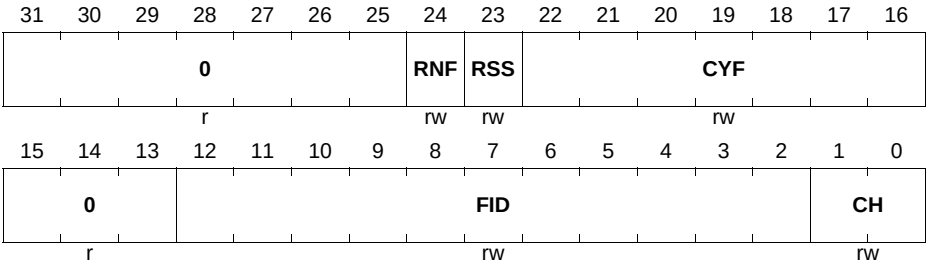
The programmer has to ensure that the configuration defined by FDB, FFB, and LCB is valid. **The Communication Controller does not check for erroneous configurations!**

Note: The maximum number of Header Sections is 128. This means a maximum of 128 Message Buffer can be configured. The maximum length of a Data Section is 254 byte. The length of the Data Section may be configured differently for each Message Buffer. For details see ***"Message RAM" on Page 23-239****.*
In case two or more Message Buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffers" or at the beginning of the "Static + Dynamic Buffers" section.
The payload length configured and the length of the Data Section need to be configured identically for all Message Buffers belonging to the FIFO via WRHS2.PLC and WRHS3.DP. When the Communication Controller is not in "DEFAULT_CONFIG" or "CONFIG" state reconfiguration of Message Buffers belonging to the FIFO is locked.

FIFO Rejection Filter (FRF)

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, Frame ID, and cycle count of the incoming Frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO. The FRF register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRF
FIFO Rejection Filter **(0304_H)** **Reset Value: $0180\ 0000_H$**



Field	Bits	Type	Description
CH	[1:0]	rw	**Channel Filter** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_B receive on both channels[1)] 01_B receive only on channel B 10_B receive only on channel A 11_B no reception
FID	[12:2]	rw	**Frame ID Filter** Determines the Frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding Frame ID filter bits are ignored, which results in further rejected Frame IDs. When FRFM.MFID is zero, a Frame ID filter value of zero means that no Frame ID is rejected. 000_H …$7FF_H$ Frame ID filter values

Field	Bits	Type	Description
CYF	[22:16]	rw	**Cycle Counter Filter** The 7-bit cycle counter filter determines the cycle set to which Frame ID and channel rejection filter are applied. In cycles **not** belonging to the cycle set specified by CYF, all Frames are rejected. For details about the configuration of the cycle counter filter see **“Cycle Counter Filtering” on Page 23-215**. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only.
RSS	23	rw	**Reject in Static Segment** If this bit is set, the FIFO is used only be used in dynamic segment. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B FIFO also used in static segment 1_B Reject messages for static segment
RNF	24	rw	**Reject NULL Frames** If this bit is set, received NULL Frames are not stored in the FIFO. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B NULL Frames are stored in the FIFO 1_B Reject all NULL Frames
0	[15:13], [31:25]	r	**Reserved** Returns 0 if read; should be written with 0.

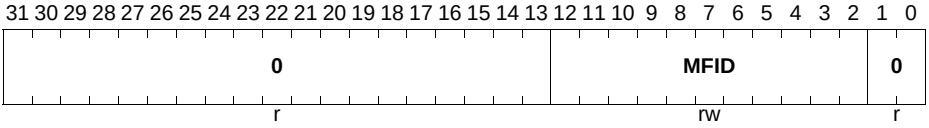
1) If reception on both channels is configured, also in static segment always both Frames (from channel A and B) are stored in the FIFO, even if they are identical.

FIFO Rejection Filter Mask (FRFM)

The FIFO Rejection Filter Mask specifies which of the corresponding Frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the corresponding bit in the FRF register will not be considered for rejection filtering. The FRFM register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRFM

FIFO Rejection Filter Mask **(0308_H)** **Reset Value: $0000\ 0000_H$**

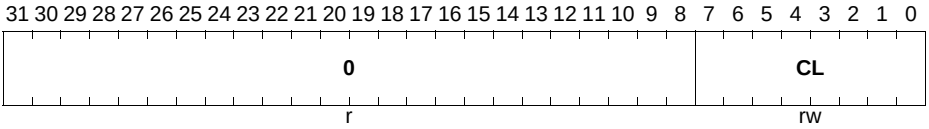


Field	Bits	Type	Description
MFID	[12:2]	rw	**Mask Frame ID Filter** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B Corresponding Frame ID filter bit is used for rejection filtering. 1_B Ignore corresponding Frame ID filter bit.
0	[1:0], [31:13]	r	**Reserved** Returns 0 if read; should be written with 0.

FIFO Critical Level (FCL)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

FCL
FIFO Critical Level **($030C_H$)** **Reset Value: $0000\ 0080_H$**



Field	Bits	Type	Description
CL	[7:0]	rw	**Critical Level** When the receive FIFO fill level FSR.RFFL is equal or greater than the critical level configured by CL, the receive FIFO critical level flag FSR.RFCL is set. If CL is programmed to values > 128, bit FSR.RFCL is never set. When FSR.RFCL changes from 0 to 1 bit **SIR.RFCL** is set to 1, and if enabled, a service request is generated.
0	[31:8]	r	**Reserved** Returns 0 if read; should be written with 0.

23.5.2.7 Message Buffer Status Registers

Message Handler Status (MHDS)

The Message Handler Status register gives the Host access to the current state of the Message Handler. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register. If one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1 EIR.EERR is set.

MHDS
Message Handler Status **(0310_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				MBU				0			MBT				
r				rh				r				rh			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				FMB				CRAM	MFMB	FMBD	ETBF2	ETBF1	EMR	EOBF	EIBF
r				rh				rh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

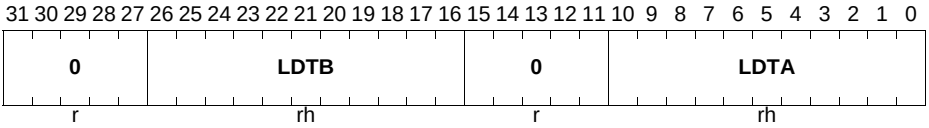
Field	Bits	Type	Description
EIBF	0	rwh	**ECC Error Input Buffer RAM 1,2** 0_B No error 1_B Error occurred when reading Input Buffer RAM 1 or Input Buffer RAM 2
EOBF	1	rwh	**ECC Error Output Buffer RAM 1,2** 0_B No error 1_B Error occurred when reading Output Buffer RAM 1 or Output Buffer RAM 2
EMR	2	rwh	**ECC Error Message RAM** 0_B No error 1_B Error occurred when reading the Message RAM
ETBF1	3	rwh	**ECC Error Transient Buffer RAM A** 0_B No error 1_B Error occurred when reading Transient Buffer RAM A
ETBF2	4	rwh	**ECC Error Transient Buffer RAM B** 0_B No error 1_B Error occurred when reading Transient Buffer RAM B

Field	Bits	Type	Description
FMBD	5	rwh	**Faulty Message Buffer Detected** 0_B No faulty Message Buffer 1_B Message Buffer referenced by MHDS.FMB holds faulty data due to a ECC error
MFMB	6	rwh	**Multiple Faulty Message Buffers detected** 0_B No additional faulty Message Buffer 1_B Another faulty Message Buffer was detected while flag MHDS.FMBD is set
CRAM	7	rh	**Clear all internal RAM's** Signals that execution of the CHI command CLEAR_RAMS is ongoing (all bits of all internal RAM blocks are written to 0). The bit is set by CHI command CLEAR_RAMS. 0_B No execution of the CHI command CLEAR_RAMS 1_B Execution of the CHI command CLEAR_RAMS ongoing
FMB	[14:8]	rh	**Faulty Message Buffer** ECC error occurred when reading from the Message Buffer or when transferring data from Input Buffer or Transient Buffer A or Transient Buffer B to the Message Buffer referenced by MHDS.FMB. Value only valid when one of the flags MHDS.EIBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2, and flag MHDS.FMBD is set. Updated only after the Host has reset flag MHDS.FMBD.
MBT	[22:16]	rh	**Message Buffer Transmitted** Number of last successfully transmitted Message Buffer. If the Message Buffer is configured for single-shot mode, the respective TXR flag in the Transmission Request Registers TXRQ1 to TXRQ4 was reset. MBT is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
MBU	[30:24]	rh	**Message Buffer Updated** Number of Message Buffer that was updated last. For this Message Buffer the respective NDn (n = 0-31) to NDn (n = 96-127)and / or MBCn (n = 0-31) to MBCn (n = 96-127) flag in the New Data Registers NDAT1 to NDAT4 and the Message Buffer Status Changed MBSC1 to MBSC4 registers are also set. MBU is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
0	15, 23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

Last Dynamic Transmit Slot (LDTS)

The Last Dynamic Transmit Slot Register stores the Slot Counter value at the time of the last Frame transmission in the dynamic segment. This register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

LDTS
Last Dynamic Transmit Slot **(0314_H)** **Reset Value: $0000\ 0000_H$**

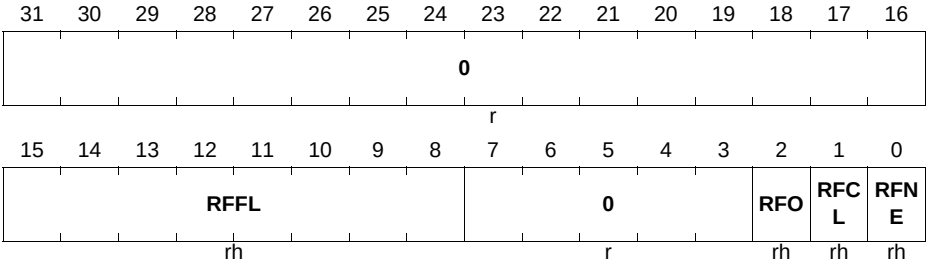


Field	Bits	Type	Description
LDTA	[10:0]	rh	**Last Dynamic Transmission Channel A** Value of (vSlotCounter[A]) at the time of the last Frame transmission on channel A in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
LDTB	[26:16]	rh	**Last Dynamic Transmission Channel B** Value of (vSlotCounter[B]) at the time of the last Frame transmission on channel B in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

FIFO Status Register (FSR)

The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

FSR
FIFO Status Register **(0318_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RFNE	0	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame (data or NULL Frame depending on rejection mask) was stored in the FIFO. In addition, service request flag SIR.RFNE is set. The bit is reset after the Host has read all message from the FIFO. 0_B Receive FIFO is empty 1_B Receive FIFO is not empty
RFCL	1	rh	**Receive FIFO Critical Level** This flag is set when the receive FIFO fill level RFFL is equal or greater than the critical level as configured by FCL.CL. The flag is cleared by the Communication Controller as soon as RFFL drops below FCL.CL. When RFCL changes from 0 to 1 bit SIR.RFCL is set to 1, and if enabled, an service request is generated. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached

Field	Bits	Type	Description
RFO	2	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, service request flag EIR.RFO is set.The flag is cleared by the next FIFO read access issued by the Host. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected
RFFL	[15:8]	rh	**Receive FIFO Fill Level** Number of FIFO buffers filled up with new data not yet read by the Host. Maximum value is 128.
0	[7:3], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Message Handler Constraints Flags (MHDF)

Some constraints exist for the Message Handler regarding f_{CLC_ERAY} frequency, Message RAM configuration, and FlexRay™ bus traffic. To simplify software development, constraints violations are reported by setting flags in the MHDF. The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state. A flag is cleared by setting the corresponding bit position. Clearing has no effect on the flag. If any flag in MHDFL is set, interrupt flag EIR.MHF is set.

MHDF

Message Handler Constraints Flags (031C$_H$) **Reset Value: 0000 0000$_H$**

r							rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
SNUA	0	rwh	**Status Not Updated Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer’s status MBS with respect to channel A. 0_B No overload condition occurred when updating MBS for channel A 1_B MBS for channel A not updated
SNUB	1	rwh	**Status Not Updated Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer’s status MBS with respect to channel B. 0_B No overload condition occurred when updating MBS for channel B 1_B MBS for channel B not updated

Field	Bits	Type	Description
FNFA	2	rwh	**Find Sequence Not Finished Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel A. 0_B No find sequence not finished for channel A 1_B Find sequence not finished for channel A
FNFB	3	rwh	**Find Sequence Not Finished Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel B. 0_B No find sequence not finished for channel B 1_B Find sequence not finished for channel B
TBFA	4	rwh	**Transient Buffer Access Failure A** This flag is set by the Communication Controller when a read or write access to Transient Buffer A requested by PRT A could not complete within the available time. 0_B No TBF A access failure 1_B TBF A access failure
TBFB	5	rwh	**Transient Buffer Access Failure B** This flag is set by the Communication Controller when a read or write access to Transient Buffer B requested by PRT B could not complete within the available time. 0_B No Transient Buffer B access failure 1_B Transient Buffer B access failure
TNSA	6	rwh	**Transmission Not Started Channel A** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot. 0_B No transmission not started on channel A 1_B Transmission not started on channel A
TNSB	7	rwh	**Transmission Not Started Channel B** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot. 0_B No transmission not started on channel B 1_B Transmission not started on channel B

Field	Bits	Type	Description
WAHP	8	rwh	**Write Attempt to Header Partition** Outside “DEFAULT_CONFIG” and “CONFIG” state this flag is set by the Communication Controller when the message handler tries to write message data into the Header Partition of the Message RAM due to faulty configuration of a Message Buffer. The write attempt is not executed, to protect the Header Partition from unintended write accesses. 0_B No write attempt to Header Partition 1_B Write attempt to Header Partition
0	[31:9]	r	**Reserved** Returns 0 if read; should be written with 0.

Transmission Request 1 (TXRQ1)

This register reflect the state of the TXR flags of the configured Message Buffers 0 to 31. The flags are evaluated for transmit buffers only. If the number of configured Message Buffers is less than 31, the remaining TXRn flags have no meaning and are read as 0.

TXRQ1

Field	Bits	Type	Description
MBCn (n = 64-95)	n - 64	rh	**Message Buffer Status Changed n (n = 64-95)** An MBC flags is set whenever the Message Handler changes on of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the Header Section (see **“Message Buffer Status (MBS)” on Page 23-176**) of the respective Message Buffer 64 to Message Buffer 95. The flags are reset when the Header Section of the Message Buffer is reconfigured or when it has been transferred to the Output Buffer.

Message Buffer Status Changed 4 (MBSC4)

This register reflect the state of the MBC flags of all configured Message Buffers. If the number of configured Message Buffers is less than 127, the remaining MBCn flags have no meaning. The register is reset when the communication controller leaves “CONFIG” state or enters “STARTUP” state.

MBSC4

Message Buffer Status Changed 4 ($034C_H$) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
MBCn (n = 96-127)	n - 96	rh	**Message Buffer Status Changed n (n = 96-127)** An MBC flags is set whenever the Message Handler changes on of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the Header Section (see **“Message Buffer Status (MBS)” on Page 23-176**) of the respective Message Buffer 96 to Message Buffer 127. The flags are reset when the Header Section of the Message Buffer is reconfigured or when it has been transferred to the Output Buffer.

23.5.2.8 Identification Registers

Core Release Register (CREL)

This register contains bit fields about the ERAY module identification. It is read only.

CREL
Core Release Register **($03F0_H$)** **Reset Value: $XXXX\ XXXX_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REL				STEP				SUB STEP				YEAR				MON								DAY							
r				r				r				r				r								r							

Field	Bits	Type	Description
DAY	[7:0]	r	**Design Time Stamp, Day** Two digits, BCD-coded.
MON	[15:8]	r	**Design Time Stamp, Month** Two digits, BCD-coded.
YEAR	[19:16]	r	**Design Time Stamp, Year** One digit, BCD-coded.
SUBSTEP	[23:20]	r	**Sub-Step of Core Release** One digits, BCD-coded. 0_H Alpha, pre-Beta, pre-Beta-update, pre-Beta2, pre-Beta2-update, Beta, Beta2, Revision 1.0.0 1_H Beta_ct, Beta-ct-fix1, Revision 1.0.1 2_H Revision1.0RC1,Beta-ct-fix2, REVISION 1.0RC1
STEP	[27:24]	r	**Step of Core Release** One digits, BCD-coded. 0_H Revision 1.0.0 1_H Alpha 2_H pre-Beta 3_H pre-Beta-update 4_H pre-Beta2 5_H pre-Beta2-update 6_H Beta 7_H Beta2

Field	Bits	Type	Description
REL	[31:28]	r	**Core Release** One digit, BCD-coded. 0_B alpha…beta2ct 1_B Revision 1.0

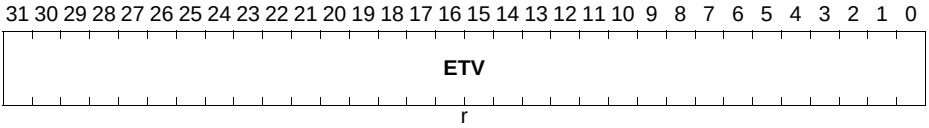
Table 23-7 Coding of releases

Release	Step	Sub-Step	Name	Release Date
0	1	0	Alpha	
0	2	0	pre-Beta	
0	3	0	pre-Beta-update	
0	4	0	pre-Beta2	
0	5	0	pre-Beta2-update	
0	6	0	Beta	
0	6	1	Beta-ct-fix1	14.10.2005
0	6	2	Beta-ct-fix2	14.12.2005
0	7	0	Beta2	03.02.2006
0	7	1	Beta2ct	24.03.2006
0	7	2	Revision 1.0RC1	07.04.2006
1	0	0	Release 1.0.0	19.05.2006
1	0	1	Release 1.0.1	2006
1	0	2	Release 1.0.2	31.10.2007

Endian Register (ENDN)

This register may be used to check, if the data of the E-Ray is handled by a host with the correct endian format. It is read only.

ENDN
Endian Register **($003F4_H$)** **Reset Value: $8765\ 4321_H$**



Field	Bits	Type	Description
ETV	[31:0]	r	**Endianness Test Value** The endianness test value.

23.5.2.9 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the Header and Data Sections to be transferred to the selected Message Buffer in the Message RAM. It is used to configure the Message Buffers in the Message RAM and to update the Data Sections of transmit buffers.

When updating the Header Section of a Message Buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in **“Message Buffer Status (MBS)” on Page 23-176** is automatically reset to zero.

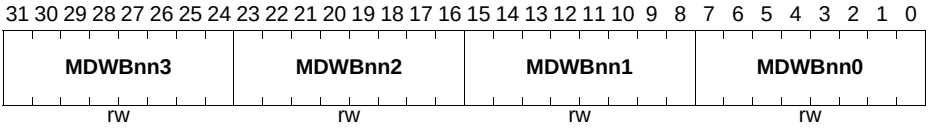
The Header Sections of Message Buffers belonging to the receive FIFO can only be (re)configured when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For those Message Buffers only the payload length configured and the data pointer need to be configured via WRHS2.PLC and WRHS2.DP. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

The data transfer between Input Buffer (IBF) and Message RAM is described in detail in **“Data Transfer from Input Buffer to Message RAM” on Page 23-224**.

Write Data Section [01 - 64] (WRDSnn (nn = 01-64))

The Write Data Section (WRDSnn, nn = 01-64) holds the data words to be transferred to the Data Section of the addressed Message Buffer. The data words (DW_n) are written to the Message RAM in transmission order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the payload length configured by WRHS2.PLC).

WRDSnn (nn = 01-64)
Write Data Section nn **($03FC_H$ + nn * 4)** **Reset Value: $0000\ 0000_H$**



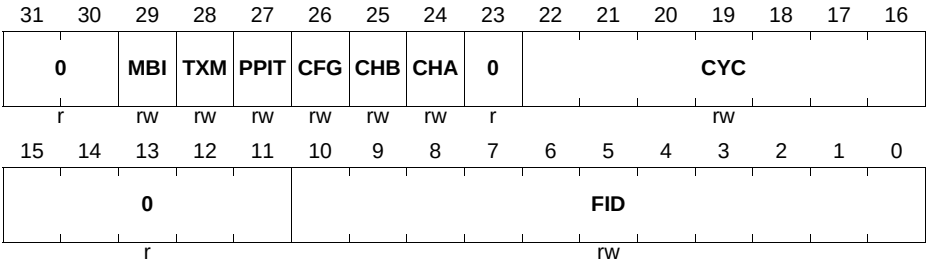
Field	Bits	Type	Description
MDWB0	[7:0]	rw	**32-Bit Word nn, Byte 0**
MDWB1	[15:8]	rw	**32-Bit Word nn, Byte 1**
MDWB2	[23:16]	rw	**32-Bit Word nn, Byte 2**
MDWB3	[31:24]	rw	**32-Bit Word nn, Byte 3**

Note: 16-bit Word 127 is located on WRDS64.MDW. In this case WRDS64.MDW is unused (no valid data). The Input Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMS.

Note: When writing to the WRDSnn (nn = 01-64), each 32-bit word has to be filled up by one 32-bit access OR two consecutive 16-bit accesses OR four consecutive 8-bit accesses before the transfer from the Input Buffer to the Message RAM is started by writing the number of the target Message Buffer in the Message RAM to the Input Buffer Command Request register. If a 32-bit word of the Input Buffer has been filled with less then two consecutive 16-bit accesses OR four consecutive 8-bit accesses (less then 32-bit), random data is transferred into the Input buffer for every not written 16-bit or 8-bit of a 32-bit word.

Write Header Section 1 (WRHS1)

WRHS1
Write Header Section 1 **(0500_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FID	[10:0]	rw	**Frame ID** Frame ID of the selected Message Buffer. The Frame ID defines the slot number for transmission / reception of the respective message. Message Buffers with Frame ID = 0 are considered as not valid.
CYC	[22:16]	rw	**Cycle Code** The 7-bit cycle code determines the cycle set used for cycle counter filtering. For details about the configuration of the cycle code see **Section 23.6.7.3**.
CHA	24	rw	**Channel Filter Control A** The channel filtering field A associated with the buffer serves of channel A as a filter for receive buffers, and as a control field for transmit buffers
CHB	25	rw	**Channel Filter Control B** The channel filtering field B associated with the buffer serves of channel B as a filter for receive buffers, and as a control field for transmit buffers
CFG	26	rw	**Message Buffer Direction Configuration Bit** This bit is used to configure the corresponding buffer as a transmit buffer or as a receive buffer. For Message Buffers belonging to the receive FIFO the bit is not evaluated. 0_B The corresponding buffer is configured as Receive Buffer 1_B The corresponding buffer is configured as Transmit Buffer

Field	Bits	Type	Description
PPIT	27	rw	**Payload Preamble Indicator Transmit** This bit is used to control the state of the Payload Preamble Indicator in transmit Frames. If the bit is set in a static Message Buffer, the respective Message Buffer holds Network Management information. If the bit is set in a dynamic Message Buffer the first two byte of the Payload Segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay™ Frames is not supported by the E-Ray module, but can be done by the Host. 0_B Payload Preamble Indicator not set 1_B Payload Preamble Indicator set
TXM	28	rw	**Transmission Mode** This bit is used to select the transmission mode (see **“Transmit Buffers” on Page 23-217**). 0_B Continuous mode 1_B Single-shot mode
MBI	29	rw	**Message Buffer Service Request** This bit enables the receive / transmit service request for the corresponding Message Buffer. After a dedicated receive buffer has been updated by the Message Handler, flag SIR.RXI and /or SIR.MBSI in the Status Service Request register are set. After a transmission has completed flag SIR.TXI is set. 0_B The corresponding Message Buffer service request is disabled 1_B The corresponding Message Buffer service request is enabled
0	[15:11], 23, [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The Input Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMS. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required.

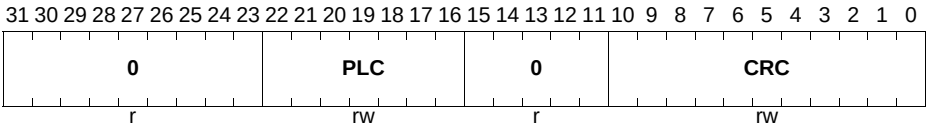
Table 23-8 Channel Filter Control Bits

CHA	CHB	Transmit Buffer transmit Frame on	Receive Buffer store Frame received from
1[1)]	1[1)]	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

1) If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Write Header Section 2 (WRHS2)

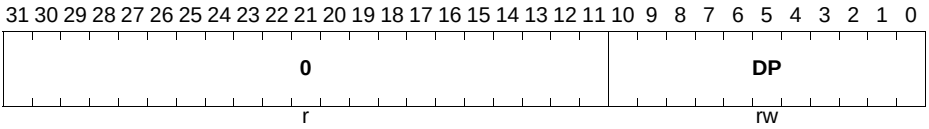
WRHS2
Write Header Section 2 **(0504_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CRC	[10:0]	rw	**Header CRC** (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required Transmit Buffer: Header CRC calculated and configured by the Host. For calculation of the Header CRC the payload length of the Frame send on the bus has to be considered. In static segment the payload length of all Frames is configured by MHDC.SFDL.
PLC	[22:16]	rw	**Payload Length Configured** Length of Data Section (number of 2-byte words) as configured by the Host. During static segment the static Frame payload length as configured by MHDC.SFDL in the MHD Configuration Register defines the payload length for all static Frames. If the payload length configured by PLC is shorter than this value padding byte are inserted to ensure that Frames have proper physical length. The padding pattern is logical zero.
0	[15:11], [31:23]	r	**Reserved** Returns 0 if read; should be written with 0.

Write Header Section 3 (WRHS3)

WRHS3
Write Header Section 3 **(0508_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DP	[10:0]	rw	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
0	[31:11]	r	**Reserved** Returns 0 if read; should be written with 0.

Input Buffer Command Mask (IBCM)

Configures how the Message Buffer in the Message RAM selected by the Input Buffer Command Request register IBCR is updated. If IBF Host and IBF Shadow are swapped, also masked bits IBCM.LHSH, IBCM.LDSH, and IBCM.STXRH are swapped with bits IBCM.LHSS, IBCM.LDSS, and IBCM.STXRS to keep them attached to the respective Input Buffer transfer.

IBCM
Input Buffer Command Mask **(0510_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0													STXRS	LDSS	LHSS
r													rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0													STXRH	LDSH	LHSH
r													rwh	rwh	rwh

Field	Bits	Type	Description
LHSH	0	rwh	**Load Header Section Host** 0_B Header Section is not updated 1_B Header Section selected for transfer from Input Buffer to the Message RAM
LDSH	1	rwh	**Load Data Section Host** 0_B Data Section is not updated 1_B Data Section selected for transfer from Input Buffer to the Message RAM
STXRH	2	rwh	**Set Transmission Request Host** If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) are evaluated for transmit buffer only. 0_B Reset Transmission Request flag 1_B Set Transmission Request flag, transmit buffer released for transmission

Field	Bits	Type	Description
LHSS	16	rh	**Load Header Section Shadow** 0_B Header Section is not updated 1_B Header Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)
LDSS	17	rh	**Load Data Section Shadow** 0_B Data Section is not updated 1_B Data Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)
STXRS	18	rh	**Transmission Request Shadow** If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) are evaluated for transmit buffer only. 0_B Reset Transmission Request flag 1_B Set Transmission Request flag, transmit buffer released for transmission (operation is ongoing of finalized)
0	[15:3], [31:19]	r	**Reserved** Returns 0 if read; should be written with 0.

Input Buffer Command Request (IBCR)

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register, IBF Host and IBF Shadow are swapped. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped (see also **“Data Transfer from Input Buffer to Message RAM” on Page 23-224**).

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0. IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped. Any write access to an Input Buffer register while both IBSYS and IBSYH are set will cause the error flag EIR.IIBA to be set. In this case the Input Buffer will not be changed.

IBCR
Input Buffer Command Request (0514_H) Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IBSYS	0								IBRS						
rh	r								rh						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IBSYH	0								IBRH						
rh	r								rwh						

Field	Bits	Type	Description
IBRH	[6:0]	rwh	**Input Buffer Request Host** Selects the target Message Buffer in the Message RAM for data transfer from Input Buffer. Valid values are 00_H to $7F_H$ (0…127).

Field	Bits	Type	Description
IBSYH	15	rh	**Input Buffer Busy Host** Set to 1 by writing IBRH while IBSYS is still 1. After the ongoing transfer between IBF Shadow and the Message RAM has completed, the IBSYH is set back to 0. 0_B No request pending 1_B Request while transfer between IBF Shadow and Message RAM in progress
IBRS	[22:16]	rh	**Input Buffer Request Shadow** Number of the target Message Buffer actually updated/lately updated. Valid values are 00_H to $7F_H$ (0…127).
IBSYS	31	rh	**Input Buffer Busy Shadow** Set to 1 after writing IBRH. When the transfer between IBF Shadow and the Message RAM has completed, IBSYS is set back to 0. 0_B Transfer between IBF Shadow and Message RAM completed 1_B Transfer between IBF Shadow and Message RAM in progress
0	[14:7], [30:23]	r	**Reserved** Returns 0 if read; should be written with 0.

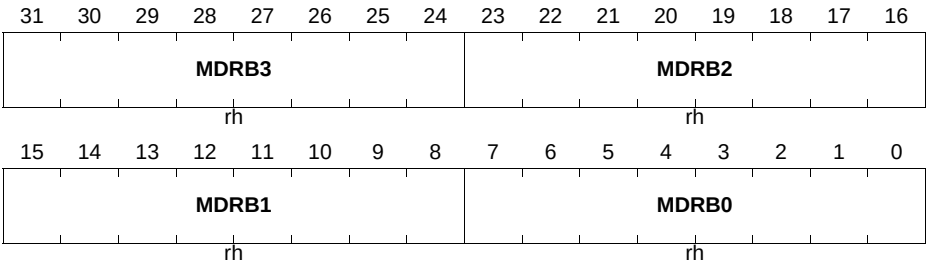
23.5.2.10 Output Buffer

Double buffer structure consisting of Output Buffer Host and Output Buffer Shadow. Used to read out Message Buffers from the Message RAM. While the Host can read from Output Buffer Host, the Message Handler transfers the selected Message Buffer from Message RAM to the respective Output Buffer Shadow. The data transfer between Message RAM and Output Buffer (OBF) is described in **"Data Transfer from Message RAM to Output Buffer" on Page 23-226**.

Read Data Section [1…64] (RDDSn)

The Read Data Section nn (RDDSnn, nn = 01-64) holds the data words read from the Data Section of the addressed Message Buffer. The data words are read from the Message RAM in reception order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the Payload Length).

RDDSnn (nn = 01-64)
Read Data Section nn **($05FC_H$ + nn * 4)** **Reset Value: $0000\ 0000_H$**



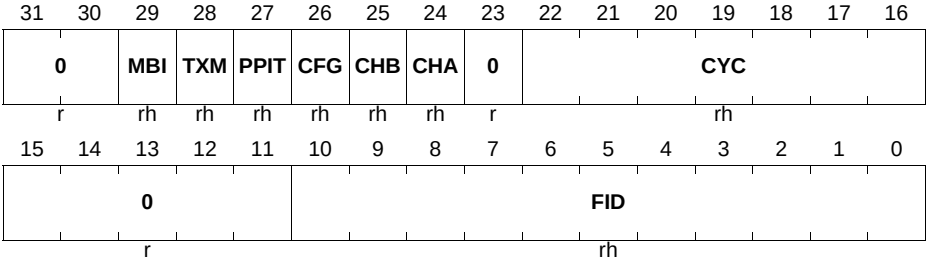
Field	Bits	Type	Description
MDRB0	[7:0]	rh	**32-Bit Word nn, Byte 0**
MDRB1	[15:8]	rh	**32-Bit Word nn, Byte 1**
MDRB2	[23:16]	rh	**32-Bit Word nn, Byte 2**
MDRB3	[31:24]	rh	**32-Bit Word nn, Byte 3**

Note: DW127 is located on RDDS64.MDW. In this case RDDS64.MDW is unused (no valid data). The Output Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMS.

Read Header Section 1 (RDHS1)

Values as configured by the Host via WRHS1 Register:

RDHS1
Read Header Section 1 **(0700_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FID	[10:0]	rh	**Frame ID**
CYC	[22:16]	rh	**Cycle Code**
CHA	24	rh	**Channel Filter Control A**
CHB	25	rh	**Channel Filter Control B**
CFG	26	rh	**Message Buffer Direction Configuration Bit**
PPIT	27	rh	**Payload Preamble Indicator Transmit**
TXM	28	rh	**Transmission Mode**
MBI	29	rh	**Message Buffer Service Request**
0	[15:11], 23, [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case that the Message Buffer read from the Message RAM belongs to the receive FIFO, FID holds the received Frame ID, while CYC, CHA, CHB, CFG, PPIT, TXM, and MBI are reset to zero.

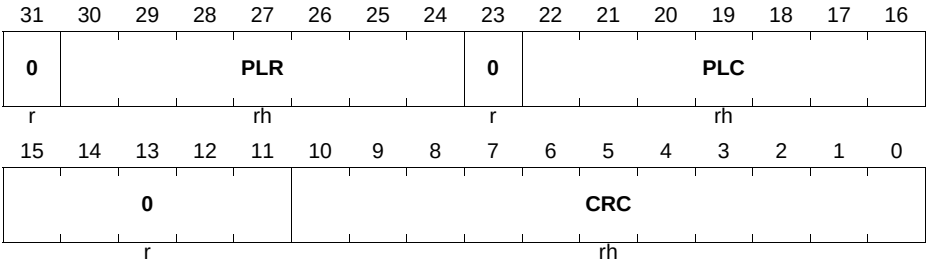
Table 23-9 Channel Filter Control Bits

CHA	CHB	Transmit Buffer transmit Frame on	Receive Buffer store Frame received from
1[1)]	1[1)]	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

1) If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Read Header Section 2 (RDHS2)

RDHS2
Read Header Section 2 **(0704_H)** **Reset Value: $0000\ 0000_H$**



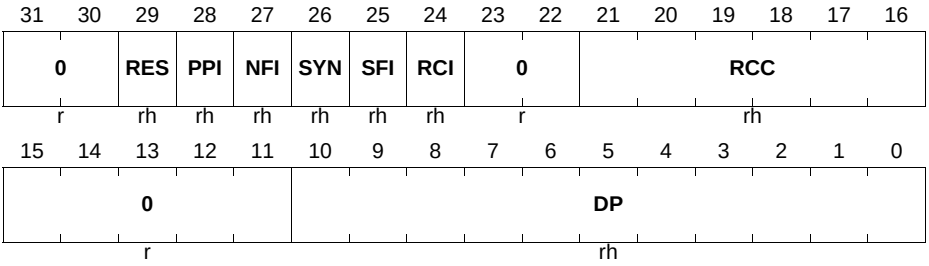
Field	Bits	Type	Description
CRC	[10:0]	rh	**Header CRC** (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required. Header CRC updated from receive Data Frames. Transmit Buffer: Header CRC calculated and configured by the Host
PLC	[22:16]	rh	**Payload Length Configured** Length of Data Section (number of 2-byte words) as configured by the Host.

Field	Bits	Type	Description
PLR	[30:24]	rh	**Payload Length Received** (vRF!Header!Length) Payload length value updated from received Data Frame (exception: if Message Buffer belongs to the receive FIFO PLR is also updated from received NULL Frames). When a message is stored into a Message Buffer the following behavior with respect to payload length received and payload length configured is implemented: • **PLR > PLC:** The payload data stored in the Message Buffer is truncated to the payload length configured for even PLC or else truncated to PLC + 1. • **PLR ≤ PLC:** The received payload data is stored into the Message Buffers Data Section. The remaining data bytes of the Data Section as configured by PLC are filled with undefined data. • **PLR = 0:** The Message Buffer's Data Section is filled with undefined data. • **PLC = 0:** Message Buffer has no Data Section configured. No data is stored into the Message Buffer's Data Section.
0	[15:11], 23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The Message RAM is organized in 4-byte words. When received data is stored into a Message Buffer's Data Section, the number of 2-byte data words written into the Message Buffer is PLC rounded to the next even value. PLC should be configured identical for all Message Buffers belonging to the receive FIFO. Header 2 is updated from Data Frames only.

Read Header Section 3 (RDHS3)

RDHS3
Read Header Section 3 **(0708_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DP	[10:0]	rh	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
RCC	[21:16]	rh	**Receive Cycle Count** (vRF!Header!CycleCount) Cycle counter value updated from received Data Frame.
RCI	24	rh	**Received on Channel Indicator** (vSS!Channel) Indicates the channel from which the received Data Frame was taken to update the respective receive buffer. 0_B Frame received on channel B 1_B Frame received on channel A
SFI	25	rh	**Startup Frame Indicator** (vRF!Header!SuFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0_B The received Frame is not a startup Frame 1_B The received Frame is a startup Frame
SYN	26	rh	**SYNC Frame Indicator** (vRF!Header!SyFIndicator) A SYNC Frame is marked by the SYNC Frame indicator. 0_B The received Frame is not a SYNC Frame 1_B The received Frame is a SYNC Frame
NFI	27	rh	**NULL Frame Indicator** (vRF!Header!NFIndicator) Is set to 1 after storage of the first received Data Frame. 0_B Up to now no Data Frame has been stored into the respective Message Buffer 1_B At least one Data Frame has been stored into the respective Message Buffer

Field	Bits	Type	Description
PPI	28	rh	**Payload Preamble Indicator** (vRF!Header!PPIndicator) The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. 0_B The Payload Segment of the received Frame does not contain a Network Management vector nor a message ID 1_B Static segment: Network Management vector in the first part of the payload Dynamic segment: Message ID in the first part of the payload
RES	29	rh	**Reserved Bit** (vRF!Header!Reserved) Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.
0	[15:11], [23:22], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: Header 3 is updated from Data Frames only.

Message Buffer Status (MBS)

The Message Buffer status is updated by the Communication Controller with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the Message Buffer. The flags are updated only when the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state. If only one channel (A or B) is assigned to a Message Buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a Message Buffer, the channel-specific status flags of both channels are updated. The Message Buffer status is updated only when the slot counter reached the configured Frame ID and when the cycle counter filter matched. When the Host updates a Message Buffer via Input Buffer, all MBS flags are reset to zero independent of which IBCM bits are set or not. For details about receive / transmit filtering see **“Filtering and Masking” on Page 23-213**, **“Transmit Process” on Page 23-217**, and **“Receive Process” on Page 23-220**.

Whenever the Message Handler changes one of the flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB the respective Message Buffer’s MBC flag in registers MBSC1 to MBSC4 is set

MBS

Field	Bits	Type	Description
VFRA	0	rh	**Valid Frame Received on Channel A** (vSS!ValidFrameA) A valid Frame indication is set if a valid Frame was received on channel A. 0_B No valid Frame received on channel A 1_B Valid Frame received on channel A
VFRB	1	rh	**Valid Frame Received on Channel B** (vSS!ValidFrameB) A valid Frame indication is set if a valid Frame was received on channel B. 0_B No valid Frame received on channel B 1_B Valid Frame received on channel B

Field	Bits	Type	Description
SEOA	2	rh	**Syntax Error Observed on Channel A** (vSS!SyntaxErrorA) A syntax error was observed in the assigned slot on channel A. 0_B No syntax error observed on channel A 1_B Syntax error observed on channel A
SEOB	3	rh	**Syntax Error Observed on Channel B** (vSS!SyntaxErrorB) A syntax error was observed in the assigned slot on channel B. 0_B No syntax error observed on channel B 1_B Syntax error observed on channel B
CEOA	4	rh	**Content Error Observed on Channel A** (vSS!ContentErrorA) A content error was observed in the assigned slot on channel A. 0_B No content error observed on channel A 1_B Content error observed on channel A
CEOB	5	rh	**Content Error Observed on Channel B** (vSS!ContentErrorB) A content error was observed in the assigned slot on channel B. 0_B No content error observed on channel B 1_B Content error observed on channel B
SVOA	6	rh	**Slot Boundary Violation Observed on Channel A** (vSS!BViolationA) A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A. 0_B No slot boundary violation observed on channel A 1_B Slot boundary violation observed on channel A
SVOB	7	rh	**Slot Boundary Violation Observed on Channel B** (vSS!BViolationB) A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B. 0_B No slot boundary violation observed on channel B 1_B Slot boundary violation observed on channel B
TCIA	8	rh	**Transmission Conflict Indication Channel A** (vSS!TxConflictA) A transmission conflict indication is set if a transmission conflict has occurred on channel A. 0_B No transmission conflict occurred on channel A 1_B Transmission conflict occurred on channel A

Field	Bits	Type	Description
TCIB	9	rh	**Transmission Conflict Indication Channel B** (vSS!TxConflictB) A transmission conflict indication is set if a transmission conflict has occurred on channel B. 0_B No transmission conflict occurred on channel B 1_B Transmission conflict occurred on channel B
ESA	10	rh	**Empty Slot Channel A** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel A 1_B No bus activity detected in the assigned slot on channel A
ESB	11	rh	**Empty Slot Channel B** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel B 1_B No bus activity detected in the assigned slot on channel B
MLST	12	rh	**Message Lost** The flag is set in case the Host did not read the message before the Message Buffer was updated from a received Data Frame. Not affected by reception of NULL Frames except for Message Buffers belonging to the receive FIFO. The flag is reset by a Host write to the Message Buffer via IBF or when a new message is stored into the Message Buffer after the Message Buffers ND flag was reset by reading out the Message Buffer via OBF. 0_B No message lost 1_B Unprocessed message was overwritten
FTA	14	rh	**Frame Transmitted on Channel A** Indicates that this node has transmitted a Data Frame in the assigned slot on channel A. 0_B No transmission transmitted on channel A 1_B Data Frame transmitted on channel A in cycle defined by CCS bit field *Note: The FlexRay™ protocol specification requires that FTA can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1*

Field	Bits	Type	Description
FTB	15	rh	**Frame Transmitted on Channel B** Indicates that this node has transmitted a Data Frame in the assigned slot on channel B. 0_B No transmission transmitted on channel B 1_B Data Frame transmitted on channel B in cycle defined by CCS bit field *Note: The FlexRay™ protocol specification requires that FTB can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1*
CCS	[21:16]	rh	**Cycle Count Status** Cycle Count when status (MBS register) has been updated.
RCIS	24	rh	**Received on Channel Indicator Status** (vSS!Channel) Indicates the channel on which the Frame was received. 0_B Frame received on channel B 1_B Frame received on channel A *Note: For receive buffers (CFG = 0) the RCIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
SFIS	25	rh	**Startup Frame Indicator Status** (vRF!Header!SuFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0_B No Startup Frame received 1_B The received Frame is a startup Frame *Note: For receive buffers (CFG = 0) the SFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
SYNS	26	rh	**SYNC Frame Indicator Status** (vRF!Header!SyFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0_B No SYNC Frame received 1_B The received Frame is a SYNC Frame *Note: For receive buffers (CFG = 0) the SYNS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*

Field	Bits	Type	Description
NFIS	27	rh	**NULL Frame Indicator Status** (vRF!Header!NFIndicator) If reset to 0 the Payload Segment of the received Frame contains no usable data. 0_B Received Frame is a NULL Frame 1_B Received Frame is not a NULL Frame *Note: For receive buffers (CFG = 0) the NFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
PPIS	28	rh	**Payload Preamble Indictor Status** (vRF!Header!PPIndicator) The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. 0_B Static Segment: The Payload Segment of the received Frame does not contain a Network Management vector or a message ID Dynamic Segment: The Payload Segment of the received Frame does not contain a Network Management vector or a message ID 1_B Static Segment: Network Management vector at the beginning of the payload Dynamic Segment: Message ID at the beginning of the payload *Note: For receive buffers (CFG = 0) the PPIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
RESS	29	rh	**Reserved Bit Status** (vRF!Header!Reserved) Reflects the state of the received reserved bit. The reserved bit is transmitted as 0. *Note: For receive buffers (CFG = 0) the RESS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*

Field	Bits	Type	Description
0	13, [23:22], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Output Buffer Command Mask (OBCM)

Configures how the Output Buffer is updated from the Message Buffer in the Message RAM selected by the Output Buffer Command Request register. If OBF Host and OBF Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer.

OBCM
Output Buffer Command Mask **(0710_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0														RDSH	RHSH
r														rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														RDSS	RHSS
r														rwh	rwh

Field	Bits	Type	Description
RHSS	0	rwh	**Read Header Section Shadow** 0_B Header Section is not read 1_B Header Section selected for transfer from Message RAM to Output Buffer
RDSS	1	rwh	**Read Data Section Shadow** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer
RHSH	16	rh	**Read Header Section Host** 0_B Header Section is not read 1_B Header Section selected for transfer from Message RAM to Output Buffer
RDSH	17	rh	**Read Data Section Host** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer
0	[15:2], [31:18]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: After the transfer of the Header Section from the Message RAM to OBF Shadow has completed, the Message Buffer status changed flag MBCn (n = 0-31) to MBCn (n = 96-127) of the selected Message Buffer in the Message Buffer Changed MBSC1 to MBSC4 registers is cleared. After the transfer of the Data Section from the Message RAM to OBF Shadow has completed, the New Data flag NDn (n = 0-31) to NDn (n = 96-127) of the selected Message Buffer in the New Data NDAT1 to NDAT4 registers is cleared.

Output Buffer Command Request (OBCR)

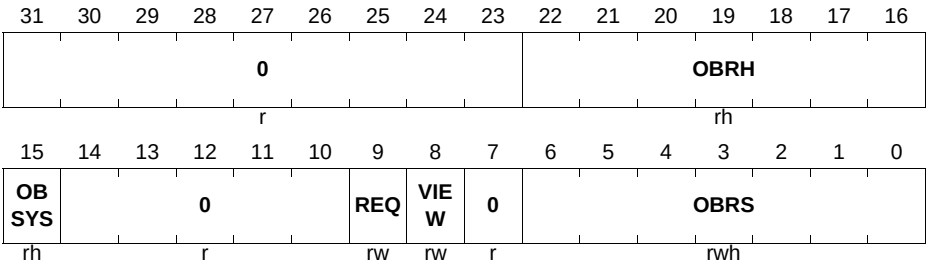
The Message Buffer selected by OBCR.OBRS is transferred from the Message RAM to the Output Buffer as soon as the Host has set OBCR.REQ. Bit OBCR.REQ can only be set while OBCR.OBSYS is 0 (see also **“Data Transfer from Message RAM to Output Buffer” on Page 23-226**).

After setting OBCR.REQ, OBCR.OBSYS is automatically set, and the transfer of the Message Buffer selected by OBCR.OBRS from the Message RAM to Output Buffer Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signalled by clearing OBCR.OBSYS. By setting OBCR.VIEW while OBCR.OBSYS is 0, OBF Host and OBF Shadow are swapped. When Output Buffer Host and Output Buffer Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer. Now the Host can read the transferred Message Buffer from OBF Host. In parallel the Message Handler may transfer the next message from the Message RAM to OBF Shadow if OBCR.VIEW and OBCR.REQ are set at the same time.

Any write access to an Output Buffer register while OBCR.OBSYS is set will cause the error flag EIR.IOBA to be set. In this case the Output Buffer will not be changed.

OBCR

Output Buffer Command Request (0714_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OBRS	[6:0]	rw	**Output Buffer Request Shadow** Number of source Message Buffer to be transferred from the Message RAM to OBF Shadow. Valid values are 00_H to $7F_H$ (0 to 127). If the number of the first Message Buffer of the receive FIFO is written to this register the Message Handler transfers the Message Buffer addressed by the GET Index Register (GIDX, **"FIFO Function" on Page 23-221**) to OBF Shadow.
VIEW	8	rw	**View Shadow Buffer** Toggles between OBF Shadow and OBF Host. Only writeable while OBCR.OBSYS = 0. 0_B No action 1_B Swap OBF Shadow and OBF Host
REQ	9	rw	**Request Message RAM Transfer** Requests transfer of Message Buffer addressed by OBCR.OBRS from Message RAM to OBF Shadow. Only writeable while OBCR.OBSYS = 0. 0_B No request 1_B Transfer to OBF Shadow requested
OBSYS	15	rh	**Output Buffer Busy Shadow** Set to 1 after setting bit OBCR.REQ. When the transfer between the Message RAM and OBF Shadow has completed, OBCR.OBSYS is cleared again. 0_B No transfer in progress 1_B Transfer between Message RAM and OBF Shadow in progress

Field	Bits	Type	Description
OBRH	[22:16]	rh	**Output Buffer Request Host** Number of Message Buffer currently accessible by the Host via RDHS1 to RDHS3, MBS, and RDDSnn (nn = 01-64). By setting OBCR.VIEW OBF Shadow and OBF Host are swapped and the transferred Message Buffer is accessible by the Host. Valid values are 00_H to $7F_H$ (01 to 27).
0	7, [14:10], [31:23]	r	**Reserved** Returns 0 if read; should be written with 0.

23.6 Functional Description

This chapter describes the E-Ray implementation together with the related FlexRay™ protocol features. More information about the FlexRay™ protocol itself can be found in the FlexRay™ protocol specification v2.1.

Communication on FlexRay™ networks is based on Frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

23.6.1 Communication Cycle

A communication cycle in FlexRay™ consists of the following elements:

- Static Segment
- Dynamic Segment
- Symbol Window
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized Macrotick.

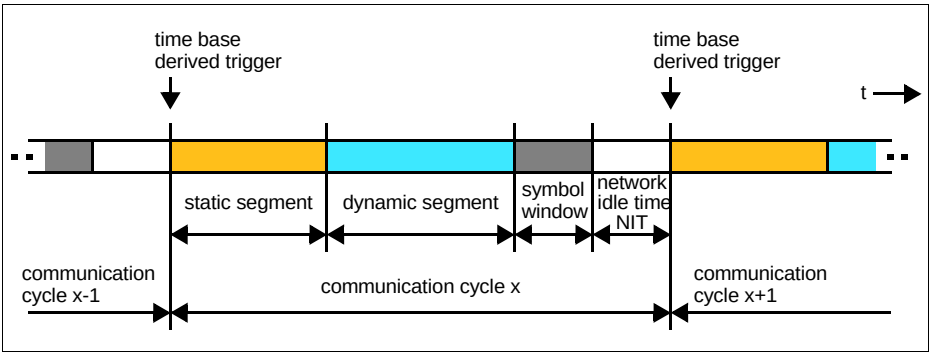


Figure 23-4 Structure of Communication Cycle

23.6.1.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of Frame transmission at action point of the respective static slot
- Payload length same for all Frames on both channel

Parameters: Number of Static Slots **GTUC07.NSS**, Static Slot Length **GTUC07.SSL**, Payload Length Static **MHDC.SFDL**, Action Point Offset **GTUC09.APO**.

23.6.1.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters: Number of Minislots **GTUC08.NMS**, Minislot Length **GTUC08.MSL** Minislot Action Point Offset **GTUC09.MAPO**, Start of Latest Transmit (last minislot) **MHDC.SLT**.

23.6.1.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are send in “NORMAL_ACTIVE” state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters: Symbol Window Action Point Offset **GTUC09.APO** (same as for static slots), Network Idle Time Start **GTUC04.NIT**.

23.6.1.4 Network Idle Time (NIT)

During network idle time the Communication Controller has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple Macroticks
- Perform cluster cycle related tasks

Parameters: Network Idle Time Start **GTUC04.NIT**, Offset Correction Start **GTUC04.OCS**.

23.6.1.5 Configuration of Network Idle Time (NIT) Start and Offset Correction Start

The number of Macroticks per cycle (gMacroPerCycle) is assumed to be m. It is configured by programming **GTUC02.MPC** = m.

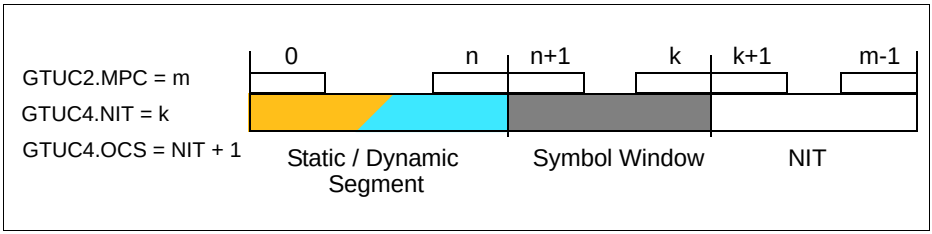

Figure 23-5 Configuration of network idle time (NIT) start and offset correction start

The static / dynamic segment starts with Macrotick 0 and ends with Macrotick n:
n = static segment length + dynamic segment offset + dynamic segment length - 1 Macrotick

n = gNumberOfStaticSlots • gdStaticSlot + dynamic segment offset
+ gNumberOfMinislots • gdMinislot - 1 Macroticks

The static segment length is configured by **GTUC07.SSL** and **GTUC07.NSS**.
The dynamic segment length is configured by **GTUC08.MSL** and **GTUC08.NMS**.

The dynamic segment offset is:

If gdActionPointOffset ≤ gdMinislotActionPointOffset:

dynamic segment offset = 0 MT

Else if gdActionPointOffset > gdMinislotActionPointOffset:

dynamic segment offset = gdActionPointOffset - gdMinislotActionPointOffset

The network idle time (NIT) starts with Macrotick k+1 and ends with the last Macrotick of cycle m-1. It has to be configured by setting **GTUC04.NIT** = k.

For the E-Ray the offset correction start is required to be

GTUC04.OCS ≥ **GTUC04.NIT** + 1 = k+1.

The length of symbol window results from the number of Macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by k - n.

23.6.2 Communication Modes

The FlexRay™ Protocol Specification v2.1 defines the Time-Triggered Distributed (TT-D) mode.

Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- **Pure static**: minimum 2 static slots + symbol window (optional)
- **Mixed static/dynamic**: minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes need to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each Startup Frame must be a SYNC Frame, therefore all coldstart nodes are sync nodes.

23.6.3 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received SYNC Frames from other nodes.

23.6.3.1 Global Time

Activities in a FlexRay™ node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates the FlexRay™ cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (Macrotick counter).

Cluster specific:

- Macrotick = basic unit of time measurement in a FlexRay™ network, a Macrotick consists of an integer number of Microticks
- Cycle length = duration of a communication cycle in units of Macroticks

23.6.3.2 Local Time

Internally, nodes time their behavior with Microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore Microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a Microtick.

Node specific:

- Oscillator clock → prescaler → Microtick
- Microtick = basic unit of time measurement in a Communication Controller, clock correction is done in units of Microticks
- Cycle counter + Macrotick counter = nodes local view of the global time

23.6.3.3 Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during network idle time (NIT) of **every** communication cycle, value may be negative
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values (violation: “NORMAL_ACTIVE” → “NORMAL_PASSIVE” → “HALT”)
- Correction value is an integer number of Microticks
- Correction done in **odd** numbered cycles, distributed over the Macroticks beginning at offset correction start up to cycle end (end of network idle time (NIT)) to shift nodes next start of cycle (Macroticks lengthened / shortened)

Rate (frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during network idle time (NIT) of **odd** numbered cycles, value may be negative
- Cluster drift damping is performed using global damping value

- Checked against limit values
- Correction value is a signed integer number of Microticks
- Distributed over Macroticks comprising the next **even / odd** cycle pair (Macroticks lengthened / shortened)

Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

SYNC Frame Transmission

SYNC Frame transmission is only possible from buffer 0 and 1. Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames should have different payloads on the two channels. In this case bit **MRC.SPLM** has to be programmed to 1.

Message Buffers used for SYNC Frame transmission have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. For nodes transmitting SYNC Frames **SUCC1.TXSY** must be set to 1.

23.6.3.4 External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

23.6.4 Error Handling

The implemented error handling concept is intended to ensure that in case of a lower layer protocol error in a single node communication between non-affected nodes can be maintained. In some cases, higher layer program command activity is required for the Communication Controller to resume normal operation. A change of the error handling state will set bit **EIR.PEMC** in the Error Service Request Register and may trigger an service request to the Host if enabled. The actual error mode is signalled by **CCEV.ERRM** in the Communication Controller Error Vector register.

Table 23-10 Error Modes of the POC (Degradation Model)

Error Mode	Activity
ACTIVE (green)	**Full operation**, State: “NORMAL_ACTIVE” The Communication Controller is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers **EIR** and **SIR**.
PASSIVE (yellow)	**Reduced operation**, State: “NORMAL_PASSIVE”, Communication Controller self rescue allowed The Communication Controller stops transmitting Frames and symbols, but received Frames are still processed. Clock synchronization mechanisms are continued based on received Frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers **EIR** and **SIR**.
COMM_HALT (red)	**Operation halted**, State: “HALT”, Communication Controller self rescue not allowed The Communication Controller stops Frame and symbol processing, clock synchronization processing, and the Macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers **EIR** and **SIR**. The bus drivers are disabled.

23.6.4.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the maximum “without clock correction passive” limit defined by **SUCC3.WCP**, the POC transits from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. When it reaches the “maximum without clock correction fatal” limit defined by **SUCC3.WCF**, it transits “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to the “HALT” state. Both limits are defined in the SUC Configuration Register 3.

The Clock Correction Failed Counter **CCEV.CCFC** allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the Communication Controller passed protocol startup phase. It will be incremented by one at the end of any **odd** numbered communication cycle where either the Missing Offset Correction signal **SFS.MOCS** nor the Missing Rate Correction signal **SFS.MRCS** flag is set. The two flags are located in the SYNC Frame Status register, while the Clock Correction Failed Counter is located in the Communication Controller Error Vector register.

The Clock Correction Failed Counter is reset to zero at the end of an **odd** communication cycle if neither the Missing Offset Correction signal **SFS.MOCS** nor the Missing Rate Correction signal **SFS.MRCS** flag is set.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value **SUCC3.WCF** as defined in the SUC Configuration Register 3 is reached (i.e. incrementing the counter at its maximum value will not cause it to “wraparound” back to zero). The Clock Correction Failed Counter is initialized to zero when the Communication Controller enters “READY” state or when “NORMAL_ACTIVE” state is entered.

23.6.4.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. **SUCC1.PTA** in the SUC Configuration Register 1 defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If **SUCC1.PTA** is reset to zero the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state.

23.6.4.3 HALT Command

In case the Host wants to stop FlexRay™ communication of the local node it can bring the Communication Controller into “HALT” state by asserting the HALT command. This can be done by writing **SUCC1.CMD** = 0110_B in the SUC Configuration Register 1. When called in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the POC transits to “HALT” state at the end of the current cycle. When called in any other state **SUCC1.CMD** will be reset to 0000_B = “COMMAND_NOT_ACCEPTED” and bit **EIR.CNA** in the Error Service Request Register is set to 1. If enabled an service request to the Host is generated.

23.6.4.4 FREEZE Command

In case the Host detects a severe error condition it can bring the Communication Controller into “HALT” state by asserting the FREEZE command. This can be done by writing **SUCC1.CMD** = 0111_B in the SUC Configuration Register 1. The FREEZE

command triggers the entry of the “HALT” state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from **CCSV.PSL**.

23.6.5 Communication Controller States

This chapter introduces the states of the Communication Controller.

23.6.5.1 Communication Controller State Diagram

State transitions are controlled by externals the application reset or RXDA/B, by the POC state machine, and by the CHI Command Vector **SUCC1.CMD** located in the SUC Configuration Register 1.

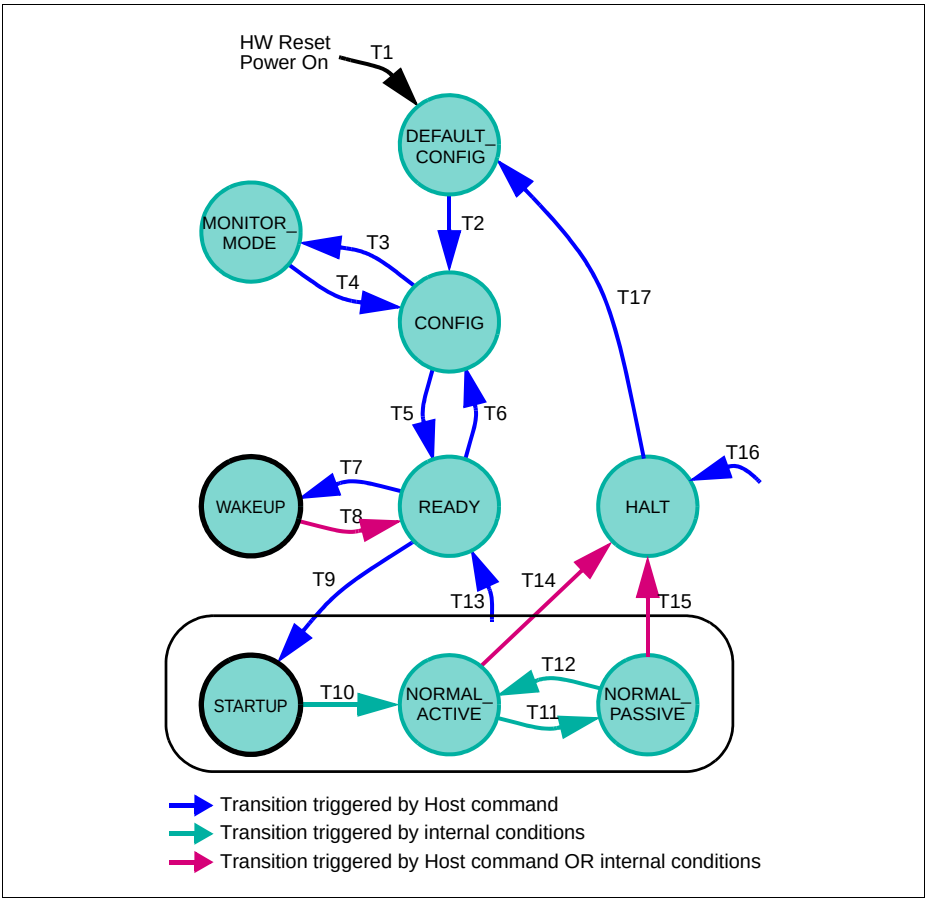

Figure 23-6 Overall State Diagram of E-Ray Communication Controller

The Communication Controller exits from all states to “HALT” state after application of the FREEZE command (SUCC1.CMD = 0111_B).

Table 23-11 State Transitions of E-Ray Overall State Machine

T#	Condition	From	To
1	application reset	HW Reset	DEFAULT_CONFIG
2	Command CONFIG, SUCC1.CMD = 0001_B	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command MONITOR_MODE, SUCC1.CMD = 1011_B	CONFIG	MONITOR_MODE
4	Command CONFIG, SUCC1.CMD = 0001_B	MONITOR_MODE	CONFIG
5	Unlock sequence followed by command READY, SUCC1.CMD = 0010_B	CONFIG	READY
6	Command CONFIG, SUCC1.CMD = 0001_B	READY	CONFIG
7	Command WAKEUP, SUCC1.CMD = 0011_B	READY	WAKEUP
8	Complete, non-aborted transmission of wakeup pattern OR received WUP OR received Frame Header OR command READY, SUCC1.CMD = 0010_B	WAKEUP	READY
9	Command RUN, SUCC1.CMD = 0100_B	READY	STARTUP
10	Successful startup	STARTUP	NORMAL_ACTIVE
11	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by WCP in SUC Configuration Register 3	NORMAL_ACTIVE	NORMAL_PASSIVE
12	Number of valid correction terms reached the Passive to Active limit configured by PTA in SUC Configuration Register 1	NORMAL_PASSIVE	NORMAL_ACTIVE
13	Command READY, SUCC1.CMD = 0010_B	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY

Table 23-11 State Transitions of E-Ray Overall State Machine (cont'd)

T#	Condition	From	To
14	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_ACTIVE	HALT
15	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_PASSIVE	HALT
16	Command FREEZE, SUCC1.CMD = 0111_B	All States	HALT
17	Command CONFIG, SUCC1.CMD = 0001_B	HALT	DEFAULT_CONFIG

23.6.5.2 DEFAULT_CONFIG State

In "DEFAULT_CONFIG" state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The Communication Controller enters this state

- When leaving application reset
- When exiting from "HALT" state

To leave "DEFAULT_CONFIG" state the Host has to write SUCC1.CMD = 0001_B in the SUC Configuration Register 1. The Communication Controller transits to "CONFIG" state.

CONFIG State

In "CONFIG" state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the Communication Controller configuration.

The Communication Controller enters this state

- When exiting from “DEFAULT_CONFIG” state
- When exiting from “MONITOR_MODE” or “READY” state

When the state has been entered via “HALT” and “DEFAULT_CONFIG” state, the Host can analyze status information and configuration. Before leaving “CONFIG” state the Host has to assure that the configuration is fault-free.

To leave “CONFIG” state, the Host has to perform the unlock sequence as described on **“LCK” on Page 23-30**. Directly after unlocking the “CONFIG” state the Host has to write **SUCC1.CMD** in the SUC Configuration Register 1 to enter the next state.

Internal counters and the Communication Controller status flags are reset when the Communication Controller leaves “CONFIG”.

*Note: The Message Buffer Status Registers (**MHDS**, **TXRQ1** to **TXRQ4**, **NDAT1** to **NDAT4**, **MBSC1** to **MBSC4**) and status data stored in the Message RAM and are not affected by the transition of the POC from “CONFIG” to “READY” state.*

When the Communication Controller is in “CONFIG” state it is also possible to bring the Communication Controller into a power saving mode by halting the module clocks (f_{SCLK}, f_{CLC_ERAY}). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

23.6.5.3 MONITOR_MODE

After unlocking “CONFIG” state and writing **SUCC1.CMD** = 0011_B the Communication Controller enters “MONITOR_MODE”. In this mode the Communication Controller is able to receive FlexRay™ Frames and to detect wakeup pattern. The temporal integrity of received Frames is not checked, and therefore cycle counter filtering is not supported. It is not possible to distinguish between static and dynamic frames, because limited functions in Monitor Mode (FRF.RSS will be ignored, filtering not functional).This mode can be used for debugging purposes in case e.g. that startup of a FlexRay™ network fails. After writing **SUCC1.CMD** = 0001_B the Communication Controller transits back to “CONFIG” state.

In MONITOR_MODE the pick first valid mechanism is disabled. This means that a receive Message Buffer may only be configured to receive on one channel. Received Frames are stored into Message Buffers according to Frame ID and receive channel. NULL Frames are handled like Data Frames. After Frame reception only status bits **MBS.VFRA**, **MBS**, **MBS.MLST**, **MBS.RCIS**, **MBS.SFIS**, **MBS.SYNS**, **MBS.NFIS**, **MBS.PPIS**, **MBS.RESS** have valid value.

In “MONITOR_MODE” the Communication Controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags **SIR.MTSA** resp. **SIR.MTSB** are set. **SIR.CAS** has no function in “MONITOR_MODE”.

23.6.5.4 READY State

After unlocking “CONFIG” state and writing **SUCC1.CMD** = 0010_B the Communication Controller enters “READY” state. From this state the Communication Controller can transit to WAKEUP state and perform a cluster wakeup or to “STARTUP” state to perform a coldstart or to integrate into a running communication.

The Communication Controller enters this state

- When exiting from “CONFIG”, “WAKEUP”, “STARTUP”, “NORMAL_ACTIVE”, or “NORMAL_PASSIVE” state by writing **SUCC1.CMD** = 0010_B (READY command).

The Communication Controller exits from this state

- To “CONFIG” state by writing **SUCC1.CMD** = 0001_B (CONFIG command)
- To “WAKEUP” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command)
- To “STARTUP” state by writing **SUCC1.CMD** = 0100_B (RUN command)

Internal counters and the Communication Controller status flags are reset when the Communication Controller enters “STARTUP” state.

*Note: Status bits **MHDS**, registers **TXRQ1** to **TXRQ4**, and status data stored in the Message RAM are not affected by the transition of the POC from “READY” to “STARTUP” state.*

23.6.5.5 WAKEUP State

The description below is intended to help configuring wakeup for the E-Ray IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.1.

The Communication Controller enters this state

- When exiting from “READY” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command).

The Communication Controller exits from this state to “READY” state

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a Frame Header
- By writing **SUCC1.CMD** = 0010_B (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all mechanisms defined for the startup work properly. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an **external** wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the Communication Controller and configures bus guardian

(if available) and Communication Controller to perform the cluster wakeup. The Communication Controller provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The Communication Controller needs to recognize the wakeup pattern only during “WAKEUP” state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the Communication Controller is in “CONFIG” state by writing bit **SUCC1.WUCS** in the SUC Configuration Register 1. The Communication Controller ensures that ongoing communication on this channel is not disturbed. The Communication Controller cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the Communication Controller returns to “READY” state and signals the change of the wakeup status to the Host by setting bit **SIR.WST** in the Status Service Request Register. The wakeup status vector can be read from the Communication Controller Status Vector register **CCSV.WSV**. If a valid wakeup pattern was received also either flag **SIR.WUPA** or flag **SIR.WUPB** in the Status Service Request Register is set.

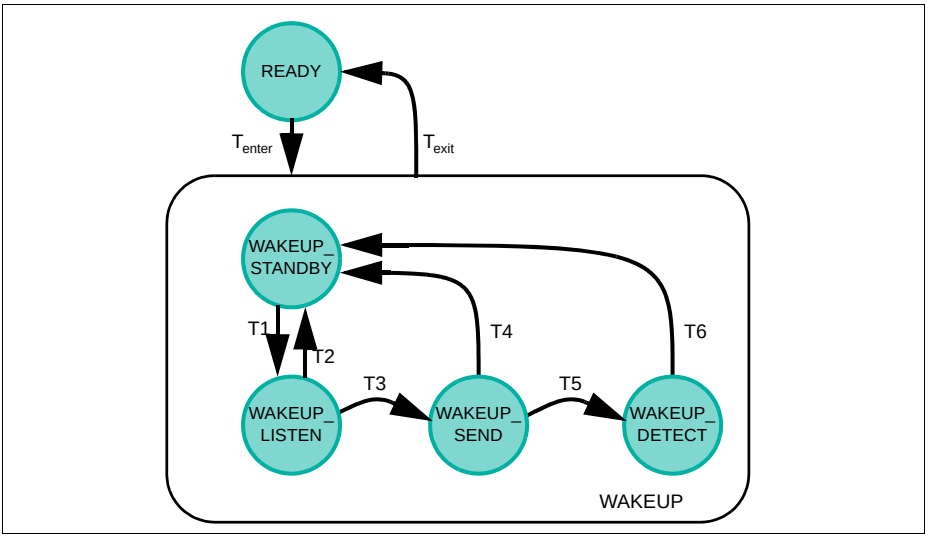

Figure 23-7 Structure of POC State WAKEUP

Table 23-12 State Transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to “WAKEUP” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to “WAKEUP_LISTEN” state	WAKEUP_ STANDBY	WAKEUP_ LISTEN
2	Received WUP on wakeup channel selected by flag **SUCC1.WUCS** in the SUC Configuration Register 1 OR Frame Header on either available channel	WAKEUP_ LISTEN	WAKEUP_ STANDBY
3	Timer event	WAKEUP_ LISTEN	WAKEUP_ SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_ SEND	WAKEUP_ STANDBY

Table 23-12 State Transitions WAKEUP (cont'd)

T#	Condition	From	To
5	Collision detected	WAKEUP_ SEND	WAKEUP_ DETECT
6	Wakeup timer expired OR WUP detected on wakeup channel selected by flag **SUCC1.WUCS** in the SUC Configuration Register 1 OR Frame Header received on either available channel	WAKEUP_ DETECT	WAKEUP_ STANDBY
exit	Wakeup completed (after T2 or T4 or T6) OR Host commands change to "READY" state by writing **SUCC1.CMD** = 0010_B (READY command). This command also resets the wakeup FSM to "WAKEUP_STANDBY" state	WAKEUP	READY

The "WAKEUP_LISTEN" state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen time-out **SUCC2.LT** and listen time-out noise **SUCC2.LTN**. Both values can be configured in the SUC Configuration Register 2. listen time-out enables a fast cluster wakeup in case of a noise free environment, while listen time-out noise enables wakeup under more difficult conditions regarding noise interference.

In "WAKEUP_SEND" state the Communication Controller transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the Communication Controller into "STARTUP" state by CHI command RUN.

In "WAKEUP_DETECT" state the Communication Controller attempts to identify the reason for the wakeup collision detected in "WAKEUP_SEND" state. The monitoring is bounded by the expiration of listen time-out as configured by **SUCC2.LT** in the SUC Configuration Register 2. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a Frame Header indication existing communication, causes the direct transition to "READY" state. Otherwise WAKEUP_DETECT is left after expiration of listen time-out; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay™ Protocol Specification v2.1 recommends that two different Communication Controllers shall awake the two channels.

Host activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host and generated by the Communication Controller. The wakeup pattern is detected by the remote BDs and signalled to their local Hosts.

Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the Communication Controller in “CONFIG” state
  - Select wakeup channel by programming bit **SUCC1.WUCS**
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command Communication Controller to start wakeup on the configured channel by writing **SUCC1.CMD** = 0011_B
  - Communication Controller enters “WAKEUP
  - Communication Controller returns to “READY” state and signals status of wakeup attempt to Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node: wait for WUP on the other channel
  - In a dual channel cluster wait for WUP on the other channel
  - Reset coldstart inhibit flag **CCSV.CSI** by writing **SUCC1.CMD** = 1001_B (ALLOW_COLDSTART command))
- Reset Coldstart Inhibit flag **CCSV.CSI** in the CCSV register by writing **SUCC1.CMD** = 1001_B (ALLOW_COLDSTART command), coldstart node only
- Command Communication Controller to enter startup by writing **SUCC1.CMD** = 0100_B (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local Communication Controller
- If necessary Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands Communication Controller to enter “STARTUP” state by writing **SUCC1.CMD** = 0100_B (RUN command)

Wakeup pattern (WUP)

The wakeup pattern is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by the PRT Configuration Registers **PRTC1** and **PRTC2**.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time

- Wakeup symbol collision resilient for up to two sending nodes (two overlapping wakeup symbols still recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by **PRTC2.TXL**
- Wakeup symbol idle time used to listen for activity on the bus, configured by **PRTC2.TXI**
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by **PRTC1.RWP** (2 to 63 repetitions)
- Wakeup symbol receive window length configured by **PRTC1.RXW**
- Wakeup symbol receive low time configured by **PRTC2.RXL**
- Wakeup symbol receive idle time configured by **PRTC2.RXI**

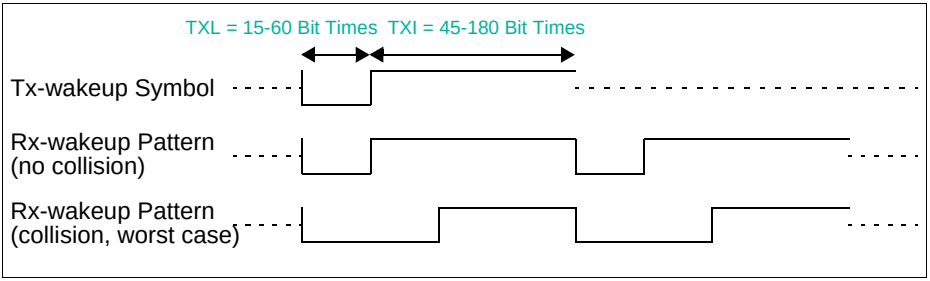

Figure 23-8 Timing of Wakeup Pattern

23.6.5.6 STARTUP State

The description below is intended to help configuring startup for the E-Ray IP-module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.2.

Any node entering “STARTUP” state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup Frames.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter “NORMAL_ACTIVE” state via (see **Figure 23-9**):

- Coldstart path initiating the schedule synchronization (leading coldstart node)
- Coldstart path joining other coldstart nodes (following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits Frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has the Transmit SYNC Frame in Key Slot bits **SUCC1.TXST** and **SUCC1.TXSY** in the SUC Configuration Register 1 set to 1. The Message Buffer 0 holds the key slot ID which defines the slot number where the Startup Frame is send. In the Frame Header of the Startup Frame the Startup Frame indicator bit is set.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each Startup Frame must also be a SYNC Frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by **SUCC1.CSA** in the SUC Configuration Register 1.

A non-coldstart node requires at least two startup Frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive SYNC Frames from which to derive the TDMA schedule information. During integration the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

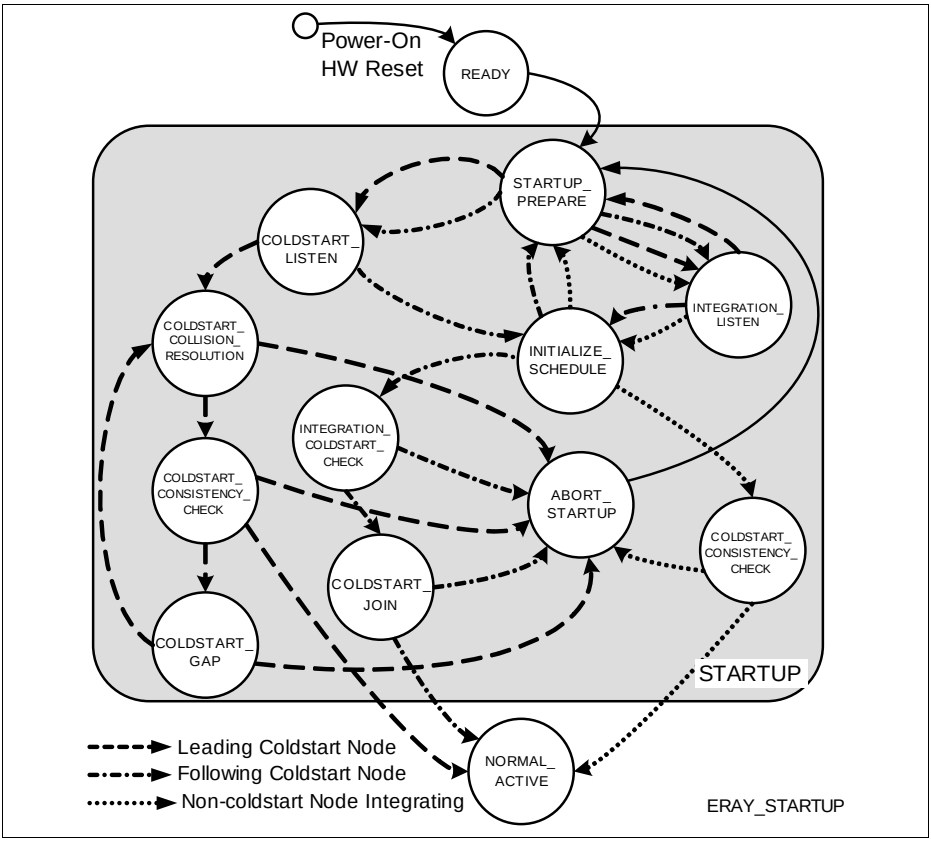

Figure 23-9 State Diagram Time-Triggered Startup

Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit **CCSV.CSI** in the Communication Controller Status Vector register is set, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup Frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit **CCSV.CSI** is set whenever the POC enters “READY” state. The bit has to be cleared under control of the Host by CHI command ALLOW_COLDSTART (**SUCC1.CMD** = 1001_B)

23.6.5.7 Startup Time-outs

The Communication Controller supplies two different Microtick timers supporting two time-out values, startup time-out and startup noise time-out. The two timers are reset when the Communication Controller enters the “COLDSTART_LISTEN” state. The expiration of either of these timers causes the node to leave the initial sensing phase (“COLDSTART_LISTEN” state) with the intention of starting up communication.

*Note: The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values **SUCC2.LT** and **SUCC2.LTN** from the SUC Configuration Register 2.*

Startup Time-out

The startup time-out limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others.

The startup timer is configured by programming **SUCC2.LT** (pdListenTimeout) in the SUC Configuration Register 2.

The startup timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Both channels reaching idle state while in “COLDSTART_LISTEN” state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the “COLDSTART_LISTEN” state
- When the “COLDSTART_LISTEN” state is left

Once the startup time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

Startup Noise Time-out

At the same time the startup timer is started for the first time (transition from “STARTUP_PREPARE” state to “COLDSTART_LISTEN” state), the startup noise timer is started. This additional time-out is used to improve reliability of the startup procedure in the presence of noise.

The startup noise timer is configured by programming **SUCC2.LTN** (gListenNoise - 1) in the SUC Configuration Register 2 (see **“SUC Configuration Register 2 (SUCC2)” on Page 23-87**).

The startup noise time-out is:
pdListenTimeout • ´gListenNoise = **SUCC2.LT** • (**SUCC2.LTN** + 1)

The startup noise timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Reception of correctly decoded Headers or CAS symbols while the node is in “COLDSTART_LISTEN” state

The startup noise timer is stopped when the “COLDSTART_LISTEN” state is left.

Once the startup noise time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won’t be restarted when random channel activity is sensed, this time-out defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

23.6.5.8 Path of leading Coldstart Node (initiating coldstart)

When a coldstart node enters “COLDSTART_LISTEN”, it listens to its attached channels.

If no communication is detected, the node enters the “COLDSTART_COLLISION_RESOLUTION” state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup Frame. Since each coldstart node is allowed to perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a Frame Header during these four cycles, it re-enters the “COLDSTART_LISTEN” state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup Frames.

After four cycles in “COLDSTART_COLLISION_RESOLUTION” state, the node that initiated the coldstart enters the “COLDSTART_CONSISTENCY_CHECK” state. It collects all startup Frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid Startup Frame pair, the node leaves “COLDSTART_CONSISTENCY_CHECK” and enters “NORMAL_ACTIVE” state.

The number of coldstart attempts that a node is allowed to perform is configured by **SUCC1.CSA** in the SUC Configuration Register 1. The number of remaining coldstarts attempts **CCSV.RCA** can be read from Communication Controller Status Vector register. The number of remaining attempts is reduced by one for each attempted coldstart. A node may enter the “COLDSTART_LISTEN” state only if this value is larger than one and it may enter the “COLDSTART_COLLISION_RESOLUTION” state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

Path of following Coldstart Node (responding to leading Coldstart Node)

When a coldstart node enters the “COLDSTART_LISTEN” state, it tries to receive a valid pair of startup Frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and can derive a schedule from this startup Frames, the “INTEGRATION_COLDSTART_CHECK” state is entered.

In “INTEGRATION_COLDSTART_CHECK” state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all SYNC Frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient Frames from the same node it has integrated on, the “COLDSTART_JOIN” state is entered.

In “COLDSTART_JOIN” state integrating coldstart nodes begin to transmit their own startup Frames. Thereby the node that initiated the coldstart and the nodes joining it can check if their schedules agree to each other. If for the following three cycles the clock correction does not signal errors and at least one other coldstart node is visible, the node leaves “COLDSTART_JOIN” state and enters “NORMAL_ACTIVE” state. Thereby it leaves “STARTUP” at least one cycle after the node that initiated the coldstart.

Path of Non-coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels and tries to receive FlexRay™ Frames.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In “INTEGRATION_CONSISTENCY_CHECK” state it is verified that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) send startup Frames that agree to the nodes own schedule. Clock correction is activated, and if any errors are signalled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup Frames or the Startup Frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid Startup Frame pairs or the Startup Frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup Frames are received within an even cycle, or less than two valid Startup Frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid Startup Frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

23.6.5.9 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering “STARTUP” via coldstart path) and one additional node have entered the “NORMAL_ACTIVE” state, the startup phase for the cluster has finished. In the “NORMAL_ACTIVE” state, all configured messages are scheduled for transmission. This includes all Data Frames as well as the SYNC Frames. Rate and offset measurement is started in all even cycles (even/odd cycle pairs required).

In “NORMAL_ACTIVE” state the Communication Controller supports regular communication functions

- The Communication Controller performs transmissions and reception on the FlexRay™ bus as configured
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from that state to

- “HALT” state by writing **SUCC1.CMD** = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing **SUCC1.CMD** = 0111_B (FREEZE command, immediately)
- “HALT” state due to change of the error state from “ACTIVE” to “COMM_HALT”
- “NORMAL_PASSIVE” state due to change of the error state from “ACTIVE” to “PASSIVE”
- “READY” state by writing **SUCC1.CMD** = 0010_B (READY command)

23.6.5.10 NORMAL_PASSIVE State

“NORMAL_PASSIVE” state is entered from “NORMAL_ACTIVE” state when the error state changes from ACTIVE (green) to PASSIVE (yellow).

In “NORMAL_PASSIVE” state, the node is able to receive all Frames (node is fully synchronized and performs clock synchronization). In comparison to the “NORMAL_ACTIVE” state the node does not actively participate in communication, i.e. neither symbols nor Frames are transmitted.

In “NORMAL_PASSIVE” state

- The Communication Controller performs reception on the FlexRay™ bus
- The Communication Controller does not transmit any Frames or symbols on the FlexRay™ bus
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from this state to

- “HALT” state by writing **SUCC1.CMD** = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing **SUCC1.CMD** = 0111_B (FREEZE command, immediately)
- “HALT” state due to change of the error state from “PASSIVE” to “COMM_HALT”
- “NORMAL_ACTIVE” state due to change of the error state from “PASSIVE” to “ACTIVE”. The transition takes place when **CCEV.PTAC** from the Communication Controller Error Vector register equals **SUCC1.PTA** - 1.
- “READY” state by writing **SUCC1.CMD** = 0010_B (READY command)

23.6.5.11 HALT State

In this state all communication (reception and transmission) is stopped.

The Communication Controller enters this state

- By writing **SUCC1.CMD** = 0110_B (HALT command) while the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state
- By writing **SUCC1.CMD** = 0111_B (FREEZE command) from all states
- When exiting from “NORMAL_ACTIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit
- When exiting from “NORMAL_PASSIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit

The Communication Controller exits from this state to “CONFIG” state

- By writing **SUCC1.CMD** = 0001_B (DEFAULT_CONFIG command)

When the Communication Controller enters “HALT” state, all configuration and status data is maintained for analyzing purposes.

When the Host writes **SUCC1.CMD** = 0110_B (HALT command) in the SUC Configuration Register 1 to 1, the Communication Controller sets bit **CCSV.HRQ** in the Communication Controller Status Vector register and enters “HALT” state after the current communication cycle has finished.

When the Host writes **SUCC1.CMD** = 0111_B (FREEZE command) in the SUC Configuration Register to 1, the Communication Controller enters “HALT” state immediately and sets the **CCSV.FSI** bit in the Communication Controller Status Vector register.

The POC state from which the transition to HALT state took place can be read from **CCSV.PSL**.

23.6.6 Network Management

The accrued Network Management (NM) vector is located in the Network Management Register 1 to Network Management Register 3 (**NMVx (x = 1-3)**). The Communication Controller performs a logical OR operation over all Network Management (NM) vectors out of all received valid Network Management (NM) Frames with the Payload Preamble Indicator (PPI) bit set. Only a static Frame may be configured to hold Network Management (NM) information. The Communication Controller updates the Network Management (NM) vector at the end of each cycle.

The length of the Network Management (NM) vector can be configured from 0 to 12 byte by NML in the NEM Configuration Register. The Network Management (NM) vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay™ Frames with the PPI bit set, the PPIT bit in the Header Section of the respective transmit buffer has to be set via **WRHS1.PPIT**. In addition the Host has to write the Network Management (NM) information to the Data Section of the respective transmit buffer.

The evaluation of the Network Management (NM) vector has to be done by the application running on the Host.

*Note: In case a Message Buffer is configured for transmission / reception of Network Management Frames, the payload length configured in Header 2 of that Message Buffer should be equal or greater than the length of the NM Vector configured by **NEMC.NML**.*

When the Communication Controller transits to “HALT” state, the cycle count is not incremented and therefore the NM Vector is not updated. In this case NMV1 to NMV3 holds the value from the cycle before.

23.6.7 Filtering and Masking

Filtering is done by checking specific fields in a received Frame against the corresponding configuration constants of the valid Message Buffers and the actual slot and cycle counter values (acceptance filtering), or by comparing the configuration constants of the valid Message Buffers against the actual slot and cycle counter values (transmit filtering). A Message Buffer is only updated / transmitted if the required matches occur.

Filtering is done on the following fields:

- Channel ID
- Frame ID
- Cycle Counter

The following filter combinations for acceptance / transmit filtering are allowed:

- Frame ID + Channel ID
- Frame ID + Channel ID + Cycle Counter

In order to store a received message in a Message Buffer all configured filters must match.

Note: For the FIFO the acceptance filter is configured by the FIFO Rejection Filter and the FIFO Rejection Filter Mask.

A message will be transmitted in the time slot corresponding to the configured Frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

23.6.7.1 Frame ID Filtering

Every transmit and receive buffer contains a Frame ID stored in the Header Section. This Frame ID is used differently for receive and transmit buffers.

Receive Buffers

A received message is stored in the first receive buffer where the received Frame ID matches the configured Frame ID, provided channel ID and cycle counter criteria are also met.

Transmit Buffers

For transmit buffers the configured Frame ID is used to determine the appropriate slot for message transmission. The Frame will be transmitted in the time slot corresponding to the configured Frame ID, provided channel ID and cycle counter criteria are also met.

23.6.7.2 Channel ID Filtering

There is a 2-bit channel filtering field (CHA, CHB) located in the Header Section of each Message Buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see **Table 23-13**).

Table 23-13 Channel Filtering Configuration

CHA	CHB	Transmit Buffer transmit Frame	Receive Buffer store valid receive Frame
1	1	on both channels (static segment only)	received on channel A or B (store first semantically valid Frame, static segment only)
1	0	on channel A	received on channel A
0	1	on channel B	received on channel B
0	0	no transmission	ignore Frame

Note: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Receive Buffers

Valid received Frames are stored if they are received on the channels specified in the channel filtering field. Only in static segment a receive buffer may be setup for reception on both channels (CHA and CHB set). Other filtering criteria must also be met.

If a valid Header Segment was stored, the respective MBC flag in the Message Buffer Status Changed register is set. If a valid Payload Segment was stored, the respective **NDn (n = 0-31)** to **NDn (n = 96-127)** flag in the New Data **NDAT1** to **NDAT4** register is set. In both cases, if bit **RDHS1.MBI** in the Header Section of the respective Message Buffer is set, the RXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

Transmit Buffers

The content of the buffer is transmitted only on the channels specified in the channel filtering field when the Frame ID filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be setup for transmission on both channels (CHA and CHB set). After transmission has completed, and if bit **WRHS1.MBI** in the Header Section of the respective Message Buffer is set, the TXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

23.6.7.3 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in the Header Section of each Message Buffer.

If Message Buffer 0 is configured to hold the startup / SYNC Frame or the single slot Frame by bits TXST, TXSY, and TSM in the SUC Configuration Register 1, cycle counter filtering for Message Buffer 0 should be disabled.

*Note: Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.*

The set of cycle numbers belonging to a cycle set is determined as described in **Table 23-14**.

Table 23-14 Definition of Cycle Set

Cycle Code	Matching Cycle Counter Values		
$000000x_B$	all Cycles		
$000001c_B$	every second Cycle	at (Cycle Count)mod2	= c
$00001cc_B$	every fourth Cycle	at (Cycle Count)mod4	= cc
$0001ccc_B$	every eighth Cycle	at (Cycle Count)mod8	= ccc
$001cccc_B$	every sixteenth Cycle	at (Cycle Count)mod16	= cccc
$01ccccc_B$	every thirty-second Cycle	at (Cycle Count)mod32	= ccccc
$1cccccc_B$	every sixty-fourth Cycle	at (Cycle Count)mod64	= cccccc

Table 23-15 below gives some examples for valid cycle sets to be used for cycle counter filtering:

Table 23-15 Examples for Valid Cycle Sets

Cycle Code	Matching Cycle Counter Values
0000011_B	1-3-5-7- ….-63 ↵
0000100_B	0-4-8-12- ….-60 ↵
0001110_B	6-14-22-30- ….-62 ↵
0011000_B	8-24-40-56 ↵
0100011_B	3-35 ↵
1001001_B	9 ↵

Receive Buffers

The received message is stored only if the received cycle counter matches an element of the receive buffer's cycle set. Channel ID and Frame ID criteria must also be met.

Transmit Buffers

The content of the buffer is transmitted on the configured channels when an element of the cycle set matches the current cycle counter value and the Frame ID matches the slot counter value.

23.6.7.4 FIFO Filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO rejection filter consists of 20 bits for **Channel** (2 bits), **Frame ID** (11 bits), and **Cycle Code** (7 bits). Rejection filter and rejection filter mask can be configured in

DEFAIULT_CONGIF or “CONFIG” state only. The filter configuration in the Header Sections of Message Buffers belonging to the FIFO is ignored.

A valid received Frame is stored in the FIFO if channel ID, Frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

23.6.8 Transmit Process

The transmit process is described in the following sections.

23.6.8.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the Frame ID corresponding to the next sending slot is selected for transmission.

The Data Section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

23.6.8.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest Frame ID) is selected next. Only Frame ID’s which are higher than the largest static Frame ID are allowed for the dynamic segment.

In the dynamic segment different slot counter sequences are possible (concurrent sending of different Frame ID’s on both channels). Therefore pending messages are selected according to their Frame ID and their channel configuration bit.

The Data Section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by SLT in the MHD Configuration Register 1 defines the maximum minislot value allowed before inhibiting new Frame transmission in the dynamic segment of the current cycle.

23.6.8.3 Transmit Buffers

A portion of the E-Ray Message Buffers can be configured as transmit buffers by programming bit CFG in the Header Section of the respective Message Buffer to 1. This can be done via the Write Header Section 1 register.

There exist the following possibilities to assign a transmit buffer to the Communication Controller channels:

- Static segment: channel A **or** channel B, channel A **and** channel B

- Dynamic segment: channel A **or** channel B

Message Buffer 0 is dedicated to hold the startup Frame, the SYNC Frame, or the designated single slot Frame as configured by TXST, TXSY, and TSM in the SUC Configuration Register 1. In this case it can be reconfigured in “DEFAULT_CONFIG” or “CONFIG” state only. This ensures that any node transmits at most one startup / SYNC Frame per communication cycle. Transmission of startup / SYNC Frames from other Message Buffers is not possible.

All other Message Buffers configured for transmission in static or dynamic segment are reconfigurable during runtime. Due to the organization of the Data Partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the Header Section of a Message Buffer may lead to erroneous configurations. If a Message Buffer is reconfigured during runtime it may happen that this Message Buffer is not send out in the respective communication cycle.

The Communication Controller does not have the capability to calculate the Header CRC. The Host is supposed to provide the Header CRCs for all transmit buffers. If Network Management is required the Host has to set the PPIT bit in the Header Section of the respective Message Buffer to 1 and write the Network Management information to the Data Section of the Message Buffer (see **Section 23.6.6**).

The payload length field configures the data payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by SFDL in the Message Handler Configuration Register 1, the Communication Controller generates padding byte to ensure that Frames have proper physical length. The padding pattern is logical zero.

Each transmit buffer provides a transmission mode flag TXM that allows the Host to configure the transmission mode for the transmit buffer in the static segment. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode. In dynamic segment the transmitter always works in single-shot mode.

If a Message Buffer is configured in the continuous mode, the Communication Controller does not reset the transmission request flag TXR after successful transmission. In this case a Frame is sent out each time the Frame ID and cycle counter filter match. The TXR flag can be reset by the Host by writing the respective Message Buffer number to the Input Buffer Command Request register while bit **STXRH** in the Input Buffer Command Mask register is reset to 0.

If two or more transmit buffers are configured with the same Frame ID **and** cycle counter filter value, the transmit buffer with the lowest Message Buffer number will be transmitted in the respective slot.

23.6.8.4 Frame Transmission

To prepare a transmit buffer for transmission the following steps are required:

- Configure the Message Buffer as transmit buffer by writing bit CFG = 1 in the Write Header Section 1 register
- Write transmit message (Header and Data Section) to the Input Buffer.
- To transfer a transmit message from Input Buffer to the Message RAM proceed as described on **“Data Transfer from Input Buffer to Message RAM” on Page 23-224**.
- If configured in the Input Buffer Command Mask register the Transmission Request flag for the respective Message Buffer will be set as soon as the transfer has completed, and the Message Buffer is ready for transmission.
- Check whether the Message Buffer has been transmitted by checking the TXR bits (TXR = 0) in the Transmission Request 1,2 registers (single-shot mode only).

In single-shot mode the Communication Controller resets the TXR flag after transmission has been completed. Now the Host may update the transmit buffer with the next message. The Communication Controller does not transmit the message before the Host has indicated that the update is completed by setting the Transmission Request flag TXR again. The Host can check the actual state of the TXR flags of all Message Buffers by reading the Transmission Request registers. After successful transmission, if bit **WRHS1.MBI** in the Header Section of the respective Message Buffer is set, the transmit service request flag in the Status Service Request Register is set (TXI = 1). If enabled an service request is generated.

23.6.8.5 NULL Frame Transmission

If in static segment the Host does not set the transmission request flag before transmit time, and if there is no other transmit buffer with matching filter criteria (matching Frame ID and cycle counter filter), the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0 and the payload data reset to zero.

In the following cases the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0, and the rest of the Frame Header and the Frame length unchanged (payload data is reset to zero):

- All transmit buffers configured for the slot have cycle counter filters that do not match the current cycle
- There are matching Frame ID’s and cycle counter filters, but none of these transmit buffers has the transmission request flag TXR set

NULL Frames are not transmitted in the dynamic segment.

23.6.9 Receive Process

The receive process is described in the following sections.

23.6.9.1 Frame Reception

To prepare or change a Message Buffer for reception the following steps are required:

- Configure the Message Buffer as receive buffer by writing bit CFG = 0 in the Write Header Section 1 register
- Configure the receive buffer by writing the configuration data (Header Section) to the Input Buffer
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target Message Buffer to the Input Buffer Command Request register.

Once these steps are performed, the Message Buffer functions as an active receive buffer and participates in the internal acceptance filtering process, which takes place every time the Communication Controller receives a message. The first matching receive buffer is updated from the received message. If the Message Buffer holds an unprocessed Data Section (ND = 1) it is overwritten with the new message and the MLST bit in the respective Message Buffer Status register is set.

If the payload length of a received Frame PLC is longer than the value programmed by PLC in the Header Section of the respective Message Buffer, the data field stored in the Message Buffer is truncated to that length.

If no Frame, a NULL Frame, or a corrupted Frame is received in a slot, the Data Section of the Message Buffer configured for this slot is not updated. In this case only the flags in the Message Buffer Status register are updated to signal the cause of the problem. In addition the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

When the Data Section of a receive buffer has been updated from a received Frame, the respective New Data **NDn (n = 0-31)** to **NDn (n = 96-127)** flag in the New Data **NDAT1** to **NDAT4** registers is set. When the Message Handler has updated the Message Buffer status, the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set. If bit **RDHS1.MBI** in the Header Section of the respective Message Buffer is set, the receive service request flag in the Status Service Request Register is set (RXI = 1). If enabled an service request is generated.

To read a receive buffer from the Message RAM via the Output Buffer proceed as described on **“Data Transfer from Message RAM to Output Buffer” on Page 23-226**.

Note: The ND and MBC flags are automatically cleared by the Message Handler when the received message has been transferred to the Output Buffer.

23.6.9.2 NULL Frame reception

The Payload Segment of a received NULL Frame is **not** copied into the matching receive buffer. If a NULL Frame has been received, the Header Section of the matching Message Buffer is updated from the received NULL Frame. The NULL Frame indication bit in the Header Section 3 of the respective Message Buffer is reset (NFI = 0) and the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

In case that bit ND and / or MBC were already set before this event because the Host did not read the last received message, bit MLST in the Message Buffer Status register of the respective Message Buffer is also set.

23.6.10 FIFO Function

A group of the Message Buffers can be configured as a cyclic First-In-First-Out (FIFO). The group of Message Buffers belonging to the FIFO is contiguous in the register map starting with the Message Buffer referenced by FFB and ending with the Message Buffer referenced by LCB in the Message RAM Configuration register. Up to 128 Message Buffers can be assigned to the FIFO.

23.6.10.1 Description

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case Frame ID, payload length, receive cycle count, and the status bits of the addressed FIFO Message Buffer are overwritten with Frame ID, payload length, receive cycle count, and the status from the received message and can be read by the Host for message identification. Bit RFNE in the Status Service Request Register shows that the FIFO is not empty, bit RFF in the Status Service Request Register is set when the last available Message Buffer belonging to the FIFO is written, bit RFO in the Error Service Request Register shows that a FIFO overrun has been detected. If enabled, service requests are generated.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the Message Buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available Message Buffer. If the PIDX register is incremented past the highest numbered Message Buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) Message Buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next Message Buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a Message Buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message

overwrites the oldest message in the FIFO. This will set FIFO overrun flag RFO in the Error Service Request Register.

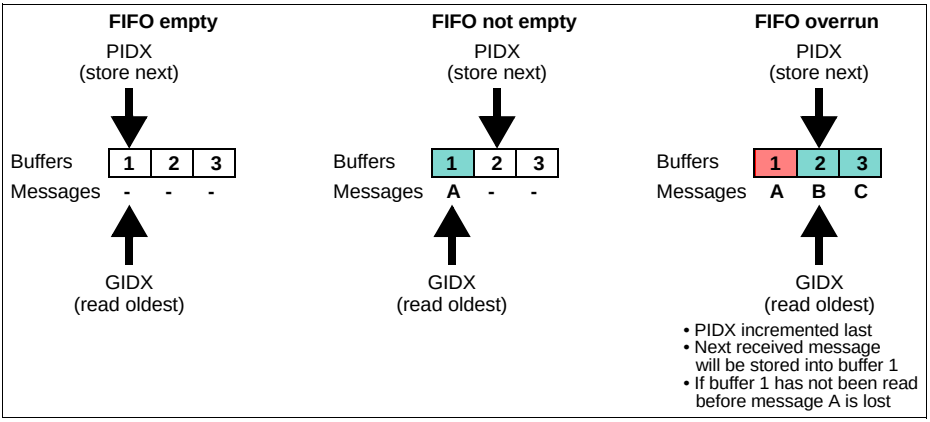

Figure 23-10 FIFO Status: Empty, Not Empty, Overrun

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag RFNE is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in **Figure 23-10** for a three Message Buffer FIFO.

There is a programmable FIFO rejection filter for the FIFO. The FIFO Rejection Filter register (FRF) defines a filter pattern for messages to be rejected. The FIFO rejection filter consists of channel filter, Frame ID filter, and cycle counter filter. If bit RSS is set to 1 (default), all messages received in the static segment are rejected by the FIFO. If bit RNF is set to 1 (default), received NULL Frames are not stored in the FIFO.

The FIFO Rejection Filter Mask register (FRFM) specifies which bits of the Frame ID filter in the FIFO Rejection Filter register are marked “don’t care” for rejection filtering.

23.6.10.2 Configuration of the FIFO

For all Message Buffers belonging to the FIFO the data pointer to the first 32-bit word of the Data Section of the respective Message Buffer in the Message RAM has to be configured via the Write Header Section 3 register. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask and needs not be configured in the Header Sections of the Message Buffers belonging to the FIFO.

When programming the data pointers for the Message Buffers belonging to the FIFO, the payload length of all Message Buffers should be programmed to the same value.

*Note: It is recommended to program the MBI bits of the Message Buffers belonging to the FIFO to 0 via **WRHS1.MBI** to avoid generation of RX interrupts.*
*If the payload length of a received Frame is longer than the value programmed by **WRHS2.PLC** in the Header Section of the respective Message Buffer, the data field stored in a Message Buffer of the FIFO is truncated to that length.*

23.6.10.3 Access to the FIFO

To read from the FIFO the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first Message Buffer of the FIFO (referenced by FFB) to the Output Buffer Command Request register. The Message Handler then transfers the Message Buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

23.6.11 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two Transient Buffer RAMs. All accesses to the internal RAM's are 32 bit accesses.

Access to the Message Buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two protocol controllers and the Host to the Message RAM.

Frame IDs of Message Buffers assigned to the static segment have to be in the range from 1 to NSS as configured in the GTU Configuration Register 7. Frame IDs of Message Buffers assigned to the dynamic segment have to be in the range from NSS + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

23.6.11.1 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source Message Buffer to be accessed to the Input or Output Buffer Command Request register.

The Input / Output Buffer Command Mask registers can be used to write / read Header and Data Section of the selected Message Buffer separately. If bit **STXRS** in the Input Buffer Command Mask register is set (**STXRS** = 1), the transmission request flag TXR of the selected Message Buffer is automatically set after the Message Buffer has been updated.

If bit **STXRS** in the Input Buffer Command Mask register is reset (**STXRS** = 0), the transmission request flag TXR of the selected Message Buffer is reset. This can be used to stop transmission from Message Buffers operated in continuous mode.

Input Buffer (IBF) and the Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

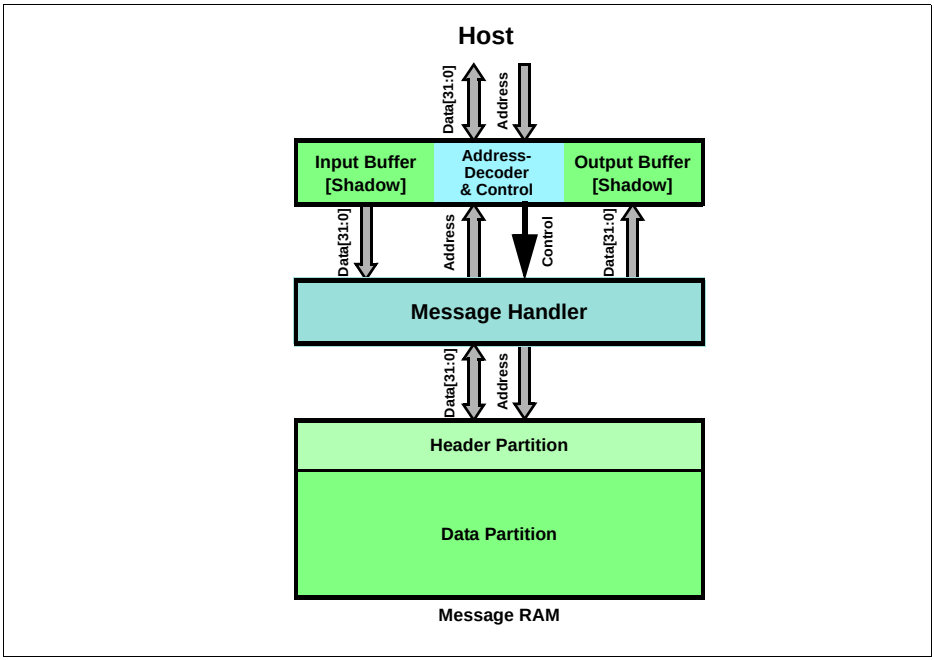

Figure 23-11 Host Access to Message RAM

Data Transfer from Input Buffer to Message RAM

To configure / update a Message Buffer in the Message RAM, the Host has to write the data to **WRDSnn (nn = 01-64)** and the Header to **WRHS1**, **WRHS2**, **WRHS3**. Two sets of **WRDSnn (nn = 01-64)** are available in parallel and selected by **CUST1.IBF1PAG**and **CUST1.IBF2PAG**. **CUST1.IBFS** shows which Input Buffer is currently used as Input Shadow Buffer and which as Input Host Buffer. **WRHS1**, **WRHS2**, and **WRHS2** does only exist once. The specific action is selected by configuring the Input Buffer Command Mask **IBCM**.

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register **IBCR**, IBF Host and IBF Shadow are swapped (see **Figure 23-12**).

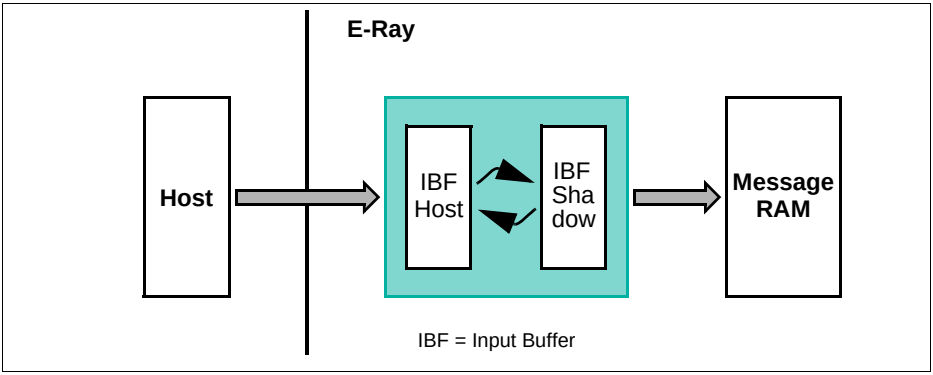

Figure 23-12 Double Buffer Structure Input Buffer

In addition the bits in the Input Buffer Command Mask and Input Buffer Command Request registers are also swapped to keep them attached to the respective IBF section (see **Figure 23-13**).

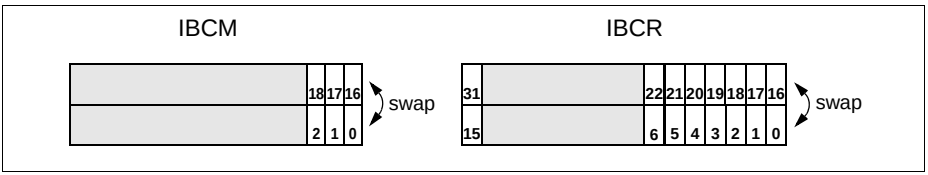

Figure 23-13 Swapping of IBCM and IBCR Bit

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH in the Input Buffer Command Request register.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0, IBSYS remains set to 1, and the next transfer

to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS and the Command Mask flags are also swapped.

Table 23-16 Assignment of Input Buffer Command Mask Bit

Pos.	Access	Bit	Function
18	rh	**STXRS**	Set Transmission Request Shadow
17	rh	**LDSS**	Load Data Section Shadow
16	rh	**LHSS**	Load Header Section Shadow
2	rw	**STXRH**	Set Transmission Request Host
1	rw	**LDSH**	Load Data Section Host
0	rw	**LHSH**	Load Header Section Host

Table 23-17 Assignment of Input Buffer Command Request Bit

Pos.	Access	Bit	Function
31	rh	IBSYS	**IBF Busy Shadow,** signals ongoing transfer from IBF Shadow to Message RAM
21–16	rh	IBRS	**IBF Request Shadow,** number of Message Buffer currently / last updated
15	rh	IBSYH	**IBF Busy Host,** transfer request pending for Message Buffer referenced by IBRH
5-0	rwh	IBRH	**IBF Request Host,** number of Message Buffer to be updated next

Data Transfer from Message RAM to Output Buffer

To read a Message Buffer from the Message RAM, the Host has to write to Command Request register **OBCR** to trigger the data transfer as configured in Output Buffer Command Mask **OBCM** register. After the transfer has completed, the Host can read the transferred data from **RDDSnn (nn = 01-64)**, **RDHS1**, **RDHS2**, **RDHS2**, and **MBS**.

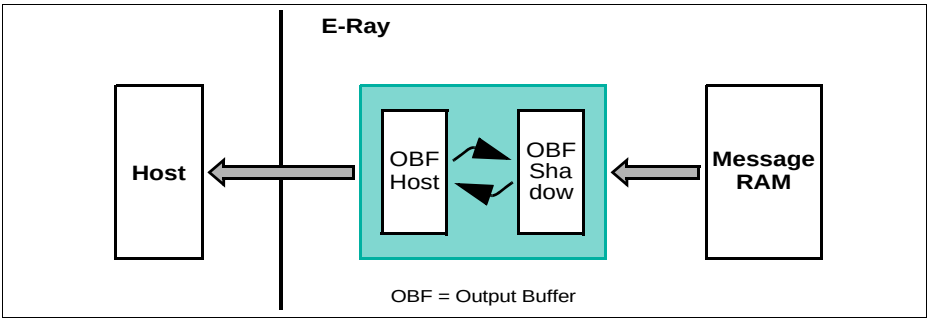

Figure 23-14 Double Buffer Structure Output Buffer

OBF Host and OBF Shadow as well as bits **OBCM.RHSS**, **OBCM.RDSS**, **OBCM.RHSH**, **OBCM.RDSH** and bits **OBCR.OBRS**, **OBCR.OBRH** are swapped under control of bits **OBCR.VIEW** and **OBCR.REQ**.

Writing bit **OBCR.REQ** to 1 copies bits **OBCM.RHSS**, **OBCM.RDSS** and bits **OBCR.OBRS** to an internal storage (see **Figure 23-15**).

After setting **OBCR.REQ** to 1, **OBCR.OBSYS** is set to 1, and the transfer of the Message Buffer selected by **OBCR.OBRS** from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, the **OBCR.OBSYS** bit is set back to 0. Bits **OBCR.REQ** and **OBCR.VIEW** can only be set to 1 while **OBCR.OBSYS** is 0.

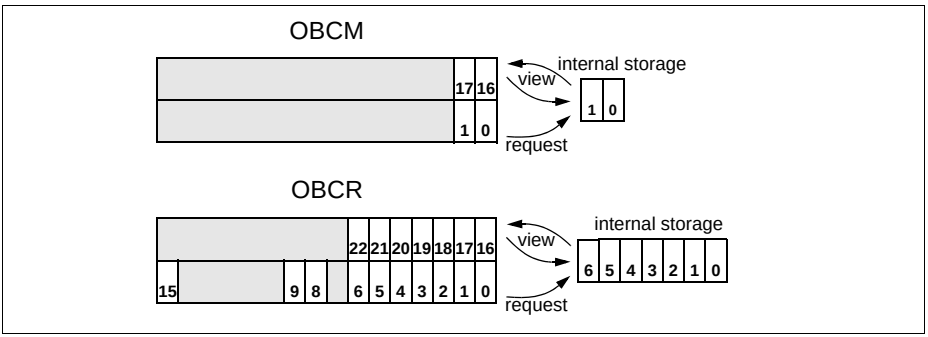

Figure 23-15 Swapping of OBCM and OBCR Bit

OBF Host and OBF Shadow are swapped by setting bit **OBCR.VIEW** to 1 while bit **OBCR.OBSYS** is 0 (see **Figure 23-14**).

In addition bits **OBCR.OBRH** and bits **OBCM.RHSH**, **OBCM.RDSH** are swapped with the registers internal storage thus assuring that the Message Buffer number stored in

OBCR.OBRH and the mask configuration stored in **OBCM.RHSH**, **OBCM.RDSH** matches the transferred data stored in OBF Host (see **Figure 23-15**).

Now the Host can read the transferred Message Buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

Table 23-18 Assignment of Output Buffer Command Mask Bit

Pos.	Access	Bit	Function
17	rh	RDSH	Data Section available for Host access
16	rh	RHSH	Header Section available for Host access
1	rw	RDSS	Read Data Section Shadow
0	rw	RHSS	Read Header Section Shadow

Table 23-19 Assignment of Output Buffer Command Request Bit

Pos.	Access	Bit	Function
22–16	rh	OBRH	**OBF Request Host,** number of Message Buffer available for Host access
15	rh	OBSYS	**OBF Busy Shadow,** signals ongoing transfer from Message RAM to OBF Shadow
9	rw	REQ	**Request Transfer from Message RAM to OBF Shadow**
8	rwh	VIEW	**View OBF Shadow, swap OBF Shadow, and OBF Host**
6–0	rwh	OBRS	**OBF Request Shadow,** number of Message Buffer for next request

23.6.11.2 Data Transfers between IBF / OBF and Message RAM

This document uses the following terms and abbreviations:

Table 23-20 Terms and Abbreviations

Term	Meaning
MHD	Message Handler
IBF	Input Buffer 1 or 2 RAM
OBF	Output Buffer 1 or 2 RAM
MBF	Message Buffer RAM
TBF	Transient Buffer RAM Channel A (TBF1) or Channel B (TBF2)

Table 23-20 Terms and Abbreviations (cont'd)

IBF ⇒ MBF	Transfer from IBF to MBF
MBF ⇒ OBF	Transfer from MBF to OBF
MBF ⇒ TBF	Transfer from MBF to TBF
TBF ⇒ MBF	Transfer from TBF to MBF
SS	Slot Status
SS ⇒ MBF	Transfer SS to MBF

Message Handler functionality

The MHD controls the access to the MBF. It manages data-transfer between MBF and IBF, OBF, TBF1, TBF2. The data-path are shown in Figure 23-16.

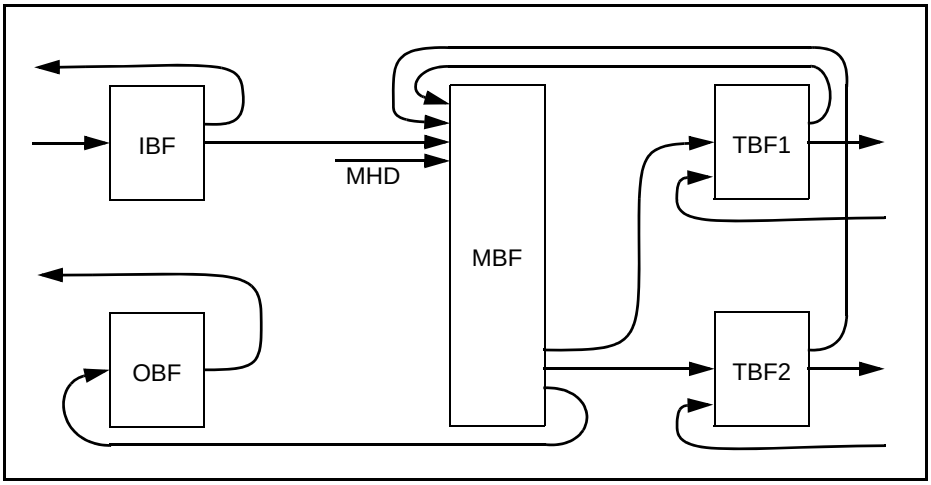

Figure 23-16 Interconnection of RAMs

Furthermore a search-algorithm allows to find the next valid message object in the MBF for transmission or reception.

Each transfer consists of a setup-time, four time steps to transfer the Header-section and a payload-length-dependent number of time steps to transfer the data-section. The internal data-busses have a width of 32 bits. Thereby it is possible to transfer two 2-byte words in one time step. If the payload consists of an odd number of 2-byte words the last time step of the data-section contains only 16 bit of valid data. If the Payload-Length (PL) is e.g. 7, the data-section consists of 4 time steps.

The maximum length for the data-section is 64 time steps, the minimum length is zero time steps.

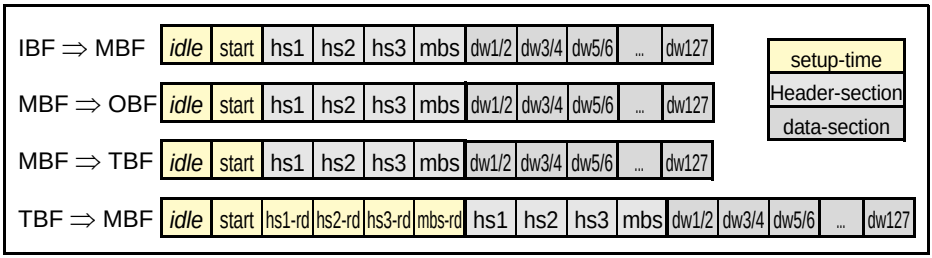

Figure 23-17 Different Possible Buffer Transfers

The update of the Slot-Status consists of a setup-time and one time-step to write the new Slot-Status.

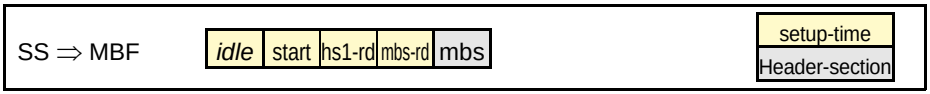

Figure 23-18 Update of Slot Status

The length of a time step depends on the number of concurrent tasks.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Thereby the time step length can vary between one and three f_{CLC_ERAY}periods.

Under certain conditions it is possible that a transfer is stopped or interrupted for a number of time steps until it is continued.

When a IB F⇒ MBF is started short after a TBF ⇒ MBF or SS ⇒ MBF the transfer from IBF has to wait until the setup-time of the internal transfer has finished (see Figure 23-19)

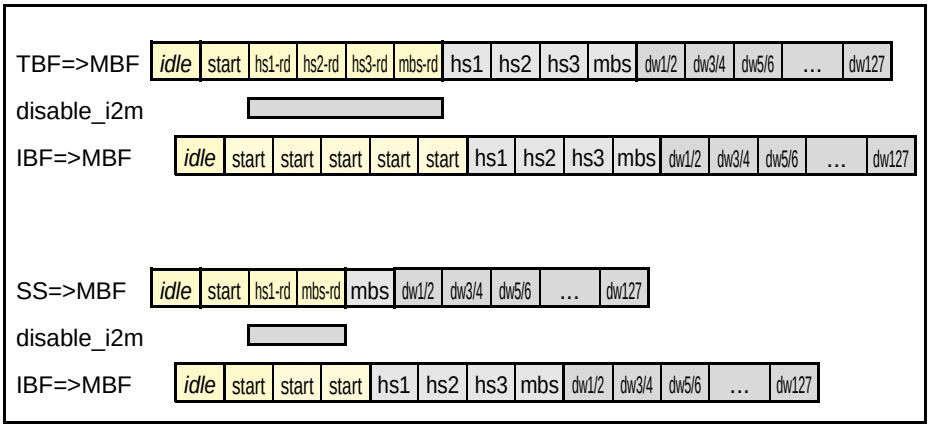

Figure 23-19 Delay start of IBF⇒MBF

The internal signal “disable_i2m” is always active when the TBF ⇒ MBF is in state “hs1-rd”, “hs2-rd”, “hs3-rd” or “mbs-rd” and when the SS ⇒ MBF is in state “hs1-rd” or “mbs-rd”.

The IBF ⇒ MBF is hold in state “start” until the internal signal “disable_i2m” gets inactive.

These additional time-steps are independent of any address-counter-values. This means, the IBF ⇒ MBF has to wait even if it writes to another buffer than the internal transfer.

Multiple requests of transfers between IBF/OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the number of 4-byte words to be transferred, the number of concurrent tasks to be managed by the Message Handler, and in special cases the type and address range of the internal transfer. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) plus a short setup time to start the first transfer, while the number of concurrent task varies from one to three. The 4 Header words have to be included in calculation even if only the Data Section is requested for transfer.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Transfers between IBF and MBF respectively MBF and OBF can only be handled one after another. In case that e.g. a IBF ⇒ MBF has been started shortly before a

MBF ⇒ OBF is requested, the MBF ⇒ OBF has to wait until the IBF ⇒ MBF has completed.

In case that e.g. a second IBF⇒MBF is requested, a MBF⇒OBF is requested and a IBF⇒MBF is ongoing, the MBF⇒OBF has to wait until the first IBF⇒IBF has completed. The second IBF=MBF has to wait until the MBF⇒OBF has completed (see figure 23-20) independent whether MBF⇒OBF or second IBF⇒MBF is requested first.

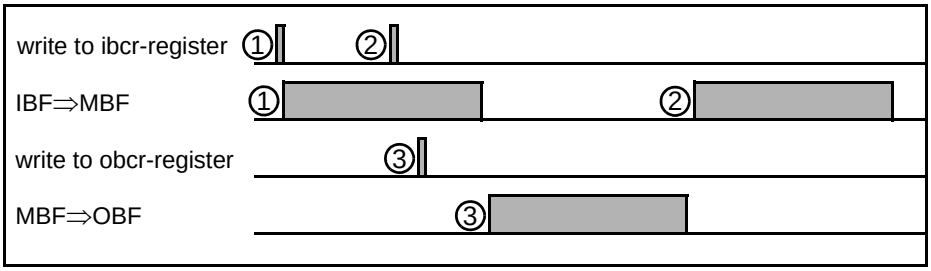

Figure 23-20 Multiple IBF/OBF Request

Worst case for single request

When a message with a large payload length is received the TBF⇒MBF is started at the begin of the next slot (n+1). If the next slot is a dynamic slot without transmission/reception (minislot), it may happen that the TBF⇒MBF has not finished until begin of the next but one slot (n+2). In this case the TBF⇒MBF will be service requested (break) to start a transmission in the next but one slot (MBF⇒TBF) and/or to update the slot status (SS⇒MBF) for the RX-buffer corresponding with next slot (n+1). After this interruption the TBF⇒MBF is continued.

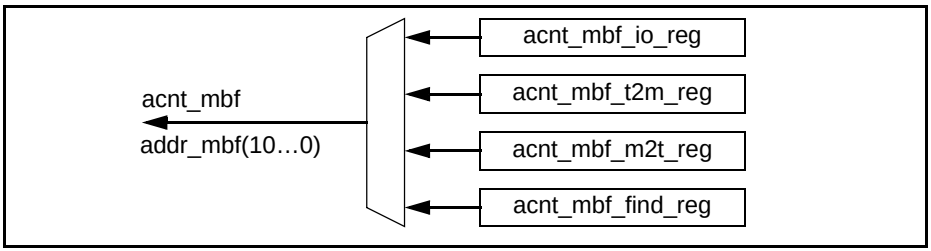

Figure 23-21 Address Counter Scheme of Message RAM (simplified)

For the transfers IBF⇒MBF / MBF⇒OBF, TBF⇒MBF and MBF⇒TBF separate address-counter are implemented (see Figure 23-21).

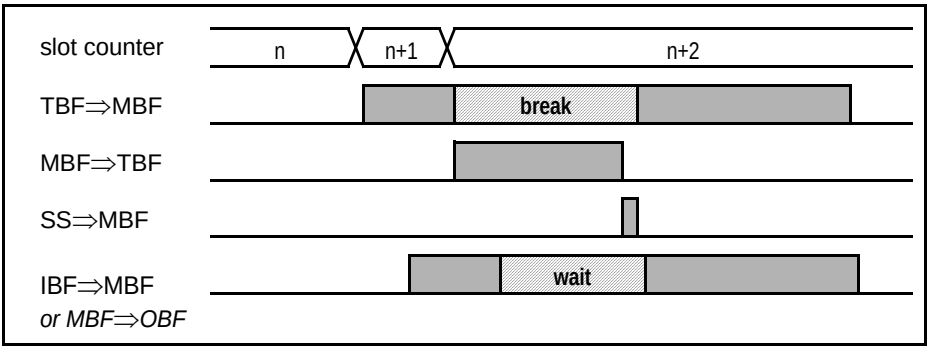

Figure 23-22 interruption of TBF⇒MBF

If the address-counter for IBF⇒MBF / MBF⇒OBF (acnt_mbf_io_reg) reaches the address of the interrupted TBF=>MBF (acnt_mbf_t2m_reg) the IBF⇒MBF / MBF⇒OBF has to wait until the TBF⇒MBF is continued (see Figure 23-22).

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

$$\text{tbf\_to\_mbf\_break time}_{max} = (\text{setup time} + \text{mbf\_to\_tbf time}_{max}) + (\text{setup time} + \text{ss\_to\_mbf})$$

$$\text{cycles}_{req} = (\text{number of concurrent tasks}) \times ((\text{setup time} + (\text{number of 4-byte words})_{req}) + \text{tbf\_to\_mbf\_break time})$$

$$\text{setup time} = 2\ f_{CLC\_ERAY}\ \text{cycles}$$

Worst case for one IBF⇒MBF or MBF⇒OBF:

Max. break time: tbf_to_mbf_break time$_{max}$ = (2+68) + (4+1) = 75

Max. number of f_{CLC_ERAY} cycles: cycles$_{req}$ = 3 × (6 + 68 + 75) = 435

Worst case for multiple transfers

If a second IBF⇒MBF and a MBF⇒OBF (see Figure 23-20) is requested directly after the first IBF⇒MBF has started following worst case timing could appear:

cycles$_{trans}$ = (remaining cycles of transfer running)
+ (cycles of second requested transfer)
+ (cycles of third requested transfer)

cycles$_{trans}$ = cycles$_{rem}$ + cycles$_{req_2}$+ cycles$_{req_3}$

Max. number of f_{CLC_ERAY} cycles: cycles$_{trans}$ = 447 + 435 + 447 = 1329

23.6.11.3 Minimum f_{CLC_ERAY}

To calculate the minimum f_{CLC_ERAY} the worst case scenario has to be considered.

The worst case scenario depends on the following parameters

- maximum payload length
- minimum minislot length
- number of configured Message Buffers (excluding FIFO)
- used channels (single/dual channel)

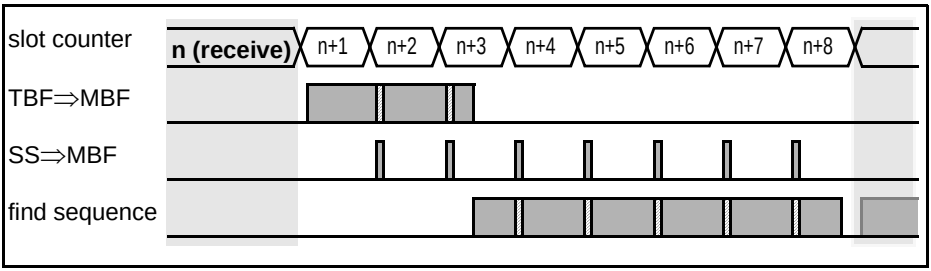

Figure 23-23 worst case scenario

Worst case scenario:

- reception of message with a maximum payload length in Slot n (n is 7,15,23,31,39,…)
- slot n+1 to n+7 are empty dynamic slots (minislot) and configured as receive buffer
- the find-sequence (usually started in slot 8,16,24,32,40,…) has to scan the maximum number of configured buffers
- the number of concurrent tasks has its maximum value of three

The find-sequence is executed each 8 Slots (slot 8,16,24,32,40,…). It has to be finished until the next find-sequence is requested.

The length of a TBF⇒MBF varies from 4 (Header Section only) to 68 (Header + maximum Data Section) time step plus a setup time of 6 time steps.

$$cycles_{t2m} = \frac{f_{CLC\_ERAY}}{\text{number of concurrent tasks}) \times (\text{setup time}_{t2m} + (\text{number of 4-byte words})_{t2m})}$$

A SS⇒MBF has a fixed length of 1 time steps plus a setup time of 4 time steps.

$$cycles_{ss2m} = \frac{f_{CLC\_ERAY}}{(\text{number of concurrent tasks}) \times 5}$$

The find sequence has a maximum length of 128 (maximum number of buffers) time steps plus a setup time of 2 time steps.

$$cycles_{find} = \frac{f_{CLC\_ERAY}}{(\text{number of concurrent tasks}) \times (\text{setup time}_{find} + (\text{number of configured buffers}))}$$

A minislot has a length of 2 to 63 Macrotick (gdMinislot). The minimum nominal Macrotick period (cdMinMTNom) is 1 µs. A sequence of 8 minislots has a length of

$$time_{8minislots} = 8 \times gdMinislot \times cdMinMTNom$$

The maximum period $T_{CLC\_ERAY} = 1/f_{CLC\_ERAY}$ can be calculated as followed:

$$time_{8minislots} \geq (f_{CLC\_ERAY}\ \text{period in}\ \mu s) \times (\ (f_{CLC\_ERAY}\ cycles_{t2m}) + 7 \times (f_{CLC\_ERAY}\ cycles_{ss2m}) + (f_{CLC\_ERAY}\ cycles_{find}))$$

$$f_{CLC\_ERAY}\ \text{period in ms} \leq \frac{time_{8mnislots}}{(\ cycles_{t2m}) + 7 \times (cycles_{ss2m}) + (cycles_{find})}$$

minimum $time_{8minislots}$ = $8 \times 2 \times 1\ \mu s = 16\ \mu s$

maximum $f_{CLC\_ERAY}\ cycles_{t2m}$ = $3 \times (6 + 68) = 222$

maximum $f_{CLC\_ERAY}\ cycles_{ss2m}$ = $3 * 5 = 15$

maximum $f_{CLC\_ERAY}\ cycles_{find}$ = $3 * (2 + 128) = 390$

$$f_{CLC\_ERAY}\ \text{period in ms} \leq \frac{16\mu s}{222 + 7 \times 15 + 390} = 22.315\ldots ns$$

The minimum f_{CLC_ERAY} frequency for this worst case scenario is 44.8125 MHz.

A too low f_{CLC_ERAY} frequency can cause a malfunction of the E-Ray.

The E-Ray can detect several malfunctions and reports this by setting the corresponding flag in the Message Handler Constraints Flags (**MHDF**) register.

Minimum f_{CLC_ERAY} for various maximum payload length

Table 23-21 summarizes the minimum required f_{CLC_ERAY} frequency for various maximum payload length assuming:

- a minimum minislot length of 2µs.
- a maximum of 128 configured Message Buffers.
- dual channels in use.

Table 23-21 Minimum f_{CLC_ERAY} for different maximum payload length

Maximum payload length of 32 bit words	4	8	16	32	64
minimum f_{CLC_ERAY}	32,82 MHz	33,57 MHz	35,07 MHz	38,07 MHz	44,1 MHz

Minimum f_{CLC_ERAY} for various minimum minislot length

Table 23-22 summarizes the minimum required f_{CLC_ERAY} frequency for various minimum minislot length assuming:

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a maximum 128 configured Message Buffers.
- dual channels in use.

Table 23-22 Minimum f_{CLC_ERAY} for different minimum minislot length

gdMinislot at dMinMTNom = 1 µs	2 µs	3 µs	4 µs	7 µs	8 µs
minimum f_{CLC_ERAY}	44,82 MHz	29,88 MHz	22,412 MHz	12,8 MHz	9,96 MHz

Minimum f_{CLC_ERAY} for various amount of configured Message Buffers

Table 23-23 summarizes the minimum required f_{CLC_ERAY} frequency for various amount of configured Message Buffers assuming:

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a minimum minislot length of 2 µs.
- dual channels in use.

Table 23-23 Minimum f_{CLC_ERAY} for different amount of configured Message Buffers

Configured maximum amount of Message Buffers	128	64	32
minimum f_{CLC_ERAY}	44,82 MHz	32,82 MHz	26,82 MHz

Minimum f_{CLC_ERAY} for a typical configuration

´The minimum required f_{CLC_ERAY} frequency for various assuming the following typical E-Ray configuration:

- a maximum payload length of 32 bytes / 8 four-byte-words.
- a minimum minislot length of 7 µs.
- a maximum 128 configured Message Buffers.
- dual channels in use

The minimum f_{CLC_ERAY} frequency for this typical example would be 10 MHz.

23.6.11.4 FlexRay™ Protocol Controller access to Message RAM

The two Transient Buffer RAMs (TBF 1, TBF 2) are used to buffer the data for transfer between the two FlexRay™ Protocol Controllers and the Message RAM.

Each Transient Buffer RAM is build up as a double buffer, able to store two complete FlexRay™ messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be send to Transient Buffer Tx, the FlexRay™ Channel Protocol Controller can access Transient Buffer Rx to store the message it is actually receiving. During transmission of the message stored in Transient Buffer Tx, the Message Handler transfers the last received message stored in Transient Buffer Rx to the Message RAM (if it passes acceptance filtering) and updates the respective Message Buffer.

Data transfers between the Transient Buffer RAMs and the shift registers of the FlexRay™ Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay™ messages.

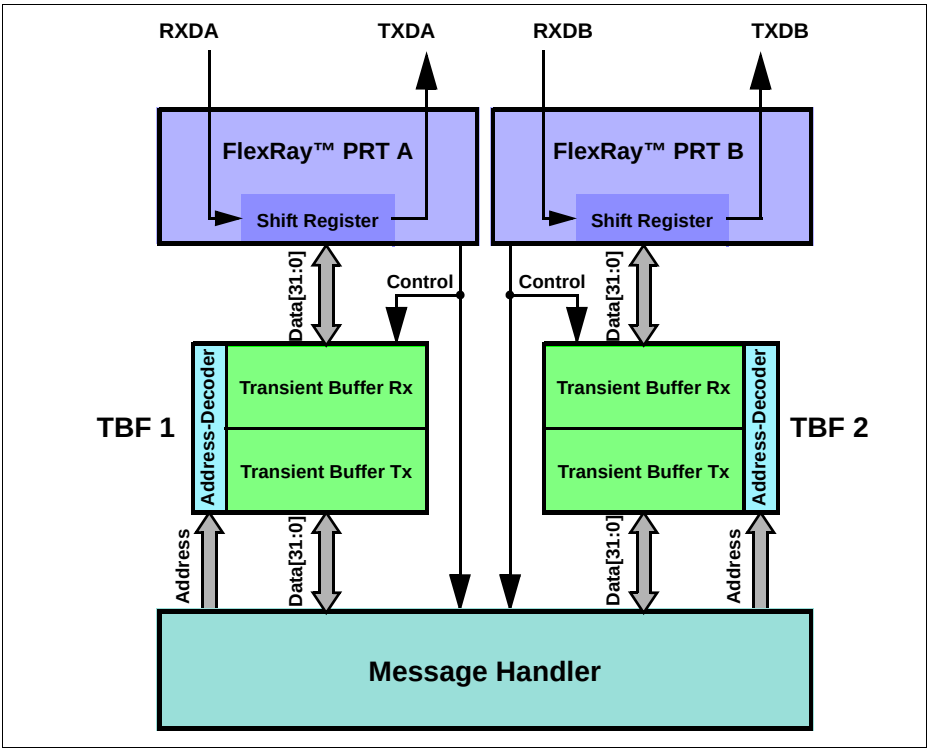

Figure 23-24 Access to Transient Buffer RAMs

23.6.12 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay™ message reception / transmission, the Host cannot directly access the Message Buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 Message Buffers depending on the configured payload length.

The Message RAM is organized 2048 x 32. To achieve the required flexibility with respect to different numbers of data byte per FlexRay™ Frame (0 to 254), the Message RAM has a structure as shown in **Figure 23-25**.

The Data Partition is allowed to start at Message RAM word number: (MRC.LCB + 1) • 4

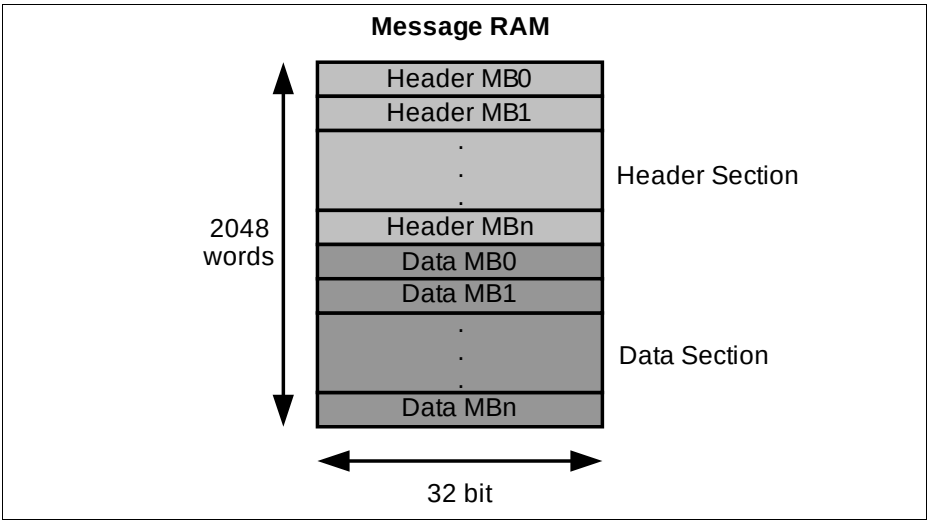

Figure 23-25 Structure of Message RAM

Header Partition

Stores Header Segments of FlexRay™ Frames:

- Supports a maximum of 128 Message Buffers
- Each Message Buffer has a Header of four 32 bit words
- Header 3 of each Message Buffer holds the11 bit pointer to the respective Data Section in the Data Partition

Data Partition

Flexible storage of Data Sections with different length. Some maximum values are:

- 30 Message Buffers with 254 byte Data Section each
- Or 56 Message Buffers with 128 byte Data Section each
- Or 128 Message Buffers with 48 byte Data Section each

Restriction: Header Partition + Data Partition may not occupy more than 2048 32-bit words.

23.6.12.1 Header Partition

The Header of each Message Buffer occupies four 32-bit words in the Header Partition of the Message RAM. The Header of Message Buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received **PLR**, Receive Cycle Count **RCC**, Received on Channel Indication **RCI**, Startup Frame Indication bit **SFI**, Sync bit **SYN**, NULL Frame Indication bit **NFI**, Payload Preamble Indication bit **PPI**, and Reserved bit **RES** are only updated from received valid Frames (including valid NULL Frames).

Header word 4 of each configured Message Buffer holds the respective Message Buffer Status **MBS** information.

Table 23-24 Header Section of a Message Buffer in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1			MBI	TXM	NME	CFG	CHB	CHA		Cycle Code												Frame ID										
2		Payload Length Received								Payload Length Configured												Tx Buffer: Header CRC Configured Rx Buffer: Header CRC Received										
3			RES	PPI	NFI	SYN	SFI	RCI		Receive Cycle Count												Data Pointer										
4			RESS	PPIS	NFIS	SYNS	SFIS	RCIS		Cycle Count Status							TFB	FTY		MLST	ESB	ESA	TCIB	TCIA	SVOB	SVOA	CEOB	CEOA	SEOB	SEOA	VFRB	VFRA

- Frame Configuration
- Filter Configuration
- Message Buffer Control
- Message RAM Configuration
- Updated from received Frame
- Message Buffer Status
- unused

Header 1 (word 0)

Write access via **WRHS1**, read access via **RDHS1**:

- Frame ID: Slot counter filtering configuration
- Cycle Code: Cycle counter filtering configuration
- CHA, CHB: Channel filtering configuration
- CFG: Message Buffer configuration: receive / transmit
- PPIT: Payload Preamble Indicator Transmit
- XMI: Transmit mode configuration: single-shot / continuous
- MBI: Message Buffer receive / transmit service request enable

Header 2 (word 1)

Write access via **WRHS2**, read access via **RDHS2**:

- Header CRC
  - Transmit Buffer: Configured by the Host (calculated from Frame Header Segment)
  - Receive Buffer: Updated from received Frame
- Payload Length Configured
  - Length of Data Section (2-byte words) as configured by the Host
- Payload Length Received
  - Length of Payload Segment (2-byte words) stored from received Frame

Header 3

Write access via **WRHS3**, read access via **RDHS3**:

- Data Pointer
  - Pointer to the beginning of the corresponding Data Section in the Data Partition

Read access via **RDHS3**, valid for receive buffers only, updated from received Frames:

- Receive Cycle Count: Cycle count from received Frame
- RCI: Received on Channel Indicator
- SFI: Startup Frame Indicator
- SYN: SYNC Frame Indicator
- NFI: NULL Frame Indicator
- PPI: Payload Preamble Indicator
- RES: Reserved bit

Message Buffer Status MBS (word 3)

Read access via MBS, updated by the Communication Controller at the end of the configured slot.

- VFRA: Valid Frame Received on channel A
- VFRB: Valid Frame Received on channel B
- SEOA: Syntax Error Observed on channel A
- SEOB: Syntax Error Observed on channel B
- CEOA: Content Error Observed on channel A
- CEOB: Content Error Observed on channel B
- SVOA: Slot boundary Violation Observed on channel A
- SVOB: Slot boundary Violation Observed on channel B
- TCIA: Transmission Conflict Indication channel A
- TCIB: Transmission Conflict Indication channel B
- ESA: Empty Slot Channel A
- ESB: Empty Slot Channel B
- MLST: Message LoST
- FTA: Frame Transmitted on Channel A
- FTA: Frame Transmitted on Channel B
- Cycle Count Status: Actual cycle count when status was updated
- RCIS: Received on CHannel Indicator Status
- SFIS: Startup Frame Indicator Status
- SYNS: SYNC Frame Indicator Status
- NFIS: NULL Frame Indicator Status
- PPIS: Payload Preamble Indicator Status
- RESS: Reserved Bit Status

23.6.12.2 Data Partition

The Data Partition of the Message RAM stores the Data Sections of the Message Buffers configured for reception / transmission as defined in the Header Partition. The number of data bytes for each Message Buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay™ Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The Data Partition starts after the last word of the Header Partition. When configuring the Message Buffers in the Message RAM the programmer has to assure that the data pointers point to addresses within the Data Partition. **Table 23-25** below shows an example how the Data Sections of the configured Message Buffers can be stored in the Data Partition of the Message RAM.

The beginning and the end of a Message Buffer's Data Section is determined by the data pointer and the payload length configured in the Message Buffer's Header Section,

respectively. This enables a flexible usage of the available RAM space for storage of Message Buffers with different data length.

If the size of the Data Section is an odd number of 2-byte words, the remaining 16 bits in the last 32-bit word are unused (see **Table 23-25** below)

Table 23-25 Example for Structure of the Data Section in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23.6.12.3 ECC Check

There is an ECC checking mechanism implemented in the E-Ray module to assure the integrity of the data stored in the seven RAM blocks of the module. The RAM blocks have an ECC generator / checker attached as shown in **Figure 23-26**. When data is written to a RAM block, the local ECC generator generates the ECC data. The ECC data is stored together with the respective data word. The ECC data is checked each time a data word is read from any of the RAM blocks.

If an ECC error is detected, the respective error flag is set. The ECC error flags **MHDS.EIBF**, **MHDS.EOBF**, **MHDS.EMR**, **MHDS.ETBF1**, **MHDS.ETBF2**, and the faulty Message Buffer indicators **MHDS.FMBD**, **MHDS.MFMB**, **MHDS.FMB** are located in the Message Handler Status register. These error flags control the error interrupt flag **EIR.EERR**.

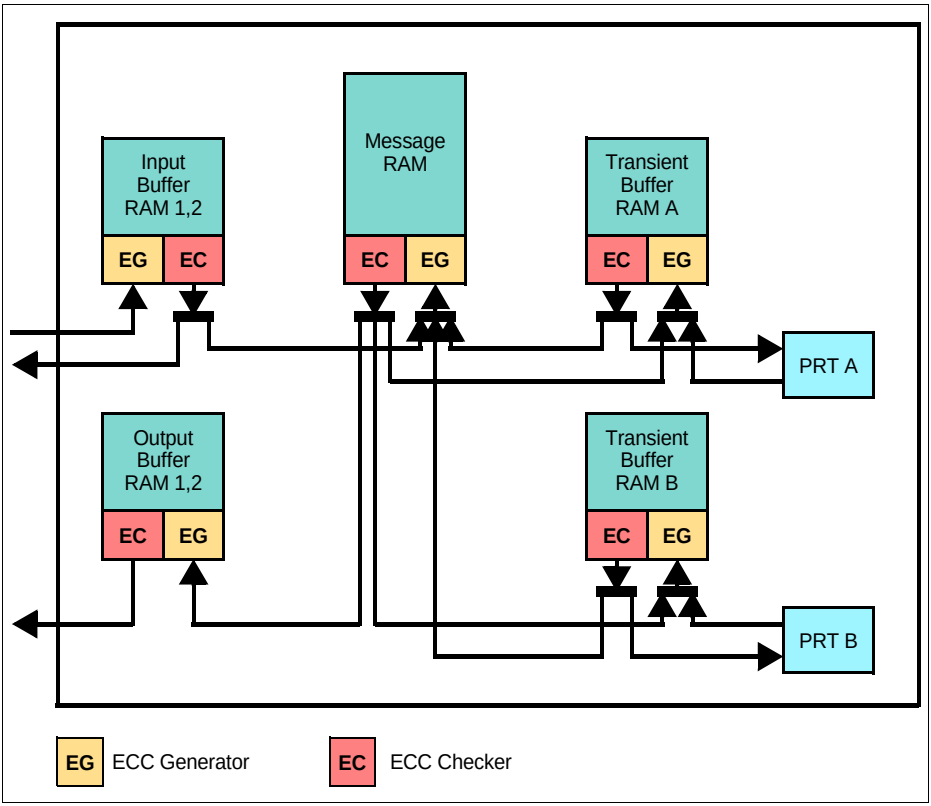

Figure 23-26 ECC Generation and Check

When an ECC error has been detected the following actions will be performed:

In all cases

- The respective ECC error flag in the Message Handler Status **MHDS** register is set
- The ECC error flag **EIR.EERR** in the Error Service Request Register is set, and if enabled, a module service request to the Host will be generated.

Additionally in specific cases

1. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM (Transfer of Header and Data Section)
   a) **MHDS.EIBF** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** has been updated
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) Transmit buffer: Transmission request for the respective Message Buffer is not set
2. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM (Transfer of Data Section only)
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) The Data Section of the respective Message Buffer is not updated
   e) Transmit buffer: Transmission request for the respective Message Buffer is not set
3. ECC error during host reading Input Buffer RAM
   a) • **MHDS.EIBF** bit is set
4. ECC error during scan of Header Sections in Message RAM
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) Ignore Message Buffer (Message Buffer is skipped)
5. ECC error during data transfer from Message RAM ⇒ Transient Buffer RAM A, B
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) Frame not transmitted, Frames already in transmission are invalidated by setting the Frame CRC to zero
6. ECC error during data transfer from Transient Buffer RAM A, B ⇒ Protocol Controller 1, 2
   a) **MHDS.ETBF1**, **MHDS.ETBF2** bit is set
7. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Header Section of respective Message Buffer from Message RAM)
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) The Data Section of the respective Message Buffer is not updated

8. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Transient Buffer RAM A, B)
   a) **MHDS.ETBF1**, **MHDS.ETBF2** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
9. ECC error during data transfer from Message RAM ⇒ Output Buffer RAM
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
10. ECC error during Host reading Output Buffer RAM
    a) • **MHDS.EOBF** bit is set
11. ECC error during data read of Transient Buffer RAM A, B

If an ECC error occurs while the Message Handler reads a Frame with Network Management information (PPI = 1) from the Transient Buffer RAM A, B the corresponding Network Management vector registers NMV1 to NMV3 are not updated from that Frame.

23.6.13 Host Handling of Errors

An ECC error caused by transient bit flips can be fixed by:

23.6.13.1 Self-Healing

ECC errors located in

- Input Buffer RAM 1,2
- Output Buffer RAM 1,2
- Data Section of Message RAM
- Transient Buffer RAM A
- Transient Buffer RAM B

are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay communication.

23.6.13.2 CLEAR_RAMS Command

When called in DEFAULT_CONFIG or CONFIG state POC command CLEAR_RAMS initializes all module-internal RAMs to zero.

23.6.13.3 Temporary Unlocking of Header Section

An ECC error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write-

access to the IBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see **“Lock Register (LCK)” on Page 23-30**).

For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by MRC.SEC[1:0], and will be updated with new data.

23.7 Module Service Request

In general, service requests provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the controller, a Frame is received or transmitted, a configured timer service request is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many service requests can cause the Host to miss deadlines required for the application. Therefore the Communication Controller supports disable / enable controls for each individual service request source separately.

An service request may be triggered when

- An error was detected
- A status flag is set
- A timer reaches a preconfigured value
- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A stop watch event occurred

Tracking status and generating service requests when a status change or an error occurs are two independent tasks. Regardless of whether an service request is enabled or not, the corresponding status is tracked and indicated by the Communication Controller. The Host has access to the actual status and error information by reading the Error Service Request Register **EIR** and the Status Service Request **SIR** Register.

Table 23-26 Module Service Request Flags and Service Request Line Enable

Register	Bit	Function
SIR	WST	Wakeup Status
	CAS	Collision Avoidance Symbol
	CYCS	Cycle Start Service Request
	TXI	Transmit Service Request
	RXI	Receive Service Request
	RFNE	Receive FIFO not Empty
	RFF	Receive FIFO Full
	NMVC	Network Management Vector Changed
	TI0	Timer Service Request 0
	TI1	Timer Service Request 1
	TIBC	Transfer Input Buffer Completed
	TOBC	Transfer Output Buffer Completed
	SWE	Stop Watch Event
	SUCS	Startup Completed Successfully
	MBSI	Message Buffer Status Interrupt
	SDS	Start of Dynamic Segment
	WUPA	Wakeup Pattern Channel A
	MTSA	MTS Received on Channel A
	WUPB	Wakeup Pattern Channel B
	MTSB	MTS Received on Channel B
ILE	EINT0	Enable Service Request Line 0
	EINT1	Enable Service Request Line 1
EIR	PEMC	Protocol Error Mode Changed
	CNA	Command Not Valid
	SFBM	SYNC Frames Below Minimum
	SFO	SYNC Frame Overflow
	CCF	Clock Correction Failure
	CCL	CHI Command Locked
	EERR	ECC Error
	RFO	Receive FIFO Overrun

Table 23-26 Module Service Request Flags and Service Request Line Enable

Register	Bit	Function
EIR	EFA	Empty FIFO Access
	IIBA	Illegal Input Buffer Access
	IOBA	Illegal Output Buffer Access
	MHF	Message Handler Constraints Flag
	EDA	Error Detected on Channel A
	LTVA	Latest Transmit Violation Channel A
	TABA	Transmission Across Boundary Channel A
	EDB	Error Detected on Channel B
	LTVB	Latest Transmit Violation Channel B
	TABB	Transmission Across Boundary Channel B

The interrupt lines to the Host TINT0SR and TINT1SR are controlled by the enabled interrupts. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit ILE.EINT0/INT0SRC.SRE and ILE.EINT1/ INT1SRC.SRE.

The interrupt lines to the Host NDAT0SR and NDAT1SR are controlled by the enabled new data interrupts (**NDIC1** to **NDIC4**). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit NDAT0SRC.SRE and NDAT1SRC.SRE.

The interrupt lines to the Host MBSC0SR and MBSC1SR are controlled by the enabled new data interrupts (**MSIC1** to **MSIC4**). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit MBSC0SRC.SRE and MBSC1SRC.SRE.

The two timer service requests generated by service request timer 0 and 1 are available on pins TINT0SR and TINT1SR. They can be configured via the Timer 0 and Timer 1 Configuration register. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit TINT0SRC.SRE and TINT1SRC.SRE.

A stop watch event may be triggered via input pin STPWn.

The status of the data transfer between IBF / OBF and the Message RAM is signalled on signals IBUSY and OBUSY. When a transfer has completed bit **SIR.TIBC** or **SIR.TOBC** is set.

23.8 Restrictions

The following restrictions have to be considered when programming the E-Ray IP-module. A violation of these restrictions may lead to an erroneous behavior of the E-Ray IP-module.

23.8.1 Message Buffers with the same Frame ID

If two or more Message Buffers are configured with the same Frame ID, and if they have a matching cycle counter filter value for the same slot, then the Message Buffer with the lowest Message Buffer number is used.

Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.

23.8.2 Data Transfers between IBF / OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the setup time to start the first transfer, the number of 4-byte words to be transferred, and the number of concurrent tasks to be managed by the Message Handler. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) while the number of concurrent task varies from one to three.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and Message RAM
- Data transfer between TBF1 and Message RAM, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and Message RAM, search next TX / RX Message Buffer CHB

Transfers between IBF and Message RAM respectively Message RAM and OBF can only be handled one after another. In case that e.g. a transfer between IBF and Message RAM has been started shortly before a transfer between Message RAM and OBF is requested, the OBF transfer has to wait until the IBF transfer has completed.

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

cyclestrans = (remaining cycles of transfer running) + (cycles of requested transfer)

cyclestrans = cyclesrem + cyclesreq

cyclesrem = (number of concurrent tasks) * (setup time + (number of 4-byte words)rem)

cyclesreq = (number of concurrent tasks) * (setup time + (number of 4-byte words)req)

setup time = 2 f_{CLC_ERAY} cycles

Under worst case conditions a transfer is requested directly after the previous transfer started:

Max. number of f_{CLC_ERAY} cycles: cyclestrans = (3 * (2 + 68)) + (3 * (2 + 68)) = 420

Worst case timing: timetrans(40MHz) = 420 * 25ns = 10.5 ms

23.9 E-Ray Module Implementation

This section describes the E-Ray interfaces as implemented in TC21x/TC22x/TC23x with the clock control, port and DMA connections, interrupt control, and address decoding.

Figure 23-27 shows a detailed view of the E-Ray interface.

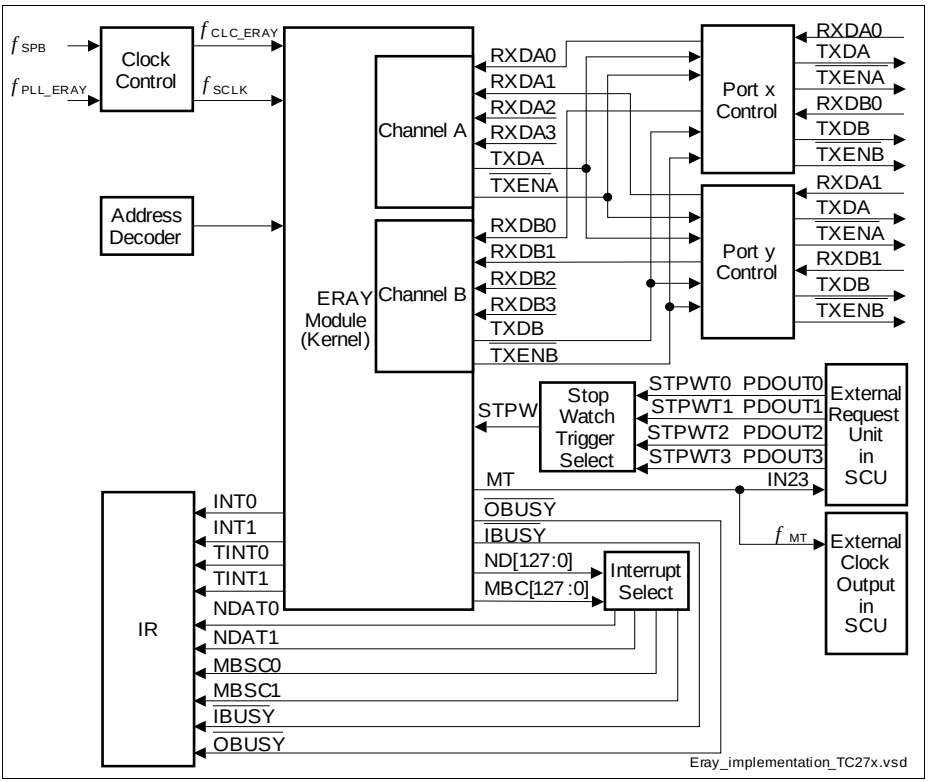

Figure 23-27 Detailed Block Diagram of the E-Ray Interface

23.9.1 Interconnections of the E-Ray Module

The E-Ray module has 2 FlexRay™ communication channels, channel A and channel B. Each channel provides a set of signals to drive a bus driver. The E-Ray module requires two different clocks, a sampling clock of the FlexRay™ bus f_{SCLK}. f_{SCLK} has to

be 8 times the baud rate of the FlexRay™ communication. A second clock f_{CLC_ERAY} is used for the main protocol controller state machine and the customer interface logic. To enable deactivation of the E-Ray Module, f_{CLC_ERAY} and f_{SCLK} may be disabled (clock gated) by the **CLC.DISR** Enable E-Ray (Clock Gating) bit.The following items are described in this section:

- E-Ray module (kernel) external registers
- Port control and connections
  - I/O port line assignment
  - I/O function selection
  - Pad driver characteristics selection
- On-chip connections
  - SCU Connections
  - DMA connections
- Module clock generation
- Interrupt registers
- E-Ray address map

23.9.2 Port Control and Connections

This section describes the I/O connections of the E-Ray module.

23.9.2.1 Input/Output Function Selection

Table 23-27 shows how bits and bit fields must be programmed for the required I/O functionality of the E-Ray I/O lines. This table also shows the values of the peripheral input select registers.

Table 23-27 E-Ray I/O Control Selection and Setup

Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
FlexRay™ Channel A			
RXDA0/ P14.8	ERAY_**CUST1.RISA** = 00_B	P14_IOCR8.PC8 = $0XXXX_B$	In
RXDA1/ P11.9	ERAY_**CUST1.RISA** = 01_B	P11_IOCR8.PC9 = $0XXXX_B$	In

23.9.3 On-Chip Connections

This section describes all on-chip interconnections of the E-Ray modules except the connections to I/O ports (see).

23.9.3.1 E-Ray Connections with IR

The E-Ray module of the TC21x/TC22x/TC23x has several on-chip interconnections to the IR. **Table 23-28** shows these interconnections. These enable the IR to handle different service request of E-Ray module via the DMA or Interrupt Service Routine.

Table 23-28 Request Assignment for IR

Line #	ERAY Output Signal	IR Request Input Line
00	INT0	SRC_ERAYINT0
01	INT1	SRC_ERAYINT1
02	TINT0	SRC_ERAYTINT0
03	TINT1	SRC_ERAYTINT1
04	NDAT0	SRC_ERAYNDAT0
05	NDAT1	SRC_ERAYNDAT1
06	MBSC0	SRC_ERAYMBSC0
07	MBSC1	SRC_ERAYMBSC1
08	OBUSY	SRC_ERAYOBUSY
09	IBUSY	SRC_ERAYIBUSY

23.9.3.2 E-Ray Connections with SMU

The E-Ray module of the TC21x/TC22x/TC23x provides to the SMU the following alarms (ALMx): SRAM ECC single bit correction, SRAM ECC uncorrectable error, SRAM address error, SRAM buffer address error..

23.9.3.3 E-Ray Connections with the External Request Unit of SCU

The E-Ray module of the TC21x/TC22x/TC23x has several on-chip interconnections to the External Request Unit (ERU) in the SCU to externally trigger stop watch events and to provide a global time e.g. to the on chip timers. **Table 23-29** and **Table 23-30** show these interconnections.

Table 23-29 External Stop Watch Request Assignment

ERAY Input Signal	ERU Request Output Line	Selected by
STPWT0	ERU_PDOUT0	**CUST1.STPWTS** = 00_B
STPWT1	ERU_PDOUT1	**CUST1.STPWTS** = 01_B
STPWT2	ERU_PDOUT2	**CUST1.STPWTS** = 10_B
STPWT3	ERU_PDOUT3	**CUST1.STPWTS** = 11_B

Table 23-30 Global Macrotick Connection to ERU

ERAY Output Signal	ERU Request Input Line	Selected by
MT	ERU_IN23	ERU_EICR1.EXIS0 = 11_B

23.9.3.4 E-Ray Connections to GTM

The E-Ray module of the TC21x/TC22x/TC23x has several on-chip interconnections to the Generic Timer Module (GTM). **Table 23-31** show these interconnection s.

Table 23-31 Global Macrotick Connection to GTM

ERAY Output Signal	TIM Input Line
MT	TIM0_7

23.9.3.5 E-Ray Connections with the External Clock Output of SCU

The E-Ray module of the TC21x/TC22x/TC23x has one on-chip interconnections to the External Clock Output Unit in the SCU to distribute externally as also internally the Macro Tick as time base for distributed system control. **Table 23-32** shows this interconnection.

Table 23-32 Global Macrotick Connection to External Clock Output

ERAY Output Signal	External Clock Output	Selected by
MT0	f_{MT0}	SCU_EXTCON.SEL0 = 1111_B

23.9.4 OCDS Trigger Bus (OTGB) Interface

The E-Ray module has two 16 bit and one 32 bit Trigger Sets (**Table 23-33**) which are selected with the **OTSS** register.

Table 23-33 E-Ray Trigger Sets

Trigger Set	Details
TS16_SEP Service Requests, Errors and POC State	Table 23-35
TS16_MC Macrotick Counter	Table 23-36
TS32_SCSC State, Cycle and Slot Counter	Table 23-37

Table 23-34 shows all possible Trigger Set mapping options. If OTGB0 and/or OTGB1 is not used for E-Ray, Trigger Sets of other sources can be added in the OTGM module.

Table 23-34 Trigger Set Mapping Options

Width	OTGB0	OTGB1	OTGB2
32 Bit	TS16_SEP/MC		
		TS16_SEP/MC	
	TS16_SEP/MC	TS16_SEP/MC	
64 Bit			TS32_SCSC
	TS16_SEP/MC		TS32_SCSC
		TS16_SEP/MC	TS32_SCSC
	TS16_SEP/MC	TS16_SEP/MC	TS32_SCSC

Table 23-35 TS16_SEP Service Requests, Errors and POC State

Bits	Description
0	Interrupt 0 Service Request (INT0SRC)
1	Interrupt 1 Service Request (INT1SRC)
2	Timer Interrupt 0 Service Request (TINT0SRC)
3	Timer Interrupt 1 Service Request (TINT1SRC)
4	New Data 0 Service Request (NDAT0SRC)
5	New Data 1 Service Request (NDAT1SRC)
6	Message Buffer Status Changed 0 Service Request (MBSC0SRC)
7	Message Buffer Status Changed 1 Service Request (MBSC1SRC)

Table 23-35 TS16_SEP Service Requests, Errors and POC State (cont'd)

Bits	Description
8	Output Buffer Busy Service Request (OBUSYSRC)
9	Input Buffer Busy Service Request (IBUSYSRC)
10	Reserved
11	Error on Channel A (EIR.EDA)
12	Error on Channel B (EIR.EDB)
[15:13]	POC State bits[2:0] (CCSV.POCS)

Table 23-36 TS16_MC Macrotick Counter

Bits	Description
[13:0]	Macrotick Value (MTCCV.MTV)
[15:14]	Reserved

Table 23-37 TS32_SCSC State, Cycle and Slot Counter

Bits	Description
[10:0]	Slot Counter Channel A (SCV.SCCA)
[22:12]	Slot Counter Channel B (SCV.SCCB)
[29:24]	Cycle Counter Value (MTCCV.CCV)
30	Transfer Input Buffer Completed (SIR.TIBC)
31	Transfer Output Buffer Completed (SIR.TOBC)
11,23	Reserved

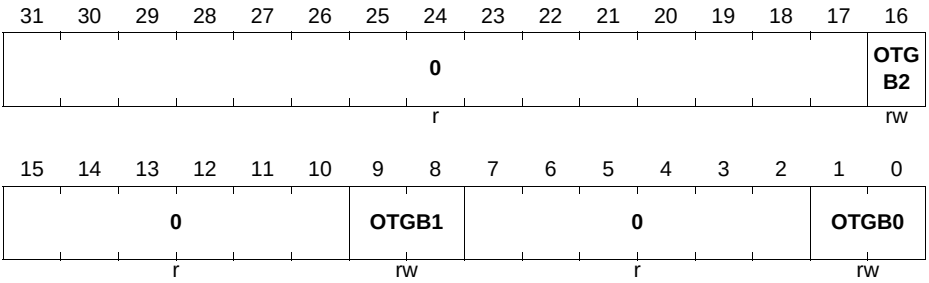
TS32_SCSC becomes valid (posedge on otgb2_valid_o) on a change of any Slot Counter or Transfer Buffer state. This covers also the Cycle Counter which will always change with a slower rate.

23.9.5 OTGB E-Ray Registers

23.9.5.1 OCDS Trigger Bus (OTGB)

The OTGB control register is cleared by Debug Reset. Write access is 32 bit wide only and requires Supervisor Mode.

OTSS
OCDS Trigger Set Select **(0870_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OTGB0	[1:0]	rw	**Trigger Set for OTGB0** 0_D No Trigger Set selected 1_D Trigger Set TS16_SEP (**Table 23-35**) 2_D Trigger Set TS16_MC (**Table 23-36**) 3_D reserved
OTGB1	[9:8]	rw	**Trigger Set for OTGB1** 0_D No Trigger Set selected 1_D Trigger Set TS16_SEP (**Table 23-35**) 2_D Trigger Set TS16_MC (**Table 23-36**) 3_D reserved
OTGB2	16	rw	**Trigger Set for OTGB2** 0_D No Trigger Set selected 1_D Trigger Set TS32_SCSC (**Table 23-37**)
0	[7:2], [15:10], [31:17]	r	**Reserved** Read as 0; must be written with 0.

23.9.6 BPI_FPI Module Registers

Note: Register bits marked "r" in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

CLC
Clock Control Register **(0000_H)** **Reset Value: 0000 0003_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					RMC			0				EDIS	0	DISS	DISR
r					rw			r				rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. *Note: This bit disables the kernel clocks f_{CLC_ERAY} and the sampling clock f_{SCLK}.*
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**External Sleep Mode Request Disable Bit** Used to control module's sleep mode. *Note: If this bit is cleared the kernel clock f_{CLC_ERAY} and the sampling clock f_{SCLK} are disabled during System Sleep Mode.*

Field	Bits	Type	Description
RMC	[10:8]	rw	**Clock Divider in Run Mode** 000_B No clock signal f_{CLC_ERAY} generated (default after reset) 001_B Clock $f_{CLC\_ERAY} = f_{SPB}$ selected 010_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /2 selected 011_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /3 selected 100_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /4 selected 101_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /5 selected 110_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /6 selected 111_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /7 selected *Note: This bit field is not affected by an application reset.* *Note: This bit field only controls the kernel clock f_{CLC_ERAY} and not the sampling clock f_{SCLK}.*
0	[31:16], [15:11], [7:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status **(08E8$_H$)** **Reset Value: 0000 0000$_H$**

SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clocks f_{CLC_ERAY} and the sampling clock f_{SCLK} are switched off immediately. No read or write access to any registers. 2_H Soft suspend. This bit forces the module into freeze state. **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

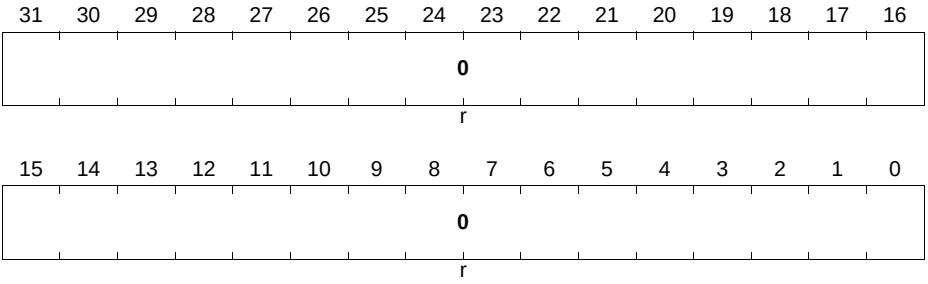
Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($08F8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

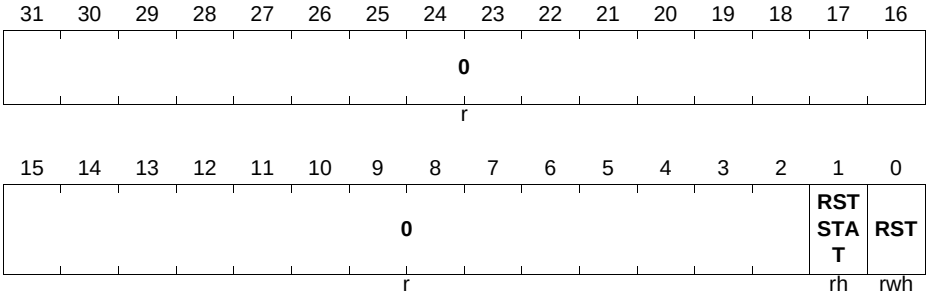
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **(08F4$_H$)** **Reset Value: 0000 0000$_H$**

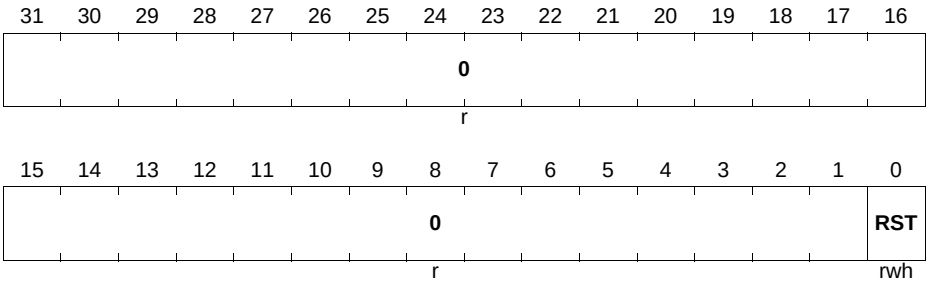


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rw	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (KRSTx1.RST and KRSTx0.RST) related to the module kernel that should be reset (kernel 0 or kernel 1). The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($08F0_H$)** **Reset Value: $0000\ 0000_H$**

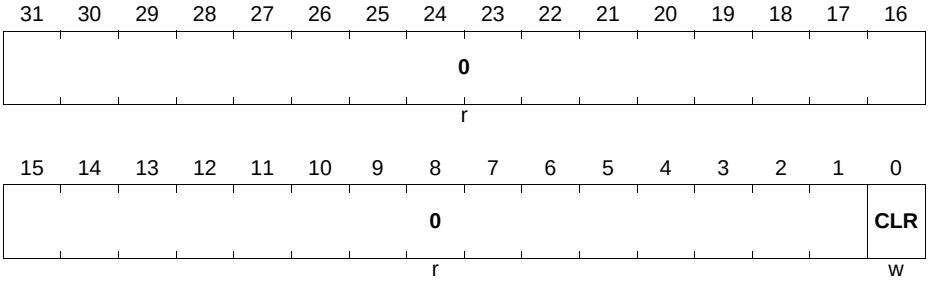


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR
Kernel Reset Status Clear Register (08EC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

23.9.7 Interrupt Registers

Two different type of Interrupt Registers are described within this chapter.
The Interrupt Control register enable the selection of the Service Request used to signal an event. The Interrupt Control registers **NDIC1** to **NDIC4** select the service request node used for New Data Events.The Interrupt Control registers **MSIC1** to **MSIC4** select the service request node used for Message Buffer Status Changed Events.
The Interrupt Service Request Control Registers control the eight service request nodes.

New Data Interrupt Control 1 (NDIC1)

This New Data Interrupt Control register controls the interrupt that becomes active (NDAT0SRC or NDAT1SRC) on a ND flag turning active of all configured Message Buffers 0 to Message Buffers 31.

NDIC1

23.10 Revision History

This User's Manual is based on the IP Specification: **Revision 1.2.6**.

Table 23-38 Revision History

Version Number	Changes to Previous Version
Rev_0.1	First Draft
Rev_0.2	Adapted to PWD 0.8
Rev_0.3	Chapters 3, 5, 6 completed
Rev_0.4	Adapted to actual state of protocol development
Rev_0.5	Adapted to actual state of protocol development
Rev_0.51	Adapted to actual state of protocol development
Rev_0.52	Adapted to actual state of protocol development
Rev_0.53	Adapted to actual state of protocol development
Rev_0.6	Adapted to actual state of protocol development
Rev_0.61	Adapted to actual state of protocol development
Rev_0.62	Adapted to actual state of protocol development
Rev_1.0	First complete revision
Rev_1.01	Message Buffer Status bits PLE, MLST, ES replaced by bits ESA, ESB, MLST
Rev_1.02	IBCR, IBCM, OBCR, OBCM: addresses changed HDC2: register removed MHDC1: renamed to MHDC Message Buffer 0 dedicated to hold key slot ID SFS: description updated ESIDn, OSIDn: description updated EIR: bit SCE removed EILS: bit SCEL removed EIES, EIER: bit SCEE removed

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.2	IDEFAULT_CONFIG added to POC working CCSV: assignment of states to $_{\text{POCS changed:}}$ $_{\text{POCS}}$ = 00 0000_B = "DEFAULT_CONFIG" POCS = 00 1111_B = "CONFIG" CCSV: bit DCREQ removed SIR: bit MBSI added SILS: bit MBSIL added SIES, SIER: bit MBSIE added Register BGSC removed EIR: bits SMEB, SMEA removed EILS: bits SMEBL, SMEAL removed EIES, EIER: bits SMEBE, SMEAE removed Registers TXRQ3, TXRQ4, NDAT3, NDAT4,MBSC3, MBSC4 added Bus guardian related pins eray_arm, eray_bgt, eray_mt, eray_bge1, and eray_bge2 have no function PRTC1: Configuration parameter CASM added WRHS1: Bit NME changed to PPIT RDHS1: Bit NME changed to PPIT Pin eray_scanmode for scan mode control added
Rev_1.3	Changed "r" bits into "rh" bits. Made ACS Register writable. Included Reserved Bits into EIES and EIER Changed access write from "rw" to "rwh" for Register CUST1.IEN. Changed access type of unused bits (0) to "rw". Changed access type of CUST1.INT0 to rwh. Changed Reset value of CUST0 to C104 0105_H Updated the "Known Limitations of E-Ray IP-Module", revision 4.07.2005.

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4	Updated the "Errata of E-Ray IP-Module", revision 1.0 30.06.2006. Renamed from "Interrupt Flag Interface" to "Internal Signal and Flag Interface" With this revision it is possible to use Message Buffer 1for SYNC Frame transmission in addition to Message Buffer 0 if SYNC Frames should have different payloads on channel A and B TEST1: Bit ELBE for control of internal / external loop back mode added, description of internal loop back added EIR: Handling of bits PERR and RFO same as for other bits, bit MHF added SIR: Bit RFF renamed to RFCL, handling of bits RFNE, RFCL same as for other bits EILS: Bit MHFL added, SILS: Bit RFFL renamed to RFCLL EIES, EIER: Bit MHFE added SIES, SIER: Bit RFFE renamed to RFCLE Register STPW renamed to STPW1 STPW2: Register added CCSV: Bits PSL added SWNIT: Bits MTSA, MTSB added MRC: Bit SPLM added FCL: Register added FSR: Register added MHDF: Register added MBSC1/2/3/4: Naming of bits changed from MBS to MBC to distinguish between Message Buffer status flag (MBC) and Message Buffer status register (MBS) CREL: Register added ENDN: Register added Message Buffers in Message RAM: Header 2 and 3 updated from received Data Frames only MBS: Bits FTA, FTB, CCS, RCIS, SFIS, SYNS,NFIS, PPIS, RESS added Description Asynchronous Transmit Mode, added: …This write operation has to be directly preceded by two consecutive write accesses to the Configuration LockKey (unlock sequence)… Description Loop Back Mode, added: …This write operation has to be directly preceded by two consecutive write accesses to the Configuration LockKey (unlock sequence).

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4 (cont'd)	Description LCK.CLK, corrected: To leave CONFIG state by writing SUCC1.CMD (commands READY, MONITOR_MODE, ATM,LOOP_BACK), …Third write: SUCC1.CMD Description EIR.MHF, added: The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB,MHDF.TBFA, MHDF.TBFB, MHDF.WAHP changes from 0 to 1. Description SIR.CAS, added: This flag is set by the Communication Controller during STARTUP state when a CAS or a potential CAS was received. 1 = Bit pattern matching the CAS symbol received 0 = No bit pattern matching the CAS symbol received. Description SIR.MBSI, corrected: This flag is set by the Communication Controller when the Message Buffer status MBS has changed if bit MBI of that Message Buffer is set. Description T0C, added: Note: The configuration of timer 0 is compared against the Macrotick counter value, there is no separate counter for timer 0… Description SUCC1.CMD, modified: Note included into description of CHI command CLEAR_RAMS. …Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS… Description SUCC1.TSM, changed: …The key slot ID is configured in the Header Section of Message Buffer 0 respectively Message Buffers 0 and 1 depending on bit MRC.SPLM. In case TSM = 1, Message Buffer 0 respectively Message Buffers 0,1 can be (re)configured in "DEFAULT_CONFIG" or "CONFIG" state only. In ALL slot mode the Communication Controller may transmit in all slots. TSM is a configuration bit which can only be set / reset by the Host. The bit can be written in "DEFAULT_CONFIG" or "CONFIG" state only. The Communication COntroller changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing CMD = "0101" in POC states "NORMAL_ACTIVE" or "NORMAL_PASSIVE"... Description PRTC1.SPP, added: Note: The current revision 2.1 of the FlexRay™ protocol requires that SPP = "00". The alternate strobe point positions could be used to compensate for asymmetries in the physical layer. Description CCSV.CSNI, corrected: …Reset by CHI command RESET_STATUS_INDICATORS or by transition from "HALT" to "DEFAULT_CONFIG" state or from "READY" to "STARTUP" state.

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4 (cont'd)	Description CCSV.CSAI, corrected: …Reset by CHI command RESET_STATUS_INDICATORS or by transition from "HALT" to "DEFAULT_CONFIG" state or from "READY" to "STARTUP" state. Description CCSV.WSV, corrected: …Reset by CHI command RESET_STATUS_INDICATORS or by transition from "HALT" to "DEFAULT_CONFIG" state or from "READY" to "STARTUP" state. Description SFS.VSAE, modified: Holds the number of valid SYNC Frames received on channel A in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one… Description SFS.VSAO, modified: Holds the number of valid SYNC Frames received on channel A in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one… Description SFS.VSBE, modified: Holds the number of valid SYNC Frames received on channel B in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one… Description SFS.VSBO, modified: Holds the number of valid SYNC Frames received on channel B in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one… Description ACS, added: Note: The set condition of flags CIA and CIB is also fulfilled if there is only one single Frame in the slot and the slot boundary at the end of the slot is reached during the Frames channel idle recognition phase… Description MRC.SEC1:0, changed: …Exception: In nodes configured for SYNC Frame transmission or for single slot mode operation Message Buffer 0 (and if SPLM = 1, also Message Buffer 1) is always locked Description MRC.SPLM, changed: This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1)… Description MRC.SPLM, changed: Note: In case the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1), Message Buffer 0 resp. 1 is reserved for SYNC Frames or single slot Frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation Message Buffer 0 resp. 1 is treated like all other Message Buffers.

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4 (cont'd)	Description Parity Check, changed: …When a parity error occurs when the Message Handler reads a Frame with Network Management information (PPI = 1) from the Transient Buffer RAM A, B the corresponding Network Management vector register NMV1…3 is not updated from that Frame. Included TC1797 O Ports the Physical Layer Interface is connected to. Description MBS.MLST, added: The flag is set in case the Host did not read the message before the Message Buffer was updated from a received Data Frame… …The flag is reset by a Host write to the Message Buffer via IBF or when a new message is stored into the Message Buffer after the Message Buffers ND flag was reset by reading out the Message Buffer via OBF. Description MBS, corrected: Note: The FlexRay™ protocol specification requires that FTA, and FTB can only be reset by the Host… Description NULL Frame Transmission, changed: …In this case, no Message Buffer status MBS is updated.
Rev_1.5	Included BPI Register (Service Request Nodes: INT0SRC, INT1SRC, TINT0SRC, TINT1SRC, NDAT0SRC, NDAT0SRC, MBSC0SRC, MBSC1SRC, CLC). Included for New Data and Message Buffer Status Changed Flags eight Interrupt Select Register (NDIC0, NDIC1, NDIC2, NDIC3, MSIC0, MSIC1, MSIC2, MSIC3) Included new address range for TC1797. Included into CUST1 Register Control (IBF1PAG, IBF1PAG) and Status Bits (IBS) for multiple buffer control. Included for TC1797 the IO Ports the Physical Layer Interface is connected to. Included into CUST1 1 out of 4 multiplexer Select Input Control for RXA (CUST1.RISA), RXB (CUST1.RISB) and STPWT (CUST1.STPWTS). Included DMA Trigger connections for TC1797.
Rev_1.6	Included a description of the Delayed Write Scheme to OBF and IBF. Corrected an erroneous description of IBF1PAG and IBF2PAG concerning the write access for specific values of IBFS. Included a verification scheme to verify correct polarity of IBFS and logic for IBF1PAG and IBF2PAG.
Rev_1.7	Changed P6.7 to P6.10 to use only p6.PDR1 only. Included table summarizing access wait states.
Rev_1.8	Included a description of registering the reset when E-Ray module is disabled and executing the reset when it is enabled hereafter.

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.9	Included IP Specification changes of Revision 1.2.3. **DescriptionTEST1, added**: When the E-Ray IP is operated in one of its test modes that requires WRTEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available. The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the E-Ray module. Therefore normal operation as specified outside this chapter and as required by the FlexRay™ protocol specification and the FlexRay™ conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay™ protocol functions. The test mode features are intended for hardware testing or for FlexRay™ bus analyzer tools. They are not intended to be used in FlexRay™ applications. **Description TEST1.ELBE, modified:** …Bit ELBE is evaluated only when POC is in loop back mode and test multiplexer control is in non-multiplexing mode TMC = 00. **Description TEST1.TMC, modified:** TMC Test Multiplexer Control 00, 11= Normal signal path (default); 01 = RAM Test Mode - Internal busses are multiplexed to make all RAM blocks of the E-Ray module directly accessible by the Host… **Description Loop Back Mode, corrected:** …Reading CCSV.POCS will return "00 1101" while the E-Ray module is in loop back mode… **Description Loop Back mode, completed:** …When the CC is in loop back mode, a loop back test is started by the Host writing a message to the Input Buffer and requesting the transmission by writing to register IBCR… **Description LCK.CLK, corrected:** …If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the Communication Controller remains in CONFIG state and the sequence has to be repeated. **Description LCK.TMK, corrected:** …If the write sequence below is interrupted by other write accesses between the second write to the Test Mode Key and the write access to the TEST1 register, TEST1.WRTEN is not set to '1' and the sequence has to be repeated. **Description EIR.CCL, corrected:** The flag signals that the write access to the CHI command vector SUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed… **Description SIR.MTSA,B, modified:** Media Access Test symbol received on channel A,B during the preceding symbol window…

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.9 (cont'd)	**Description T1C, removed:** … In case the configured Macrotick count is not within the valid range, timer 1 will not start… **Description SUCC1.CMD, corrected:** …In case the previous CHI command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, a POC state change command applied while the CC is already in the requested POC state will be ignored. **Description SUCC1.CMD, added:** ALLOW_COLDSTART; …When called in states DEFAULT_CONFIG, CONFIG, HALT, or MONITOR_MODE, CMD will be reset to 0000 = command_not_accepted… D**escription SUCC1.CMD, completed:** RESET_STATUS_ INDICATORS; …Flags internally evaluated in the actual POC state are not reset… **Description SUCC1.CMD, corrected:** MONITOR_MODE; …In this mode the CC is able to receive FlexRay™ Frames and wakeup pattern… **Description SUCC1.CMD, added:** Table added which references the CHI commands from the FlexRay™ Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the E-Ray CHI command vector CMD. **Description CCSV.RCA, completed:** …The READY command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA. **Description SWNIT.MTSA,B, modified:** Media Access Test symbol received on channel A,B during the preceding symbol window… **Description ESID[1…15].RXEA,B completed:** …sorted in ascending order, … …If the node transmits a SYNC Frame in an even communication cycle by itself, register ESID1 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXEA, RXEB are set… RXEA,B Received / Configured Even Sync ID on Channel A,B Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = EID (ESID1 only). 1 = SYNC Frame received on channel A / node configured to transmit SYNC Frames; 0 = No SYNC Frame received on channel A / node not configured to transmit SYNC Frames.

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.9 (cont'd)	**Description OSID[1…15].RXOA,B completed:** … sorted in ascending order, … …If the node transmits a SYNC Frame in an odd communication cycle by itself, register OSID1 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXOA, RXOB are set…RXOA,B Received / Configured Odd Sync ID on Channel A,B Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = OID(OSID1 only). 1 = SYNC Frame received on channel A / node configured to transmit SYNC Frames;0 = No SYNC Frame received on channel A / node not configured to transmit SYNC Frames **Description FRF.FID, modified:** Determines the Frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding Frame ID filter bits are ignored, which results in further rejected Frame IDs. When FRFM.MFID is zero, a Frame ID filter value of zero means that no Frame ID is rejected. **Description MHDF.WAHP, added:** Outside DEFAULT_CONFIG and CONFIG state this flag is set by the CC when the message handler tries to write message data into the Header Partition of the Message RAM due to faulty configuration of a Message Buffer… **Description MONITOR_MODE, completed:** …In this mode the CC is able to receive FlexRay™ Frames and to detect wakeup pattern… **Modified the description of CUST1.POBFEN to:** Parity Error Reporting of Output Buffer (OBF1/OBF1) RAMs Enable/Test Disable; 0_B: Parity error in Output Buffer (OBF1,OBF2) RAMs is not reported to SCU nor to OBF1, OBF2 RAM wrapper.1_B: The parity error reporting and thus the activation of error signals to SCU as also to OBF1 and OBF2 RAM wrapper is enabled. **Modified the description of CUST1.PMBFEN to:** Parity Error Reporting of Message Buffer (MBF) RAMs Enable/Test Disable; 0_B: Parity error in Message Buffer (MBF) RAMs is not reported to SCU nor to MBF RAM wrapper.1_B: The parity error reporting and thus the activation of error signals to SCU as also to MBF RAM wrapper is enabled. **Modified the description of CUST1.PITBFEN to:** Parity Error Reporting of Message Buffer (IBF1, IBF2, TBF1, TBF2) RAMs Enable/Test Disable; 0_B: Parity error in Input Buffer and Transient Buffer (IBF1, IBF2, TBF1, TBF2) RAMs is not reported to SCU nor to IBF1, IBF2, TBF1, and TBF2 RAM wrapper.1_B: The parity error reporting and thus the activation of error signals to SCU as also to IBF1, IBF2, TBF1, and TBF2 RAM wrapper is enabled

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_2.0	Modified the address of INT0SRC, INT1STC, TINT0SRC, TINT1SRC, NDIC1…NDIC4, MSIC1…MSIC4, NDAT_NDAT0SRC, NDAT1SRC, MBSC0SRC, MBSC1SRC. Cleared up the Index entries. Changed Address Range from to 00000000_H …$00007FFF_H$ to $F0010000_H$ …$F0017FFF_H$
Rev_2.1	Inserted additional information on the minimal eray_bclk required to work properly. Corrected some Typos in the port implementation. Renamed the Interrupt Control Registers due to some problems extracting register names by automatic tools. Changed in Figure 2-1 the names of the clock signals. Changed the Long Name of Register ACS to Aggregated Channel Status Register. Included Message Handler Timing Details. Modified the Clock Signal Names in Figure 2-37.
Rev_2.2	Modified the Pinning of TC1797: TXDA: P0.14, RXDA:P0.9; TXENA: P0.10; TXDB: P0.12; RXDB: P0.12; TXENB: P0.11. Changed the name of the Bit RFCLL in SILS Register.
Rev_2.3	Included IP Specification changes of Revision 1.2.3. Description write access to Data Section of IBF, changed: …If not all bytes of a 32-bit word have been written by the Host (8/16-bit access only), WRDSn holds partly undefined data. Description SIR.WST, completed: This flag is set when the wakeup status vector CCSV.WSV is changed by a protocol event. Description SIR.SWE, modified: This flag is set after a stop watch activation when the actual cycle counter and Macrotick value are stored in the Stop Watch register (see section Stop Watch Register 1 (STPW1)). Description STPW1.ESWT, corrected: …In single-shot mode this bit is reset to 0 after the actual cycle counter and Macrotick value are stored in the Stop Watch register. Description SUCC1.CMD3:0, changed: RESET_STATUS_INDICATORS Resets status flags CCSV.CSNI, CCSV.CSAI, and CCSV.WSV to their default values. May be called in POC state "READY". When called in any other state, CMD will be reset to 0000_B = command_not_accepted. Description CCSV.POC, added: …101011_B = STARTUP_SUCCESS state 101100_B … 111111_B = reserved

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_2.3	Description SUCC1.MTSA,B, added: Note: MTSA,B may also be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUCC1 register is directly preceded by the unlock sequence as described in chapter Lock Register (LCK). This may be combined with CHI command SEND_MTS… Description Communication Controller Status Registers, added: …The status vector may change faster than the Host can poll the status vector, depending on eray_bclk frequency. Description Communication Controller Status Registers, removed: …All internal counters and the Communication Controller status flags are reset when the Communication Controller transits from "CONFIG" to "READY" state. Description CCSV.FSI, changed: …Reset by transition from HALT to "DEFAULT_CONFIG" state. Description CCSV.HRQ, changed: …Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state. Description CCSV.SLM, changed: …Set to the value defined by SUCC1. TSM when entering "READY", "CONFIG", or "DEFAULT_CONFIG" state. Description CCSV.CSI, completed: …The flag is set whenever the POC enters READY state due to CHI command READY. Description CCSV.WSV, modified: …000_B = UNDEFINED. Wakeup not yet executed by the Communication Controller… Description CCSV.RCA, corrected: …The "RUN" command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA. Description Communication Controller Status Registers, removed: …Note: CHI command "RESET_STATUS_INDICATORS" (SUCC1.CMD = 1010_B) resets flags FSI, HRQ, CSNI, CSAI, the slot mode SLM, and the wakeup status WSV. Description CC Error Vector, changed: Reset by transition from "HALT" to "DEFAULT_CONFIG" state or when entering "READY" state... Description MONITOR_MODE, added: …In "MONITOR_MODE" the Communication Controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags SIR.MTSA resp. SIR.MTSB are set. SIR.CAS has no function in "MONITOR_MODE". Inserted remark to negate eray_ibusy and eray_obusy signal to simplify the usage for DMA requesting and interrupt triggering. Corrected Typo in CMD field of SUCC1.

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_2.4	Updated ERAY Kernel Errata List (Bosch Errata List from November 24th, 2006: "Errata_E-Ray_R1.0_20061124")
Rev_2.5	**Modified RISA: Receive Input Select Channel A** 00_B Channel A receiver input RXDA0 selected 01_B Channel A receiver input RXDA1 selected 10_B Channel A receiver input RXDA2 selected 11_B Channel A receiver input RXDA3 selected **Modified RISB: Receive Input Select Channel B** 00_B Channel B receiver input RXDB0 selected 01_B Channel B receiver input RXDB1 selected 10_B Channel B receiver input RXDB2 selected 11_B Channel B receiver input RXDB3 selected Description MONITOR_MODE, removed: …In "MONITOR_MODE" the receive FIFO is not available. Description Message RAM Configuration Register, added: … Note: … In case two or more Message Buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffers" or at the beginning of the "Static + Dynamic Buffers" section… Description CCSV.POC[5:0], added: …101011_B = "STARTUP_SUCCESS" state 101100_B…111111_B = reserved. Inserted text condition to commonly cover IP revision 1.0.0 and IP revision 1.0.1. Updated ERAY Kernel Errata List (Bosch Errata List from December 20th, 2006: "Errata_E-Ray_R1.0.0_20061220"). Included IP Specification changes of Revision 1.2.5. Description EIR.SFO, changed: Set when either the number of SYNC Frames received during the last communication cycle or the total number of SYNC Frames received during the last double cycle exceeds the maximum number of SYNC Frames as defined by GTUC2.SNM. Description SUCC1.CMD[3:0], changed: RESET_STATUS_INDICATORS … May be called in POC states "READY" and "STARTUP"…

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_2.6	Description CCSV.SLM, changed: Indicates the actual slot mode of the POC in states "READY", "STARTUP", "NORMAL_ACTIVE", and "NORMAL_PASSIV"E. Default is SINGLE. Changes to ALL, depending on SUCC1.TSM. In "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL. Set to SINGLE in all other states. Description SFS.VSAE, removed: … (vSyncFramesEvenA) Description SFS.VSAO, removed: … (vSyncFramesOddA) Description SFS.VSBE[3:0], removed:… (vSyncFramesEvenB) Description SFS.VSBO[3:0], removed: …(vSyncFramesOddB) Description MBS.RCIS, MBS.SFIS, MBS.SYNS, MBS.NFIS, MBS.PPIS, MBS.RESS, completed: For receive buffers (CFG = 0) the following status bits are updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored. Description Network Management, added: Note: …When the Communication Controller transits to "HALT" state, the cycle count is not incremented and therefore the NM Vector is not updated. In this case NMV1…3 holds the value from the cycle before. Description Configuration of the FIFO, added: Note: It is recommended to program the MBI bits of the Message Buffers belonging to the FIFO to 0 via WRHS1.MBI to avoid generation of RX interrupts… Updated the CLC reset value to 0000 0100_H. Included the ERAY trigger signals to the DMA channels 10 -17. Modified the stop watch clock input. Shifted them from GOUT to PDOUT. Removed a description of the non implemented fractional divider. Updated ERAY Kernel Errata List (Bosch Errata List from February 19th, 2007: "E-Ray_Errata_Sheet_20070219"). Connected Macrotick signal to ERU input IN23. Modified the DMA connection. Included IBUSY and OBUSY and TINT0. Included Service Request node for IBUSY and OBUSY. Modified the addresses of NDIC1, NDIC2, NDIC3, NDIC4, MSIC1, MSIC2, MSIC3, and MSIC4 to have a continues address range for the new service request registers OBUSYSRC and IBUSYSRC.
Rev_2.7	Removed Parity Bit generation and checking Added ECC generation and checking Wording and typos correction Signal name clean up (e.g. clock signals, ERAY internal signals etc.) CLC is endinit protected

Table 23-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_3.0	Included IP Specification changes of Revision 1.2.6 Inserted text condition to commonly cover IP revision 1.0.0, IP revision 1.0.1 and IP revision 1.0.2. It is not possible to change the Stop Watch Mode (STPW1.SWMS) during enabled stop watch trigger (STPW1.ESWT) Implemented AI00042258. It is not possible to distinguish between static and dynamic frames, because limited functions in Monitor Mode (FRF.RSS will be ignored, filtering not functional). Added note in TEST1L/H register about the change of TEST1H.CERA/B if accessing TEST1H or L Reset value for KSCFG changed to $0x0001_h$. Was the initial value $0x0000_h$. ECC control and status registers added (SEC_CON, SED_CON, DED_CON, ECCR, ECCW) Removed ECC control form CUST1 Removed ECC test description from Register TEST2 Address space enlarged from 2k to 4k Figure E-Ray Register Map contains the new registers
Rev_3.1	ECC control and status registers renamed (SEC_CON -> SECCON, SED_CON -> SEDCON, DED_CON -> DEDCON Corrected RDHS3H.0 length field Renamed STPW1, 2, 3, 4 to STPWT0, 1, 2, 3 16-Bit: Detailed KSCFG functionality MT connected to ERU_3B2 (was ERU_3A2 in V3.0 16-Bit: KSCFG moved to 0x0000h 16-Bit: MT connected to ERU_3B2 (was ERU_3A2 in V3.0) Completed Register Table with page numbers Corrected address spaces that are reserved for customer specific purposes

Rev_3.17	32-bit: updated pin out description (typo fix)

24 Generic Timer Module (GTM)

24.1 Introduction

This document is based on the GTM_IP Specification Revision 2.02.1 (Released on 30.1.2013) of the Robert Bosch GmbH.

24.1.1 Overview

This document is the specification for the Generic Timer Module (GTM). It contains a module framework with submodules of different functionality. These submodules can be combined in a configurable manner to form a complex timer module that serves different application domains and different classes within one application domain. Because of this scalability and configurability the timer is called generic.

The hardware submodules have dedicated functionalities, e.g. there are timer input modules where incoming signals can be captured and characterized together with a notion of time.

Each GTM is build up therefore with submodules coming from those four groups. The application class is defined by the amount of components of those submodules integrated into the implemented GTM.

24.1.2 Document Structure

The structure of this document is motivated out of the aforementioned submodule classes. **Section 24.2** describes the dedicated GTM implementation this specification is written for. It gives an overview about the implemented submodules.

Section 24.3 up to **Section 24.4** deal with the so called infrastructural components for routing, clock management and common time base functions. **Section 24.5** to **Section 24.7** describe the signal input and output modules. **Section 24.8** describes a module that bundles several interrupts coming from the other submodules and connect them to the outside world.

These submodule groups are shown in the following table:

Table 24-1 Submodule groups

Section	Submodule	Group
Section 24.3	Clock Management Unit (CMU)	Infrastructural components
Section 24.4	Time Base Unit (TBU)	Infrastructural components
Section 24.5	Timer Input Module (TIM)	IO Modules
Section 24.6	Timer Output Module (TOM)	IO Modules

Table 24-1 Submodule groups (cont'd)

Section	Submodule	Group
Section 24.7	Dead Time Module (DTM)	IO Modules
Section 24.8	Interrupt Concentrator Module (ICM)	Interrupt services

24.2 GTM Architecture

24.2.1 Overview

As already mentioned in **Section 24.1** the GTM forms a generic timer platform that serves different application domains and different classes within these application domains. Depending on these multiple requirements of application domains multiple device configurations with different count of submodules (i.e.TIM, TOM, DTM) are possible. In this section the GTM realization is outlined. The architecture of the GTM is depicted in.

24.2.1.1 GTM Architecture Block Diagram

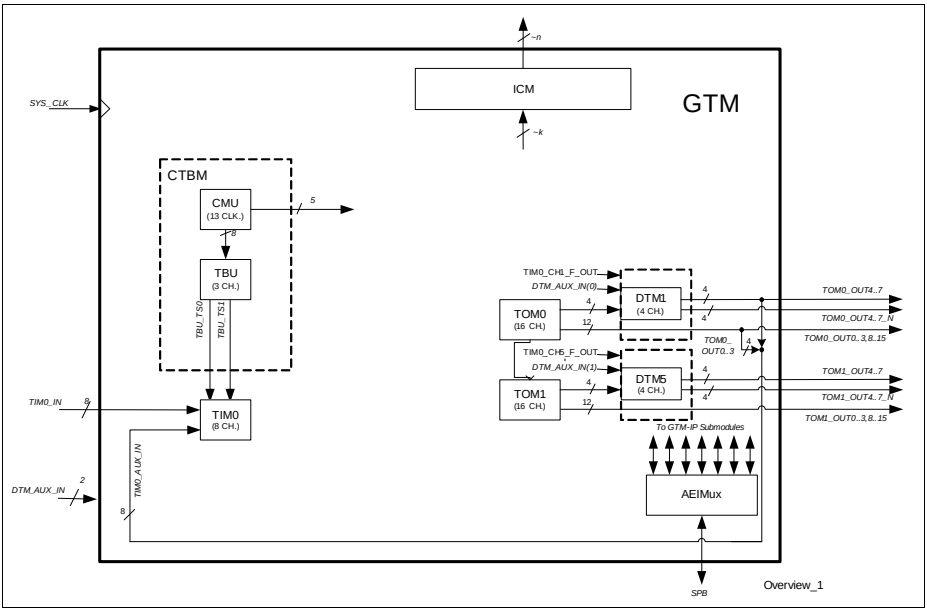

Figure 24-1 GTM Architecture Block Diagram

Signals are transferred into the GTM at the Timer Input Modules (TIM). These modules are able to filter the input signals and annotate additional information. Each channel is for example able to measure pulse high or low times and the period of a PWM signal in parallel. The internal operation registers of the TIM submodule are 24 bits wide.

The Clock Management Unit (CMU) serves up to 13 different clocks for the GTM and up to three external clock pins GTM_ECLK0…2. It acts as a clock divider for the system clock. The counters implemented inside other submodules are typically driven from this submodule. Please note, that the CMU clocks are implemented as enable signals for the counters while the whole system runs with the GTM global clock SYS_CLK. This global clock typically corresponds to the microcontroller bus clock the GTM is connected to.

The TBU provides up to three independent common time bases for the GTM.

Signal outputs are generated with the Dead Time Module (DTM) and Timer Output Modules (TOM). Each TOM channel is able to generate a PWM signal at its output. Because of the integrated shadow register even the generation of complex PWM outputs is possible with the TOM channels by serving the parameters with the CPU. It is possible to trigger TOM channels for a successor TOM submodule through a trigger line between TOM(x)_CH(15) and TOM(x+1)_CH(0). But to avoid long trigger paths the trigger signal is registered at the TOM submodule output, resulting in one SYS_CLK cycle delay of the trigger signal.

In the described implementation the submodules of the GTM have a huge amount of different interrupt sources. These interrupt sources are grouped and concentrated by the Interrupt Concentrator Module (ICM) to form a much easier management bunch of interrupts that are visible outside of the GTM.

On the GTM top level there are some configurable signal connections from the signal output of the DTM modules to the input signals of the TIM modules.

24.2.1.2 GTM signal multiplex

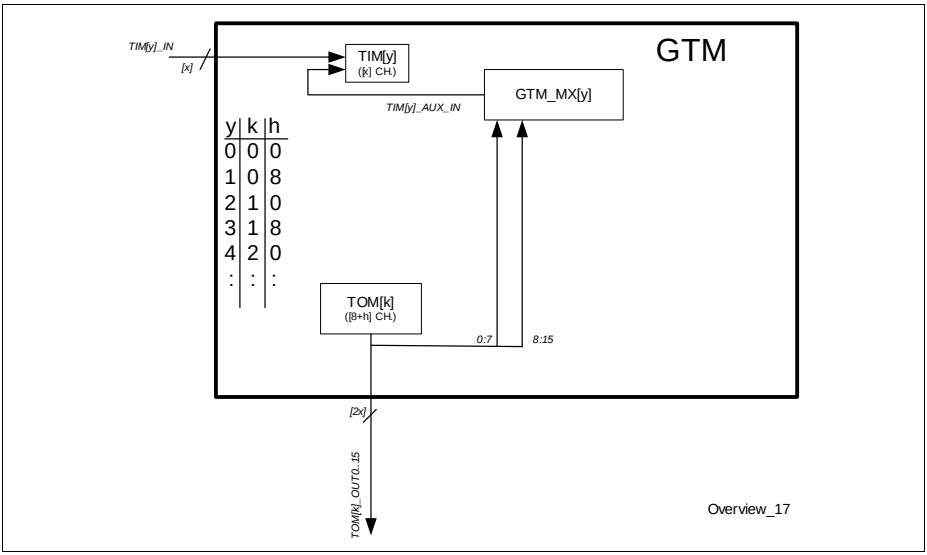

Figure 24-2 GTM Signal Multiplexer

The next diagram gives an overview of the connectivity. The source selection is defined with the bit SRXx in the register GTM_TIM0_AUX_IN_SRC.

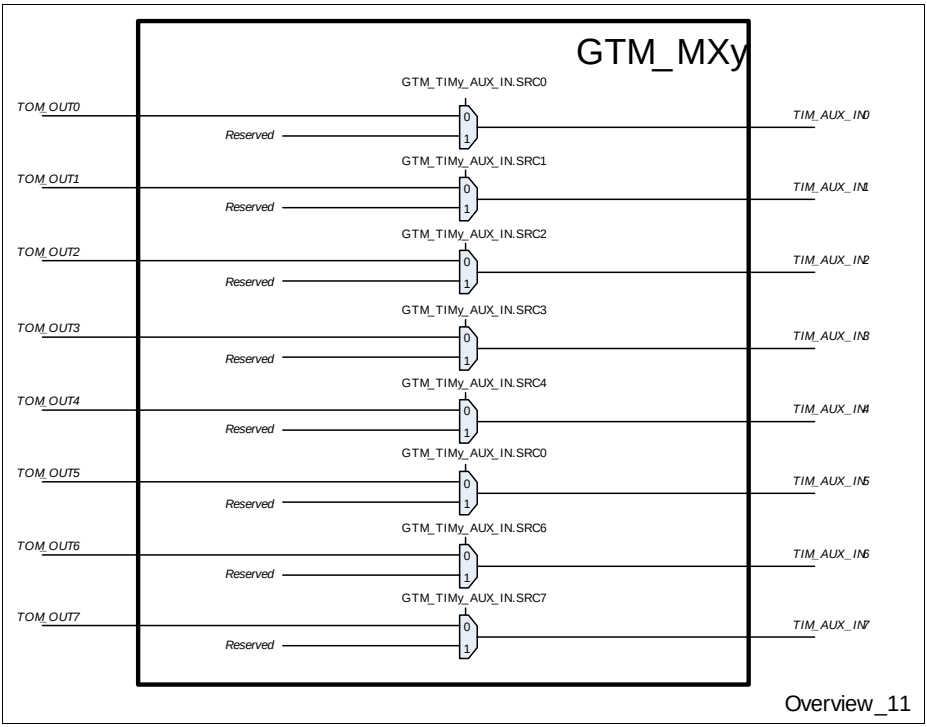

Figure 24-3 GTM TOM to TIM Multiplexer

the trigger out of TIM (i.e. the signals TIM[i]_EXT_CAPTURE(7:0) of each TIMi) are routed to TOM instance [i] with i=0...1.

This TIM trigger can be used to trigger inside TOMi either a channel or a global control register of AGC or TGC0/TGC1 unit.

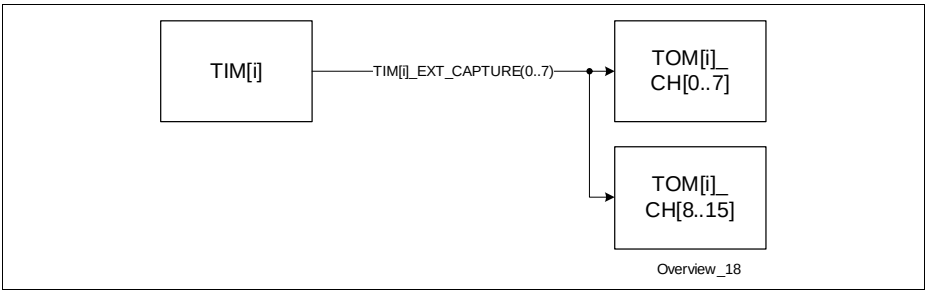

Figure 24-4 TIM to TOM triggers

24.2.2 GTM Interfaces

In general the GTM can be divided into four interface groups. Two interface groups represent the ports of the GTM where incoming signals are assembled and outgoing signals are created. These interfaces are therefore connected to the GTM input submodule TIM and to the GTM output submodules DTM.

Another interface is the bus interface where the GTM can be connected to the SoC system bus. This generic bus interface is described in more detail in **Section 24.2.2.1**. The last interface is the interrupt controller interface. The GTM provides several interrupt lines coming from the various submodules. These interrupt lines are concentrated inside the ICM and have to be adapted to the dedicated microcontroller environment where each interrupt handling can look different. The interrupt concept is described in more detail in **Section 24.2.4**.

24.2.2.1 GTM Generic Bus Interface (AEI)

The GTM is equipped with a generic bus interface that can be widely adapted to different SoC bus systems. This generic bus interface is called AE-Interface (AEI). The adaptation of the AEI to SoC buses is done with a bridge module translating the AEI signals to the SPB bus signals. The AEI bus signals are depicted in the following table:

Table 24-2 AEI Bus Signals

Signal name	I/O	Description	Bit width
AEI_SEL	I	GTM select line	1
AEI_ADDR	I	GTM address	32
AEI_PIPE	I	AEI Address phase signal	1
AEI_W1R0	I	Read/Write access	1
AEI_WDATA	I	Write data bus	32
AEI_RDATA	O	Read data bus	32
AEI_READY	O	Data ready signal	1
AEI_STATUS	O	AEI Access status	2

The AEI Status Signal may drive on of the following values:

Table 24-3 AEI Status Options

AEI_STATUS	Description
00	No Error
01	Illegal Byte Addressing

Table 24-3 AEI Status Options (cont'd)

AEI_STATUS	Description
10	Illegal Address Access
11	Unsupported Address

The signal value "00" is driven if no error occurred during AEI access.

The signal value "01" is driven if the bus address is not an integer multiple of 4 (byte addressing).

The signal value "11" is driven if the address is not handled in the GTM.

The signal value "10" is driven if an illegal write access to one of the following protected register is performed (e.g. protected by bit RF_PROT). Read only register return the status “00”.

Write access to following addresses returns status “10” under special conditions:

CMP_IRQ_FORCINT

CMU_GCLK_NUM

CMU_GCLK_DEN

CMU_CLKx_CTRL (x = 0…7)

CMU_ECLK_NUM

CMU_ECLK_DEN

CMU_FXCLK_CTRL

GTM_IRQ_FORCINT

GTM_RST

TIM0_CHx_CNTS

TIM0_CHx-GPR1

TIM0_CHx_IRQ_FORCINT

TOMi_CHx_IRQ_FORCINT

TBU_CHx_BASE

TBU_CHx_CTRL

24.2.2.2 GTM Multi-master and multi-tasking support

To support multi-master and multi-task access to the registers of the GTM a dedicated write-access scheme is used for critical control bits inside the GTM that need such a mechanism. This can be for example a shared register where more than one channel can be controlled globally by one register write access. Such register bits are implemented inside the GTM with a double bit mechanism, where the writing of '00' and '11' has no effect on the register bit and where '01' sets the bit and '10' resets the bit. If

the CPU wants to read the status of the bit it always gets a '00' if the bit is reset and it gets an '11' if the bit is set.

Note: CPU accesses have to consider the configured SPB to SYS_CLK ratio if SPB > SYSCLK.

24.2.3 GTM Clock and Time Base Management (CTBM)

Inside the GTM several subunits are involved in the clock and time base management of the whole GTM. **Figure 24-5** shows the connections and subblocks involved in these tasks. The subblocks involved are called Clock and Time Base Management (CTBM) modules further on.

24.2.3.1 GTM Clock and time base management architecture

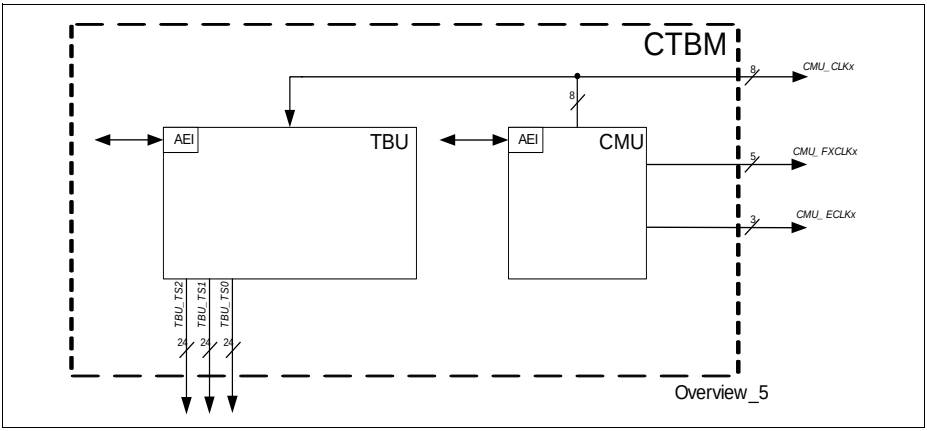

Figure 24-5 GTM Clock and time base management architecture

One important module of the CTBM is the Clock Management Unit (CMU) which generates 13 clocks for the submodules of the GTM and up to three GTM external clocks CMU_ECLK[z] (z: 0…2). For a detailed description of the CMU functionality and clocks please refer to **Section 24.3**.

The five (5) CMU_FXCLK[y] (y: 0…4) clocks are used by the TOM submodule for PWM generation. The eight (8) CMU_CLK[x] (x: 0…7) clocks are used by other submodules of the GTM for signal generation.

Inside the Time Base Unit (TBU) one of these eight clocks is used per channel to generate a common time base for the GTM. The TBU functionality is described in **Section 24.4**.

The TBU submodule generates the three time base signals TBU_TS0, TBU_TS1 and TBU_TS2 which are widely used inside the GTM as common time bases for signal characterization and generation.

24.2.4 GTM Interrupt Concept

The submodules of the GTM can generate many interrupts on behalf of internal events. This high amount of interrupts is combined inside the Interrupt Concentrator Module (ICM) into interrupt groups. In this interrupt groups the GTM submodule interrupt signals are bundled to a smaller set of interrupts. Out of these interrupt sets a smaller amount of interrupt signals is created and signalled outside of the GTM as a signal GTM_<MOD>_IRQ, where as <MOD> identifies the name of the corresponding GTM submodule.

The controlling of the individual interrupts is done inside the submodules. If a submodule consists of several submodule channels that are most likely to work independent from each other (like TIM and TOM), each submodule channel has its own interrupt control and status register set, named as interrupt set in the following. The global GTM functionality have a common interrupt set.

The interrupt set consists of four registers: The IRQ_EN register, the IRQ_NOTIFY register, the IRQ_FORCINT register, and the IRQ_MODE register. While the registers IRQ_EN, IRQ_NOTIFY, and IRQ_FORCINT signalize the status and allow controlling of each individual interrupt source within an interrupt set, the register IRQ_MODE configures the interrupt mode that is applied to all interrupts that belong to the same interrupt set.

In order to support a wide variety of microcontroller architectures and interrupt systems with different interrupt signal output characteristics and internal interrupt handling the following four modes can be configured:

Level mode

Pulse mode

Pulse-Notify mode

Single-Pulse mode

It is recommended to use the Pulse-Notify mode as interrupt mode.

These interrupt modes are described in more details in the following subsections.

The register IRQ_EN allows the enabling and disabling of an individual interrupt within an interrupt set. Independent of the configured mode, only enabled interrupts can signalize an interrupts on its signal GTM_<MOD>_IRQ.

The register IRQ_NOTIFY collects the occurrence of interrupt events.The behaviour for setting a bit in this register depends on the configured mode and thus it is described later on in the mode descriptions.

Independent of the configured mode any write access with value '1' to a bit in the register IRQ_NOTIFY always clears the corresponding IRQ_NOTIFY bit.

Moreover, the enabling of a disabled interrupt sources with a write access to the register IRQ_EN also clears the corresponding bit in the IRQ_NOTIFY register but only if the error interrupt source EIRQ_EN is disabled. However, if the enabling of a disabled interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register IRQ_NOTIFY is not cleared.

Additionally, each write access to the register IRQ_MODE, clears all bits in the IRQ_NOTIFY register. It should be notified that the clearing of IRQ_NOTIFY is applied independently of the written data (e.g. no mode change).

Thus, a secure way for reconfiguring the interrupt mode of an interrupt set, is to disable all interrupts of the interrupt set with the register IRQ_EN, define the new interrupt mode by writing register IRQ_MODE, followed by enabling the desired interrupts with the register IRQ_EN.

Thus, a secure way for reconfiguring the interrupt mode of an error interrupt set, is to disable all error interrupts of the error interrupt set with the register EIRQ_EN, define the new interrupt mode by writing register IRQ_MODE, followed by enabling the desired error interrupts with the register EIRQ_EN.

The register IRQ_FORCINT is used by software for triggering individual interrupts with a write access with value '1'. Since a write access to IRQ_FORCINT only generates a single pulse, IRQ_FORCINT is not implemented as a true register and thus any read access to IRQ_FORCINT always results with a value of '0'.

It should be noted, that the mechanism for triggering interrupts with IRQ_FORCINT is globally disabled after reset. It has to be explicitly enabled by clearing the bit RF_PROT in the register GTM_CTRL (see **Section 24.2.8.3**)

For the modules AEI-bridge and TIM, each interrupt may configured to raise instead of the normal interrupt an error interrupt if enabled by the corresponding error interrupt enable bit in register EIRQ_EN.

Note, it is possible for one source to enable the normal interrupt and the error interrupt in parallel. Because of both interrupt clear signals could reset the notify bit this is expected to cause problems in a system and therefore it is strongly recommended to not enable both interrupt types at the same point in time.

Similar to enabling an interrupt, the enabling of a disabled error interrupt source with a write access to the register EIRQ_EN also clears the corresponding bit in the IRQ_NOTIFY register only if the interrupt source is disabled. However, if the enabling of a disabled error interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register IRQ_NOTIFY is not cleared.

All enabled error interrupts are or-combined inside the ICM and assigned to the dedicated GTM port gtm_err_irq.

To be able to detect the module source of the error interrupt the ICM provides the register ICM_IRQG_MEI. The error interrupt causing channel can be determined for the modules TIM by evaluating the ICM register ICM_IRQG_CEI1.

24.2.4.1 Level interrupt mode

The default interrupt mode is the Level Interrupt Mode. In this mode each occurred interrupt event is collected in the register IRQ_NOTIFY, independent of the corresponding enable bit of register IRQ_EN and EIRQ_EN.

An interrupt event, which is defined as a pulse on the signal int_out of **Figure 24-6**, may be triggered by the interrupt source of the submodule or by software performing a write access to the corresponding register IRQ_FORCINT, with a disabled bit RF_PROT in register GTM_CTRL.

Level interrupt mode scheme

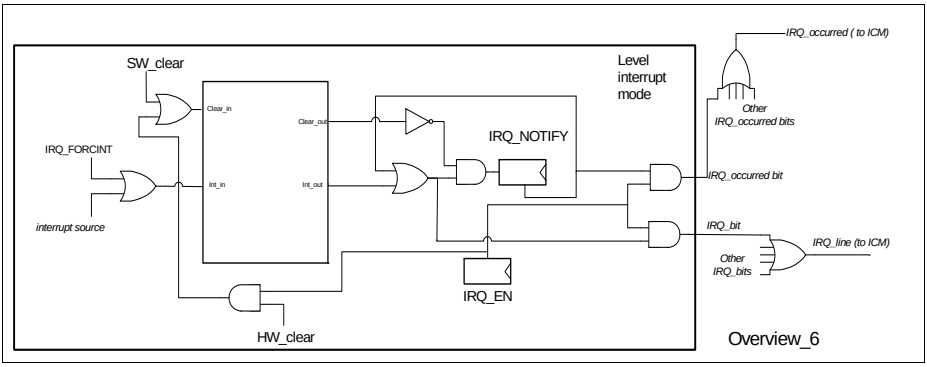

Figure 24-6 Level interrupt mode scheme

A collected interrupt bit in register IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal clr_out of **Figure 24-6**. A clear event can be performed with a write access with value '1' to the corresponding bit in the register IRQ_NOTIFY leading to a pulse on signals SW_clear. A clear event may also result from an externally connected signal GTM_<MOD>_IRQ_CLR, which is routed to the signal HW_clr of **Figure 24-6**. However, the hardware clear mechanism is only possible, if the corresponding interrupt is enabled by register IRQ_EN.

As the **Table 24-4** shows, interrupt events are dominant in the case of a simultaneous interrupt event and clear event.

Table 24-4 IRQ_NOTIFY behaviour

int_in	clear_in	int_out	clear_out
0	0	0	0
0	1	0	1
1	0	1	0
1	1	1	0

Priority of Interrupt Events and Clear Events

As it can be seen from the **Figure 24-6** an occurred interrupt event is signaled as a constant signal level with value 1 to the signal IRQ_bit, if the corresponding interrupt is enabled in register IRQ_EN.

The signal IRQ_bit is OR-combined with the neighboring IRQ_bit signals of the same interrupt set and they are routed as a single signal IRQ_line to the interrupt concentrator module (ICM). In some cases (submodules TOM) the ICM may further OR-combine several IRQ_line signals to an outgoing interrupt signal GTM_<MOD>_IRQ. In the other cases the IRQ_line signals are directly connected to the outgoing signals GTM_<MOD>_IRQ. within the submodule ICM.

The signal IRQ_occurred is connected in a similar way as the signal IRQ_line, however this signal is used for monitoring the interrupt state of the register IRQ_NOTIFY in the registers of the ICM.

The additional error interrupt enable mechanism for level interrupt is shown in **Level interrupt scheme for modules AEI-bridge and TIM**.

Level interrupt scheme for modules AEI-bridge and TIM

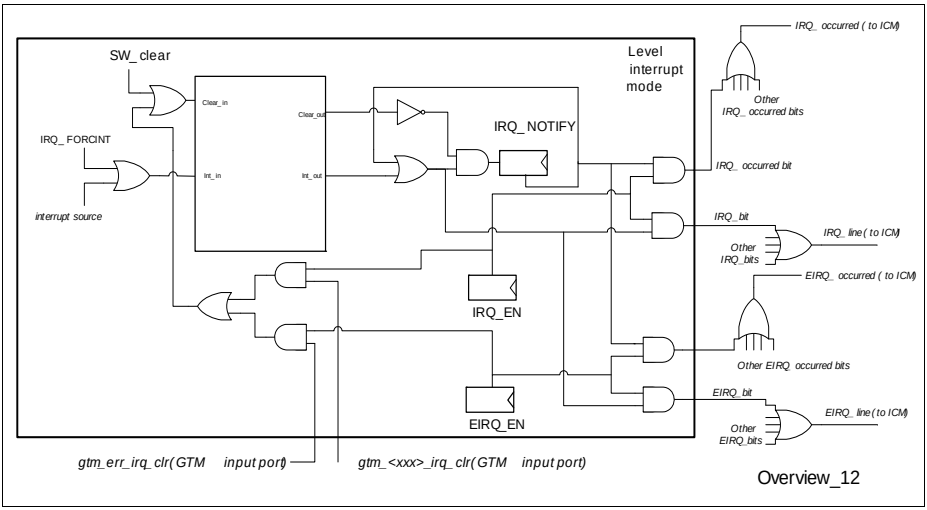

Figure 24-7 Level interrupt scheme

A collected interrupt bit in register IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal clr_out of **Figure 24-6**. A clear event can be performed with a write access with value '1' to the corresponding bit in the register IRQ_NOTIFY leading to a pulse on signals SW_clear. A clear event may also result from externally connected signal GTM_<MOD>_IRQ_CLR or GTM_ERR_IRQ_CLR, which is routed to the signal HW_clr of **Figure 24-6**. However, the hardware clear mechanism is only possible, if the corresponding interrupt or error interrupt is enabled by register IRQ_EN or EIRQ_EN.

As it can be seen from the **Figure 24-7** an occurred interrupt event is signalled as a constant signal level with value 1 to the signal IRQ_bit, if the corresponding interrupt is enabled in register IRQ_EN.

24.2.4.2 Pulse interrupt mode

The Pulse interrupt mode behaviour can be observed from **Figure 24-8**.

Pulse interrupt mode scheme

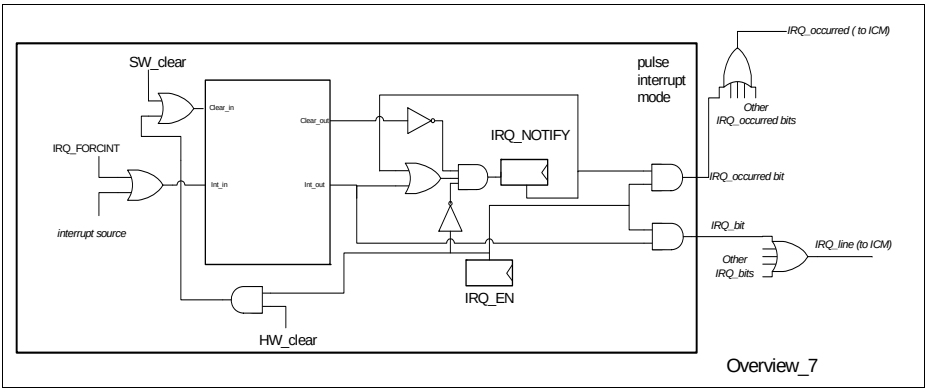

Figure 24-8 Pulse interrupt mode scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the IRQ_bit signal if IRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if IRQ_EN or IRQ_EN are enabled.

However, if an interrupt is disabled in the register IRQ_EN, an occurred interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled interrupts by software.

Disabled interrupts may be cleared by an interrupt clear event.

In Pulse interrupt mode, the signal IRQ_occurred is always 0.

The additional error interrupt enable mechanism for pulse interrupt is shown below.

Pulse interrupt scheme for modules AEI-bridge and TIM

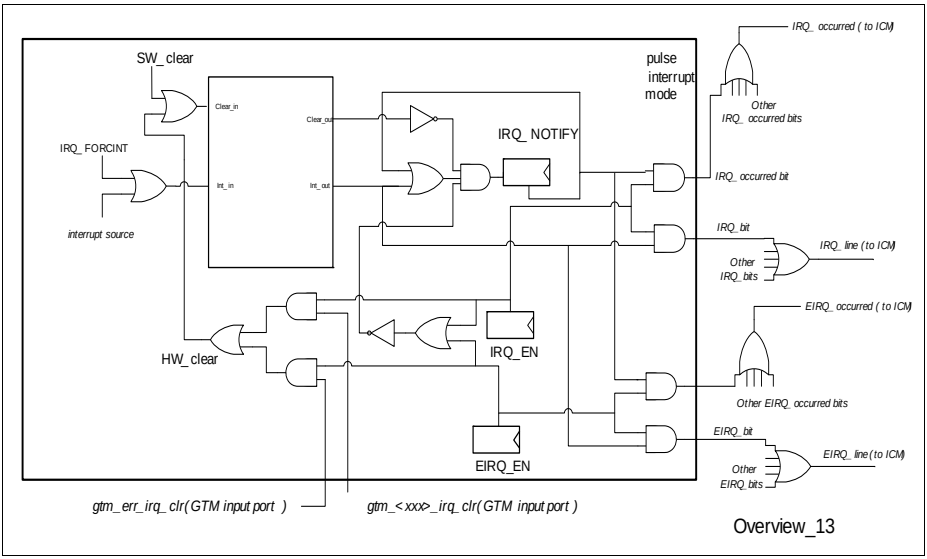

Figure 24-9 Pulse interrupt scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the EIRQ_bit signal if EIRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if EIRQ_EN is enabled.

However, if an error interrupt is disabled in the register EIRQ_EN, an occurred error interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled error interrupts by software.

Disabled error interrupts may be cleared by an error interrupt clear event.

In Pulse interrupt mode, the signal EIRQ_occurred is always 0.

24.2.4.3 Pulse-notify interrupt mode

In Pulse-notify Interrupt mode, all interrupt events are captured in the register IRQ_NOTIFY. If an interrupt is enabled by the register IRQ_EN, each interrupt event will also generate a pulse on the IRQ_bit signal. The signal IRQ_occurred will be high if interrupt is enabled in register IRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode is shown in **Figure 24-10**.

Pulse-notify interrupt mode scheme

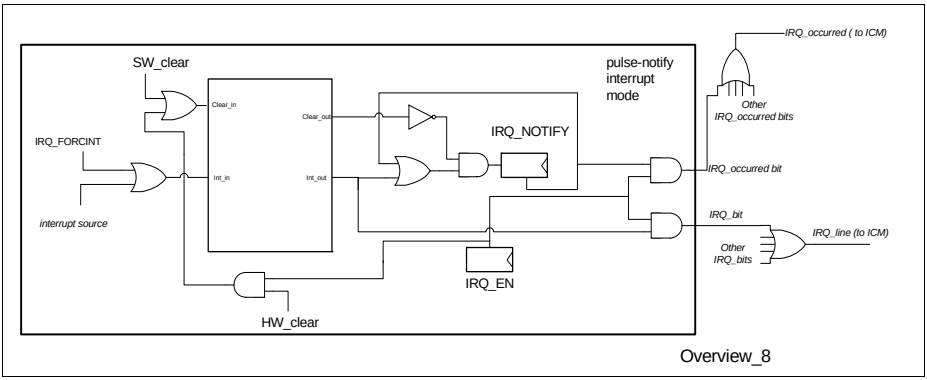

Figure 24-10 Pulse-notify interrupt mode scheme

The additional error interrupt enable mechanism for pulse-notify interrupt is shown below

Pulse-notify interrupt scheme for modules AEI-bridge and TIM

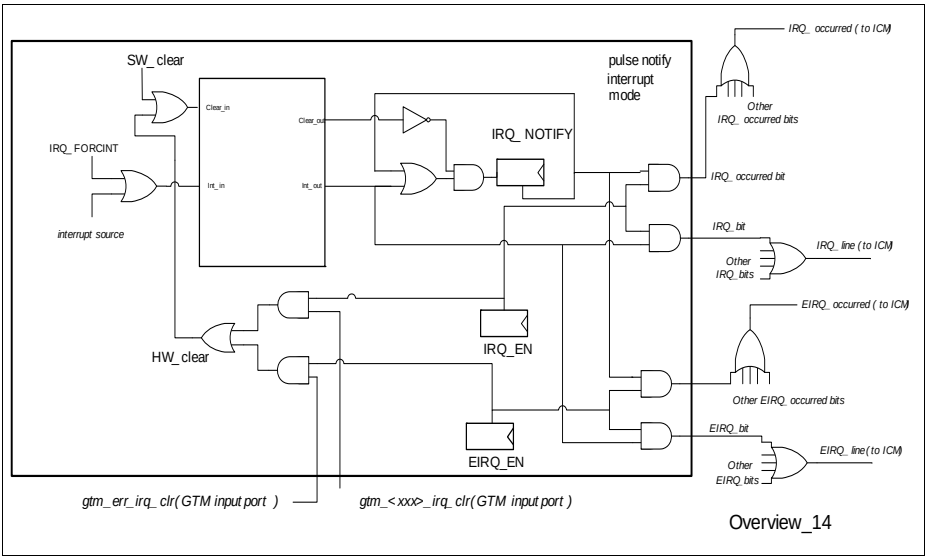

Figure 24-11 Pulse-notify interrupt scheme

In Pulse-notify Interrupt mode, all error interrupt events are captured in the register IRQ_NOTIFY. If an error interrupt is enabled by the register EIRQ_EN, each error

interrupt event will also generate a pulse on the EIRQ_bit signal. The signal EIRQ_occurred will be high if error interrupt is enabled in register EIRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode for error interrupts is shown in figure 2.5.3.2.

24.2.4.4 Single-pulse interrupt mode

In Single-pulse Interrupt Mode, an interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of IRQ_EN. However, only the first interrupt event of an enabled interrupt within an common interrupt set is forwarded to signal IRQ_line. Additional interrupt events of the same interrupt set cannot generate pulses on the signal IRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled interrupts are cleared by a clear event. The IRQ_occurred signal line will be high, if the IRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode is shown in **Figure 24-12**.

Single-pulse interrupt mode scheme

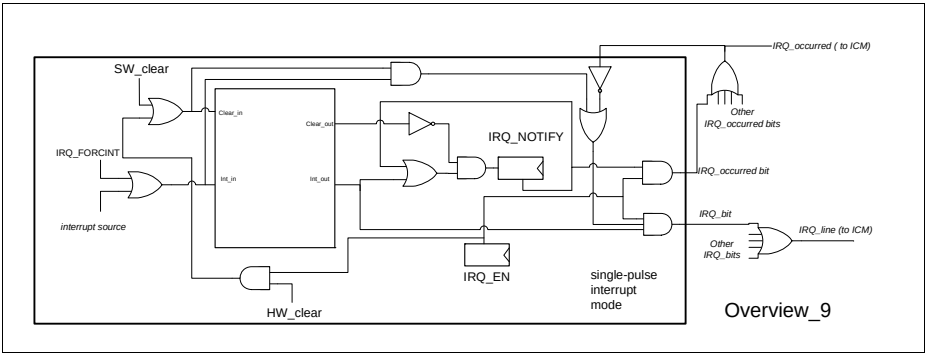

Figure 24-12 Single-pulse interrupt mode scheme

To avoid unexpected IRQ behaviour in the single pulse mode, all desired interrupt sources should be enabled by a single write access to IRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

The additional error interrupt enable mechanism for single-pulse interrupt is shown below

Single-pulse interrupt scheme for modules AEI-bridge and TIM

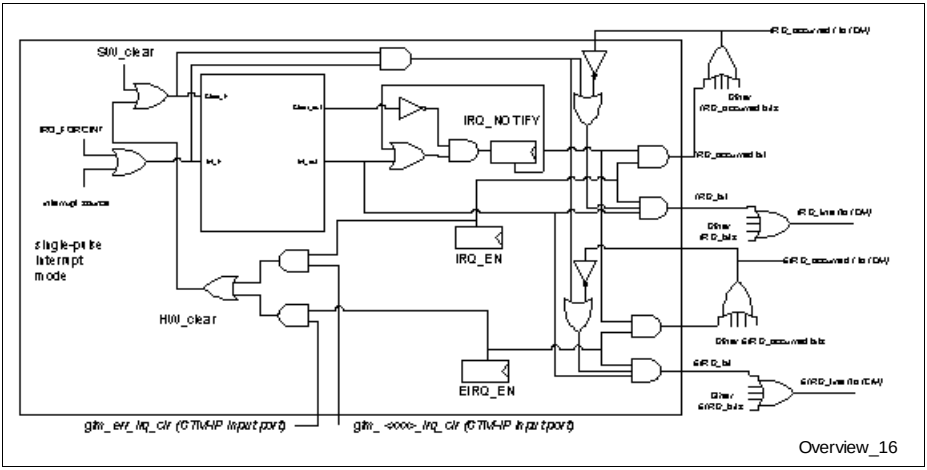

Figure 24-13 Single-pulse interrupt mode scheme

In Single-pulse Interrupt Mode, an error interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of EIRQ_EN. However, only the first error interrupt event of an enabled error interrupt within a common error interrupt set is forwarded to signal EIRQ_line. Additional error interrupt events of the same error interrupt set cannot generate pulses on the signal EIRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled error interrupts are cleared by a clear event. The EIRQ_occurred signal line will be high, if the EIRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode for error interrupts is shown in figure 2.5.4.2.

To avoid unexpected EIRQ behaviour in the single pulse mode, all desired error interrupt sources should be enabled by a single write access to EIRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

24.2.4.5 GTM Interrupt concentration method

Because of the grouping of interrupts inside the ICM, it can be necessary for the software to access the ICM submodule first to determine the interrupt set that is responsible for an interrupt. A second access to the responsible register IRQ_NOTIFY is then necessary to identify the interrupt source, serve it and to reset the interrupt flag in register IRQ_NOTIFY afterwards. The interrupt flags are never reset by an access to the ICM. For a detailed description of the ICM submodule please refer to **Chapter 24.8**.

24.2.5 GTM Software Debugger Support

For software debugger support the GTM comes with several features. E.g. status register bits must not be altered by a read access from a software debugger. To avoid this behaviour to reset a status register bit by software, the CPU has to write a '1' explicitly to the register bit to reset its content.

The **Table 24-5** describes the behaviour of some GTM registers with special functionality on behalf of read accesses from the AEI bus interface.

24.2.5.1 Register behaviour in case of Software Debugger accesses

Table 24-5 Register behaviour in case of Software Debugger accesses

Module	Register	Description
TIM	TIM0_CHx_GPR0 / 1	The overflow bit is not altered in case of a debugger read access to this register.

Further on, some important states inside the GTM submodule have to be signalled to the outside world, when reached and should for example trigger the software debugger to stop program execution. For this internal state signalling please refer to the GTM module integration guide.

The GTM provides an external signal gtm_halt, which disables clock signal SYS_CLK for debugging purposes. If SYS_CLK is disabled, a connected debugger can read any GTM related register using AEI. Moreover, the debugger can also perform write accesses to several GTM related registers in order to enable advanced debugging features (e.g. modifications of register contents in single step mode).

24.2.6 GTM Programming conventions

To serve different application domains the GTM is a highly configurable module with many configuration modes. In principle the submodules of the GTM are intended to be configured at system startup to fulfil certain functionality for the application domain the microcontroller runs in.

For example, a TIM input channel can be used to monitor an application specific external signal, and this signal has to be filtered. Therefore, the configuration of the TIM channel filter mode will be specific to the external signal characteristic. While it can be necessary to adapt the filter thresholds during runtime an adaptation of the filter mode during runtime is not reasonable. Thus, the change of the filter mode during runtime can lead to an unexpected behaviour.

In general, the programmer has to be careful when reprogramming configuration registers of the GTM submodules during runtime. It is recommended to disable the channels before reconfiguration takes place to avoid unexpected behaviour of the GTM.

24.2.7 GTM TOP-Level Configuration Registers Overview

GTM TOP-level contains following configuration registers:

Table 24-6 GTM TOP-Level Configuration Registers Overview

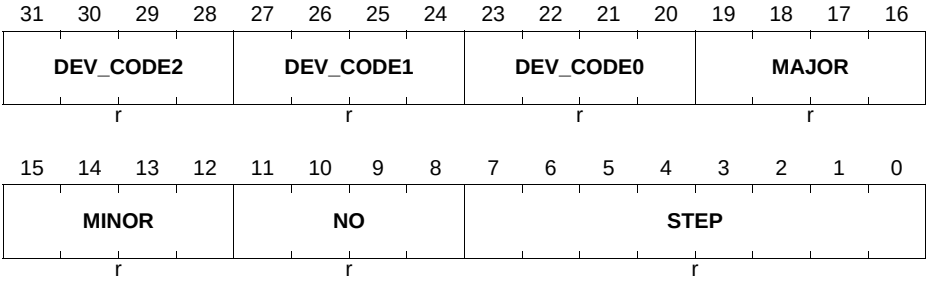
Register name	Description	Details in Section
GTM_REV	GTM Version control register	Section 24.2.8.1
GTM_RST	GTM Global reset register	Section 24.2.8.2
GTM_CTRL	GTM Global control register	Section 24.2.8.3
GTM_AEI_ADDR_XPT	GTM AEI Timeout exception address register	Section 24.2.8.4
GTM_IRQ_NOTIFY	GTM Interrupt notification register	Section 24.2.8.5
GTM_IRQ_EN	GTM Interrupt enable register	Section 24.2.8.6
GTM_IRQ_EIRQ_EN	GTM Error interrupt generation register	Section 24.2.8.12
GTM_IRQ_FORCINT	GTM Software interrupt generation register	Section 24.2.8.7
GTM_IRQ_MODE	GTM top level interrupts mode selection. Please note that this mode selection is only valid for the three interrupts described in Section 24.2.8.5	Section 24.2.8.8
GTM_TIM0_AUX_IN_SRC (i= 0…n)	GTM TIM0 module AUX_IN source selection register	Section 24.2.8.13
GTM_HW_CONF	GTM Hardware Configuration	Section 24.2.8.14

24.2.8 GTM TOP-Level Configuration Registers Description

All of the following registers are 32-bit only accessible.

24.2.8.1 Register GTM_REV

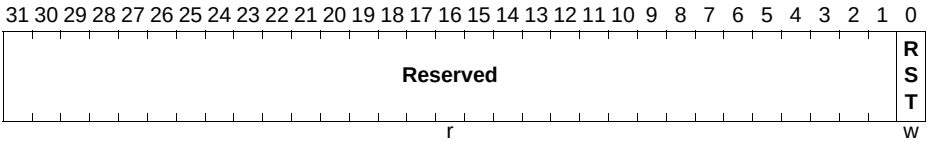
GTM_REV
GTM Version Control Register (00000_H) Reset Value: $210202A1_H$



Field	Bits	Type	Description
STEP	[7:0]	r	**Release Step**
NO	[11:8]	r	**Define delivery number of GTM specification**
MINOR	[15:12]	r	**Define minor version number of GTM specification**
MAJOR	[19:16]	r	**Define major version number of GTM specification**
DEV_CODE0	[23:20]	r	**Device encoding digit 0**
DEV_CODE1	[27:24]	r	**Device encoding digit 1**
DEV_CODE2	[31:28]	r	**Device encoding digit 2** Note: The numbers are encoded in BCD.

24.2.8.2 Register GTM_RST

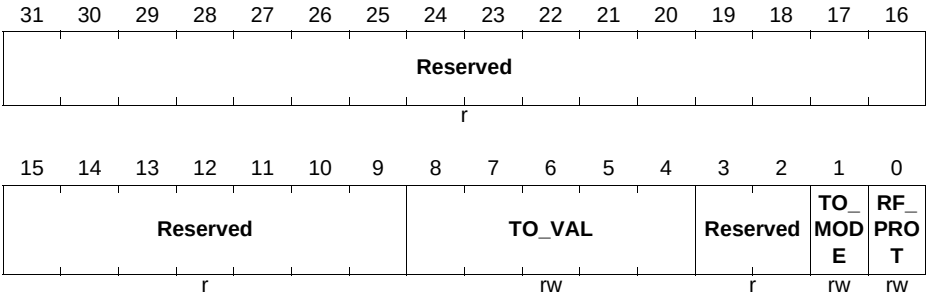
GTM_RST
GTM Global Reset Register (00004_H) Reset Value: 00000000_H



Field	Bits	Type	Description
RST	0	w	**GTM Reset** 0_B No reset action 1_B Initiate reset action for all submodules Note: This bit is automatically cleared by hardware after it was written. Therefore, the register is always read as zero (0) by the software. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
Reserved	[31:1]	r	**Reserved** Read as zero, should be written as zero

24.2.8.3 Register GTM_CTRL

GTM_CTRL
GTM Global Control Register (00008_H) Reset Value: 00000001_H

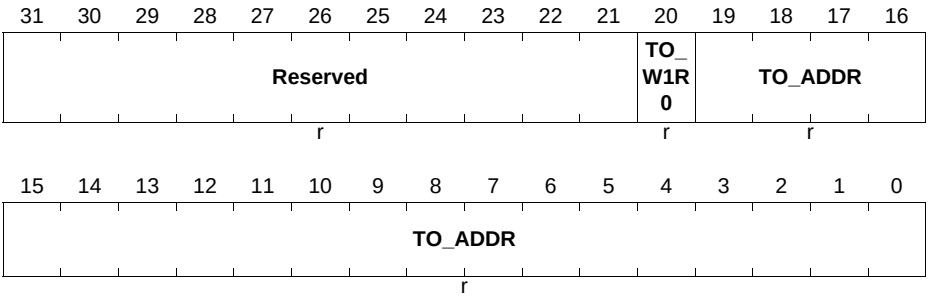


Field	Bits	Type	Description
RF_PROT	0	rw	**RST and FORCINT protection** 0_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is enabled 1_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is disabled
TO_MODE	1	rw	**AEI Timeout mode** 0_B Observe: If timeout_counter=0 the address and rw signal in addition with timeout flag will be stored to the GTM_AEI_ADDR_XPT register. Following timeout_counter=0 accesses will not overwrite the first entry in the aei_addr_timeout register. Clearing the timeout flag/aei_status error_code will reenable the storing of a next faulty access. 1_B Abort: In addition to observe mode the pending access will be aborted by signalling an illegal module access on aei_status and sending ready. In case of a read deliver as data 0 by serving of next AEI accesses.
Reserved	[3:2]	r	**Reserved** Read as zero, should be written as zero

Field	Bits	Type	Description
TO_VAL	[8:4]	rw	**AEI Timeout value** Note: These bits define the number of cycles after which a timeout event occurs. When TO_VAL equals zero (0) the AEI timeout functionality is disabled.
Reserved	[31:9]	r	**Reserved** Read as zero, should be written as zero

24.2.8.4 Register GTM_AEI_ADDR_XPT

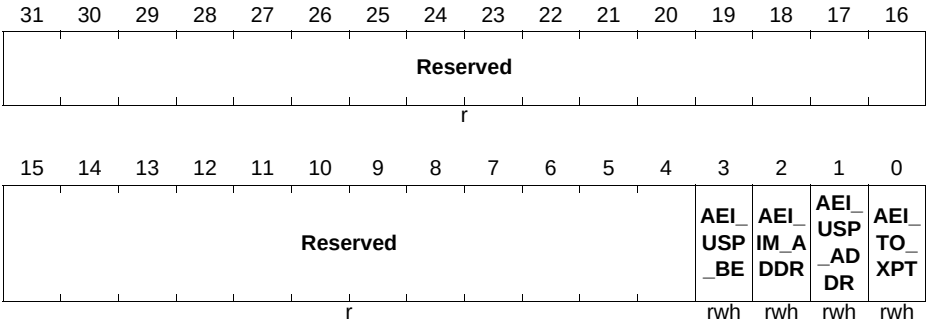
GTM_AEI_ADDR_XPT
GTM AEI Timeout Exception Address Register
(0000C$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
TO_ADDR	[19:0]	r	**AEI Timeout address** Note: This bit field defines the AEI address for which the AEI timeout event occurred.
TO_W1R0	20	r	**AEI Timeout Read/Write flag** Note: This bit defines the AEI Read/Write flag for which the AEI timeout event occurred.
Reserved	[31:21]	r	**Reserved** Read as zero, should be written as zero

24.2.8.5 Register GTM_IRQ_NOTIFY

GTM_IRQ_NOTIFY
GTM Interrupt Notification Register (00010_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
AEI_TO_XPT	0	rwh	**AEI Timeout exception occurred** 0_B No interrupt occurred 1_B AEI_TO_XPT interrupt was raised by the AEI Timeout detection unit Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
AEI_USP_ADDR	1	rwh	**AEI Unsupported address interrupt** 0_B No interrupt occurred 1_B AEI_USP_ADDR interrupt was raised by the AEI interface Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
AEI_IM_ADDR	2	rwh	**AEI Illegal Module address interrupt** 0_B No interrupt occurred 1_B AEI_IM_ADDR interrupt was raised by the AEI interface Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Field	Bits	Type	Description
AEI_USP_BE	3	rwh	**AEI Unsupported byte enable interrupt** 0_B No interrupt occurred 1_B AEI_USP_BE interrupt was raised by the AEI interface Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

24.2.8.6 Register GTM_IRQ_EN

GTM_IRQ_EN
GTM Interrupt Enable Register (00014_H) Reset Value: 00000000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

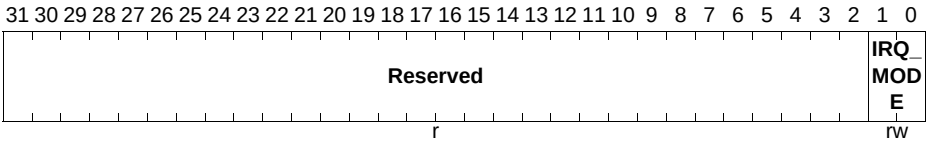
r												w	w	w	w

Field	Bits	Type	Description
TRG_AEI_TO_XPT	0	w	**Trigger AEI_TO_XPT_IRQ interrupt by software.** 0_B No interrupt triggering 1_B Assert AEI_TO_XPT_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.

Field	Bits	Type	Description
TRG_AEI_USP_ADDR	1	w	**Trigger AEI_USP_ADDR_IRQ interrupt by software.** 0_B No interrupt triggering 1_B Assert AEI_USP_ADDR_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_AEI_IM_ADDR	2	w	**Trigger AEI_IM_ADDR_IRQ interrupt by software.** 0_B No interrupt triggering 1_B Assert AEI_IM_ADDR_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_AEI_USP_BE	3	w	**Trigger AEI_USP_BE_IRQ interrupt by software.** 0_B No interrupt triggering 1_B Assert AEI_USP_BE_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

24.2.8.8 Register GTM_IRQ_MODE

GTM_IRQ_MODE
GTM Top Level Interrupts Mode Selection
($0001C_H$) **Reset Value: 00000000_H**

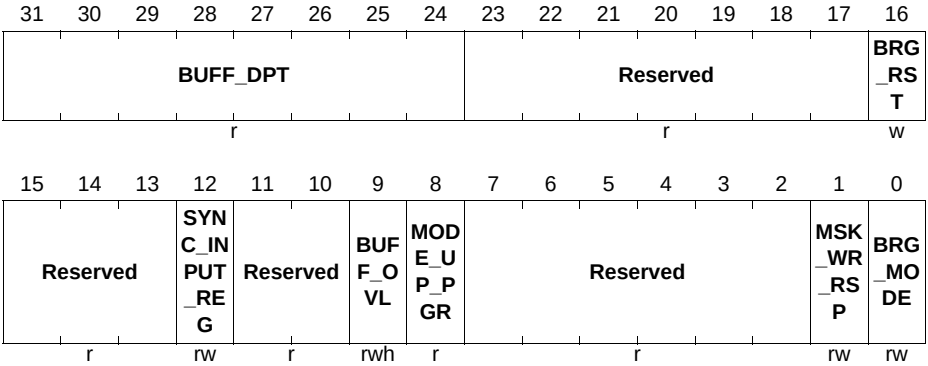


Field	Bits	Type	Description
IRQ_MODE	[1:0]	rw	**Interrupt strategy mode selection for the AEI timeout and address monitoring interrupts** 00_B Level mode 01_B Pulse mode 10_B Pulse-Notify mode 11_B Single-Pulse mode Note: The interrupt modes are described in **Section 24.2.4**.
Reserved	[31:2]	r	**Reserved** Read as zero, should be written as zero

24.2.8.9 Register GTM_BRIDGE_MODE

Note: The content of this register should never be changed.

GTM_BRIDGE_MODE
GTM to SPB BRIDGE MODE **(00030_H)** **Reset Value: 04001001_H**

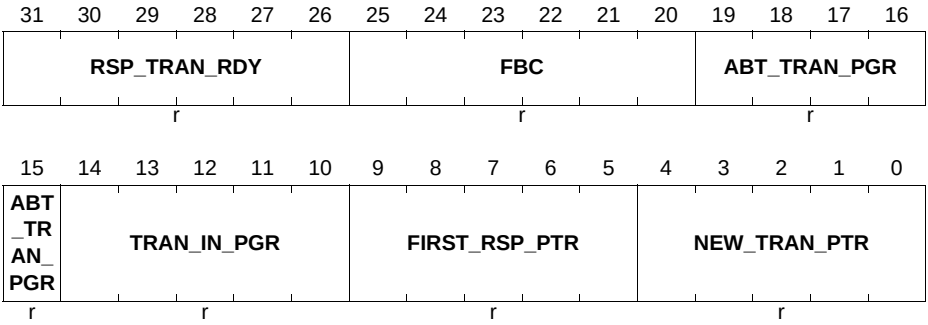


Field	Bits	Type	Description
BRG_MODE	0	rw	**Defines the operation mode for the AEI bridge** 0_B AEI bridge operates in sync_bridge mode 1_B AEI bridge operates in async_bridge mode
MSK_WR_RSP	1	rw	**Mask write response** 0_B Do not mask the write response 1_B Mask write response
Reserved	[7:2]	r	**Reserved** Read as zero, should be written as zero
MODE_UP_PGR	8	r	**Mode update in progress** 0_B No update in progress. 1_B Update in progress.
BUFF_OVL	9	rwh	**Buffer overflow register** 0_B No buffer overflow occurred. 1_B Buffer overflow occurred. Note: A buffer overflow can occur while multiple aborts are issued by the external bus or a pipelined instruction is started while FBC = 0 (see GTM_BRIDGE_PTR1 register). This bit always read as zero.

Field	Bits	Type	Description
Reserved	[11:10]	r	**Reserved** Read as zero, should be written as zero.
SYNC_INPUT_REG	12	rw	**Additional Pipeline Stage in Synchronous Bridge Mode** 0_B No additional pipeline stage implemented 1_B Additional pipeline stage implemented. All accesses in synchronous mode will be increased by one clock cycle.
Reserved	[15:13]	r	**Reserved** Read as zero, should be written as zero.
BRG_RST	16	w	**Bridge software reset** 0_B No bridge reset request. 1_B Bridge reset request. Note: This bit is cleared automatically after write. This bit always read as zero.
BUFF_DPT	[31:24]	r	**Buffer depth of AEI bridge** Signals the buffer depth of the GTM AEI bridge implementation.
Reserved	[23:17]	r	**Reserved** Read as zero, should be written as zero

24.2.8.10 Register GTM_BRIDGE_PTR1

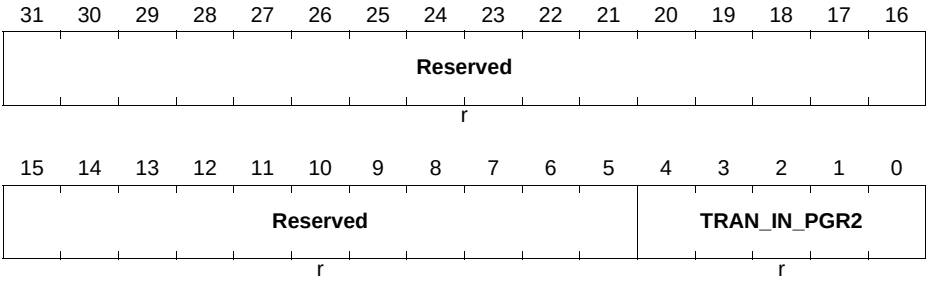
GTM_BRIDGE_PTR1
GTM to SPB BRIDGE PTR1 **(00034_H)** **Reset Value: $00X00000_H$**



Field	Bits	Type	Description
NEW_TRAN_PTR	[4:0]	r	**New transaction pointer** Signals the actual value of the new transaction pointer.
FIRST_RSP_PTR	[9:5]	r	**First response pointer** Signals the actual value of first response pointer.
TRAN_IN_PGR	[14:10]	r	**Transaction in progress pointer (acquire)** Transaction in progress pointer.
ABT_TRAN_PGR	[19:15]	r	**Aborted transaction in progress pointer** Aborted transaction in progress pointer.
FBC	[25:20]	r	**Free buffer count** Number of free buffer entries.
RSP_TRAN_RDY	[31:26]	r	**Response transactions ready** Amount of ready response transactions. Note: This register operates on the AEI_CLK domain.

24.2.8.11 Register GTM_BRIDGE_PTR2

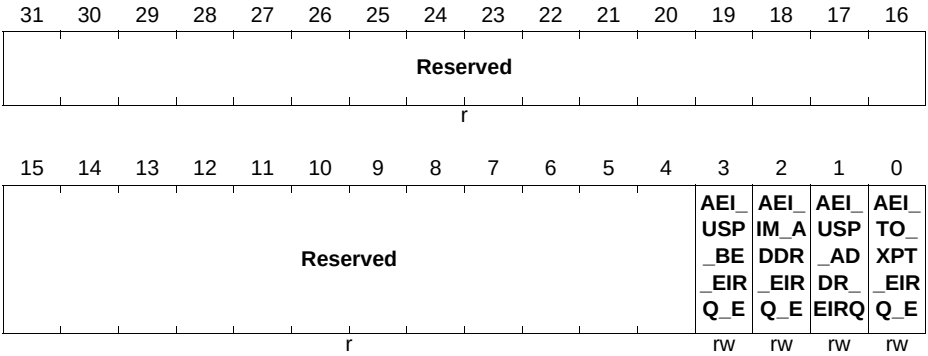
GTM_BRIDGE_PTR2
GTM to SPB BRIDGE PTR2 (00038_H) Reset Value: 00000000_H



Field	Bits	Type	Description
TRAN_IN_PGR2	[4:0]	r	**Transaction in progress pointer (aquire2)** Transaction in progress pointer 2.
Reserved	[31:5]	r	**Reserved** Read as zero, should be written as zero *Note: This register operates on the GTM_CLK domain*

24.2.8.12 Register GTM_EIRQ_EN

GTM_EIRQ_EN
GTM Error Interrupt Enable Register (00020_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
AEI_TO_XPT_EIRQ_EN	0	rw	**AEI_TO_XPT_EIRQ error interrupt enable** 0_B Disable error interrupt, interrupt is not visible outside GTM 1_B Enable error interrupt, interrupt is visible outside GTM
AEI_USP_ADDR_EIRQ_EN	1	rw	**AEI_USP_ADDR_EIRQ error interrupt enable** 0_B Disable error interrupt, interrupt is not visible outside GTM 1_B Enable error interrupt, interrupt is visible outside GTM
AEI_IM_ADDR_EIRQ_EN	2	rw	**AEI_IM_ADDR_EIRQ error interrupt enable** 0_B Disable error interrupt, interrupt is not visible outside GTM 1_B Enable error interrupt, interrupt is visible outside GTM
AEI_USP_BE_EIRQ_EN	3	rw	**AEI_USP_BE_EIRQ error interrupt enable** 0_B Disable error interrupt, interrupt is not visible outside GTM 1_B Enable error interrupt, interrupt is visible outside GTM

Field	Bits	Type	Description
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

24.2.8.13 Register GTM_TIM0_AUX_IN_SRC

GTM_TIM0_AUX_IN_SRC
GTM TIM0 AUX_IN_SRC **(00040_H)** **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

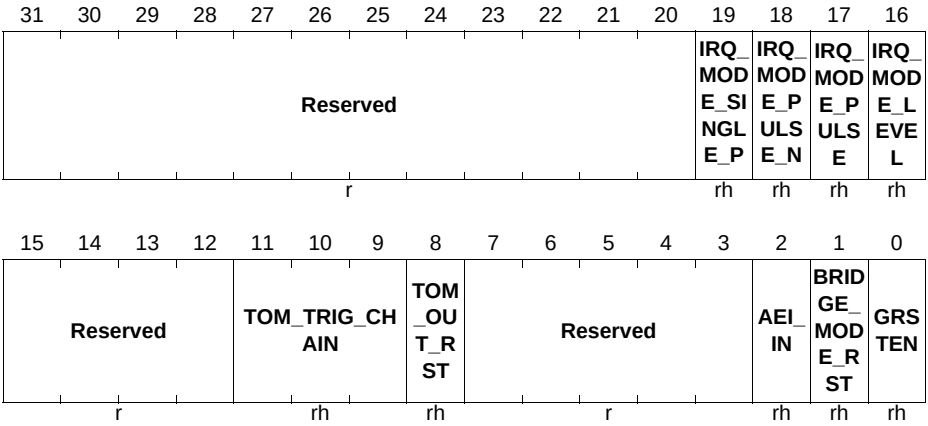
r								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
SRC_CH0	0	rw	**Defines AUX_IN source of TIM0 channel 0 x=0** 0_B TOM Output selected TOM[a] channel [b] with a= (i* 8 +x) div 16; b=(i* 8 +x) mod 16; 1_B Reserved, do not use this combination
SRC_CH1	1	rw	**Defines AUX_IN source of TIM0 channel 1 x=1, see bit 0**
SRC_CH2	2	rw	**Defines AUX_IN source of TIM0 channel 2 x=2, see bit 0**
SRC_CH3	3	rw	**Defines AUX_IN source of TIM0 channel 3 x=3, see bit 0**
SRC_CH4	4	rw	**Defines AUX_IN source of TIM0 channel 4 x=4, see bit 0**
SRC_CH5	5	rw	**Defines AUX_IN source of TIM0 channel 5 x=5, see bit 0**
SRC_CH6	6	rw	**Defines AUX_IN source of TIM0 channel 6 x=6, see bit 0**
SRC_CH7	7	rw	**Defines AUX_IN source of TIM0 channel 7 x=7, see bit 0**
Reserved	[31:8]	r	**Reserved** Read as zero, should be written as zero

24.2.8.14 Register GTM_HW_CONF

GTM_HW_CONF
GTM Hardware Configuration (00024_H) Reset Value: $000F2247_H$



Field	Bits	Type	Description
GRSTEN	0	rh	**Global Reset Enable** 0_B Global GTM reset register disabled 1_B Global GTM reset register enabled
BRIDGE_MODE_RST	1	rh	**Bridge Mode after Reset** 0_B Bridge starts in synchronous mode after reset 1_B Bridge starts in asynchronous mode after reset
AEI_IN	2	rh	**Input Register in Bridge** 0_B no input register in bridge 1_B input register in bridge
TOM_OUT_RST	8	rh	**TOM_OUT Reset Level** 0_B TOM_OUT reset level is ‘0’ 1_B TOM_OUT reset level is ‘1’ *Note: This reset level defines the reset value of bit SL for all TOM channels*

Field	Bits	Type	Description
TOM_TRIG_CHAIN	[11:9]	rh	**TOM Trigger Chain length without Synchronisation** It defines after which TOM instance count a synchronisation register is introduced into trigger chain (after TOM_TRIG_<i> output if instance i and TOM_TRIG_<i+1> input of instance i+1). Valid values are 1 to 7. 1 means that after each instance a synchronisation register is placed.
IRQ_MODE_LEVEL	16	rh	**IRQ Mode Level** 0_B Level Mode not available 1_B Level Mode available
IRQ_MODE_PULSE	17	rh	**IRQ Mode Pulse** 0_B Pulse Mode not available 1_B Pulse Mode available
IRQ_MODE_PULSE_NOTIFY	18	rh	**IRQ Mode Pulse Notify** 0_B Pulse Notify Mode not available 1_B Pulse Notify Mode available
IRQ_MODE_SINGLE_PULSE	19	rh	**IRQ Mode Single Pulse** 0_B Single Pulse Mode not available 1_B Single Pulse Mode available
Reserved	[7:3], [15:12], [31:20]	r	**Reserved** Read as zero, should be written as zero

24.3 Clock Management Unit (CMU)

24.3.1 Overview

The Clock Management Unit (CMU) is responsible for clock generation of the counters and of the GTM. The CMU consists of three subunits that generate different clock sources for the whole GTM. **Figure 24-14** shows a block diagram of the CMU.

The Configurable Clock Generation (CFGU) subunit provides eight dedicated clock sources for the following GTM submodules: TIM and TBU. Each instance of such a submodule can choose an arbitrary clock source, in order to specify wide-ranging time bases.

The Fixed Clock Generation (FXU) subunit generates predefined non-configurable clocks CMU_FXCLK[y] (y: 0…4) for the TOM submodules. The CMU_FXCLK[y] signals are derived from the CMU_GCLK_EN signal generated by the Global Clock Divider. The dividing factors are defined as 2^0, 2^4, 28, 2^{12}, and 2^{16}.

The External Clock Generation (EGU) subunit is able to generate up to three GTM external clock signals visible at CMU_ECLK[z] (z: 0…2) with a duty cycle of about 50%.

The clock source signals CMU_CLK[x] (x: 0…7) and CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the SYS_CLK signal.

The four configurable clock signals CMU_CLK0, CMU_CLK1, CMU_CLK6 and CMU_CLK7 are connected to the TIM filter counters.

24.3.1.1 CMU Block Diagram

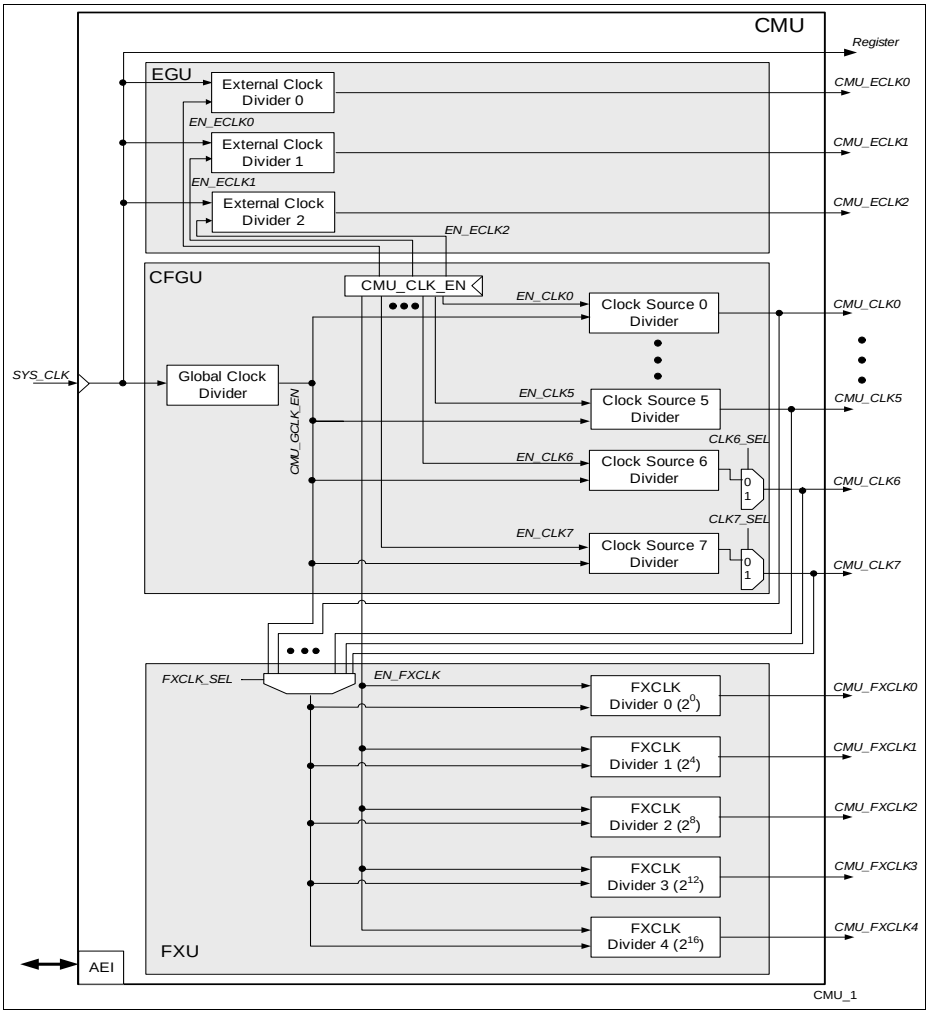


Figure 24-14 CMU Block Diagram

24.3.2 Global Clock Divider

The subblock Global Clock Divider can be used to divide the GTM global input clock signal SYS_CLK into a common subdivided clock signal.

The divided clock signal of the subblock Global Clock Divider is implemented as an enable signal that enables dedicated clocks from the SYS_CLK signal to generate the user specified divided clock frequency.

The resulting fractional divider (Z/N) specified through equation:

TCMU_GCLK_EN=(Z/N)*TSYS_CLK

is implemented according the following algorithm

(Z: CMU_GCLK_NUM(23:0); N: CMU_GCLK_DEN(23:0); Z,N >0):

(1) Set remainder (r), operand1 (OP1) and operand2 (OP2) register during init-phase (with implicit conversion to signed):

r=Z, OP1=N, OP2=N-Z;

(2) After leaving init-phase (at least one CMU_CLK[x] has been enabled) the sign of remainder r for each SYS_CLK cycle will be checked:

(3) If r>0 keep updating remainder and keep CMU_GCLK_EN='0':

r=r-OP1;

(4) If r<0 update remainder and set CMU_GCLK_EN='1':

r=r-OP2;

After at most (Z/N+1) subtractions (3) there will be a negative r and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder r is a measure for the distance to a real Z/N clock and will be regarded for the next generated clock enable cycle phase. The new r value will be r=r+(Z-N). In the worst case the remainder r will sum up to an additional cycle in the generated clock enable period after Z-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock enable. If Z is an integer multiple of N no additional cycles will be included for the generated clock enable at all.

Note that for a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder r uses the complement of (Z-N).

24.3.3 Configurable Clock Generation Subunit (CFGU)

The CMU subunit CFGU provides eight configurable clock divider blocks that divide the common CMU_GCLK_EN signal into dedicated enable signals for the GTM subblocks.

The configuration of the eight different clock signals CMU_CLK[x] (x: 0…7) always depends on the configuration of the global clock enable signal CMU_GCLK_EN. Additionally, each clock source has its own configuration data, provided by the control register CMU_CLK_x_CTRL (x: 0…7).

According to the configuration of the Global Clock Divider, the configuration of the Clock Source x Divider is done by setting an appropriate value in the bit field CLK_CNT[x] of the register CMU_CLK_x_CTRL.

The frequency $f_x = 1/T_x$ of the corresponding clock enable signal CMU_CLK[x] can be determined by the unsigned representation of CLK_CNT[x] of the register CMU_CLK_x_CTRL in the following way:

TCMU_CLK[x]=(CLK_CNT[x]+1)*TCMU_GCLK_EN

The corresponding wave form is shown in **Figure 24-15**.

Each clock signal CMU_CLK can be enabled individually by setting the appropriate bit field EN_CLK[x] in the register CMU_CLK_EN. Except for CMU_CLK6 and CMU_CLK7 individual enabling and disabling is active only if CLK6_SEL and CLK7_SEL is cleared.

To avoid unexpected behaviour of the hardware, the configuration of a register CMU_CLK_x_CTRL can only be changed, when the corresponding clock signal CMU_CLK[x] is disabled.

Further, any changes to the registers CMU_GCLK_NUM and CMU_GCLK_DEN can only be performed, when all clock enable signals CMU_CLK[x] and the EN_FXCLK bit inside the CMU_CLK_EN register are disabled.

The clock source signals CMU_CLK[x] (x:0…7) and CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the SYS_CLK signal.

The hardware guarantees that all clock signals CMU_CLK[x], which were enabled simultaneous, are synchronized to each other. Simultaneous enabling does mean that the bits EN_CLK[x] in the register CMU_CLK_EN are set by the same write access.

After EN_CLK[x] entries in CMU_CLK_EN have been disabled, internal states of these EN_CLK[x] paths will be reset to start with the same behaviour after enable.

24.3.4 Wave Form of Generated Clock Signal CMU_CLK[x]

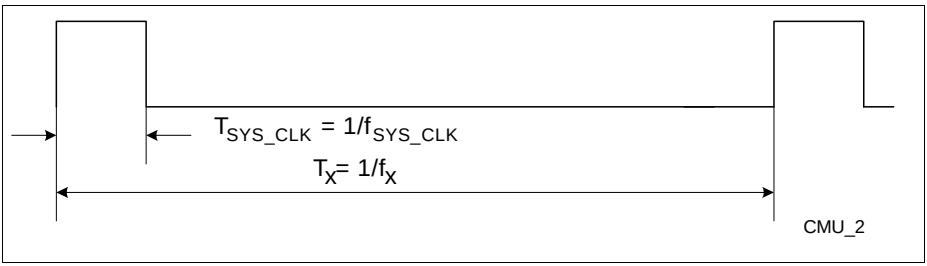

Figure 24-15 Example clock signal

24.3.5 Fixed Clock Generation (FXU)

The FXU subunit generates fixed clock enables out of the CMU_GCLK_EN or one of the eight CMU_CLKx enable signal depending on the CMU_CLK_5.FXCLK_SEL bit field of the CMU_FXCLK_CTRL register. These clock enables are used for the PWM generation inside the TOM submodules.

All clock enables CMU_FXCLK[y] can be enabled or disabled simultaneous by setting the appropriate bit field EN_FXCLK in the register CMU_CLK_EN.

The dividing factors are defined as 2^0, 2^4, 2^8, 2^{12}, and 2^{16}. The signals CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers (see also **Section 24.3.4**)

After EN_FXCLK entry in CMU_CLK_EN have been disabled, internal states of EN_FXCLK paths will be reset to start with the same behaviour after enable.

24.3.6 External Generation Unit (EGU)

The EGU subunit generate three separate clock output signals CMU_ECLK[z] (z: 0…2).

Each of these clock signals is derived from the corresponding External Clock Divider z subblock, which generates a clock signal derived from the GTM input clock SYS_CLK.

In contrast to the signals CMU_CLK[x] and CMU_FXCLK[y], which are treated as simple enable signals for the registers, the signals CMU_ECLK[z] have a duty cycle of about 50% that is used as a true clock signal for external peripheral components.

Each of the external clocks are enabled and disabled by setting the appropriate bit field EN_ECLK[z] in the register CMU_CLK_EN.

After EN_ECLK[z] entries in CMU_CLK_EN have been disabled, internal states of these EN_ECLK[z] paths will be reset to start with the same behaviour after enable.

The clock frequencies $f_{CMU\_ECLK[z]} = 1/T_{CMU\_ECLK[z]}$ of the external clocks are controlled with the registers CMU_ECLK_z_NUM and CMU_ECLK_z_DEN as follows:

$$T_{CMU\_ECLK[z]} = 2*(ECLK[z]\_NUM/ECLK[z]\_DEN)*T_{SYS\_CLK}$$

and is implemented according the following algorithm

(Z: CMU_ECLK_z_NUM(23:0); N: CMU_ECLK_z_DEN(23:0); Z,N >0; Z>=N; CMU_ECLK[z]='0'):

(1) Set remainder (r), operand1 (OP1) and operand2 (OP2) register during init-phase (with implicit conversion to signed):

r=Z, OP1=N, OP2=N-Z;

(2) After leaving init-phase (CMU_ECLK[z] has been enabled) the sign of remainder r for each SYS_CLK cycle will be checked:

(3) If r>0 keep updating remainder and keep CMU_ECLK[z]:

r=r-OP1;

(4) If r<0 update remainder and toggle CMU_ECLK[z]:

r=r-OP2;

After at most (Z/N+1) subtractions (3) there will be a negative r and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder r is a measure for the distance to a real Z/N clock and will be regarded for the next generated clock toggle phase. The new r value will be r=r+(Z-N). In the worst case the remainder r will sum up to an additional cycle in the generated clock toggle period after Z-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock toggle. If Z is an integer multiple of N no additional cycles will be included for the generated clock toggle at all.

Note that for a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder r uses the complement of (Z-N).

The default value of the CMU_ECLK[z] output is low.

24.3.7 CMU Configuration Registers Overview

Following configuration registers are considered in CMU submodule:

Table 24-7 CMU Configuration Registers Overview

Register Name	Description	Details in Section
CMU_CLK_EN	CMU Clock enable register	Section 24.3.8.1
CMU_GCLK_NUM	CMU Global clock control numerator register	Section 24.3.8.2
CMU_GCLK_DEN	CMU Global clock control denominator register	Section 24.3.8.3
CMU_CLK_x_CTRL	CMU Control for clock source x register (x:0…5)	Section 24.3.8.4
CMU_CLK_6_CTRL	CMU Control for clock source 6 register	Section 24.3.8.5
CMU_CLK_7_CTRL	CMU Control for clock source 7 register	Section 24.3.8.6
CMU_ECLK_z_NUM	CMU External clock z control numerator register (x:0…2)	Section 24.3.8.7
CMU_ECLK_z_DEN	CMU External clock z control denominator register (z:0…2)	Section 24.3.8.8
CMU_FXCLK_CTRL	Control FXCLK subunit input clock	Section 24.3.8.9

24.3.8 CMU Configuration Register Description

All of the following registers are 32-bit only accessible.

24.3.8.1 Register CMU_CLK_EN

GTM_CMU_CLK_EN
CMU Clock Enable Register **(00300_H)** **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								EN_FXCLK		EN_ECLK2		EN_ECLK1		EN_ECLK0	
r								rw		rw		rw		rw	

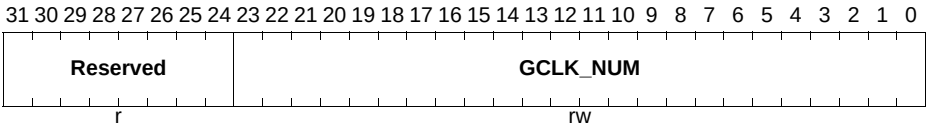
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN_CLK7		EN_CLK6		EN_CLK5		EN_CLK4		EN_CLK3		EN_CLK2		EN_CLK1		EN_CLK0	
rw		rw		rw		rw		rw		rw		rw		rw	

Field	Bits	Type	Description
EN_CLK0	[1:0]	rw	**Enable clock source 0** 00_B clock source is disabled (ignore write access) 01_B disable clock signal and reset internal states 10_B enable clock signal 11_B clock signal enabled (ignore write access) *Note: Any read access to an EN_CLKx, EN_ECLKz or EN_FXCLK bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored.* *Note: Any disabling to EN_CLKx will be reset internal counters for configurable clocks.* *Note: Any disabling to EN_ECLKz will be reset internal counters for external clocks.* *Note: An enable to EN_FXCLK from disable state will be reset internal fixed clock counters.*
EN_CLK1	[3:2]	rw	**Enable clock source 1** see bits [1:0]

Field	Bits	Type	Description
EN_CLK2	[5:4]	rw	**Enable clock source 2** see bits [1:0]
EN_CLK3	[7:6]	rw	**Enable clock source 3** see bits [1:0]
EN_CLK4	[9:8]	rw	**Enable clock source 4** see bits [1:0]
EN_CLK5	[11:10]	rw	**Enable clock source 5** see bits [1:0]
EN_CLK6	[13:12]	rw	**Enable clock source 6** see bits [1:0]
EN_CLK7	[15:14]	rw	**Enable clock source 7** see bits [1:0]
EN_ECLK0	[17:16]	rw	**Enable ECLK 0 generation subunit** see bits [1:0]
EN_ECLK1	[19:18]	rw	**Enable ECLK 1 generation subunit** see bits [1:0]
EN_ECLK2	[21:20]	rw	**Enable ECLK 2 generation subunit** see bits [1:0]
EN_FXCLK	[23:22]	rw	**Enable all CMU_FXCLK** see bits [1:0]
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.3.8.2 Register CMU_GCLK_NUM

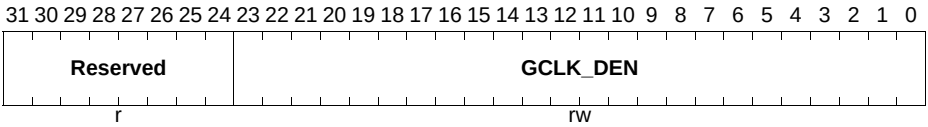
GTM_CMU_GCLK_NUM
CMU Global Clock Control Numerator Register
(00304_H) **Reset Value: 00000001_H**



Field	Bits	Type	Description
GCLK_NUM	[23:0]	rw	**Numerator for global clock divider** Defines numerator of the fractional divider. *Note: Value can only be modified when all clock enables EN_CLK[x] and the EN_FXCLK are disabled.* *Note: The CMU hardware alters the content of CMU_GCLK_NUM and CMU_GCLK_DEN automatically to 0x1, if CMU_GCLK_NUM is specified less than CMU_GCLK_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_GCLK_NUM followed by a single write to register CMU_GCLK_DEN.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.3.8.3 Register CMU_GCLK_DEN

GTM_CMU_GCLK_DEN
CMU Global Clock Control Denominator Register
(00308_H) **Reset Value: 00000001_H**

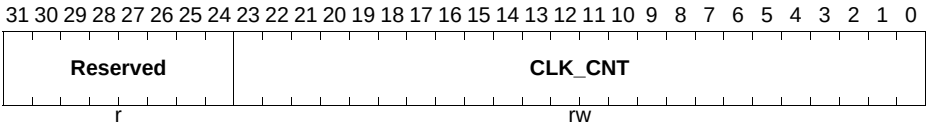


Field	Bits	Type	Description
GCLK_DEN	[23:0]	rw	**Denominator for global clock divider** Defines denominator of the fractional divider. *Note: Value can only be modified when all clock enables EN_CLK[x] and the EN_FXCLK are disabled.* *Note: The CMU hardware alters the content of CMU_GCLK_NUM and CMU_GCLK_DEN automatically to 0x1, if CMU_GCLK_NUM is specified less than CMU_GCLK_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_GCLK_NUM followed by a single write to register CMU_GCLK_DEN.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.3.8.4 Register CMU_CLK_x_CTRL (x:0…5)

GTM_CMU_CLK_x_CTRL (x=0-5)
CMU Control For Clock Source x Register

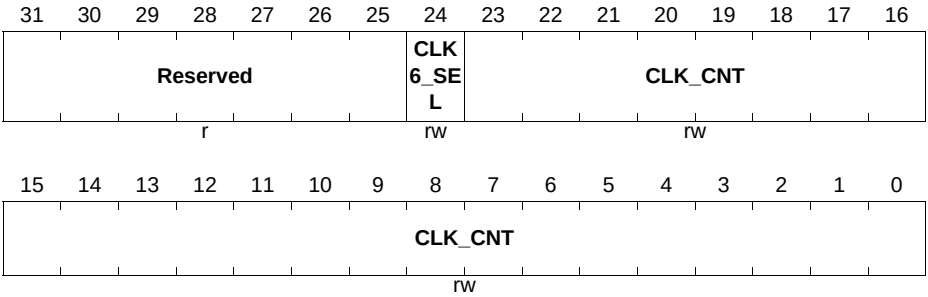
($0030C_H$+x*04_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CLK_CNT	[23:0]	rw	**Clock count Defines count value for the clock divider of clock source CMU_CLK[x] (x:0…5)** Note: Value can only be modified when clock enable EN_CLKx (x:0…5) is disabled.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.3.8.5 Register CMU_CLK_6_CTRL

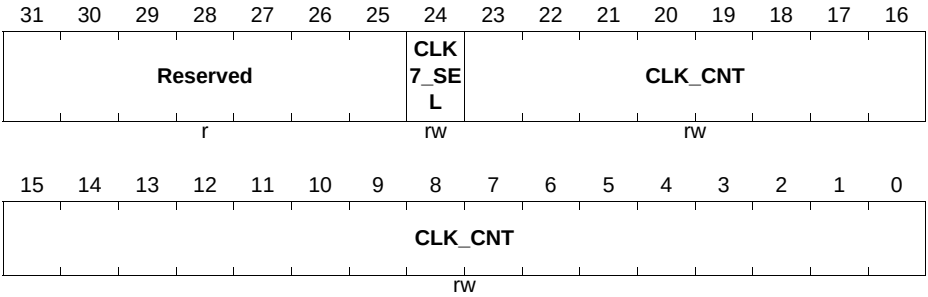
GTM_CMU_CLK_6_CTRL
CMU Control For Clock Source 6 Register
(00324_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CLK_CNT	[23:0]	rw	**Clock count. Define count value for the clock divider of clock source CMU_CLK6** Note: Value can only be modified when clock enable EN_CLK6 is disabled
CLK6_SEL	24	rw	**Clock source selection for CMU_CLK6** 0_B use Clock Source 6 Divider 1_B Reserved Note: Value can only be modified when clock enable EN_CLK6 is disabled.
Reserved	[31:25]	r	**Reserved** Read as zero, should be written as zero

24.3.8.6 Register CMU_CLK_7_CTRL

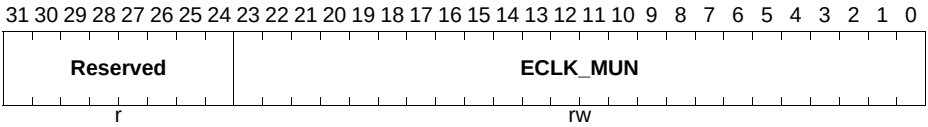
GTM_CMU_CLK_7_CTRL
CMU Control For Clock Source 7 Register
(00328_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CLK_CNT	[23:0]	rw	**Clock count. Define count value for the clock divider of clock source CMU_CLK7** Note: Value can only be modified when clock enable EN_CLK7 is disabled
CLK7_SEL	24	rw	**Clock source selection for CMU_CLK7** 0_B use Clock Source 7 Divider 1_B Reserved Note: Value can only be modified when clock enable EN_CLK7 is disabled.
Reserved	[31:25]	r	**Reserved** Read as zero, should be written as zero

24.3.8.7 Register CMU_ECLK_z_NUM (z:0…2)

GTM_CMU_ECLK_z_NUM (z=0-2)
CMU External Clock z Control Numerator Register
($0032C_H$+z*08_H) **Reset Value: 00000001_H**

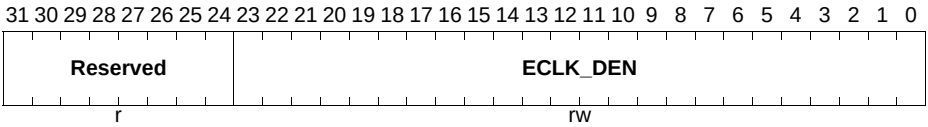


Field	Bits	Type	Description
ECLK_NUM	[23:0]	rw	**Numerator for external clock divider** Defines numerator of the fractional divider. *Note: Value can only be modified when clock enable EN_ECLK[z] is disabled.* *Note: The CMU hardware alters the content of CMU_ECLK_z_NUM and CMU_ECLK_z_DEN automatically to 0x1, if CMU_ECLK_z_NUM is specified less than CMU_ECLK_z_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_ECLK_z_NUM followed by a single write to register CMU_ECLK_z_DEN.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.3.8.8 Register CMU_ECLK_z_DEN (z:0…2)

GTM_CMU_ECLK_z_DEN (z=0-2)
CMU External Clock z Control Denominator Register

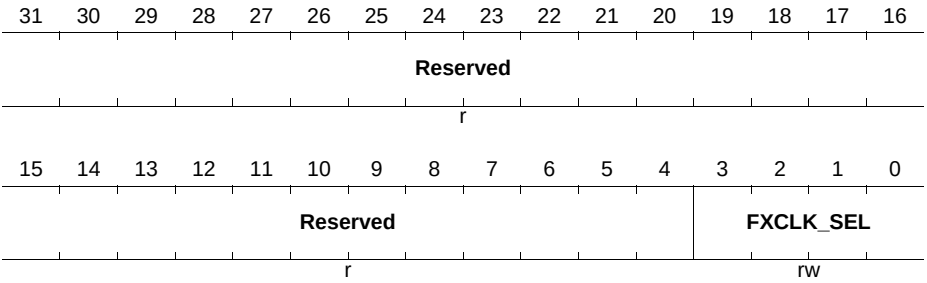
(00330_H + z*08_H) **Reset Value: 00000001_H**



Field	Bits	Type	Description
ECLK_DEN	[23:0]	rw	**Denominator for external clock divider** Defines denominator of the fractional divider. *Note: Value can only be modified when clock enable EN_ECLK[z] is disabled.* *Note: The CMU hardware alters the content of CMU_ECLK_z_NUM and CMU_ECLK_z_DEN automatically to 0x1, if CMU_ECLK_z_NUM is specified less than CMU_ECLK_z_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_ECLK_z_NUM followed by a single write to register CMU_ECLK_z_DEN.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.3.8.9 Register CMU_FXCLK_CTRL

GTM_CMU_FXCLK_CTRL
CMU FXCLK Control Register **(00344_H)** **Reset Value: 00000000_H**



Field	Bits	Type	Description
FXCLK_SEL	[3:0]	rw	**Input clock selection for EN_FXCLK line** 0000_BCMU_GCLK_EN selected 0001_BCMU_CLK0 selected 0010_BCMU_CLK1 selected 0011_BCMU_CLK2 selected 0100_BCMU_CLK3 selected 0101_BCMU_CLK4 selected 0110_BCMU_CLK5 selected 0111_BCMU_CLK6 selected 1000_BCMU_CLK7 selected *Note: This value can only be written, when the CMU_FXCLK generation is disabled. See bits 23…22 in register CMU_CLK_EN.* *Note: Other values for FXCLK_SEL are reserved and should not be used, but they behave like FXCLK_SEL = 0.*
Reserved	[31:4]	r	**Reserved bits** Read as zero, should be written as zero

24.4 Time Base Unit (TBU)

24.4.1 Overview

The Time Base Unit TBU provides common time bases for the GTM. The TBU submodule is organized in channels, where the number of channels is device dependent. There are at most three channels implemented inside the TBU. The TBU channel 0 time base register TBU_CH0_BASE is 27 bits and it is configurable whether the lower 24 bit or the upper 24 bit are provided to the GTM as signalTBU_TS0. The two TBU channels 1 and 2 have a time base register TBU_CHy_BASE (y: 1, 2) of 24 bit length. The time base register value TBU_TSy and the time base register update event TBU_UP[y] are provided to subsequent submodules of the GTM.

The TBU_UP[z] (z:1…2) signals are set to high for a single SYS_CLK period, whenever the corresponding signal TBU_TS[z] (z:1…2) or TBU_TS0 is getting updated. The signal TBU_UP0_L is set to high for a single SYS_CLK period if the signal TBU_TS0 and TBU_TS0 is getting updated and TBU_UP0_H is set to high for a single SYS_CLK period, whenever if the upper 24 bit of TBU_TS0 are updated.

The time base channels can run independently of each other and can be enabled and disabled synchronously by control bits in a global TBU channel enable register TBU_CHEN. **Section 24.4.1.1** shows a block diagram of the Time Base Unit.

24.4.1.1 TBU Block Diagram

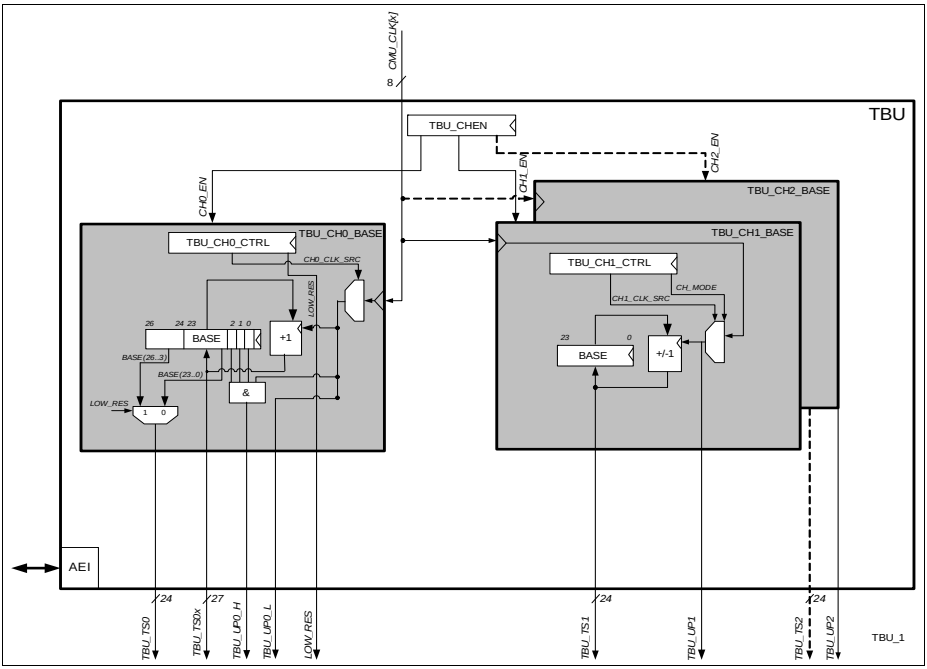


Figure 24-16 TBU Block Diagram

Dependent on the device a third TBU channel exists which offers the same functionality as the time base channel 1.

The configuration of the independent time base channels TBU_BASE_[z] is done via the AEI interface. Each TBU channel may select one of the eight CMU_CLK[x] (x: 0…7) signals coming from the CMU submodule.

24.4.2 TBU Time Base Channels

The time base values are generated within the TBU time base channels in two independent operation modes.

24.4.2.1 TBU Channel Modes

TBU channel 0 provides a 27 bit counter in a free running counter mode. Dependent on the bit field LOW_RES of register TBU_CH0_CTRL, the lower 24 bits (bit 0 to 23) or the upper 24 bits (bits 3 to 26) are provided to the GTM submodules.

TBU channel 1 and channel 2 can run in one mode; the free running counter mode.

In both modes, the time base register TBU_CH[z]_BASE can be initialized with a start value just before enabling the corresponding TBU channel.

Moreover, the time base register TBU_CH[z]_BASE can always be read in order to determine the actual value of the counter.

Free Running Counter Mode

In TBU Free running counter mode, the time base register TBU_CHy_BASE is updated on every specified incoming clock event by the selected signal CMU_CLK[x] (dependent on TBU_CH[z]_CTRL register). In general the time base register TBU_CHy_BASE is increment on every CMU_CLK[x] clock tick.

24.4.3 TBU Configuration Registers Overview

Following table shows a conclusion of configuration registers address offsets and initial values.

Table 24-8 TBU Configuration Registers Overview

Register Name	Description	Details in Section
TBU_CHEN	TBU global channel enable register	Section 24.4.4.1
TBU_CH0_CTRL	TBU channel 0 control register	Section 24.4.4.2
TBU_CH0_BASE	TBU channel 0 base register	Section 24.4.4.3
TBU_CHy_CTRL	TBU channel y control register (y:1,2)	Section 24.4.4.4
TBU_CHy_BASE	TBU channel y base register (y:1,2)	Section 24.4.4.5

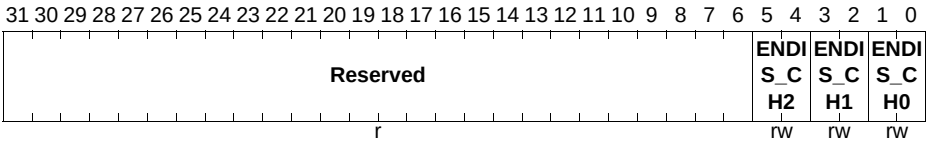
Note: In a typical application the Time Base Unit (TBU) considers channels 0 and 1 only. In this case register addresses 0x20…0x2C are reserved and shall be read as zero. Channel 2 can be additionally implemented on special high-end application requirements.

24.4.4 TBU Registers description

All of the following registers are 32-bit only accessible.

24.4.4.1 Register TBU_CHEN

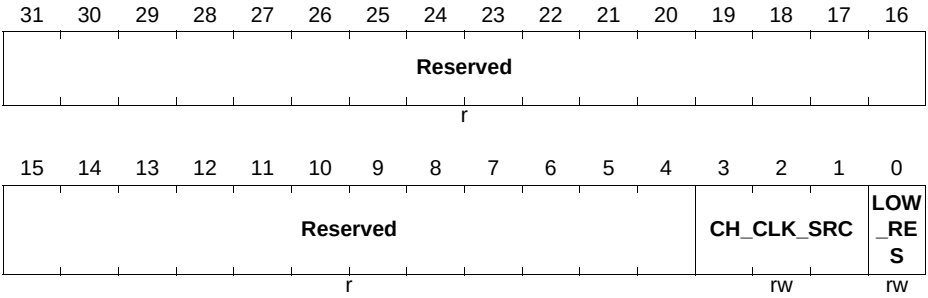
GTM_TBU_CHEN
TBU Global Channel Enable Register(00100_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
ENDIS_CH0	[1:0]	rw	**TBU channel 0 enable/disable control** Write of following double bit values is possible: 00_B don't care, bits 1:0 will not be changed 01_B channel disabled: is read as 00 (see below) 10_B channel enabled: is read as 11 (see below) 11_B don't care, bits 1:0 will not be changed Note: Read of following double values means: 00_B channel disabled 11_B channel enabled
ENDIS_CH1	[3:2]	rw	**TBU channel 1 enable/disable control** See bits 1:0
ENDIS_CH2	[5:4]	rw	**TBU channel 2 enable/disable control** See bits 1:0 Note: These bits are only applicable if channel is implemented for this device, otherwise read and write as zero
Reserved	[31:6]	r	**Reserved** Read as zero, should be written as zero

24.4.4.2 Register TBU_CH0_CTRL

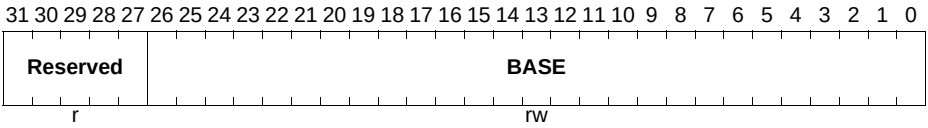
GTM_TBU_CH0_CTRL
TBU Channel 0 Control Register (00104_H) Reset Value: 00000000_H



Field	Bits	Type	Description
LOW_RES	0	rw	**TBU_CH0_BASE register resolution** 0_B TBU channel uses lower counter bits (bit 0 to 23) 1_B TBU channel uses upper counter bits (bit 3 to 26) Note: The two resolutions for the TBU channel 0 can be used in the TIM channel 0 submodule. Note: This value can only be modified if channel 0 is disabled.
CH_CLK_SRC	[3:1]	rw	**Clock source for channel x (x:0…2) time base counter** 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected Note: This value can only be modified (written) if channel 0 was disabled
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

24.4.4.3 Register TBU_CH0_BASE

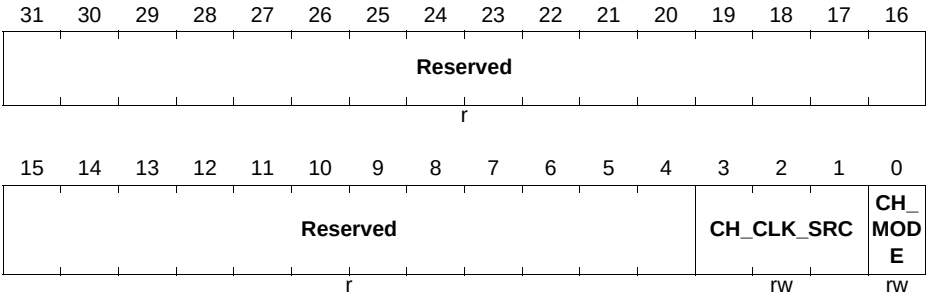
GTM_TBU_CH0_BASE
TBU Channel 0 Base Register (00108_H) Reset Value: 00000000_H



Field	Bits	Type	Description
BASE	[26:0]	rw	**Time base value for channel 0** Note: The value of BASE can only be written if the TBU channel 0 is disabled Note: If channel 0 is enabled, a read access to this register provides the current value of the underlying 27 bit counter.
Reserved	[31:27]	r	**Reserved** Read as zero, should be written as zero

24.4.4.4 Register TBU_CHy_CTRL (y:1, 2)

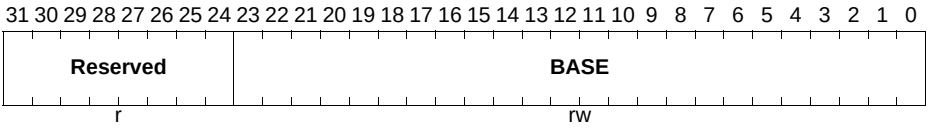
GTM_TBU_CHy_CTRL (y=1-2)
TBU Channel y Control Register (00104_H+y*08_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CH_MODE	0	rw	**Channel mode** 0_B Free running counter mode 1_B Reserved Note: This value can only be modified if channel y (y:1,2) was disabled. In Free running counter mode the CMU clock source specified by CH_CLK_SRC is used for the counter.
CH_CLK_SRC	[3:1]	rw	**Clock source for channel x (x1…2) time base counter** 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected Note: This value can only be modified if channel y was disabled
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

24.4.4.5 Register TBU_CHy_BASE (y:1,2)

GTM_TBU_CHy_BASE (y=1-2)
TBU Channel y Base Register (00108_H+y*08_H) Reset Value: 00000000_H



Field	Bits	Type	Description
BASE	[23:0]	rw	**Time base value for channel x (x 1, 2)** Note: The value of BASE can only be written if the corresponding TBU channel y is disabled Note: If the corresponding channel y is enabled, a read access to this register provides the current value of the underlying counter.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.5 Timer Input Module (TIM)

24.5.1 Overview

The Timer Input Module (TIM) is responsible for filtering and capturing input signals of the GTM. Several characteristics of the input signals can be measured inside the TIM channels.

Input characteristics mean either time stamp values of detected input rising or falling edges together with the new signal level or the number of edges received since channel enable together with the actual time stamp or PWM signal durations for a whole PWM period.

The architecture of TIM is shown in **Figure 24-17**.

24.5.1.1 TIM Block Diagram

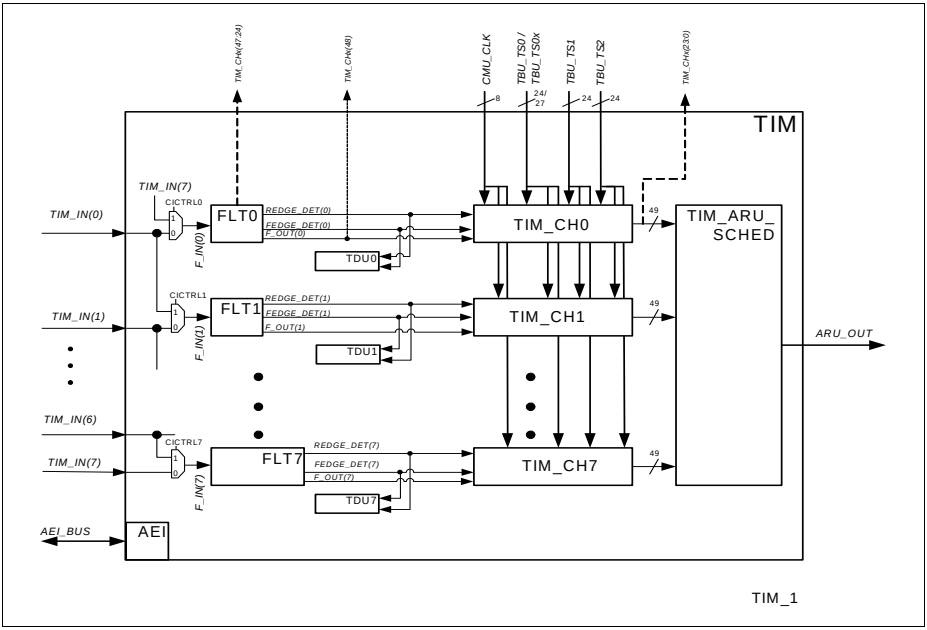


Figure 24-17 TIM Block Diagram

Each of the eight (8) dedicated input signals is filtered inside the FLTx subunit of the TIM Module. It should be noted that the incoming input signals are synchronized to the clock SYS_CLK, resulting in a delay of two SYS_CLK periods for the incoming signals.

The submodule TIM provides different filter mechanisms described in more detail in **Section 24.5.2**. After filtering, the signal is routed to the corresponding TIM channel.

The measurement values can be read by the CPU directly via the AEI-Bus.

For timeout detection of an incoming signal (no subsequent edge detected during a specified duration) each individual channel has a Timeout Detection Unit (TDU).

The two (three) time bases coming from the TBU are connected to the TIM channels to annotate time stamps to incoming signals. For TIM0 the extended 27 bit width time base TBU_TS0 is connected to the TIM channels, and the user has to select if the lower 24 bits (TBU_TS0(23…0)) or the higher 24 bits (TBU_TS0(26…3)) are stored inside the GPRz registers.

24.5.1.2 Input source selection INPUTSRCx

It can be configured which source shall be used for processing in the FLT,TDU,TIM_CH units. It can be selected by the bit fields CICTRL and MODE_x, VAL_x in the register TIM0_CHx_IN_SRC which source is in use.

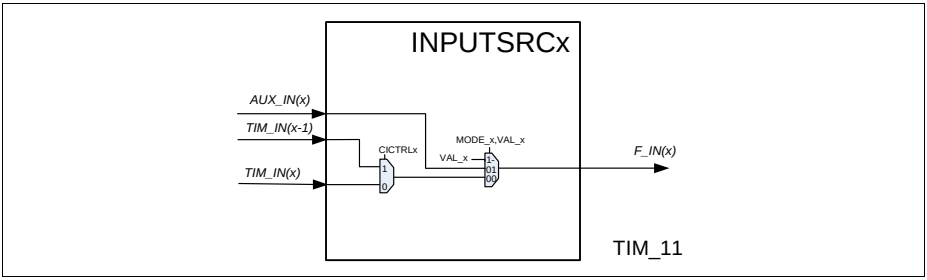

Figure 24-18 TIM Source Selection

In a certain MODE_x, VAL_x combination the input signal F_IN(x) can be driven by VAL_x with 0 or 1 directly.

Due to the fact that all 8 channels are bundled in the register TIM0_CHx_IN_SRC a synchronous control of all 8 input channels is possible.

Two adjacent channels can be combined by setting the CICTRL bit field in the corresponding TIM0_CHx_CTRL register. This allows for a combination of complex measurements on one input signal with two TIM channels.

The additional input signal AUX_IN[x] can be selected as an input signal. The source of this signal is defined in the **Section 24.2.1.2**.

24.5.1.3 Input Observation

It is possible to observe for all channels of one instance by reading TIM_INP_VAL the actual signal values of the following processing stages:

- TIM_IN(7:0) signals after TIM input synchronisation
- TIM F_IN(7:0) signals after TIM INPUTSRC selection (input to TIM_FLT)
- TIM F_OUT(7:0) signals after TIM filter functionality (output of TIM_FLT)

24.5.1.4 External capture source selection EXTCAPSRCx

Each channel can operate on an external capture signal EXT_CAPTURE. The source to use for this signal can be configured by the bit field EXT_CAP_SRCx in the register TIM0_CHx_ECTRL.

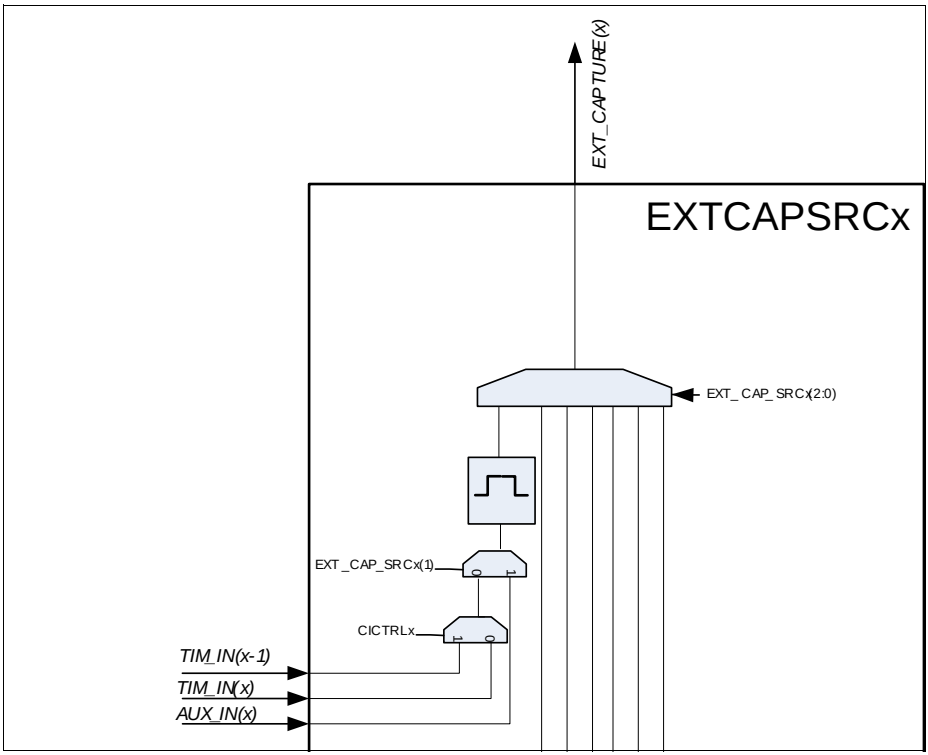

Figure 24-19 TIM external Capture Interrupt

The external capture functionality can be enabled with the bit EXT_CAP_EN

in the register TIM0_CHx_CTRL, it will trigger on each rising edge. A pulse generation for each rising edge of the selected input signal TIM_IN[x] and AUX_IN[x] is applied.

The six TIM channel interrupt sources can be triggered by the operation in the certain TIM channel modes. Alternatively they can be issued by a soft trigger using the corresponding bits in the register TIM0_CHx+1_FORCINT.

24.5.2 TIM Filter Functionality (FLT)

24.5.2.1 Overview

The TIM submodule provides a configurable filter mechanism for each input signal. These filter mechanism is provided inside the FLT subunit.

FLT architecture is shown in **Figure 24-20**

The filter includes a clock synchronisation unit (CSU), an edge detection unit (EDU), and a filter counter associated to the filter unit (FLTU).

The CSU is synchronizing the incoming signal F_IN to the selected filter clock frequency, which is controlled with the bit field FLT_CNT_FRQ of register TIM0_CHx_CTRL.

The synchronized input signal F_IN_SYNC is used for further processing within the filter.

It should be noted that glitches with a duration less than the selected CMU clock period are lost.

The filter modes can be applied individually to the falling and rising edges of an input signal. The following filter modes are available:

- immediate edge propagation mode,
- individual de-glitch time mode (up/down counter), and
- individual de-glitch time mode (hold counter).

FLT Architecture

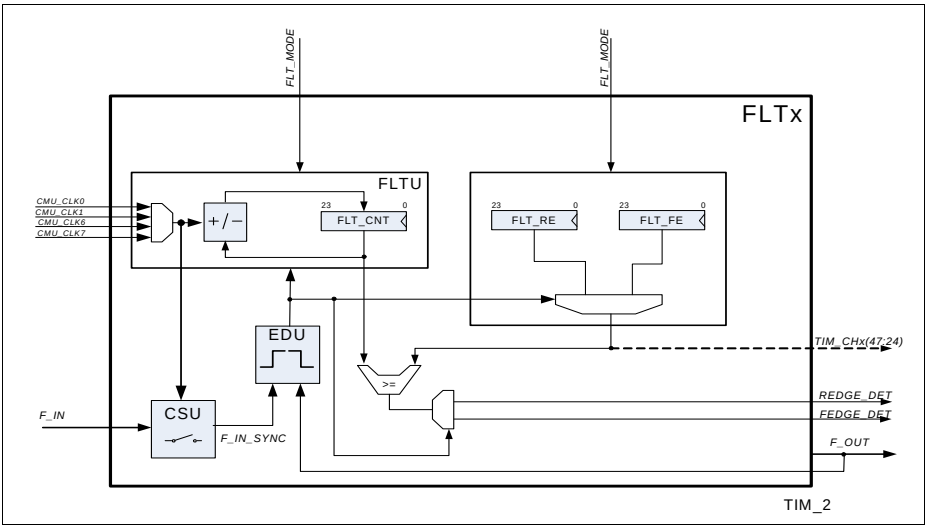

Figure 24-20 FLT Architecture

The filter parameters (deglitch and acceptance time) for the rising and falling edge can be configured inside the two filter parameter registers FLT_RE (rising edge) and FLT_FE (falling edge). The exact meaning of the parameter depends on the filter mode.

However the delay time T of both filter parameters FLT_xE can always be determined by:

T=(FLT_xE+1)*TFLT_CLK,

whereas TFLT_CLK is the clock period of the selected CMU clock signal in bit field FLT_CNT_FRQ of register TIM0_CHx_CTRL.

When a glitch is detected on an input signal a status flag GLITCHDET is set inside the TIM0_CHx_IRQ_NOTIFY register.

Table 24-9 gives an overview about the meanings for the registers FLT_RE and FLT_FE. In the individual deglitch time modes, the actual filter threshold for a detected regular edge is provided on the TIM0_CH[x](47:24) output line. In the case of immediate edge propagation mode, a value of zero is provided on the TIM0_CH[x](47:24) output line.

Filter Parameter summary for the different Filter Modes

Table 24-9 Filter Parameter summary for the different Filter Modes

Filter mode	Meaning of FLT_RE	Meaning of FLT_FE
Immediate edge propagation	Acceptance time for rising edge	Acceptance time for falling edge
Individual de-glitch time (up/down counter)	De-glitch time for rising edge	De-glitch time for falling edge
Individual de-glitch time (hold counter)	De-glitch time for rising edge	De-glitch time for falling edge

A counter FLT_CNT is used to measure the glitch and acceptance times.

The frequency of the FLT_CNT counter is configurable in bit field FLT_CNT_FRQ of register TIM0_CHx_CTRL.

The counter FLT_CNT can either be clock with the CMU_CLK0, CMU_CLK1, CMU_CLK6 or the CMU_CLK7 signal. These signals are coming from the CMU submodule.

The FLT_CNT, FLT_FE and FLT_RE registers are 24-bit width. For example, when the resolution of the CMU_CLK0 signal is 50ns this allows maximal de-glitch and acceptance times of about 838ms for the filter.

24.5.2.2 TIM Filter Modes

Immediate Edge Propagation Mode

In immediate edge propagation mode after detection of an edge the new signal level on F_IN_SYNC is propagated to F_OUT with a delay of one TFLT_CLK period and the new signal level remains unchanged until the configured acceptance time expires.

For each edge type the acceptance time can be specified separately in the FLT_RE and FLT_FE registers.

Each signal change on the input F_IN_SYNC during the duration of the acceptance time has no effect on the output signal level F_OUT of the filter but it sets the glitch GLITCHDET bit in the TIM0_CHx_IRQ_NOTIFY register.

After it expires an acceptance time the input signal F_IN_SYNC is observed and on signal level change the filter raises a new detected edge and the new signal level is propagated to F_OUT.

Independent of a signal level change the value of F_OUT is always set to F_IN_SYNC, when the acceptance time expires (see also **Figure 24-22**).

Figure 24-21 shows an example for the immediate edge propagation mode, in the case of rising edge detection. Both, the signal before filtering (F_IN) and after filtering (F_OUT) are shown. The acceptance time at1 is specified in the register FLT_RE.

Immediate Edge Propagation Mode in the case of a rising edge

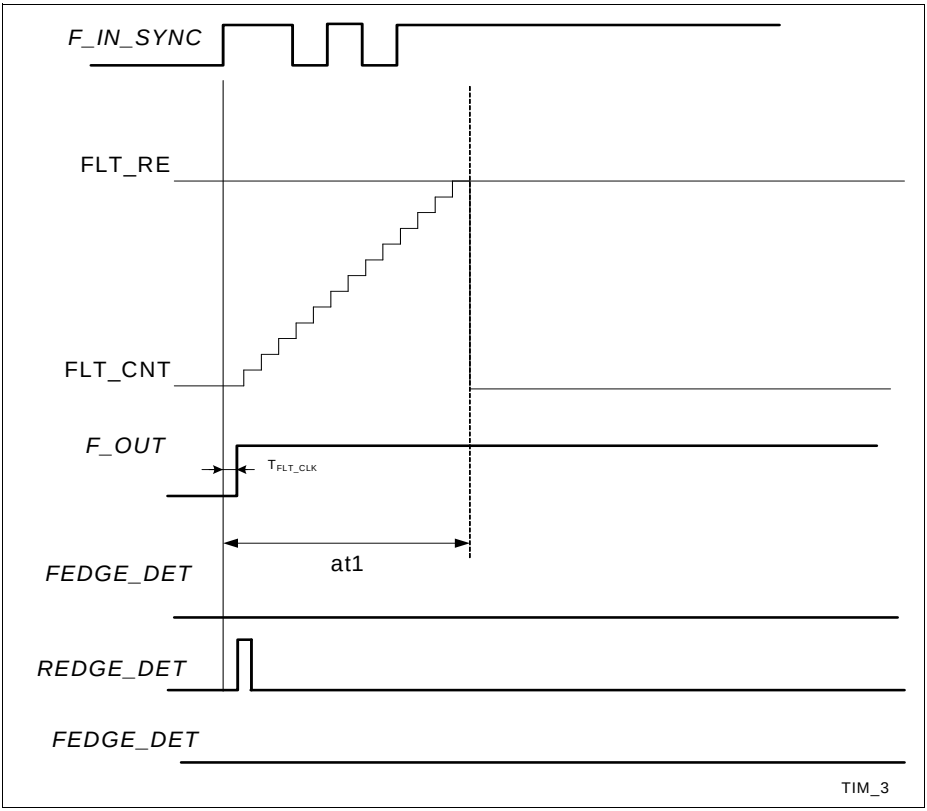

Figure 24-21 Immediate Edge Propagation Mode in the case of a rising edge

In immediate edge propagation mode the glitch measurement mechanism is not applied to the edge detection. Detected edges on F_IN_SYNC are transferred directly to F_OUT.

The counter FLT_CNT is increment until acceptance time threshold is reached.

Figure 24-22 shows a more complex example of the TIM filter, in which both, rising and falling edges are configured in immediate edge propagation mode.

Immediate Edge Propagation Mode in the case of a rising and falling edge

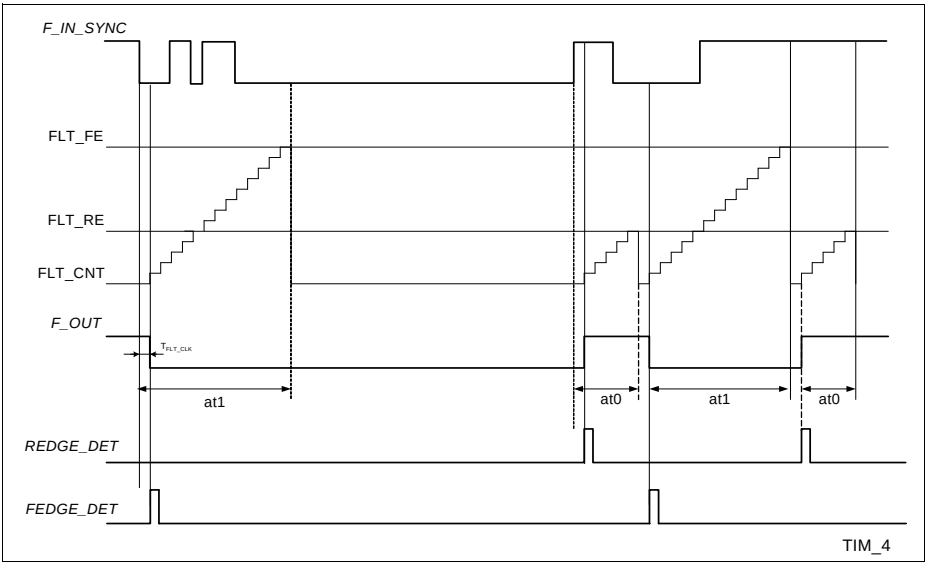

Figure 24-22 Immediate Edge Propagation Mode in the case of a rising and falling edge

If the FLT_CNT has reached the acceptance time for a specific signal edge and the signal F_IN_SYNC has already changed to the opposite level of F_OUT, the opposite signal level is set to F_OUT and the acceptance time measurement is started immediately. **Figure 24-22** shows this scenario at the detection of the first rising edge and the second falling edge.

Individual De-Glitch Time Mode (up/down counter)

In individual de-glitch time mode (up/down counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is increment when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and decremented if F_IN_SYNC equals F_OUT.

If After FLT_CNT has reached a value of zero during decrease the counter is stopped immediately.

If a glitch is detected a glitch detection bit GLITCHDET is set in the TIM0_CHx_IRQ_NOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 24-23** shows the behaviour of the filter in individual de-glitch time (up/down counter) mode in the case of the rising edge detection.

Individual Deglitch Time Mode (up/down counter) in the case of a rising edge

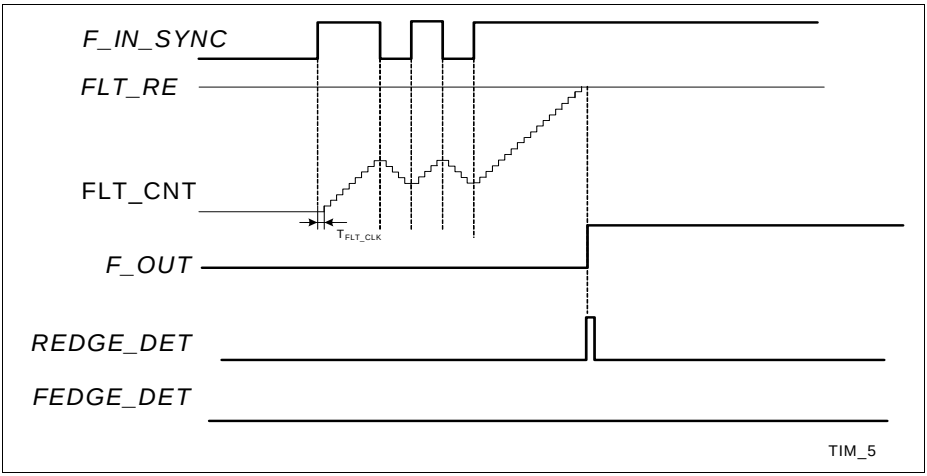

Figure 24-23 Individual Deglitch Time Mode (up/down counter) in the case of a rising edge

Individual De-Glitch Time Mode (hold counter)

In individual de-glitch time mode (hold counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is increment when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and the counter value of FLT_CNT is hold if F_IN equals F_OUT.

If a glitch is detected the glitch detection bit GLITCHDET is set in the TIM0_CHx_IRQ_NOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 24-24** shows the behaviour of the filter in individual de-glitch time (hold counter) mode in the case of the rising edge detection.

Individual Deglitch Time Mode (hold counter) in the case of a rising edge

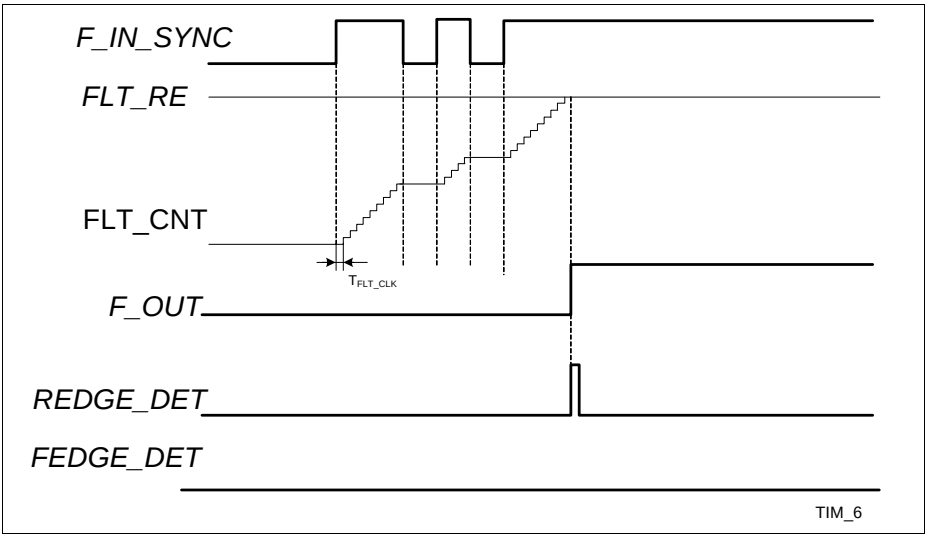

Figure 24-24 Individual Deglitch Time Mode (hold counter) in the case of a rising edge

Immediate Edge Propagation and Individual De-Glitch Mode

As already mentioned, the three different filter modes can be applied individually to each edge of the measured signal.

However, if one edge is configured with immediate edge propagation and the other edge with an individual deglitch mode (whether up/down counter or hold counter) a special consideration has to be applied.

Assume that the rising edge is configured for immediate edge propagation and the falling edge with individual deglitch mode (up/down counter) as shown in **Figure 24-25**.

If the falling edge of the incoming signal already occurs during the measuring of the acceptance time of the rising edge, the measurement of the deglitch time on the falling edge is started delayed, but immediately after the acceptance time measurement phase of the rising edge has finished.

Consequently, the deglitch counter can not measure the time TERROR, as shown in **Figure 24-25**.

Mixed mode measurement

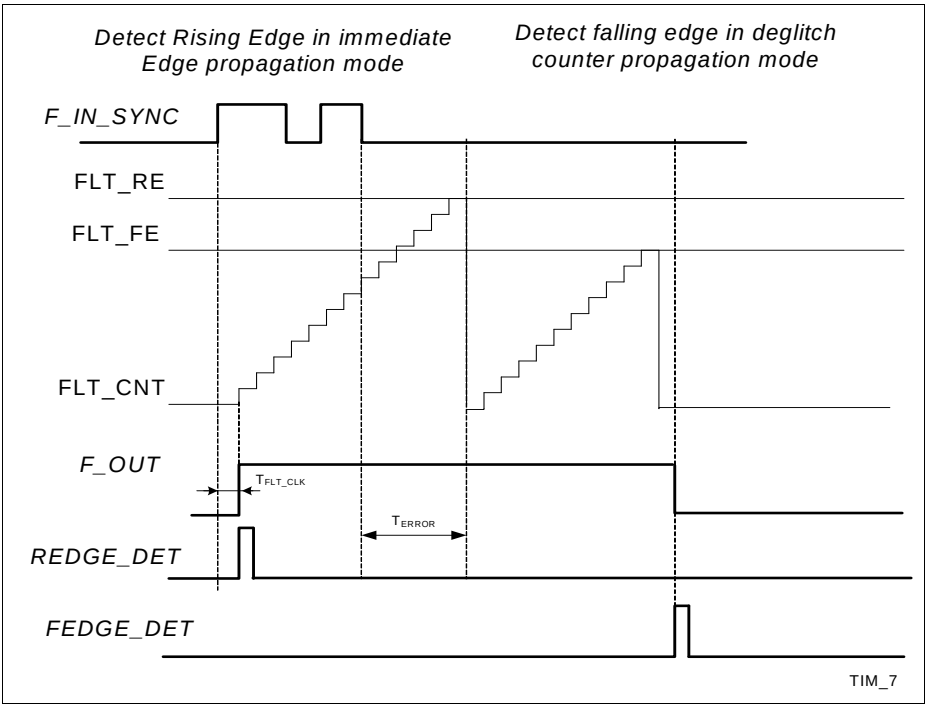

Figure 24-25 Mixed mode measurement

24.5.2.3 TIM Filter reconfiguration

If FLT_EN=1 a change of FLT_RE or FLT_FE will take place immediately. If FLT_EN=1 a change of FLT_MODE_RE or FLT_FE will be used with the next occurring corresponding edge. If mode is changed while the filter unit is processing a certain mode, it will end this edge filtering in the mode as started.

If FLT_EN=1 a change of FLT_DTR_RE or FLT_CTR_FE will take place immediately.

24.5.3 Timeout Detection Unit (TDU)

The Timeout Detection Unit (TDU) is responsible for timeout detection of the TIM input signals.

Each channel of the TIM submodule has its own Timeout Detection Unit (TDU) where a timeout event can be set up on the filtered input signal of the corresponding channel.

The TDU architecture is shown in **Figure 24-26**.

24.5.3.1 Architecture of the TDU Subunit

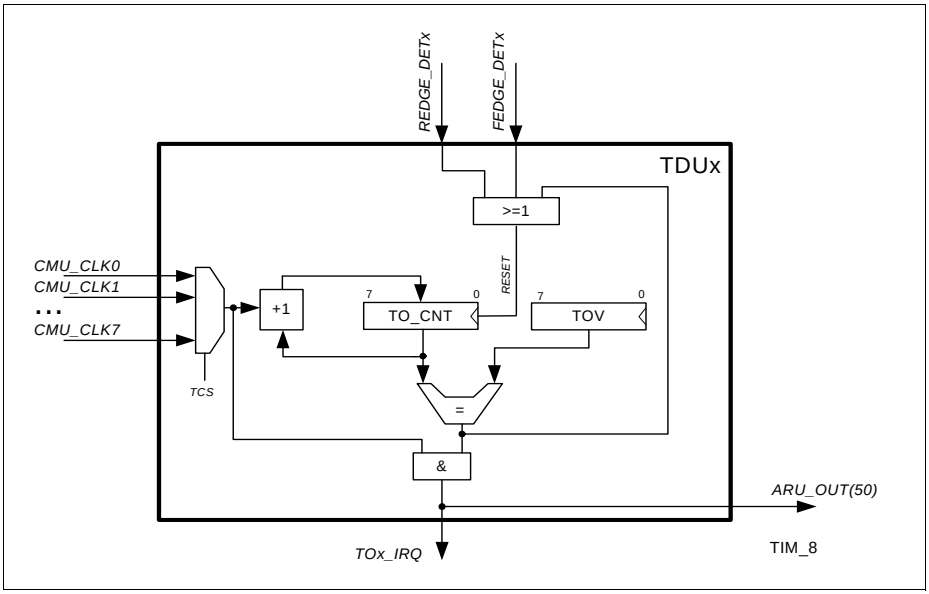

Figure 24-26 Architecture of the TDU Subunit

It is possible to detect timeouts with the resolution of the specified CMU_CLKx input signal selected with the bit field TCS of the register TIM0_CHx_TDU. The individual timeout values have to be specified in number of ticks of the selected input clock signal and have to be specified in the field TOV of timeout value register TIM0_CHx_TDUV of the TIM channel x (x:0…7).

The exact time out value TTDU can be calculated with:

$$T_{TDU}=(TOV+1)*T_{CMU\_GCLKx},$$

whereas T_{CMU_GCLKx} is the clock period of the selected CMU clock signal.

Timeout detection can be enabled or disabled individually inside the TIM0_CHx_CTRL register by setting/resetting the TO_CTRL bit.

Timeout detection can be enabled to be sensitive to falling, rising or both edges of the input signal by writing the corresponding values to the bit field TOCTRL.

The counter TO_CNT is reset by each detected input edge coming either from the filtered input signal or when the timeout value TOV is reached by the counter TO_CNT.

After such a reset or by enabling the channel inside the TIM0_CHx_CTRL register the counter TO_CNT starts counting again with the specified clock input signal.

Otherwise, timeout measurements starts immediately after the TO_CTRL bit inside the TIM0_CHx_CTRL register is written (enabled).

The TDU generates an interrupt signal TIM_TODETx_IRQ whenever a timeout is detected for an individual input signal, and the TODET bit is set inside the TIM0_CHx_IRQ_NOTIFY register.

24.5.4 TIM Channel Architecture

24.5.4.1 Overview

Each TIM channel consist of an input edge counter ECNT, a Signal Measurement Unit (SMU) with a counter CNT, a counter shadow register CNTS for SMU counter and two general purpose registers GPR0 and GPR1 for value storage.

The value TOV of the timeout register TIM0_CHx_TDU is provided to TDU subunit of each individual channel for timeout measurement. The architecture of the TIM channel is depicted in **Figure 24-27**.

TIM Channel Architecture

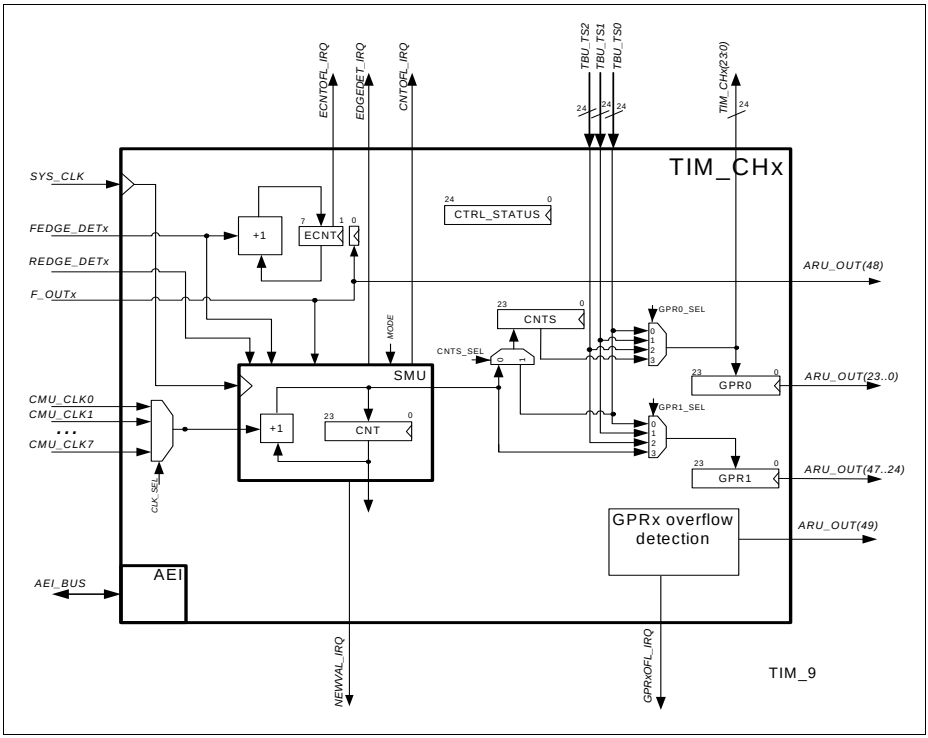

Figure 24-27 TIM Channel Architecture

Each TIM channel receives both input trigger signals REDGE_DETx and FEDGE_DETx, generated by the corresponding filter module in order to signalize a detected echo of the input signal F_INx. The signal F_OUTx shows the filtered signal of the channel's input signal F_INx.

The edge counter ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. (However, the actual counter implementation counts only falling edges on ECNT[n:1] bits. It generates ECNT by composing the ECNT[n:1] bits with F_OUTx as bit 0).

Thus, the whole counter value is always odd, when a positive edge was received and always even, when a negative edge was received.

The current ECNT[7:0] register content is made visible on the bits 31 down to 24 of the GPRz and CNTS registers. This allows the software to detect inconsistent read accesses to registers GPR0, GPR1, and CNTS. However, the update strategy of these

registers depends on the selected TIM modes, and thus the consistency check has to be adapted carefully.

It can be chosen with the bit field FR_ECNT_OFL when an ECNT overflow is signaled on ECNTOFL. An ECNT overflow can be signaled on 8 bit or full range resolution.

While reading the register TIM0_CHx_ECNT the bit ECNT[0] shows the input signal value F_OUTx independent of the state (enabled / disabled) of the channel. If a channel gets disabled (OSM mode or resetting TIM_EN) the content of TIM0_CHx_ECNT will be frozen until a read of the register takes place. this read will reset the ECNT counter. Continuing reads will show the input signal in bit ECNT[0] again.

When new data is written into GPR0 and GPR1 the NEWVAL bit is set in TIM0_CHx_IRQ_NOTIFY register and depending on corresponding enable bit value the NEWVALx_IRQ interrupt is raised.

To guarantee a consistent delivery of data from the GPR0 and GPR1 registers to the CPU each TIM channel has to ensure that the data is consumed before it is overwritten with new values.

If new data was produced by the TIM channel (bit NEWVAL is set inside TIM0_CHx_IRQ_NOTIFY register) while the old data is not consumed by the CPU, the TIM channel sets the GPRzOFL bit inside the status register TIM0_CHx_IRQ_NOTIFY and it overwrites the data inside the GPRz registers.

With the CPU as consumer for the GPRz registers, the acknowledge for reading out data is performed by a read access to the register GPR0. Thus, register GPR1 should be read always before GPR0.

24.5.4.2 TIM Channel Modes

The TIM provides six different measurement modes that can be configured with the bit field TIM_MODE of register TIM0_CHx_CTRL. The measurement modes are described in the following subsections. Besides these different basic measurement modes, there exist distinct configuration bits in the register TIM0_CHx_CTRL for a more detailed controlling of each mode. The meanings of these bits are as follows:

- DSL: control the signal level for the measurement modes (e.g. if a measurement is started with rising edge or falling edge, or if high level pulses or low level pulses are measured.
- EGPR0_SEL, GPR0_SEL and EGPR1_SEL, GPR1_SEL: control the actual content of the registers GPR0 and GPR1 after a measurement has finished.
- CNTS_SEL: control the content of the registers CNTS. The actual time for updating the CNTS register is mode dependent.
- OSM: activate measurement in one-shot mode or continuous mode. In one-shot mode only one measurement cycle is performed and after that the channel is disabled.

- NEWVAL: The NEWVAL IRQ interrupt is triggered at the end of a measurement cycle, signalling that the registers GPR0 and GPR1 are updated.
- EXT_CAP_EN: forces an update of the registers GPR0 and GPR1 and CNTS (TIM channel mode dependant) only on each rising edge of the EXT_CAPTURE signal and triggers a NEWVAL IRQ interrupt. If this mode is disabled the NEWVAL IRQ interrupt is triggered at the end of each measurement cycle.

For each channel the source of the EXT_CAPTURE signal can be configured with the bit fields EXT_CAP_SRC in the register TIM0_CHx_ECTRL.

TIM PWM Measurement Mode (TPWM)

In TIM PWM Measurement Mode the TIM channel measures duty cycle and period of an incoming PWM signal. The DSL bit defines the polarity of the PWM signal to be measured.

When measurement of pulse high time and period is requested (PWM with a high level duty cycle, DSL=1), the channel starts measuring after the first rising edge is detected by the filter.

Measurement is done with the CNT register counting with the configured clock coming from CMU_CLKx until a falling edge is detected.

Then the counter value is stored inside the shadow register CNTS (if CNTS_SEL = 0) and the counter CNT counts continuously until the next rising edge is reached.

On this following rising edge the content of the CNTS register is transferred to GPR0 and the content of CNT register is transferred to GPR1, assuming settings for the selectors GPR0_SEL=11 and GPR1_SEL=11. By this, GPR0 contains the duty cycle length and GPR1 contains the period. It should be noted, that the bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

In addition the CNT register is cleared NEWVAL status bit inside of TIM0_CHx_IRQ_NOTIFY status register and depending on corresponding interrupt enable condition TIM_NEWVALx_IRQ interrupt is raised.

If a PWM with a low level duty cycle should be measured (DSL = 0), the channel waits for a falling edge until measurement is started. On this edge the low level duty cycle time is stored first in CNTS and then finally in GPR0 and the period is stored in GPR1.

When a PWM period was successfully measured, the data in GPRz registers is marked as valid for reading, the NEWVAL bit is set inside the TIM0_CHx_IRQ_NOTIFY register, and a new measurement is started.

If the preceding PWM values were not consumed by a reader (CPU) the TIM channel set GPRzOFL status bit in TIM0_CHx_IRQ_NOTIFY and depending on corresponding interrupt enable bit value raises a GPRzOFLx_IRQ and overwrites the old values in GPR0 and GPR1. A new measurement is started afterwards.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register TIM0_CHx_IRQ_NOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIM0_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

External capture TIM PWM Measurement Mode (TPWM)

If external capture is enabled, the pwm measurement is done continuously. The actual measurement values are captured to GPRx if an external capture event occurs.

Operation is done depending on cmu clock, ISL, DSL bit and the input signal value defined in the next table:

Table 24-10 TIM PWM Measurement Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	-	0	CNT++
1	1	0	-	0	no
rising edge	-	0	0	0	capture CNT value in CNTS
falling edge	-	0	0	0	CNT = 0
rising edge	-	0	1	0	no
falling edge	-	0	1	0	capture CNT value in CNTS; CNT = 0
1	1	0	-	1	CNT++
0	1	0	-	1	no
falling edge	-	0	0	1	capture CNT value in CNTS
rising edge	-	0	0	1	CNT = 0
falling edge	-	0	1	1	no
rising edge	-	0	1	1	capture CNT value in CNTS; CNT = 0
-	-	rising edge	-	-	do GPRx capture; issue NEWVAL_IRQ
-	0	0	-	-	no

TIM Pulse Integration Mode (TPIM)

In TIM Pulse Integration Mode each TIM channel is able to measure a sum of pulse high or low times on an input signal, depending on the selected signal level bit DSL of register TIM0_CHx_CTRL register.

The pulse times are measured by incrementing the TIM channel counter CNT whenever the pulse has the specified signal level DSL. The counter is stopped whenever the input signal has the opposite signal level.

The counter CNT counts with the CMU_CLKx clock specified by the CLK_SEL bit field of the TIM0_CHx_CTRL register.

The CNT register is reset at the time the channel is activated (enabling via AEI write access) and it accumulates pulses while the channel is staying enabled.

Whenever the counter is stopped, the registers CNTS, GPR0 and GPR1 are updated according to settings of its corresponding input multiplexers, using the bits GPR0_SEL, EGPR0_SEL, EGPR1_SEL, GPR1_SEL, and CNTS_SEL. It should be noted, that the bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

External capture TIM Pulse Integration Mode (TPIM)

If external capture is enabled, the pulse integration is done until next external capture event occurs.

Operation is done depending on CMU clock, DSL bit and the input signal value defined in the next table:

Table 24-11 TIM integration Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	-	0	CNT++
1	1	0	-	0	no
1	1	0	-	1	CNT++
0	1	0	-	1	no
-	-	rising edge	-	-	do GPRx capture; issue NEWVAL_IRQ
-	0	0	-	-	no

TIM Input Event Mode (TIEM)

In TIM Input Event Mode the TIM channel is able to count edges.

It is configurable if rising, falling or both edges should be counted. This can be done with the bit fields DSL and ISL in TIM0_CHx_CTRL register.

In addition, a TIM0_NEWVAL[x]_IRQ interrupt is raised when the configured edge was received and this interrupt was enabled.

The counter register CNT is used to count the number of edges, and the bit fields EGPR0_SEL, EGPR1_SEL, GPR0_SEL, GPR1_SEL, and CNTS_SEL can be used to configure the desired update values for the registers GPR0, GPR1 and CNTS. These register are updated whenever the edge counter CNT is increment due to the arrival of a desired edge.

GPRz If the preceding data was not consumed by the CPU the TIM channel sets GPRzOFL status bit and raises a GPRzOFL[x]_IRQ if it was enabled in TIM0_CHx_IRQ_EN register and overwrites the old values in GPR0 and GPR1 with the new ones.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register TIM0_CHx_IRQ_NOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIM0_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Input Event Mode does not depend on the bit field CLK_SEL of register TIM0_CHx_CTRL.

External capture TIM Input Event Mode (TIEM)

If external capture is enabled, capturing is done depending on ISL, DSL bit and the input signal value defined in the next table:

Table 24-12 TIM Input Event Mode

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	do capture; issue NEWVAL_IRQ; CNT++
-	0	-	-	no
1	rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	-	0	1	no
0	rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	-	0	0	no

TIM Input Prescaler Mode (TIPM)

In the TIM Input Prescaler Mode the number of edges which should be detected before a TIM0_NEWVAL[x]_IRQ is raised is programmable. In this mode it must be specified in the CNTS register after how many edges the interrupt has to be raised.

A value of 0 in CNTS means that after one edge an interrupt is raised, and a value of 1 means that after two edges an interrupt is raised, and so on.

The edges to be counted can be selected by the bit fields DSL and ISL of register TIM0_CHx_CTRL.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits EGPR0_SEL, EGPR1_SEL, GPR0_SEL and GPR1_SEL.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIM0_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Input Prescaler Mode does not depend on the bit field CLK_SEL of register TIM0_CHx_CTRL.

External capture TIM Input Prescaler Mode (TIPM)

If external capture is enabled, the external capture events are counted instead of the input signal edges.

Operation is done depending on DSL, ISL bit and the input signal value defined in the next table:

Table 24-13 TIM Input Event Mode

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
-	0	1	-	no
1	rising edge	0	1	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	-	0	1	no
0	rising edge	0	0	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
1	-	0	0	no

TIM Gated Periodic Sampling Mode (TGPS)

In the TIM Gated Periodic Sampling Mode the number of CMU clock cycles which should elapse before capturing and rising TIM0_NEWVALx_IRQ is programmable. In this mode it must be specified in the CNTS register after how many CMU clock cycles the interrupt has to be raised.

A value of 0 in TIM0_CHx_CNTS means that after one CLK_SEL edge a trigger/interrupt is raised, and a value of 1 means that after two edges a trigger/interrupt is raised, and so on.

In the TIM0_CHx_CNT register the elapsed cycles were incremented and compared against TIM0_CHx_CNTS. If TIM0_CHx_CNT is greater or equal to TIM0_CHx_CNTS a trigger will be raised. This allows by writing a value to TIM0_CHx_CNTS that the actual period time can be changed on the fly.

Operation is done depending on CMU clock, DSL, ISL bit and the input signal value defined in the next table:

Table 24-14 TIM Gated Periodic Sampling Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
-	1	0	1	-	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	0	0	1	no
1	1	0	0	1	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	-	0	1	no
0	1	0	0	0	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
1	0	0	0	0	no
-	0	0	-	-	no

In this mode the TIM0_CHx_GPR1 operates as a shadow register for TIM0_CHx_CNTS. This would allow that the period for the next sampling period could be specified. The update of TIM0_CHx_CNTS will only take place once on a trigger if the TIM0_CHx_GPR1 was written by the CPU. This means that the capture value from the

previous trigger can be read by the CPU from TIM0_CHx_GPR1 and afterwards the new sampling period (the one after the actual sampling period) could be written.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits GPR0_SEL, GPR1_SEL, EGPR0_SEL and EGPR1_SEL.

When selecting ECNT as a source for the capture registers, GPRx will show the edge count and the input signal value at point of capture. Selecting GPR0_SEL = 11_B and EGPR0_SEL = 0_B for TIM channel 0 all 8 TIM input signals will captured to GPR[7:0].

In the TGPS Mode the bit field CLK_SEL of register TIM0_CHx_CTRL will define the selected CMU clock which will be used.

The behaviour of the ECNT counter is configurable by ECNT_RESET. If set to 1 on each interrupt (period expired) the ECNT will be reset. Otherwise it operates in wrap around mode.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIM0_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFLx_IRQ is raised depending on corresponding interrupt enable condition.

External capture Bit Gated Periodic Sampling Mode (TGPS)

If external capture is enabled, the external capture events will capture the GPRx, reset the counter CNT and issue a NEWVAL_IRQ.

Operation is done depending on CMU clock, DSL, ISL bit and the input signal value defined in the next table:

Table 24-15 TIM Gated Periodic Sampling Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
-	1	0	1	-	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	0	0	1	no
1	1	0	0	1	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	-	0	1	no

Table 24-15 TIM Gated Periodic Sampling Mode (cont'd)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	0	0	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
1	0	0	0	0	no
-	0	0	-	-	no
-	-	rising edge	-	-	do capture; issue NEWVAL_IRQ; CNT = 0

24.5.5 TIM Interrupt Signals

TIM provides 6 interrupt lines per channel. These interrupts are shown below:

Table 24-16 TIM Interrupt Signals

Signal	Description
TIM0_NEWVAL[x]_IRQ	New measurement value detected by SMU of channel x (x:0…7)
TIM0_ECNTOFL[x]_IRQ	ECNT counter overflow of channel x (x:0…7)
TIM0_CNTOFL[x]_IRQ	SMU CNT counter overflow of channel x (x:0…7)
TIM0_GPRzOF[x]_IRQ	GPRz data overflow, old data was not read out before new data has arrived at input pin (x:0…7)
TIM0_TODET[x]_IRQ	Time out reached for input signal of channel x (x:0…7)
TIM0_GLITCHDET_IRQ	A glitch was detected by the TIM filter of channel (x: 0…7).

24.5.6 TIM Configuration Registers Overview

TIM contains following configuration registers:

Table 24-17 TIM Configuration Registers Overview

Register Name	Description	Detail in Section
TIM0_CHx_CTRL	TIM channel x control register (x:0…7)	Section 24.5.7.1
TIM0_CHx_ECTRL	TIM channel x (x:0…7) extended control	Section 24.5.7.18
TIM0_CHx_FLT_RE	TIM channel x filter parameter 0 register (x:0…7)	Section 24.5.7.2
TIM0_CHx_FLT_FE	TIM channel x filter parameter 1 register (x:0…7)	Section 24.5.7.3
TIM0_CHx_TDUV	TIM channel x TDU control register (x:0…7)	Section 24.5.7.15
TIM0_CHx_TDUC	TIM channel x TDU counter register (x:0…7)	Section 24.5.7.16
TIM0_CHx_GPR0	TIM channel x general purpose 0 register (x:0…7)	Section 24.5.7.4
TIM0_CHx_GPR1	TIM channel x general purpose 1 register (x:0…7)	Section 24.5.7.5
TIM0_CHx_CNT	TIM channel x SMU counter register (x:0…7)	Section 24.5.7.6
TIM0_CHx_ECNT	TIM channel x (x:0…7) SMU edge counter	Section 24.5.7.17
TIM0_CHx_CNTS	TIM channel x SMU shadow counter register (x:0…7)	Section 24.5.7.7
TIM0_CHx_IRQ_NOTIFY	TIM channel x interrupt notification register (x:0…7)	Section 24.5.7.8
TIM0_CHx_IRQ_EN	TIM channel x interrupt enable register (x:0…7)	Section 24.5.7.9
TIM0_CHx_EIRQ_EN	TIM channel x (x:0…7) error interrupt enable	Section 24.5.7.14
TIM0_CHx_IRQ_FORCINT	TIM channel x software interrupt force register (x:0…7)	Section 24.5.7.10
TIM0_CHx_IRQ_MODE	TIM IRQ mode configuration register (x=0…7)	Section 24.5.7.11

Table 24-17 TIM Configuration Registers Overview (cont'd)

Register Name	Description	Detail in Section
TIM0_RST	TIM global software reset register	Section 24.5.7.12
TIM0_IN_SRC	TIM AUX IN source selection	Section 24.5.7.13
TIM0_IN_VAL	TIM input value observation	Section 24.5.7.19

24.5.7 TIM Configuration Registers Description

All of the following registers are 32-bit only accessible.

24.5.7.1 Register TIM0_CHx_CTRL (x:0…7)

GTM_TIM0_CHx_CTRL (x=0-7)
TIM Channel x Control Register (01024_H+x*80_H) **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TOCTRL		EGPR1_SEL	EGPR0_SEL	FR_ECNT_OFL	CLK_SEL			FLT_CTR_FE	FLT_MODE_FE	FLT_CTR_RE	FLT_MODE_RE	Reserved	FLT_CNT_FRQ		FLT_EN
rw		rw	rw	rw	rw			rw	rw	rw	rw	r	rw		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECNT_RESET	ISL	DSL	CNTS_SEL	GPR1_SEL		GPR0_SEL		TBU0x_SEL	CICTRL	0	OSM	TIM_MODE			TIM_EN
rw	rw	rw	rw	rw		rw		rw	rw	rw	rw	rw			rwh

Field	Bits	Type	Description
TIM_EN	0	rwh	**TIM channel x (x:0…7)enable** 0_B Channel disabled 1_B Channel enabled Note: Enabling of the channel resets the registers ECNT, TIM0_CHx_CNT, TIM0_CHx_GPR0, and TIM0_CHx_GPR1 to their reset values. Note: After finishing the action in one-shot mode the TIM_EN bit is cleared automatically. Otherwise, the bit must be cleared manually.

Field	Bits	Type	Description
TIM_MODE	[3:1]	rw	**TIM channel x (x:0…7) mode** 000_B PWM Measurement Mode (TPWM) 001_B Pulse Integration Mode (TPIM) 010_B Input Event Mode (TIEM) 011_B Input Prescaler Mode (TIPM) 100_B Reserved 101_B Gated Periodic Sampling Mode (TGPS) Note: If an undefined value is written to the TIM_MODE register, the hardware switches automatically to TIM_MODE = 000 (TPWM mode). Note: The TIM_MODE register should not be changed while the TIM channel is enabled. Note: If TIM channel is enabled and operating in TPWM or TPIM mode after the first valid edge defined by DSL has occurred, a reconfiguration of DSL, ISL, and TIM_MODE will not change the channel behavior. Reading these bit fields after reconfiguration will show the newly configured settings but the initial channel behavior will not change. Only a disabling of the TIM_EN=0 will change the channel operation mode.
OSM	4	rw	**One-shot mode** 0_B Continuous operation mode 1_B One-shot mode Note: After finishing the action in one-shot mode the TIM_EN bit is cleared automatically.
0	5	rw	**Reserved** Have to be written as zero
CICTRL	6	rw	**Channel Input Control** 0_B use signal TIM_IN(x) as input for channel x 1_B use signal TIM_IN(x-1) as input for channel x (or TIM_IN(7) if x is 0)
TBU0x_SEL	7	rw	**TBU_TS0 bits input select for TIM_CHx_GPRz (x: 0, 1)** 0_B Use TBU_TS0(23…0) to store in TIM0_CHx_GPRz 1_B Use TBU_TS0(26…3) to store in TIM0_CHx_GPRz Note: This bit is only applicable for TIM0

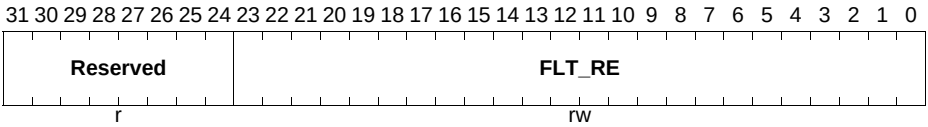
Field	Bits	Type	Description
GPR0_SEL	[9:8]	rw	**Selection for GPR0 register** If EGPR0_SEL =0: 00_B use TBU_TS0 as input 01_B use TBU_TS1 as input 10_B use TBU_TS2 as input 11_B use CNTS as input; in TGPS mode in channel = 0 use TIM filter F_OUT as input If EGPR0_SEL =1: 00_B use ECNT as input 01_B use TIM_INP_VAL as input 10_B reserved 11_B reserved *Note: In TBCM mode: EGPR1_SEL=1, GPR1_SEL=01 selects TIM_INP_VAL as input, in all cases TIM filter F_OUT is used.*
GPR1_SEL	[11:10]	rw	**Selection for GPR1 register** If EGPR0_SEL =0: 00_B use TBU_TS0 as input 01_B use TBU_TS1 as input 10_B use TBU_TS2 as input 11_B use CNT as input If EGPR0_SEL =1: 00_B use ECNT as input 01_B use TIM_INP_VAL as input 10_B reserved 11_B reserved *Note: In TBCM mode EGPR1_SEL, GPR1_SEL are ignored TIM Filter F_OUT is used as input.* *Note: If a reserved value is written to the EGPR1_SEL, GPR1_SEL bit fields, the hardware will use TBU_TS0 input.*
CNTS_SEL	12	rw	**Selection for CNTS register** 0_B use CNT register as input 1_B use TBU_TS0 as input Note: The functionality of the CNTS_SEL is disabled in the modes TIPM and TBCM.

Field	Bits	Type	Description
DSL	13	rw	**Signal level control** 0_B Measurement starts with falling edge (low level measurement) 1_B Measurement starts with rising edge (high level measurement)
ISL	14	rw	**Ignore signal level** 0_B use DSL bit for selecting active signal level 1_B ignore DSL and treat both edges as active edge Note: This bit is only applicable in Input Event mode (TIEM and TIPM)
ECNT_RESET	15	rw	**Enables resetting the ECNT counter in periodic sampling mode** 0_B ECNT counter operating in wrap around mode 1_B ECNT counter is reset with periodic sampling
FLT_EN	16	rw	**Filter enable for channel x (x:0…7)** 0_B Filter disabled and internal states are reset 1_B Filter enabled Note: If the filter is disabled all filter related units (including CSU) are bypassed, which means that the signal F_IN is directly routed to signal F_OUT.
FLT_CNT_FRQ	[18:17]	rw	**Filter counter frequency select** 00_B FLT_CNT counts with CMU_CLK0 01_B FLT_CNT counts with CMU_CLK1 10_B FLT_CNT counts with CMU_CLK6 11_B FLT_CNT counts with CMU_CLK7
EXT_CAP_EN	19	rw	**Enables external capture mode** The selected TIM mode is only sensitive to external capture pulses the input event changes are ignored 0_B External capture disabled 1_B External capture enabled
FLT_MODE_RE	20	rw	**Filter mode for rising edge** 0_B Immediate edge propagation mode 1_B individual de-glitch mode
FLT_CTR_RE	21	rw	**Filter counter mode for rising edge** 0_B Up/Down Counter 1_B Hold Counter Note: This bit is only applicable in Individual Deglitch Time Mode

Field	Bits	Type	Description
FLT_MODE_FE	22	rw	**Filter mode for falling edge** 0_B Immediate edge propagation mode 1_B individual de-glitch mode
FLT_CTR_FE	23	rw	**Filter counter mode for falling edge** 0_B Up/Down Counter 1_B Hold Counter Note: This bit is only applicable in Individual Deglitch Time Mode
CLK_SEL	[26:24]	rw	**CMU clock source select for channel** 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected
FR_ECNT_OFL	27	rw	**Extended Edge counter overflow behaviour** 0_B Overflow will be signalled on ECNT bit width = 8 1_B Overflow will be signalled on EECNT bit width (full range)
EGPR0_SEL	28	rw	**Extension of GPR0_SEL bit field** Details described in GPR0_SEL bit field.
EGPR1_SEL	29	rw	**Extension of GPR1_SEL bit field** Details described in GPR1_SEL bit field.
TOCTRL	[31:30]	rw	**Timeout control** 00_B Timeout feature disabled 01_B Timeout feature enabled for both edges 10_B Timeout feature enabled for rising edge only 11_B Timeout feature enabled for falling edge only

24.5.7.2 Register TIM0_CHx_FLT_RE(x:0…7)

GTM_TIM0_CHx_FLT_RE (x=0-7)
GTM_TIM0 Channel x Filter Parameter 0 Register
($0101C_H$+x*80_H) **Reset Value: 00000000_H**

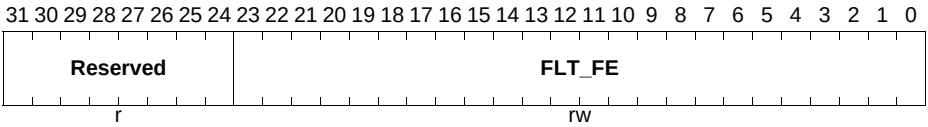


Field	Bits	Type	Description
FLT_RE	[23:0]	rw	**Filter parameter for rising edge** Note: This register has different meanings in the various filter modes. Immediate edge propagation mode = acceptance time for rising edge Individual deglitch time mode = deglitch time for rising edge
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.5.7.3 Register TIM0_CHx_FLT_FE (x:0…7)

GTM_TIM0_CHx_FLT_FE (x=0-7)
TIM0 Channel x Filter Parameter 1 Register

(01020_H+x*80_H) **Reset Value: 00000000_H**

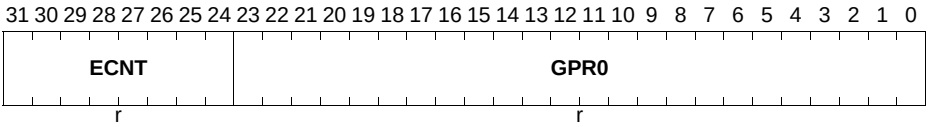


Field	Bits	Type	Description
FLT_FE	[23:0]	rw	**Filter parameter for falling edge** Note: This register has different meanings in the various filter modes. Immediate edge propagation mode = acceptance time for falling edge Individual deglitch time mode = deglitch time for falling edge
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.5.7.4 Register TIM0_CHx_GPR0 (x:0…7)

GTM_TIM0_CHx_GPR0 (x=0-7)
TIM0 Channel x General Purpose 0 Register

(01000_H+x*80_H) **Reset Value: $0X000000_H$**

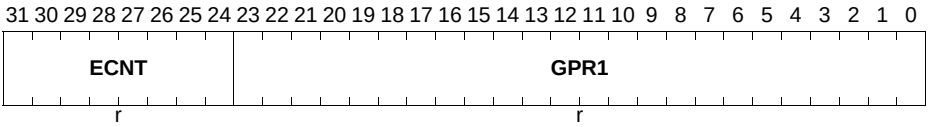


Field	Bits	Type	Description
GPR0	[23:0]	r	**Input signal characteristic parameter 0** Note: The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR0_SEL, GPR0_SEL of register TIM0_CHx_CTRL.
ECNT	[31:24]	r	**Edge counter** Note: The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.

24.5.7.5 Register TIM0_CHx_GPR1 (x:0…7)

GTM_TIM0_CHx_GPR1 (x=0-7)
TIM0 Channel x General Purpose 1 Register

(01004_H+x*80_H) **Reset Value: $0X000000_H$**

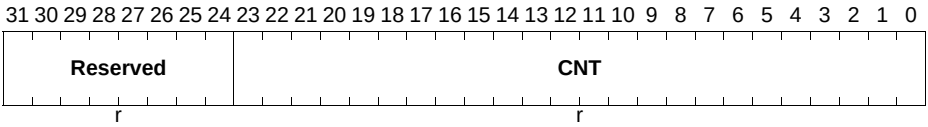


Field	Bits	Type	Description
GPR1	[23:0]	r	**Input signal characteristic parameter 1** Note: The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR1_SEL, GPR1_SEL of register TIM0_CHx_CTRL. Note: In TBCM mode if EGPR1_SEL=1, GPR1_SEL=01 then TIM_INP_VAL is used as input in all other cases TIM filter F_OUT is used as input and bits GPR1(23:8)=0.
ECNT	[31:24]	r	**Edge counter** Note: The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.

24.5.7.6 Register TIM0_CHx_CNT (x:0…7)

GTM_TIM0_CHx_CNT (x=0-7)
TIM0 Channel x SMU Counter Register

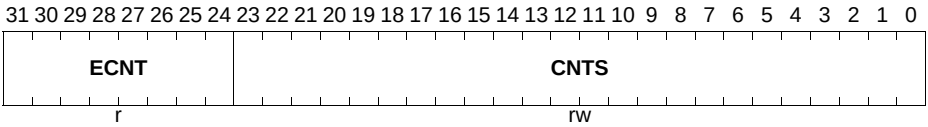
(01008_H+x*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CNT	[23:0]	r	**Actual SMU counter value** Note: The meaning of this value depends on the configured mode: TPWM = actual duration of PWM signal. TPIM = actual duration of all pulses (sum of pulses). TIEM = actual number of received edges. TIPM = actual number of received edges.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

24.5.7.7 Register TIM0_CHx_CNTS (x:0…7)

GTM_TIM0_CHx_CNTS (x=0-7)
TIM0 Channel x SMU Shadow Counter Register
(01010_H+x*80_H) **Reset Value: $0X000000_H$**

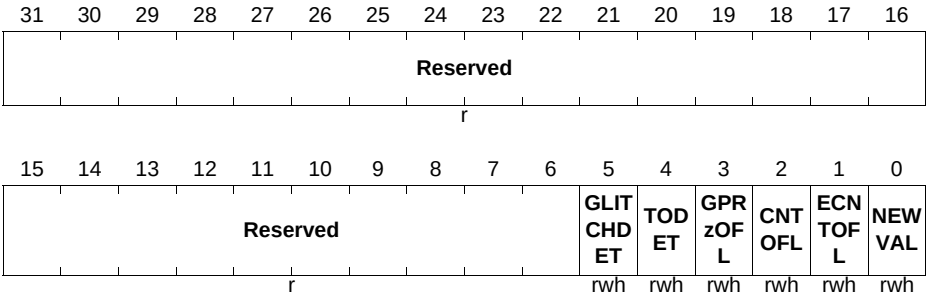


Field	Bits	Type	Description
CNTS	[23:0]	rw	**Counter shadow register** Note: The content of this register has different meaning for the TIM channels modes. The content depends directly on the bit field CNTS_SEL of register TIM0_CHx_CTRL. Note: The register TIM0_CHx_CNTS is only writable in TIPM, TBCM and TGPS mode.
ECNT	[31:24]	r	**Edge counter** Note: The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.

24.5.7.8 Register TIM0_CHx_IRQ_NOTIFY (x:0…7)

GTM_TIM0_CHx_IRQ_NOTIFY (x=0-7)
TIM0 Channel x Interrupt Notification Register

(0102C$_H$+x*80$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
NEWVAL	0	rwh	**New measurement value detected by in channel x (x:0…7)** 0_B No event was occurred 1_B NEWVAL was occurred on the TIM channel Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ECNTOFL	1	rwh	**counter overflow of channel x, (x:0…7)** See bit 0
CNTOFL	2	rwh	**SMU CNT counter overflow of channel x, (x:0…7)** See bit 0
GPRzOFL	3	rwh	**data overflow, old data not read out before new data has arrived at input pin, (x:0…7)** See bit 0
TODET	4	rwh	**Timeout reached for input signal of channel x, (x:0…7)** see bit 0
GLITCHDET	5	rwh	**Glitch detected on channel x, (x:0…7)** 0_B no glitch detected for last edge 1_B glitch detected for last edge Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Field	Bits	Type	Description
Reserved	[31:6]	r	**Reserved** Read as zero, should be written as zero

24.5.7.9 Register TIM0_CHx_IRQ_EN (x:0…7)

GTM_TIM0_CHx_IRQ_EN (x=0-7)
TIM0 Channel x Interrupt Enable Register

(01030_H+x*80_H) **Reset Value: 00000000_H**

24.6 Timer Output Module (TOM)

24.6.1 Overview

The Timer Output Module (TOM) offers 16 independent channels (index x) to generate simple PWM signals at each output pin TOM[i]_CH[x]_OUT.

Additionally, at TOM output TOM[i]_CH15_OUT a pulse count modulated signal can be generated.

The architecture of the TOM submodule is depicted in **Figure 24-28**.

Some useful indices are defined as:

y=0,1

z=0…7

24.6.1.1 TOM Block diagram

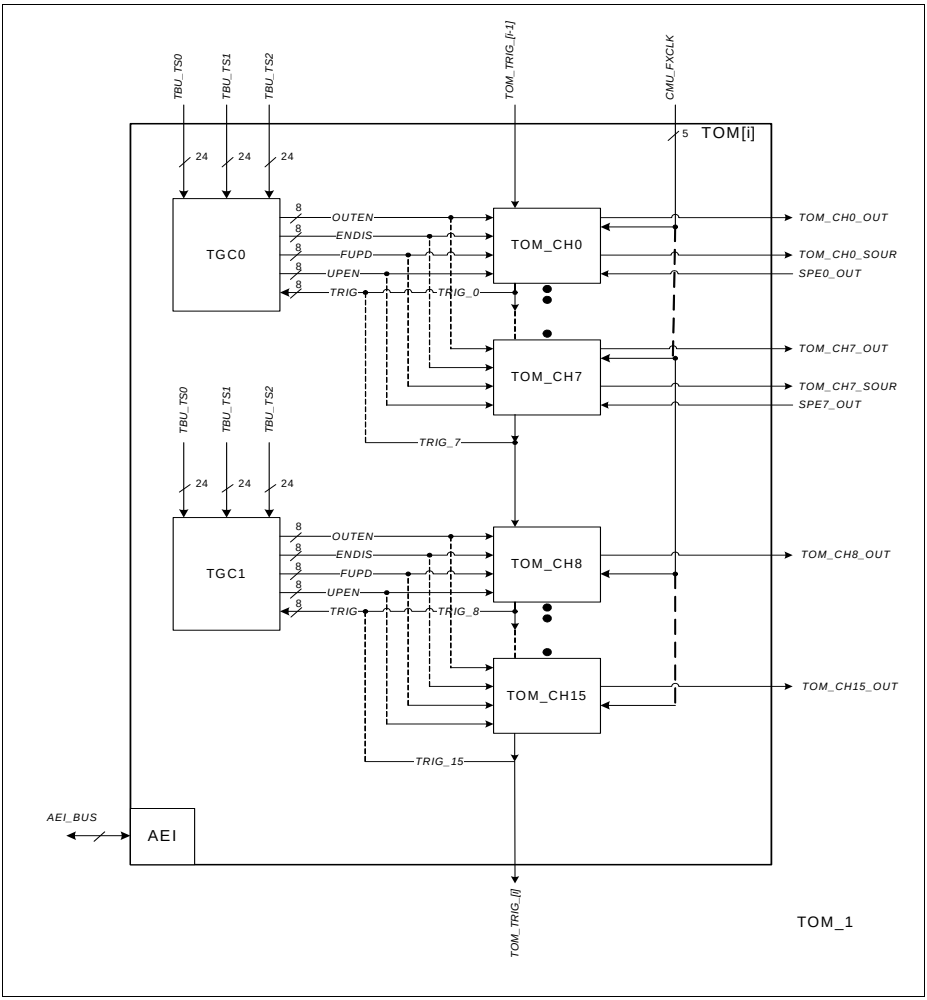

Figure 24-28 TOM Block diagram

The two submodules TGC0 and TGC1 are global channel control units that control the enabling/disabling of the channels and their outputs as well as the update of their period and duty cycle register.

The module TOM receives two (three) timestamp values TBU_TS0, TBU_TS1 (and TBU_TS2) in order to realize synchronized output behaviour on behalf of a common time base.

The 5 dedicated clock line inputs CMU_FXCLK are providing divided clocks that can be selected to clock the output pins.

The trigger signals TOM_TRIG_[i-1] of TOM instance i comes from the preceding instance i-1, the trigger TOM_TRIG_[i] is routed to succeeding instance i+1.

Note: TOM0 is connected to its own output TOMTRIG_0 i.e. the last channel of TOM instance 0 can trigger the first channel of TOM0 instance (this path is registered, which means delayed by one SYS_CLK period).

24.6.2 TOM Global Channel Control (TGC0, TGC1)

24.6.2.1 Overview

There exist two global channel control units (TGC0 and TGC1) to drive a number of individual TOM channels synchronously by external or internal events.

Each TGC[y] can drive up to eight TOM channels where TGC0 controls TOM channels 0 to 7 and TGC1 controls TOM channels 8 to 15.

The TOM submodule supports four different kinds of signalling mechanisms:

- Global enable/disable mechanism for each TOM channel with control register TOMi_TGCy_ENDIS_CTRL and status register TOMi_TGCy_ENDIS_STAT
- Global output enable mechanism for each TOM channel with control register TOMi_TGCy_OUTEN_CTRL and status register TOMi_TGCy_OUTEN_STAT
- Global force update mechanism for each TOM channel with control register TOMi_TGCy_FUPD_CTRL
- Update enable of the register CM0, CM1 and CLK_SRC_STAT for each TOM channel with the control bit field UPEN_CTRL[z] of TOMi_TGCy_GLB_CTRL

24.6.2.2 TGC Subunit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources.

The three trigger sources are:

- the host CPU (bit HOST_TRIG of register TOMi_TGCy_GLB_CTRL)
- the TBU time stamp (signal TBU_TS0, TBU_TS1, TBU_TS2)
- the internal trigger signal TRIG (bunch of trigger signals TRIG_[x]) which can be either the trigger TRIG_CCU0 of channel x, the trigger of preceding channel x-1 (i.e. signal TRIG_[x-1]) or the external trigger TIM_EXT_CAPTURE[t] of assigned TIM channel t.

The first way is to trigger the control mechanism by a direct register write access via host CPU (bit HOST_TRIG of register TOMi_TGCy_GLB_CTRL).

The second way is provided by a compare match trigger on behalf of a specified time base coming from the module TBU (selected by bits TBU_SEL) and the time stamp compare value defined in the bit field ACT_TB of register TOMi_TGCy_ACT_TB.

Note, a signed compare of ACT_TB and selected TBU_TSx with x=0,1,2 is performed.

The third possibility is the input TRIG (bunch of trigger signals TRIG_[x]) coming from the TOM channels 0 to 7 / 8 to 15.

The corresponding trigger signal TRIG_[x] coming from channel [x] can be masked by the register TOMi_TGCy_INT_TRIG.

To enable or disable each individual TOM channel, the registers TOMi_TGCy_ENDIS_CTRL and/or TOMi_TGCy_ENDIS_STAT have to be used.

The register TOMi_TGCy_ENDIS_STAT controls directly the signal ENDIS. A write access to this register is possible.

The register TOMi_TGCy_ENDIS_CTRL is a shadow register that overwrites the value of register TOMi_TGCy_ENDIS_STAT if one of the three trigger conditions matches.

TOM Global channel control mechanism

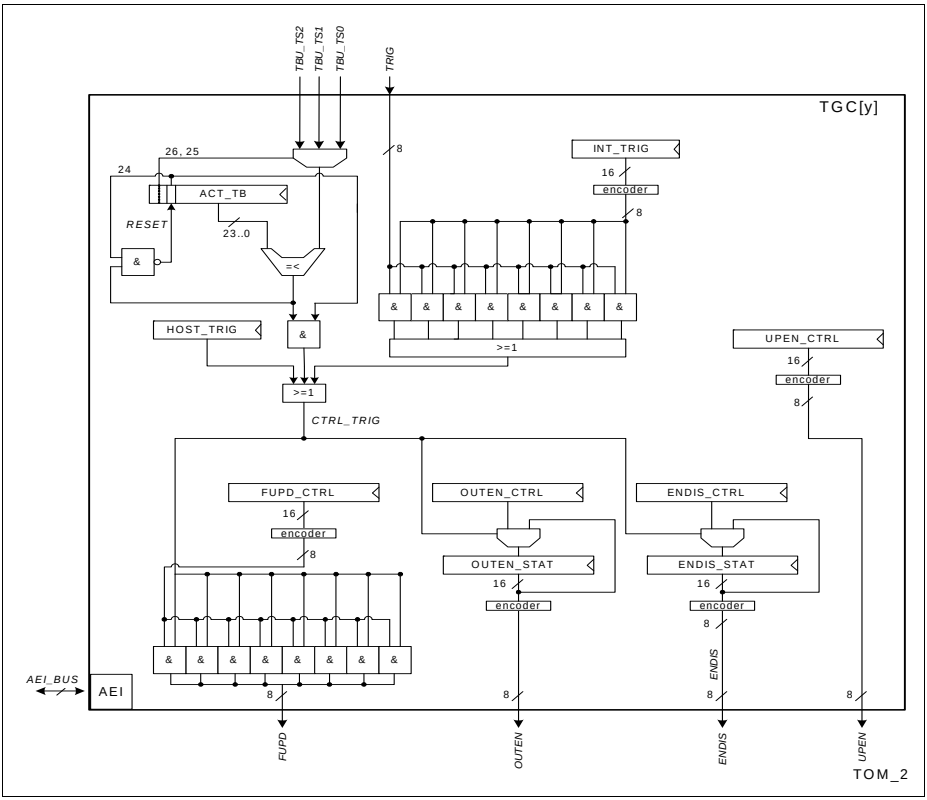

Figure 24-29 TOM Global channel control mechanism

The output of the individual TOM channels can be controlled using the register TOMi_TGCy_OUTEN_CTRL and TOMi_TGCy_OUTEN_STAT.

The register TOMi_TGCy_OUTEN_STAT controls directly the signal OUTEN. A write access to this register is possible.

The register TOMi_TGCy_OUTEN_CTRL is a shadow register that overwrites the value of register TOMi_TGCy_OUTEN_STAT if one of the three trigger conditions matches.

If a TOM channel is disabled by the register TOMi_TGCy_OUTEN_STAT, the actual value of the channel output at TOM_CH[x]_OUT is defined by the signal level bit (SL) defined in the channel control register TOMi_CHx_CTRL.

If the output is enabled, the output at TOM_CH[x]_OUT depends on value of FlipFlop SOUR.

The register TOMi_TGCy_FUPD_CTRL defines which of the TOM channels receive a FORCE_UPDATE event if the trigger signal CTRL_TRIG is raised.

The register bits UPEN_CTRL[z] defines for which TOM channel the update of the working register CM0, CM1 and CLK_SRC by the corresponding shadow register SR0, SR1 and CLK_SRC_SR is enabled. If update is enabled, the register CM0, CM1 and CLK_SRC will be updated on reset of counter register CN0 (see **Figure 24-30** and **Figure 24-31**).

24.6.3 TOM Channel (TOM_CH[x])

Each individual TOM channel comprises a Counter Compare Unit 0 (CCU0), a Counter Compare Unit 1 (CCU1) and the Signal Output Generation Unit (SOU). The architecture is depicted in **Figure 24-30** for channels 0 to 7 and in **Figure 24-31** for channels 8 to 15.

24.6.3.1 TOM Channel 0…7 architecture

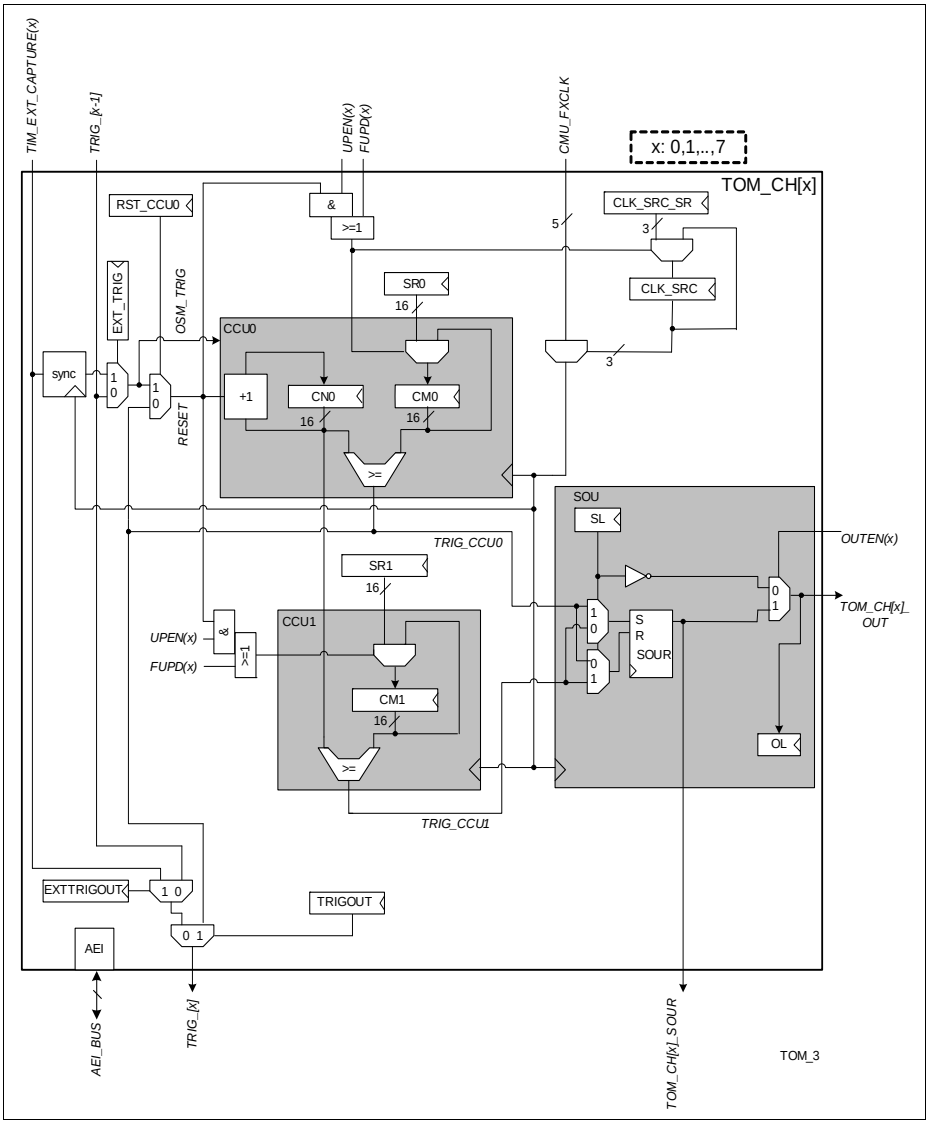

Figure 24-30 TOM Channel 0…7 architecture

24.6.3.2 TOM Channel 8…14 architecture

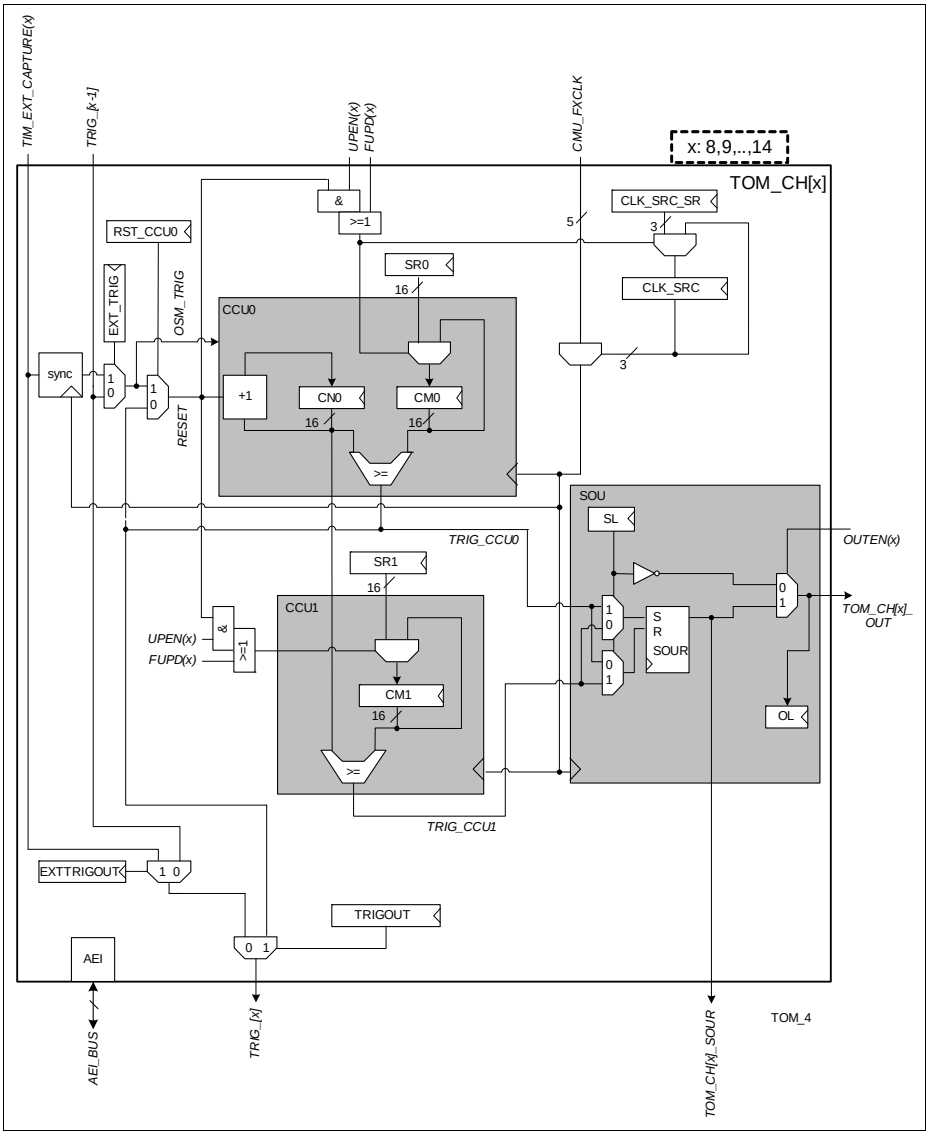

Figure 24-31 TOM Channel 8…14 architecture

24.6.3.3 TOM Channel 15 architecture for PCM generation

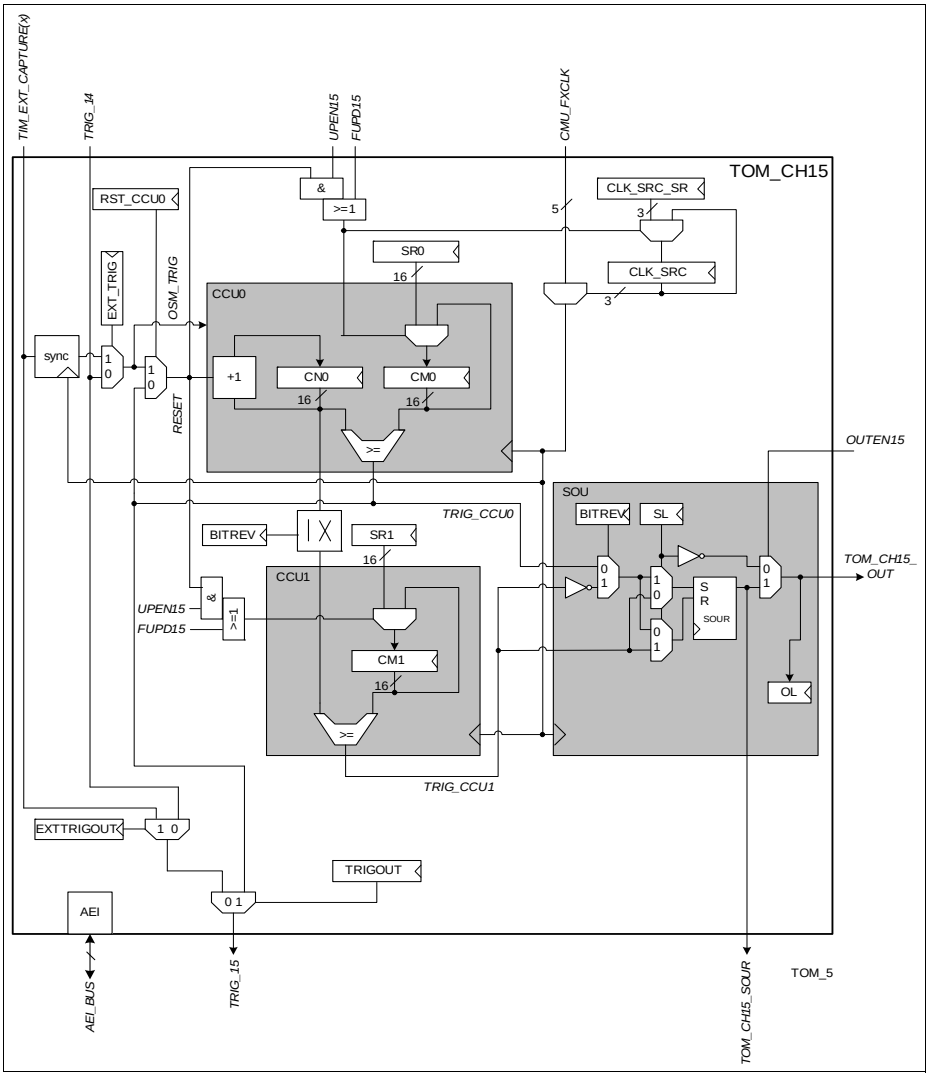

Figure 24-32 TOM Channel 15 architecture for PCM generation

The CCU0 contains a counter CN0 which is clocked with one of the selected input frequencies (CMU_FXCLK) provided from outside of the submodule.

Depending on configuration bits RST_CCU0 of register TOMi_CHx_CTRL the counter register CN0 can be reset either when the counter value is equal to the compare value CM0 or when signalled by the TOM[i] trigger signal TRIG_[x-1] of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1] or the trigger signal TIM_EXT_CAPTURE(x) of the assigned TIM channel[x].

Note: As an exception, the input TRIG_[0] of instance TOM0 is triggered by its own last channel cCTO via signal TRIG_[15].

When the counter register CN0 is greater or equal than the register CM0, the subunit CCU0 triggers the SOU subunit and the succeeding TOM submodule channel (signal TRIG_CCU0).

In the subunit CCU1 the counter register CN0 is compared with the value of register CM1. If CN0 is greater or equal than CM1 the subunit CCU1 triggers the SOU subunit (signal TRIG_CCU1).

If counter register CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CN0>=CM0 configured by RST_CCU0=0), following statements are valid.

- if CM0=0 or CM0=1, 0% duty cycle (=$\overline{SL}$) is generated independent of CM1. The counter CN0 is not counting.
- the configuration of CM1=0 represents 0% duty cycle (=$\overline{SL}$) at the output
- the configuration of CM1>=CM0 represents 100% duty cycle (=SL)

If counter register CN0 of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST_CCU0=1), following statements are valid.

- CM0 defines the edge to SL value, CM1 defines the edge to $\overline{SL}$ value
- if CM0=CM1, the output is 100% SL (CM0 has higher priority)
- if CM0=0 and CM1=MAX, the output is 100% SL (while CN0 counts from 0 to MAX-1 and is then reset by trigger)

The hardware ensures that for both 0% and 100% duty cycle no glitch occurs at the output of the TOM channel.

The SOU subunit is responsible for output signal generation. On a trigger TRIG_CCU0 from subunit CCU0 or TRIG_CCU1 from subunit CCU1 a SR-FlipFlop of subunit SOU is either set or reset. If it is set or reset depends on the configuration bit SL of the control register TOMi_CHx_CTRL. The initial signal output level for the channel is the reverse value of the bit SL.

Figure 24-35 clarifies the PWM output behaviour with respect to the SL bit definition.

The output level on the TOM channel output pin TOM[i]_CH[x]_OUT is captured in bit OL of register TOMi_CHx_STAT.

24.6.3.4 Duty cycle, period and selected counter clock frequency update mechanisms

The two action registers CM0 and CM1 can be reloaded with the content of the shadow registers SR0 and SR1. The register CLK_SRC that determines the clock frequency of the counter register CN0 can be reloaded with its shadow register CLK_SRC_SR (bit field in register TOMi_CHx_CTRL)

The update of the register CM0, CM1 and CLK_SRC with the content of its shadow register is done when the reset of the counter register CN0 is requested (via signal RESET). This reset of CN0 is done if the comparison of CN0 greater or equal than CM0 is true or when the reset is triggered by another TOM channel [x-1] via the signal TRIG_[x-1] or when signalled via the signal TIM_EXT_CAPTURE(x) of the assigned TIM channel[x].

For TOM0 channel 0 TRIG_[-1] is '0' hard coded.

With the update of the register CLK_SRC at the end of a period a new counter CN0 clock frequency can easily be adjusted.

An update of duty cycle, period and counter CN0 clock frequency becoming effective synchronously with start of a new period can easily be reached by performing following steps:

1. disable the update of the action register with the content of the corresponding shadow register by setting the channel specific configuration bit UPEN_CTRL[z] of register TOMi_TGCy_GLB_CTRL to '0'.

2. write new desired values to SR0, SR1, CLK_SRC_SR

3. enable update of the action register by setting the channel specific configuration bit UPEN_CTRL[z] of register TOMi_TGCy_GLB_CTRL to '1'.

synchronous update of duty cycle only

A synchronous update of only the duty cycle can be done by simply writing the desired new value to register SR1 without preceding disable of the update mechanism (as described in the section above). The new duty cycle is then applied in the period following the period where the update of register SR1 was done.

synchronous update of duty cycle

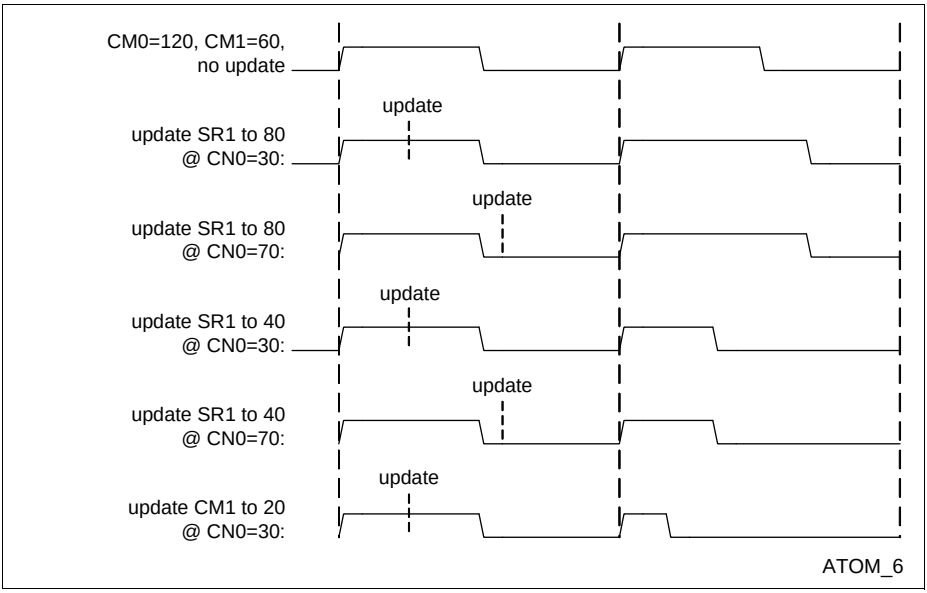

Figure 24-33 synchronous update of duty cycle

asynchronous update of duty cycle only

If the update of the duty cycle should be performed independent of the start of a new period (asynchronous), the desired new value can be written directly to register CM1. In this case it is recommended to additionally either disable the synchronous update mechanism as a whole (i.e. clearing bits UPEN_CTRL[z] of corresponding channel [x] in register TOMi_TGXy_GLB_CTRL) or updating SR1 with the same value as CM1 before writing to CM1.

Depending on the point of time of the update of CM1 in relation to the actual value of CN0 and CM1, the new duty cycle is applied in the current period or the following period (see **Figure 24-34**). In any case the creation of glitches are avoided. The new duty cycle may jitter from update to update by a maximum of one period (given by CM0). However, the period remains unchanged.

asynchronous update of duty cycle

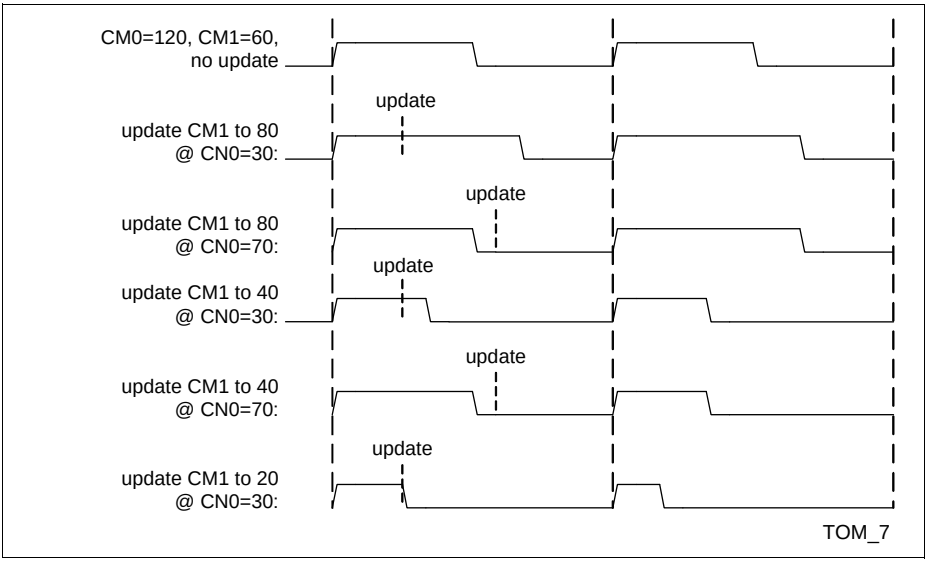

Figure 24-34 asynchronous update of duty cycle

24.6.3.5 TOM continuous mode

In continuous mode the TOM channel starts incrementing the counter register CN0 once it is enabled by setting the corresponding bits in register TOMi_TGCy_ENDIS_STAT (refer to **Section 24.6.2.2** for details of enabling a TOM channel).

The signal level of the generated output signal can be configured with the configuration bit SL of the channel configuration register TOMi_CHx_CTRL.

If the counter CN0 is reset from CM0 back to zero, the first edge of a period is generated at TOM[i]_CH[x]_OUT.

The second edge of the period is generated if CN0 has reached CM1.

Every time the counter CN0 has reached the value of CM0 it is reset back to zero and proceeds with incrementing.

PWM Output with respect to configuration bit

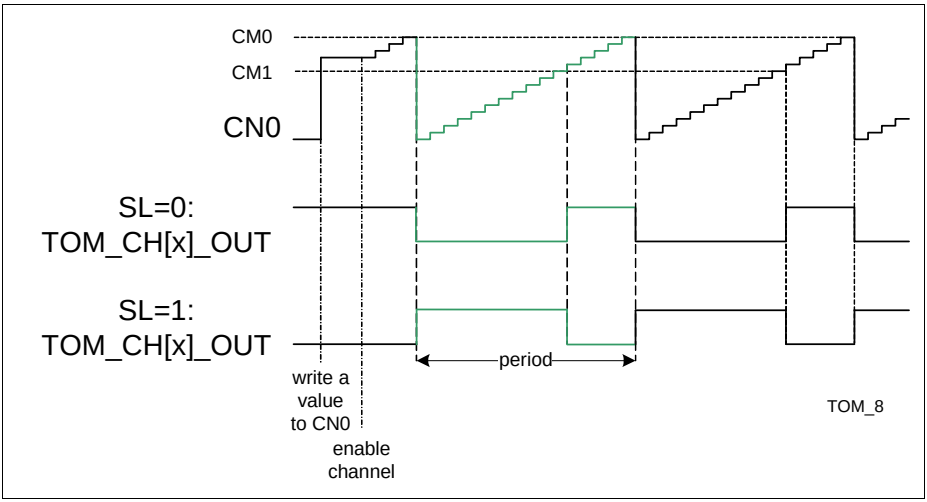

Figure 24-35 PWM Output with respect to configuration bit

24.6.3.6 TOM One shot mode

In One-shot mode, the TOM channel generates one pulse with a signal level specified by the configuration bit SL in the channel [x] configuration register TOMi_CHx_CTRL.

First the channel has to be enabled by setting the corresponding TOMi_TGCy_ENDIS_STAT value and the one-shot mode has to be enabled by setting bit OSM in register TOMi_CHx_CTRL.

In one-shot mode the counter CN0 will not be increment once the channel is enabled.

A write access to the register CN0 triggers the start of pulse generation (i.e. the increment of the counter register CN0).

The new value of CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CM0-CN0) multiplied with period defined by current value of CLK_SRC.

If the counter CN0 is reset from CM0 back to zero, the first edge at TOM[i]_CH[x]_OUT is generated.

To avoid an update of CMx register with content of SRx register at this point in time, the automatic update should be disabled by setting UPEN_CTRLx = 00 (in register TOMi_CHx_CTRL).

The second edge is generated if CN0 is greater or equal than CM1 (i.e. CN0 was increment until it has reached CM1 or CN0 is greater than CM1 after an update of CM1).

If the counter CN0 has reached the value of CM0 a second time, the counter stops.

PWM Output with respect to configuration bit SL in one-shot mode: trigger by writing to CN0

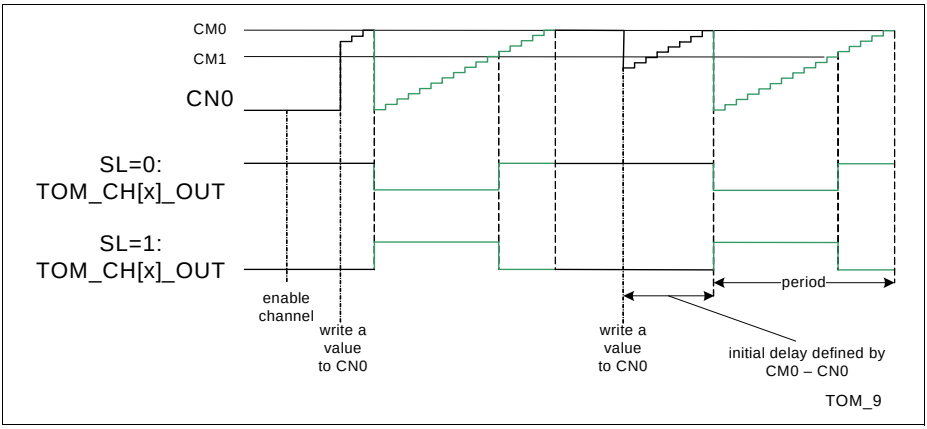

Figure 24-36 PWM Output with respect to configuration bit SL in one-shot mode: trigger by writing to CN0: trigger by writing to CN0

Further output of single periods can be started by a write access to register CN0.

Writing to incrementing counter CN0 a value CN0new < CM1 while CN0old is below CM1 leads to a lengthening of the pulse. The counter CN0 stops if is reaches CM0.

Writing to incrementing counter CN0 a value CN0new > CM1 while CN0old is already greater than CM1 leads to an immediate restart of a single pulse generation inclusive the initial delay defined by CM0 - CN0new.

If a channel is configured to one-shot mode and configuration bit OSM_TRIG is set to 1, the trigger signal OSM_TRIG (i.s. TRIG_[x-1] or TIM_EXT_CAPTURE[x]) triggers start of one pulse generation.

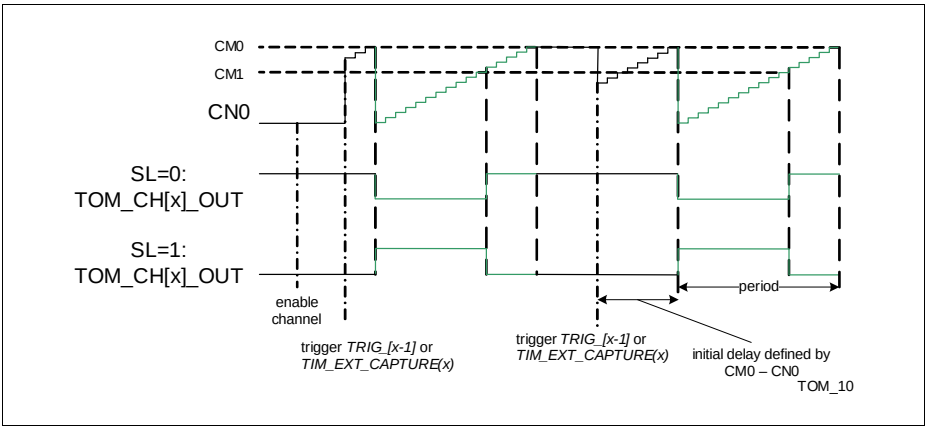

Figure 24-37 PWM Output with respect to configuration bit SL in one-shot mode: trigger by TRIG_[x-1] or TIM_EXT_CAPTURE(x)

24.6.3.7 Pulse count modulation

At the output TOM[i]_CH15_OUT a pulse count modulated signal can be generated instead of the simple PWM output signal.

Figure 24-32 outlines the circuit for Pulse Count Modulation.

The PCM mode is enabled by setting bit BITREV to 1.

With the configuration bit BITREV=1 a bit-reversing of the counter output CN0 is configured. In this case the bits LSB and MSB are swapped, the bits LSB+1 and MSB-1 are swapped, the bits LSB+2 and MSB-2 are swapped and so on.

The effect of bit-reversing of the CN0 register value is shown in the following **Figure 24-38**.

Bit reversing of counter

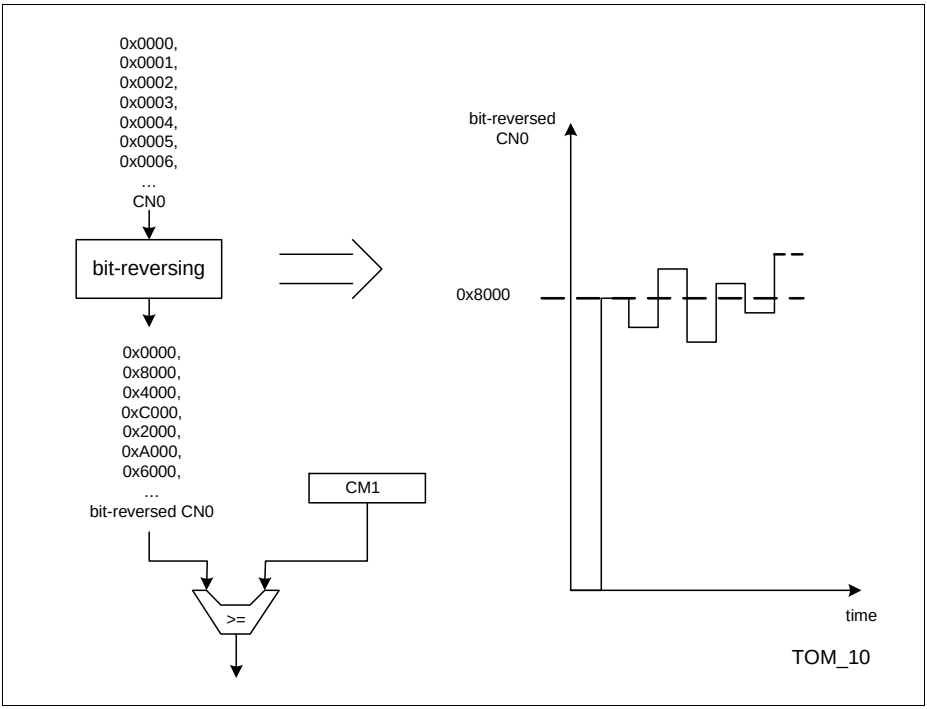

Figure 24-38 Bit reversing of counter

In the PCM mode the counter register CN0 is increment by every clock tick depending on configured CMU clock (CMU_FXCLK).

The output of counter register CN0 is first bit-reversed and than compared with the configured register value CM1.

If the bit-reversed value of register CN0 is greater than CM1, the SR-FlipFlop of submodule SOU is set (depending on configuration register SL) otherwise the SR-FlipFlop is reset. This generates at the output TOM[i]_CH15_OUT a pulse count modulated signal.

In PCM mode the CM0 register always has to be set to its maximum value 0xFFFF.

24.6.4 TOM Interrupt signals

The following table describes TOM interrupt signals:

Table 24-18 TOM Interrupt signals

Signal	Description
TOM_CCU0TCx_IRQ	CCU0 Trigger condition interrupt for channel x

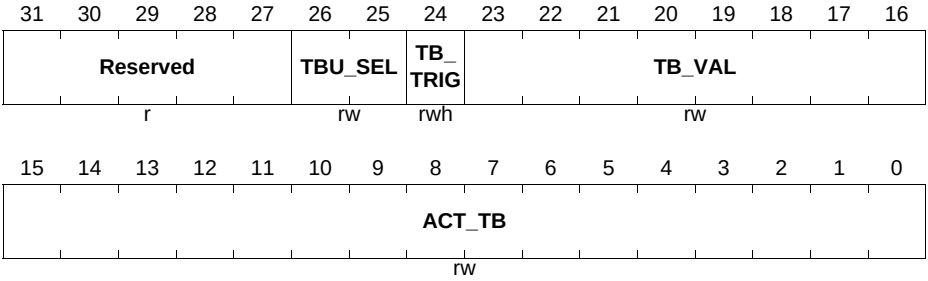
TOMi TGC0 Action Time Base Register
(08034_H+i*800_H) **Reset Value: 00000000_H**

GTM_TOMi_TGC1_ACT_TB (i=0-1)
TOMi TGC1 Action Time Base Register
(08234_H+i*800_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
ACT_TB	[23:0]	rw	**Time base value** specifies the signed compare value with selected signal TBU_TCx (x=0…2). If selected TBU_TSx value is in the interval [ACT_TB-$007FFFFF_H$,ACT_TB] the event is in the past and the trigger is generated immediately. Otherwise the event is in the future and the trigger is generated if selected TBU_TSx is equal to ACT_TB.
TB_TRIG	24	rwh	**Set trigger request** 0_B no trigger request 1_B set trigger request Note: This flag is reset automatically if the selected time base unit (TBU_TS0 or TBU_TS1 or TBU_TS2 if present) has reached the value ACT_TB and the update of the register were triggered.

Field	Bits	Type	Description
TBU_SEL	[26:25]	rw	**Selection of time base used for comparison** 00_B TBU_TS0 selected 01_B TBU_TS1 selected 10_B TBU_TS2 selected 11_B Reserved; same as 00_B Note: The bit combination “10” is only applicable if the TBU of the device contains three time base channels. Otherwise, this bit combination is also reserved. Please refer to GTM Architecture block diagram on page 3 to determine the number of channels for TBU of this device.

24.7 Dead Time Module

24.7.1 Overview

The following figure gives an overview of the structure of the Dead Time Module (DTM).

24.7.1.1 DTM overview

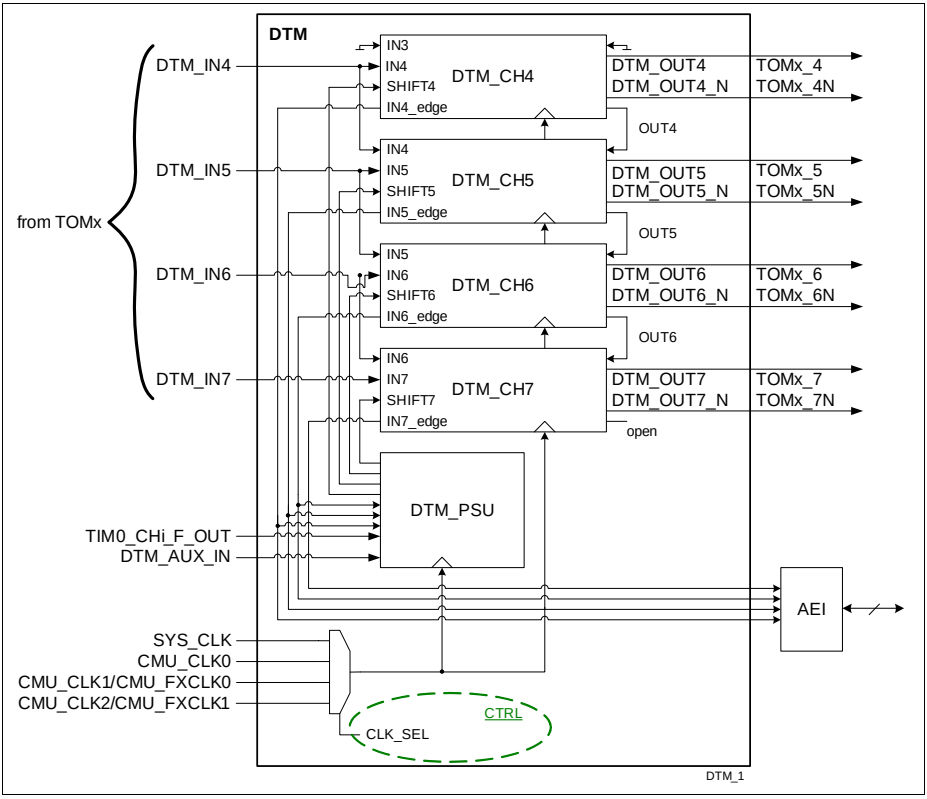

Figure 24-39 DTM Overview

The main function of the DTM is to derive for each input DTM_IN4 to DTM_IN7 the individual inverse signal (DTMi_OUT[x]_N) and to apply an edge specific delay between

the edge of the original signal and the edge of the derived inverted signal (i.e., the dead time). This function is mainly used for controlling of half bridges.

A second function provided by DTM is to set the outputs of one channel to the value of the preceding channel if requested by a trigger on input TIM0_CHi_F_OUT (TIM_CH_IN) or DTM_AUX_IN. This feature allows a phase shift on one PWM signal to the phase of the preceding PWM signal up to the next edge on this channel.

The third function provided by DTM is to (N)AND/(N)OR/X(N)OR combine the input DTM_IN[x] signal of one DTM channel with the signal on input TIM0_CHi_F_OUT (TIM_CH_IN) or DTM_AUX_IN (selected inside DTM_PSU and assigned to one of the signals SHIFT[x]) or with the output 1 (signal OUT[x]) of preceding channel.

As a result OUT5 may be the combined signal of DTM_IN4 and TIM0_CHi_F_OUT (TIM_CH_IN) or DTM_AUX_IN and the signal DTM_IN5. For OUT7 this chain can be combined again with signal DTM_IN7.

The outputs of each channel may be swapped individually to provide the function of combining signals on each output of a channel.

In general, the DTM instances are placed behind the TOM instances, i.e., the outputs TOM_OUT[x] are each routed to a DTM instance.

Additionally, some TIM instances are also connected to the DTM instances.

These connections between DTM and the modules TIM and TOM are depicted in **Section 24.7.1.2**.

24.7.1.2 Connections of TIM and TOM and to DTM

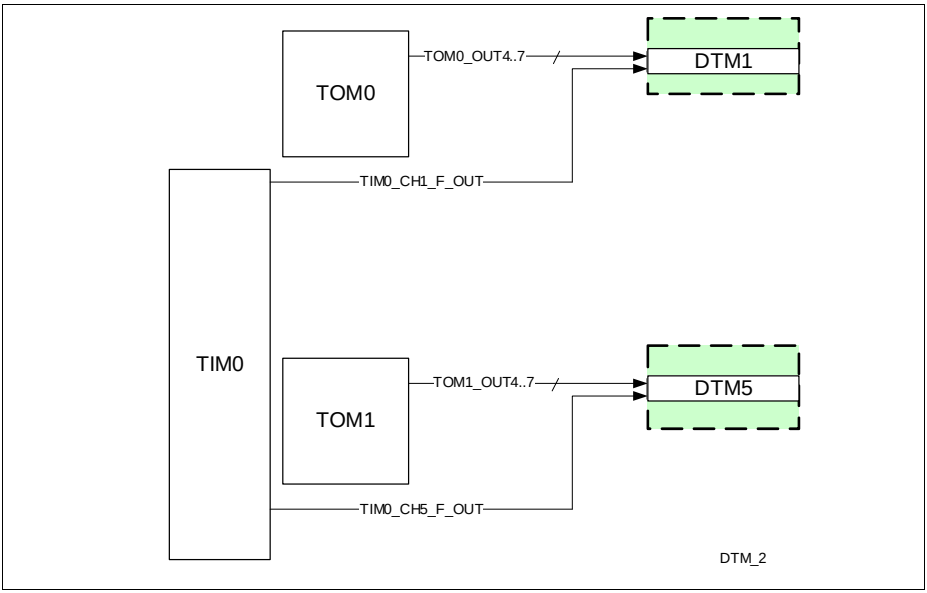

Figure 24-40 DTM Connections

For each TIM instance it can be calculated which instance of DTM and thus also which DTM channel is connected to which TIM channel or TOM channel.

24.7.2 DTM Channel

The following figure depicts the functions of a DTM channel.

24.7.2.1 DTM channel overview

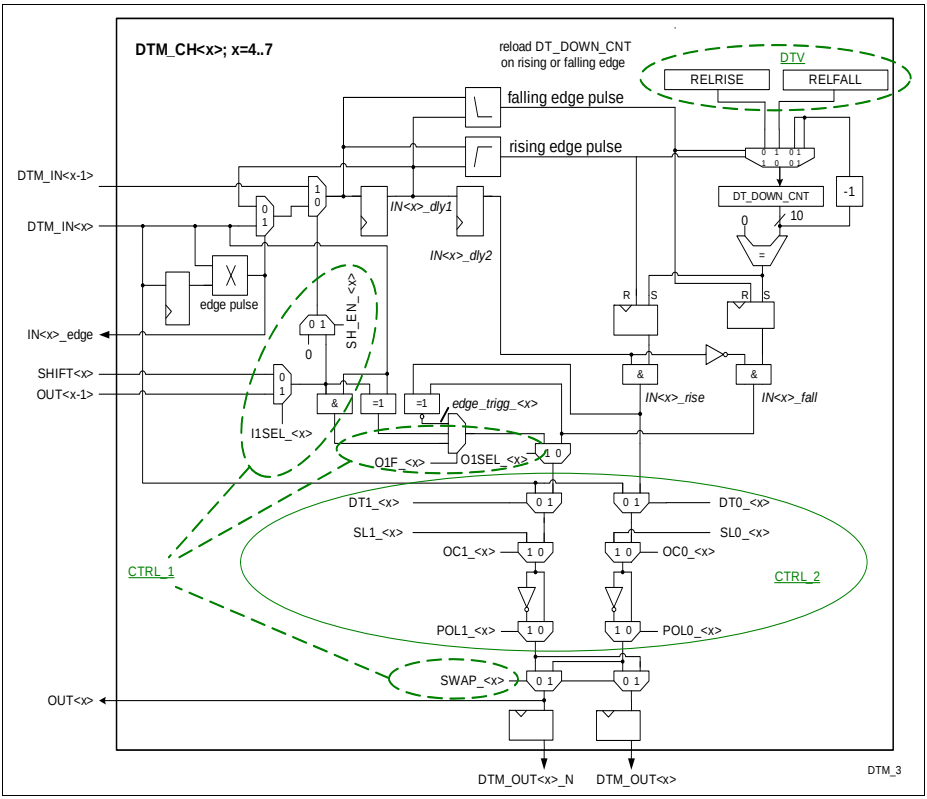

Figure 24-41 DTM Channel Overview

The main feature of each channel is to derive the inverse signal out of the input signal DTM_IN[x], apply an edge dependent delay on the two resulting signal paths and provide these signals at the outputs DTMi_OUT[x] and DTMi_OUT[x]_N.

24.7.2.2 Standard dead time generation

Standard dead time generation means that per DTM channel out of one input signal the inverse output signal is generated additionally and on both output signals the dead time between their edges is applied.

The dead time can be configured for each edge individually. The bit field RELRISE in register DTMi_CHx_DTV contains the reload value for the counter and defines the delay for rising edges in multiples of selected clock ticks.

The bit field RELFALL in register DTMi_CHx_DTV contains the reload value for the counter and defines the delay for falling edges in multiples of selected clock ticks.

The counter is reloaded with the value of RELRISE on a rising edge on input DTM_IN[x] (or DTM_IN[x-1] in case of phase shift trigger via signal SHIFT[x]) and reloaded with the value of RELFALL on a falling edge on input DTM_IN[x] (or DTM_IN[x-1] in case of shift enable SH_EN_[x].

On a reload of the counter the FlipFlop following the counter output comparator is reset and stays reset until the counter has reached 0.

After reload, the counter DT_DOWN_CNT counts down until it reaches 0 and stops at 0.

The signal flow for function of standard dead time signal generation is depicted in following figure

24.7.2.3 Wave signals for function of dead time generation

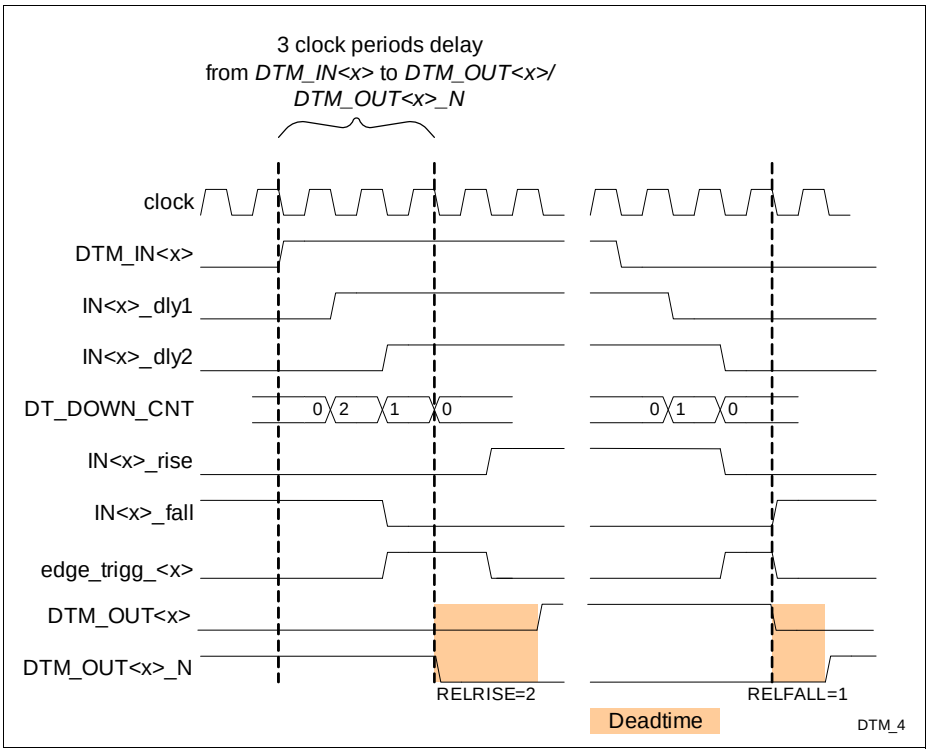

Figure 24-42 DTM Waveform

Note: The delay from the input signal DTM_IN[x] to the output signals DTMi_OUT[x] and DTMi_OUT[x]_N is three system clock periods by disabled feed through (see DT0/1_[x] in DTMi_CH_CTRL2).

Note: The delay from the input signal DTM_IN[x] to the output signals DTMi_OUT[x] and DTMi_OUT[x]_N is one system clock periods by enabled feed through (see DT0/1_[x] in DTMi_CH_CTRL2).

24.7.3 Phase Shift Control Unit

The phase shift unit (DTM_PSU) is depicted in the following figure. It supports the second major function of the DTM module to allow phase shifting of PWM signal on one of the channels.

24.7.3.1 Phase Shift Unit overview

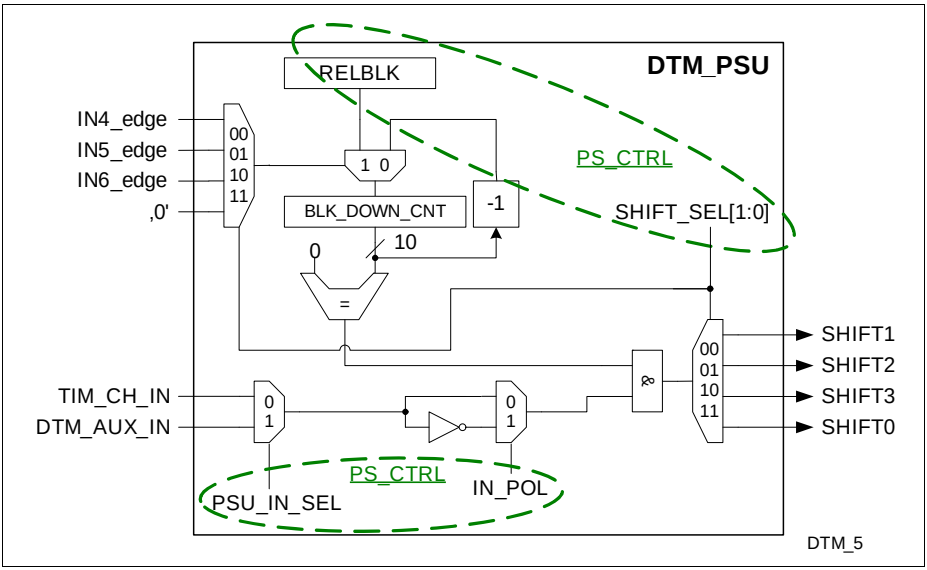

Figure 24-43 DTM Phase Shift Unit

This submodule provides an additional counter BLK_DOWN_CNT and reload bit field RELBLK (in register DTMi_PS_CTRL). The counter is reloaded on an edge detected on one of the selected signals IN0_edge to IN2_edge (selected by bit field SHIFT_SEL in register DTMi_PS_CTRL). Then, the counter counts down until it reaches 0. While the counter is counting down, it blocks the trigger (i.e. the selected one of the signals

SHIFT[x]) of one of the channels by one of the input signals TIM0_CHi_F_OUT (TIM_CH_IN) or DTM_AUX_IN.

If the counter BLK_DOWN_CNT is not counting, a pulse on the input TIM0_CHi_F_OUT (TIM_CH_IN) or DTM_AUX_IN is forwarded to one of the selected DTM_PSU outputs SHIFT[x]. This signal triggers in the selected channel (if SH_EN_x=1) the update of the first Flip-Flop on channel x (i.e. representing IN[x]_DLY) to the input value DTM_IN[x-1] of the preceding channel. If this update leads to an edge, the succeeding part of DTM channel derives the inverse signal and applies the corresponding dead time (i.e. the edge delay) to the output signals of the channel.

Note: For channel x=0 input signals DTM_IN[x-1] and OUT[x-1] are unused and I1SEL_[x] and SH_EN_[x] are defined as 0.

The following figure shows an example of phase shifting on channel 1.

24.7.3.2 Example wave of phase shift on channel 1

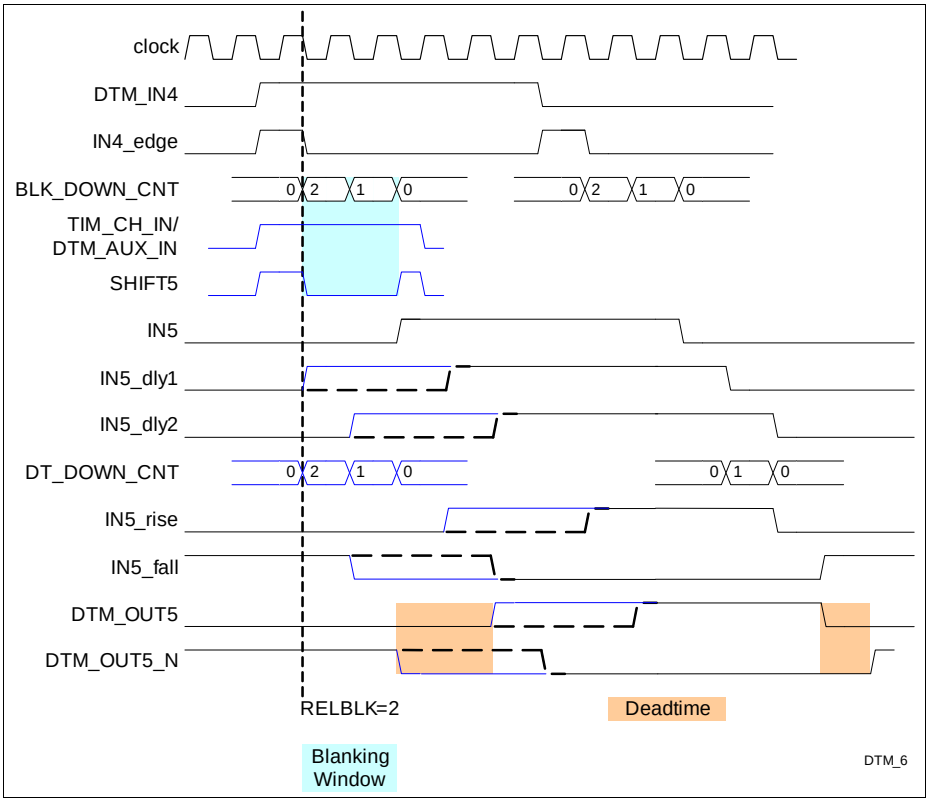

Figure 24-44 DTM Phase Shift Example

24.7.4 Multiple output signal combination

Each channel provides additionally the possibility to combine the channel inputs DTM_IN[x] and SHIFT[x] or OUT[x-1] (selected by I1SEL_[x]) by an AND or an XOR gate (selected by O1F_[x]).

It is recommended to use the combination of signals is only usable if bit field RELBLK of register DTMi_PS_CTRL is 0. Otherwise, the signals TIM0_CHi_F_OUT (TIM_CH_IN)/DTM_AUX_IN may be disturbed by the blanking window counter.

Together with the inverter inside submodule DTM_PSU (selected by IN_POL), the inverter on each output of a channel (selected by POL0_[x]/POL1_[x]) and the possibility to change polarity of DTM_IN[x] inside connected TOM channel, a (N)AND, (N)OR or X(N)OR combination of the signals is possible.

24.7.4.1 Combination of input signal TIM0_CHi_F_OUT (TIM_CH_IN)/AUX_IN with TOM signal

If the input selection I1SEL_[x] of a channel x is set to 0, the output selection O1SEL_[x] is set to 1 and SWAP_[x] is set to 0, depending on PSU_IN_SEL either TIM0_CHi_F_OUT (TIM_CH_IN) or DTM_AUX_IN can be combined with signal DTM_IN[x].

The function of combination on DTM output DTMi_OUT[x]_N (and also OUT[x]) is defined by O1F_[x] in the following way:

Table 24-20 Combination of input signal TIM0_CHi_F_OUT (TIM_CH_IN)/AUX_IN with TOM signal

	O1F_x	POL1_x	IN_POL	TOM output inverted
XOR	01	0	0	no
AND	10	0	0	no
XNOR	01	1	0	no
NAND	10	1	0	no
XNOR	01	1	1	yes
OR	10	1	1	yes
XOR	01	0	1	yes
NOR	10	0	1	yes

Note: The inversion of the TOM output can be reached by switching the SL bit (for TOM and SOMP/SOMC mode).

24.7.4.2 Combination of multiple TOM output signals

If the input selection I1SEL_[x] of a channel x (with x=1..3) is set to 1, the output selection O1SEL_[x] is set to 1 and SWAP_[x] is set to 0, the output of the preceding DTM channel OUT[x-1] can be combined with signal DTM_IN[x].

The function of combination on DTM output DTMi_OUT[x]_N (and also OUT[x]) is defined by O1F_[x] in the following way:

Table 24-21 Combination of multiple TOM output signals

	O1F_x	POL1_x	POL1_x-1	TOM output inverted
XOR	01	0	0	no
AND	10	0	0	no

Table 24-21 Combination of multiple TOM output signals (cont'd)

	O1F_x	POL1_x	POL1_x-1	TOM output inverted
XNOR	01	1	0	no
NAND	10	1	0	no
XNOR	01	1	1	yes
OR	10	1	1	yes
XOR	01	0	1	yes
NOR	10	0	1	yes

By setting I1SEL_[x] to 1 on all four channel, a combination of all four signals DTM_IN0 to DTM_IN3 can be achieved (combinatorial chain).

To allow also combination of signals generated for output DTMi_OUT[x], the outputs 0 and 1 can be swapped by setting bit SWAP_ [x] for channel x.

24.7.4.3 Pulse generation on edge

Another feature of the DTM is to generate on the second output DTM[i]_OUT[x]_N a pulse on every of corresponding input signal DTM[i]_IN[x].

This can be reached by configuring O1SEL[x] to '1', i.e. selecting signal edge_trigg[x] as the output signal (O1F[x] has to be '00'). The signal edge_trigg[x] is depicted in **Figure 24.7.2.3**.

The pulse length can be adjusted individually for each edge type by configuration value REL_RISE and REL_FALL of register DTMi_CHx_DV.

The parameter REL_RISE defines the pulse length in case of a rising edge on input DTM[i]_IN[x], the parameter REL_FALL define the pulse length in case of a falling edge in input DTM[i]_IN[x].

24.7.5 Synchronous update of channel control register 2

It is possible to use the shadow register DTMi_CH_CTRL2_SR and a selected edge of one of the channel 0 to 3 to update the work register DTMi_CH_CTRL2.

The update mechanism and its configuration is depicted in the following figure.

24.7.5.1 Synchronous update mechanism of register DTMi_CH_CTRL2

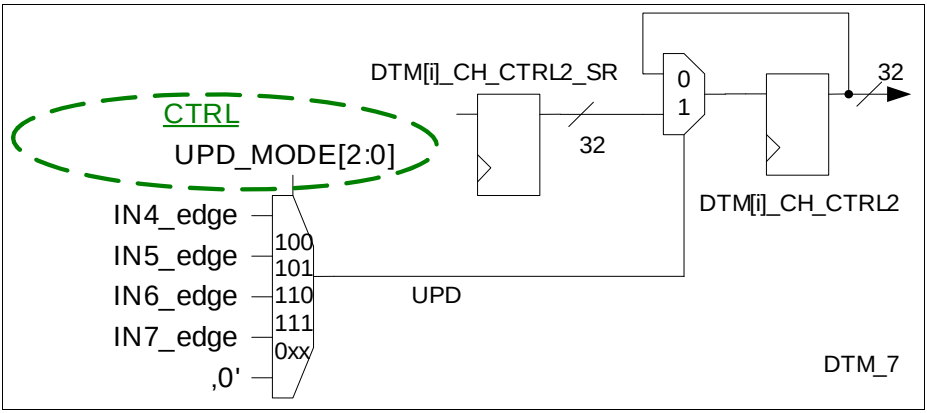

Figure 24-45 DTM Synchronous Update

If enabled by the bit field UPD_MODE of register DTMi_CTRL (i.e. UPD_MODE=1xx), the register DTMi_CH_CTRL2_SR serves as a shadow register of register DTMi_CH_CTRL2. The update is then triggered by an edge on one of the selected inputs DTM_IN4 to DTM_IN7.

The synchronous update allows the user to change output polarity, the selection of constant signal level, the constant signal level itself and the switch to/from feed through path on all four channels in parallel synchronized to one of the input edges on DTM_IN4 to DTM_IN7.

24.7.6 Configuration Register Overview

The following table gives an overview of the DTM configuration register.

Table 24-22 Configuration Register Overview

Register name	Description	Details in Section
DTMi_CTRL	Global Configuration and Control Register	13.7.1
DTMi_CH_CTRL1	Channel Control Register 1	13.7.2

24.8 Interrupt Concentrator Module (ICM)

24.8.1 Overview

The Interrupt Concentrator Module (ICM) is used to bundle the GTM interrupt lines of the individual submodules in a reasonable manner into interrupt groups. By this bundling a smaller amount of interrupt lines is visible at the outside of the GTM.

The individual interrupts of the GTM submodules and channels have to be enabled or disabled inside the submodules and channels.

The feed through architecture of bundled interrupt lines is used for the submodules AEI, TIM, and TOM.

To determine the detailed interrupt source the microcontroller has to read the submodule/channel interrupt notification register NOTIFY and serve the channel individual interrupt.

Please note, that the interrupts are only visible inside the ICM and in consequence outside of the GTM, when the interrupt is enabled inside the submodules themselves.

24.8.2 Bundling

The GTM submodule individual interrupt sources are connected to the ICM. There, the individual interrupt lines are either feed through and signalled to the outside world or bundled a second time into groups and are then signalled to the outside world.

The ICM interrupt bundling is described in the following sections.

24.8.2.1 GTM Infrastructure Interrupt Bundling

The first interrupt group contains interrupts of the infrastructure and safety components of the GTM. This interrupt group includes therefore interrupt lines coming from the AEI submodule. In this interrupt group each individual channel of the submodules has its own interrupt line to the outside world.

Thus, the active interrupt line can be used by the CPU to determine the GTM submodule channel that raised the interrupt. The interrupts are also represented in the ICM_IRQG_0 register. This register is typically not read by the CPU, but it is readable.

24.8.2.2 TIM Interrupt Bundling

Inside this group submodules which handle GTM input signals are treated. This is the case for the TIM0 submodule. Each TIM submodule channel is able to generate six (6) individual interrupts if enabled inside the TIM channel. This six interrupts are bundled into one interrupt per TIM channel connected to the ICM.

The ICM does no further bundling. Thus, for the GTM 8 interrupt lines TIM0_IRQ[y] are provided for the external microcontroller. The channel responsible for the interrupt can be determined by the raised interrupt line.

In addition, the ICM_IRQG_2 register a mirror for the TIM submodule channel interrupts and typically not read out by the CPU, but it is readable.

24.8.2.3 TOM Interrupt Bundling

For the TOM submodules, the interrupts are bundled within the ICM submodule a second time to reduce external interrupt lines. The interrupts are OR-ed in a manner that one GTM external interrupt line represents two adjacent TOM channel interrupts. For TOM[i] the bundling is shown in **TOM interrupt bundling within ICM**.

TOM interrupt bundling within ICM

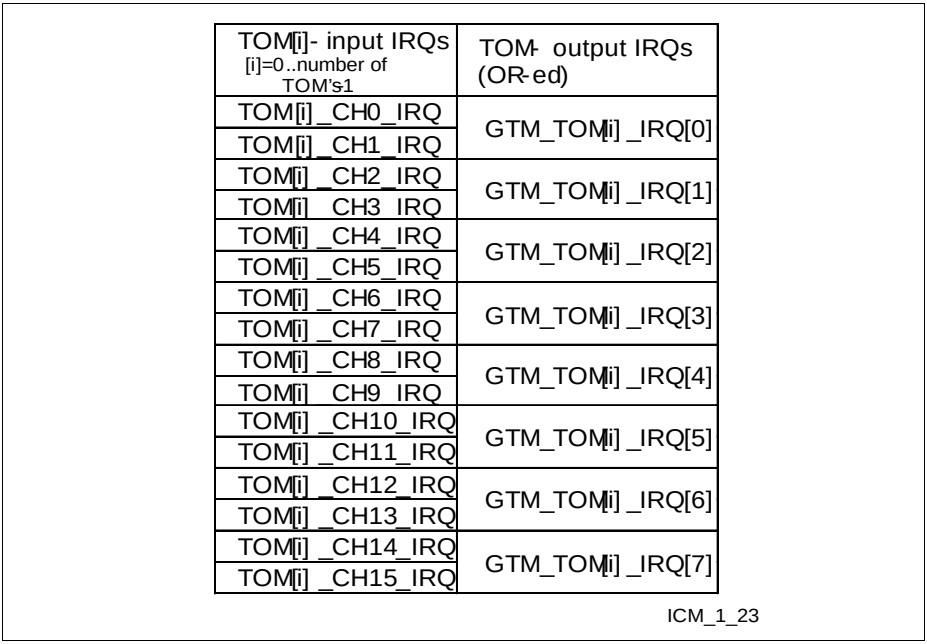

Figure 24-46 TOM interrupts

The interrupts coming from the TOM[i] submodules are registered in the ICM_IRQG_6 register. To identify the TOM submodule channel where the interrupt occurred, the CPU has to read out the ICM_IRQG_6 register first before it goes to the TOM submodule channel itself.

The ICM_IRQG_6 register bits are cleared automatically, when their corresponding interrupt in the submodule channels is cleared.

Module Error Interrupt Bundling

The Module Error Interrupt group handles the error interrupts coming from the TIM submodule of the GTM. The Module Error interrupts are additionally identified in the ICM_IRQ_MEI error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_MEI register bits are cleared automatically, when their corresponding error interrupt in the submodule is cleared.

TIM Channel Error Interrupt Bundling

The TIM Channel Error Interrupt group handles the error interrupts coming from the TIM channel of the GTM. The TIM Channel Error interrupts are additionally identified for the submodule TIM0 in the ICM_IRQ_CEI1 error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_CEI1 register bits are cleared automatically, when their corresponding error interrupt in the submodule channel is cleared.

24.8.3 ICM Interrupt Signals

Following table shows the GTM interrupt lines that are visible at the outside of the GTM.

Table 24-23 ICM Interrupt Signals

Signal	Description
GTM_AEI_IRQ	AEI Shared interrupt
GTM_TIM0_IRQ[x]	TIM Shared interrupts (x: 0…7)
GTM_TOM[i]_IRQ[x]	TOM Shared interrupts for x:0…7 = {ch0||ch1,,ch14||ch15} (i: 0…number of TOM's-1)
GTM_ERR_IRQ	GTM Error Interrupt

24.8.4 ICM Configuration Registers Overview

ICM contains following configuration registers:

Table 24-24 ICM Configuration Registers Overview

Register Name	Description	Details in Section
ICM_IRQG_0	ICM Interrupt group register covering infrastructural and safety components (AEI)	Section 24.8.5.1
ICM_IRQG_2	ICM Interrupt group register covering TIM0	Section 24.8.5.2
ICM_IRQG_6	ICM Interrupt group register covering GTM output submodules TOM0 and TOM1	Section 24.8.5.3
ICM_IRQG_MEI	ICM Interrupt group register for module error interrupt information	Section 24.8.5.4
ICM_IRQG_CEI1	ICM Interrupt group register 1 for channel error interrupt information	Section 24.8.5.5

24.8.5 ICM Configuration Registers Description

All of the following registers are 32-bit only accessible.

24.8.5.1 Register ICM_IRQG_0

GTM_ICM_IRQG_0
GTM Infrastructure Interrupt Group (600_H) **Reset Value: 00000000_H**

Field	Bits	Type	Description
Reserved	[3:0]	r	**Reserved** Read as zero, should be written as zero
AEI_IRQ	4	rh	**AEI_IRQ interrupt** See bit 0.
Reserved	[31:5]	r	**Reserved** Read as zero, should be written as zero

24.8.5.2 Register ICM_IRQG_2

GTM_ICM_IRQG_2
TIM Interrupt Group 0 **(608_H)** **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

24.9 GTM Implementation

This chapter describes product specific implementation of the Generic Timer Module (GTM).

Note: After a module reset the outputs of the TOMs are high (see TOMi_CHx_CRTL.SL) and could cause unexpected triggers in other modules.

24.9.1 GTM Registers

Table 24-25 Registers Address Space

Module	Base Address	End Address	Note
GTM	$F010\ 0000_H$	$F019\ FFFF_H$	

Table 24-26 Registers Overview - GTM Control Registers

GTM Address Ordering

The GTM address area start at F010 0000_H and ends at F019 $FFFF_H$. All given address for registers are offset addresses to the GTM base address of F010 0000_H and need to be added.

Table 24-27 Address Overview

Submodule	Base address (to be added to GTM based address)
BRIDGE	0x00000030
TBU	0x00000100
CMU	0x00000300
ICM	0x00000600
TIM0	0x00001000
TOM0	0x00008000
TOM1	0x00008800
DTM1	0x00013000
DTM5	0x00013080

The clock control register is used to switch the GTM on or off and to control its input clock rate. The GTM can be disabled by setting bit DISR to 1.

CLC
Clock Control Register (9FD00$_H$) Reset Value: 0000 0003$_H$

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the GTM module. 0_B No disable requested 1_B Disable requested
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the GTM module. 0_B GTM module is enabled 1_B GTM module is disabled
EDIS	3	rw	**Sleep Mode Enable Control** Used for module sleep mode control.
0	2, [31:4]	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset and by each System Reset when OCDS is disabled. It is not touched by System Reset when OCDS is enabled.

The OCS register includes the module related control bits for the ODDS Trigger Bus (OTGB).

The OCS control register bits are only effective while the system is in debug mode. While not in debug mode, OCS reset values/modes are effective.
Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status (9FDE8$_H$) Reset Value: 0000 0000$_H$

Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. In Hard suspend no registers beside the registers documented in the Implementation section of this chapter could be read or written. 2_H Soft suspend (GTM Halt Mode). In Soft suspend registers could be read or written, for details see **Chapter 24.2.5**. **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ,EN31 -> TAG ID 011111_B.

All registers and memories of the GTM are protected beside the following registers:

ACCEN0 and ACCEN1.

ACCEN0
Access Enable Register 0 **(9FDFC$_H$)** **Reset Value: FFFF FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register (ACCEN1)

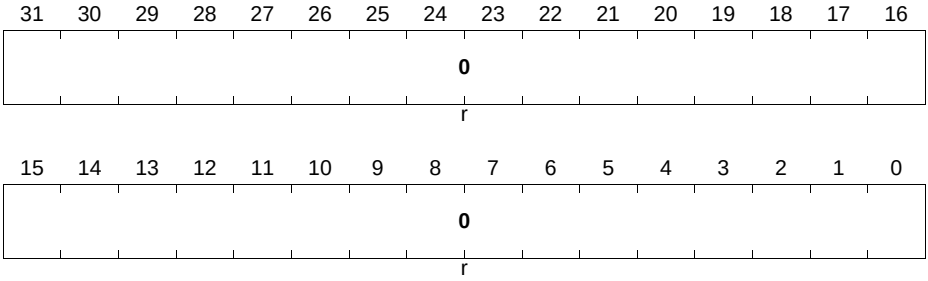
The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID master peripheral mapping).

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, , EN31 -> TAG ID 111111_B.

All registers and memories of the GTM are protected beside the following registers:

ACCEN0 and ACCEN1.

ACCEN1
Access Enable Register 1 **(9FDF8$_H$)** **Reset Value: 0000 0000$_H$**



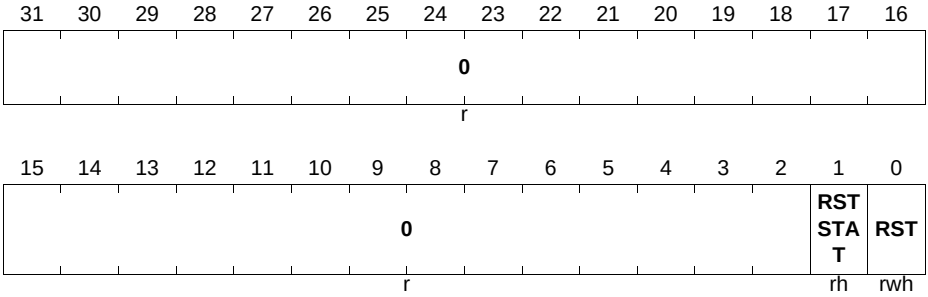
Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

The Kernel Reset Register 0 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). In order support modules with two kernel the BPI_FPI provides two set of kernel reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing to it with ´1´.

Note: This reset function has the effect as bit RST.RST.

KRST0
Kernel Reset Register 0 **(9FDF4$_H$)** **Reset Value: 0000 0000$_H$**

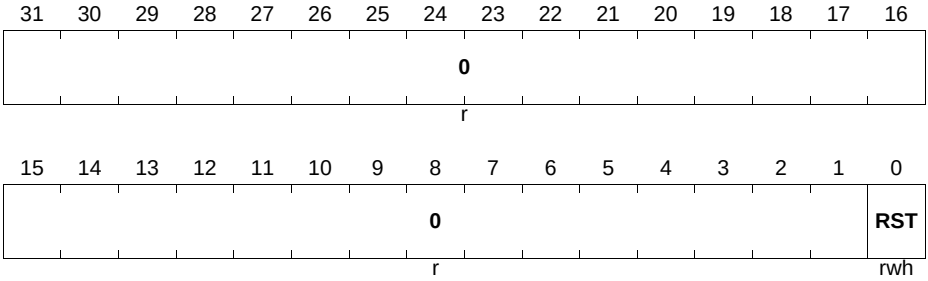


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rw	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the GTM kernel. GTM kernel registers related to the Debug Reset (Class 1) are not influenced. To reset the GTM kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be cleared with the end of the BPI kernel reset sequence.

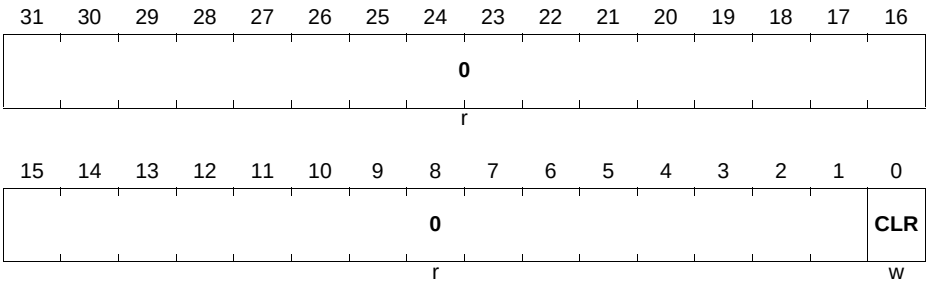
KRST1
Kernel Reset Register 1 **(9FDF0$_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR
Kernel Reset Status Clear Register (9FDEC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

24.9.2 Port Connections

The sections summarize the port connections which defined the boundary of the GTM for the TC21x/TC22x/TC23x.

The GTM outputs *cmu_eclk[2:0]* are connected directly to dedicated ports.

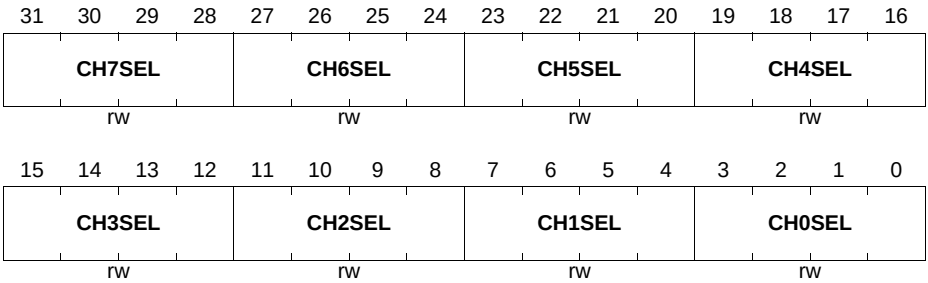
Table 24-31 GTM clock to Port Mapping

GTM Clock Output	Alternate Output of Pin
cmu_eclk0	P23.1
cmu_eclk1	P33.10
cmu_eclk2	P11.12

24.9.2.1 Port to GTM Control Registers

The inputs to the GTM TIM modules (*gtm_tim0_in[7:0]*) are not connected directly to the port input path. Each timed GPIO is connectable to two TIMs via an input multiplexer. In addition the inputs from the on chip peripherals are connected here too.

TIM0INSEL
TIM0 Input Select Register **($9FD10_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CHxSEL (x = 0-7)	[x*4+3: x*4]	rw	**TIM Channel x Input Selection** This bit defines which input is connected for TIM0 channel x of the GTM. The input is either derived from the a port pad or from a on-chip module.

Note: Please note that for inputs from pins and for the ERAY input the TIM channel frequency needs to be equal or faster as the input frequency.

24.9.2.2 GTM to Port Control Registers

The outputs of the GTM TOM or DTM modules are not connected directly to the port output path. Each DTM is connectable to several port alternate inputs via an output multiplexer.

The output signals to the mux are called *gtm_tout_x*, where x is running number.

TOUTSELn (n = 0-7)

SELx (x = 0-15)	[x*2+1: x*2]	rw	**TOUT(n*16+x) Output Selection** This bit defines which timer out is connected as TOUT(n*16+x). The mapping for each pin is defined by **Table 24-28**, **Table 24-29**, **Table 24-30**. 00_B Timer A form **Table 24-28**, **Table 24-29**, **Table 24-30** is connected as TOUT(n*16+x) to the ports 01_B Timer B form **Table 24-28**, **Table 24-29**, **Table 24-30** is connected as TOUT(n*16+x) to the ports 10_B Timer C form **Table 24-28**, **Table 24-29**, **Table 24-30** is connected as TOUT(n*16+x) to the ports 11_B Timer D form **Table 24-28**, **Table 24-29**, **Table 24-30** is connected as TOUT(n*16+x) to the ports *Note: If TOUT(n*16+x) is not defined in* **Table 24-28**, ***Table 24-29***, ***Table 24-30****this bit field has to be treated as reserved.*

24.9.3 ADC Connections

This register defines the GTM to ADC connections of TC21x/TC22x/TC23x.
The ADC trigger inputs 16 to 1 multiplexer is implemented twice per ADC module / channel. The output signal to the ADC is called *adcx_trig0* and *adcx_trig1*, The inputs of the multiplexer are called *adc_x_muxin[7:0]*, x = number of ADCs.

Mapping of ADC Triggers

Table 24-35 ADC0 / 1 Timer Triggers

SEL0 / 1	Trigger 0	Trigger 1
0000_B	No trigger is generated	No trigger is generated
0001_B	TOM0 Channel 1 output	TOM1 Channel 1 output

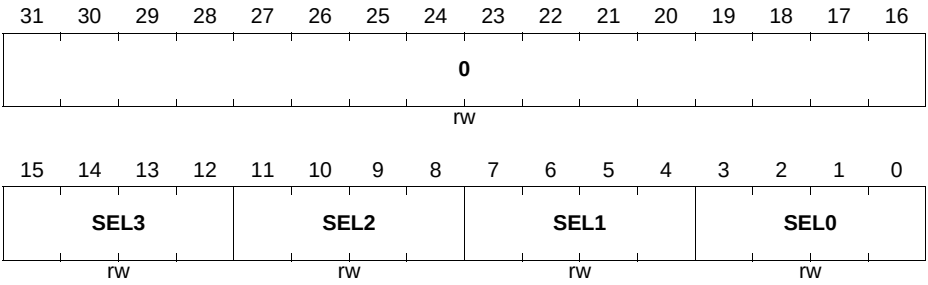
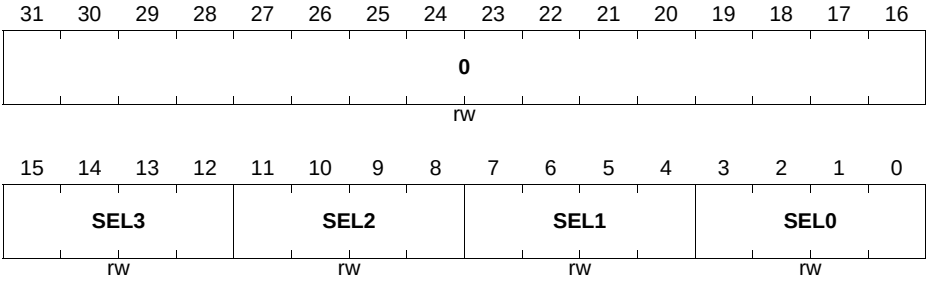
ADCTRIG0OUT0
ADC Trigger 0 Output Select 0 Register($9FDB0_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SELx (x = 0-3)	[x*4+3: x*4]	rw	**Output Selection for ADCx GTM connection** This bit field defines which TOM channel output is used as ADCx trigger 0. The decoding is defined by **Table 24-35** or **Table 24-36** depending on the ADC.
0	[31:16]	rw	**Reserved** Should be written with 0.

ADCTRIG1OUT0
ADC Trigger 1 Output Select 0 Register(9FDB8$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SELx (x = 0-3)	[x*4+3: x*4]	rw	**Output Selection for ADCx GTM connection** This bit field defines which TOM channel output is used as ADCx trigger 1. The decoding is defined by **Table 24-35** depending on the ADC.
0	[31:16]	rw	**Reserved** Should be written with 0.

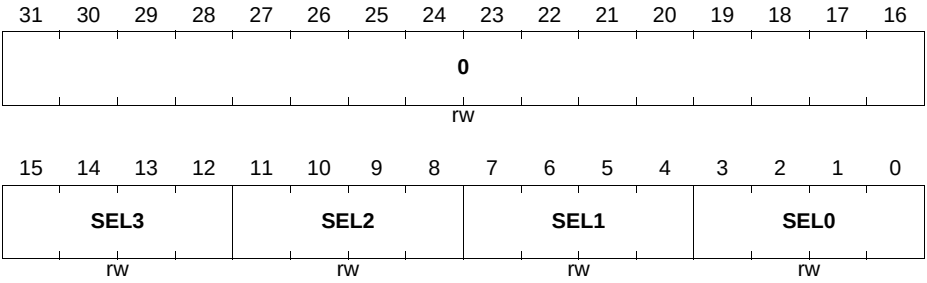
24.9.4 SENT Connections

This register defines the GTM to SENT connections of TC21x/TC22x/TC23x.
The trigger generation 16 to 1 multiplexer is implemented twice per ADC module / channel. The output signal to the ADC is called *adcx_trig0* and *adcx_trig1*. As the SENT channels overlay and replace ADC channels the ADC triggers will be also reused for the SENT channels. Therefore no additional outputs for separate operation are defined here.

adcx_trig0 is connected to sent_trig_x.

24.9.5 CAN Connection

CANOUTSEL
CAN Output Select Register (9FDA0$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SEL0	[3:0]	rw	**Output Selection for CAN GTM connection** This bit field defines which TOM channel output is used as CAN node trigger 0. The decoding is defined by **Table 24-37**
SEL1	[7:4]	rw	**Output Selection for CAN GTM connection** This bit field defines which TOM channel output is used as CAN node trigger 1. The decoding is defined by **Table 24-37**
SEL2	[11:8]	rw	**Output Selection for CAN GTM connection** This bit field defines which TOM channel output is used as CAN node trigger 2. The decoding is defined by **Table 24-38**
SEL3	[15:12]	rw	**Output Selection for CAN GTM connection** This bit field defines which TOM channel output is used as CAN node trigger 3. The decoding is defined by **Table 24-38**
0	[31:16]	rw	**Reserved** Should be written with 0.

Mapping of CAN Triggers

Table 24-37 CAN Timer Triggers

SEL0 / 1	Trigger 0	Trigger 1
0000_B	TOM0 Channel 0 output	TOM1 Channel 0 output
0001_B	TOM0 Channel 1 output	TOM1 Channel 1 output
0010_B	TOM0 Channel 2 output	TOM1 Channel 2 output
0011_B	TOM0 Channel 3 output	TOM1 Channel 3 output
0100_B	TOM0 Channel 4 output	TOM1 Channel 4 output
0101_B	TOM0 Channel 5 output	TOM1 Channel 5 output

24.9.6 CCU6x Connections

This section summarize the connections to the CCU6x.

Table 24-39 GTM to CCU60 Connections

GTM Output	CCU60 Input
TOM0_8	T12HRD
TOM1_8	T13HRD

Table 24-40 GTM to CCU61 Connections

GTM Output	CCU61 Input
TOM0_9	T13HRD

24.9.7 SCU Connections

This section summarize the connections to the SCU.

Table 24-41 GTM to SCU Connections

GTM Output	SCU Input
TOM0_12	Input41
TOM1_12	Input51

24.9.8 GTM Debug Interface

OTGB0/1 are 16-bit trigger busses, OTGB2 is 32 bit wide. Further information is available in the OTGM (OCDS Trigger Mux) section of the device specification.

Note: If triggering or tracing is to be used the GTM clock must not be faster than the SPB clock.

24.9.8.1 OCDS Trigger Bus (OTGB) Interface

GTM OTGB Features

- IO signals
  - TIM input signals (after filter)
  - TOM output signals
  - Groups of 8 signals (e.g. all inputs of a specific TIM, etc.)
  - Two arbitrary groups on one 16 bit OTGB0/1
  - OTGB0 and/or OTGB1 can be used for 2-4 groups in parallel (e.g. both with one TIM 8 and one TOM 16)
- TBUs
  - Trace one selected TBU
  - Trigger signals for individual TBU comparators

The GTM module has one 16 bit and one 32 bit Trigger Sets (**Table 24-42**) which are selected with the **OTSS** register.

Table 24-42 GTM Trigger Sets

Trigger Set	Details
TS16_IOS Trigger Set IO and Other Signals	**Table 24-44**
TS32_TTB0/1/2 TBU Time Stamps (3 Sets)	**Table 24-45**

Table 24-43 shows all sensible Trigger Set mapping options. Simple permutations of OTGB0/1 are omitted. If OTGB0 and/or OTGB1 is not used for GTM, Trigger Sets of other sources can be added in the OTGM module. The Trigger Sets which will initiate the writing of a 32 or 64 bit data word to the MCDS trace are marked with bold letters. This is by design always the case for OTGB2 Trigger Sets. Independent OTGB0/1 Trigger Sets need an independent own sensitivity to their signal changes, configured in the OTGM module.

Table 24-43 Trigger Set Mapping Options

Width	OTGB0	OTGB1	OTGB2
32 Bit	**TS16_IOS**		
	TS16_IOS	**TS16_IOS**	
64 Bit			**TTB0/1/2**
	TS16_IOS		
	TS16_IOS	**TS16_IOS**	
		TS16_IOS	
		TS16_IOS	

The GTM trigger signals relate to the GTM internal clock, which can be slower or equal to the OTGB/OTGM clock.

IO and Other Signals Trigger Sets

IO Trigger Sets consist of the most important TIM and TOM signals in groups of 8. In addition there is a group of miscellaneous signals. The multiplexer allows to map arbitrary and different signal groups to the high and the low byte of a 16 bit Trigger Set. In addition it is possible to use one or two 16 bit Trigger Sets with this flexibility. All this is controlled with **OTSC0**.

Table 24-44 TS16_IOS Trigger Set IO and Other Signals

Bits	Name	Description	
[7:0]	SG0	A group of 8 signals from a selected TIM and TOM	
		TIM	All 8 input signals after filter F_OUT
		TOML	Lower 8 output signals TOM_OUT
		TOMH	Higher 8 output signals TOM_OUT
		MISC	Bit 0: reserved Bit 1: reserved Bit 4: TBU0 trigger (OTBU0T) Bit 5: TBU1 trigger (OTBU1T) Bit 6: TBU2 trigger (OTBU2T) Others: reserved
[15:8]	SG1	Independent selection with same options as for Bits [7:0]	

TBU Trigger Sets

Table 24-45 defines the Trigger Sets for the observation of the different time bases. The Trigger Set selection (one at a time) is done with OTSS.

Table 24-45 TS32_TTB0/1/2 TBU Time Stamps

Bits	Name	Description
[26:0]	TS	Current TBU_TS0/1/2 time stamp. Effective width depends on selected time base.
[31:27]		Reserved

24.9.8.2 GTM Debug Registers

All debug control registers are cleared by Debug Reset and by each System Reset when OCDS is disabled. It is not changed by System Reset when OCDS is enabled.

OCDS Trigger Bus (OTGB)

Access are only supported for byte, halfword and word data and requires Supervisor Mode.

24.10 Revision History

Changes from version 0.1

- first version

Changes from version 0.1 to 0.2

- 2.1.1 New Block Diagram
- 2.1.1 TIM trigger out definition
- 2.4 More detailed description of IRQ_NOTIFY clearing
- 2.7 New register GTM_HW_CONF
- 2.8.14 New register GTM_HW_CONF
- 5.1.3 additional input observation functionality
- 5.4.2.5ff remove channel > 0 TBCM limitation
- 5.6 new register TIMi_INP_VAL

- 5.7.1 remove channel > 0 TBCM limitation
  more detailed information about input selection in TGPS and TBCM mode
- 5.7.5 more detailed information about input selection in TBCM mode
- 5.7.7 more detailed information about input selection in TBCM mode
- 5.7.7 register is writable also in TGPS mode
- 5.7.18 additional information about input selection for channels
- 5.7.19 new register TIMi_INP_VAL
- 6.1.1 description of TOM0 channel 0 trigger input added
- 6.2.2 new feature description: additional trigger source is TIM_EXT_CAPTURE
- 6.3.1 update figure
- 6.3.2 update figure
- 6.3.3 update figure
- 6.3ff description of trigger by TIM_EXT_CAPTURE added; behaviour on reset on CN0 by CCU0 compare
- 6.3.6.1ff figure and description of new onw shot trigger feature added
- 6.6.9 new bits OSM_TRIG, EXT_TRIG and EXTRIGOUT added
- 6.6.10 new bits OSM_TRIG, EXT_TRIG and EXTRIGOUT added
- 7.2.2 Definition path delay
- 7.3.1 More detailed description for channel 0 function
- 7.4.1ff fully truth tables
- 7.4.3 Definition pulse generation on edge
- 7.7.1 asynchronous update for 0--
- 7.7.2 No shift function for channel 0
- update mapping to package

Changes from version 0.2 to 1.0

- 2.5 more detailed description of IRQ_NOTIFY
- 2.9.13 bit 0 formula corrected
- 10.2.3 more detailed information about filter reconfiguration
- 10.5 more detailed information about MAP interface
- 10.8.1ff more detailed information about TIM MODE reconfiguration and GELx_SEL
- 10.8.6 additional information about GPR0
- 10.8.7 additional information about GPR1
- 10.8.9 additional information about CNTS
- 10.8.20 additional information about input selection by EXT_CAP_SRC

Changes from version 1.0 to 1.1

- add bit 12 to register GTM_BRIDGE_MODE
- update reset values for registers GTM_REV, GTM_BRIDGE_MODE and GTM_HW_CONF
- update pinning information for QFP100 and bigger packages
- add pinning information for QFP80 package

- removed table Port to GTM DTM Auxillary Mapping
- update figure DTM connections for correct DTM numbering
- update links for register TOUTSELn description
- update description of register DTMx_CTRL bit field CLK_SEL

25 Capture/Compare Unit 6 (CCU6)

The CCU6 is a high-resolution 16-bit capture and compare unit with application specific modes, mainly for AC drive control. Special operating modes support the control of Brushless DC-motors using Hall sensors or Back-EMF detection. Furthermore, block commutation and control mechanisms for multi-phase machines are supported.
It also supports inputs to start several timers synchronously, an important feature in devices with several CCU6 kernels.

This chapter is structured as follows:

- Introduction (see **Section 25.1**)
  including register overview (see **Section 25.1.3**)
- Operating T12 (see **Section 25.2**)
  including T12-related registers (see **Section 25.2.8**)
  and capture/compare control registers (see **Section 25.2.9**)
- Operating T13 (see **Section 25.3**)
  including T13-related registers (see **Section 25.3.6**)
- Synchronous start feature (see **Section 25.4**)
- Trap handling (see **Section 25.5**)
- Multi-Channel mode (see **Section 25.6**)
- Hall sensor mode (see **Section 25.7**)
- Modulation control registers (see **Section 25.8**)
- Interrupt handling (see **Section 25.9**)
  including interrupt registers (see **Section 25.9.2**)
- General module operation (see **Section 25.10**)
  including general registers (see **Section 25.10.5**)
  and BPI registers (see **Section 25.10.6**)
- Module implementation (see **Section 25.11**)

25.1 Introduction

The CCU6 unit is made up of a Timer T12 Block with three capture/compare channels and a Timer T13 Block with one compare channel. The T12 channels can independently generate PWM signals or accept capture triggers, or they can jointly generate control signal patterns to drive AC-motors or inverters.

A rich set of status bits, synchronized updating of parameter values via shadow registers, and flexible generation of interrupt request signals provide means for efficient software-control.

Note: The capture/compare module itself is named CCU6 (capture/compare unit 6).
A capture/compare channel inside this module is named CC6x.

25.1.1 Feature Set Overview

This section gives an overview over the different building blocks and their main features.

Timer 12 Block Features

- Three capture/compare channels, each channel can be used either as capture or as compare channel
- Generation of a three-phase PWM supported (six outputs, individual signals for high-side and low-side switches)
- 16-bit resolution, maximum count frequency = peripheral clock
- Dead-time control for each channel to avoid short-circuits in the power stage
- Concurrent update of T12 registers
- Center-aligned and edge-aligned PWM can be generated
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events
- Many interrupt request sources
- Hysteresis-like control mode

Timer 13 Block Features

- One independent compare channel with one output
- 16-bit resolution, maximum count frequency = peripheral clock
- Concurrent update of T13 registers
- Can be synchronized to T12
- Interrupt generation at period-match and compare-match
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events

Additional Specific Functions

- Block commutation for Brushless DC-drives implemented
- Position detection via Hall-sensor pattern
- Noise filter supported for position input signals
- Automatic rotational speed measurement and commutation control for block commutation
- Integrated error handling
- Fast emergency stop without CPU load via external signal ($\overline{\text{CTRAP}}$)
- Control modes for multi-channel AC-drives
- Output levels can be selected and adapted to the power stage

25.1.2 Block Diagram

The Timer T12 can operate in capture and/or compare mode for its three channels. The modes can also be combined (e.g. a channel operates in compare mode, whereas another channel operates in capture mode). The Timer T13 can operate in compare mode only. The multi-channel control unit generates output patterns which can be modulated by T12 and/or T13. The modulation sources can be selected and combined for the signal modulation.

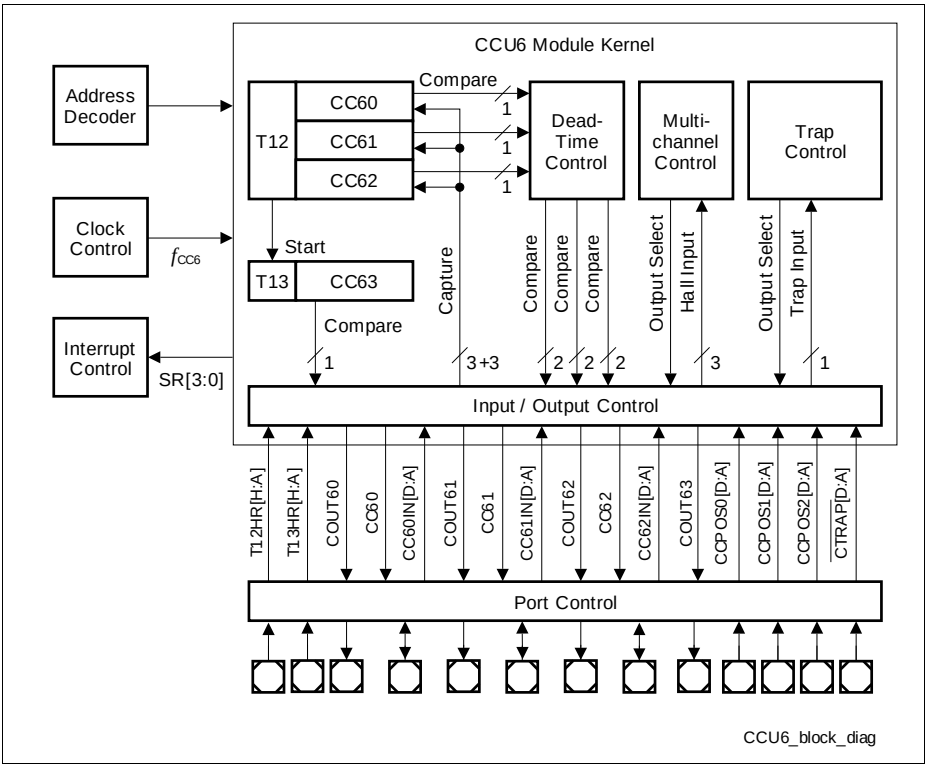

Figure 25-1 CCU6 Block Diagram

25.1.3 CCU6 Kernel Registers

For the generation of the overall register table, the prefix “CCU6x_” has to be added to the register names in this table to identify the registers of different CCU6 kernels that are implemented. In this naming convention, x indicates the kernel number.

Table 25-1 shows all registers required for programming of a CCU6. It summarizes the CCU6 kernel registers and defines their offset addresses. BPI registers are listed separately in **Table 25-14**, and Module Output Select registers are listed in **Table 25-16**.

The CCU6 module has no destructive register read mechanisms.

CCU6 Kernel Register Overview

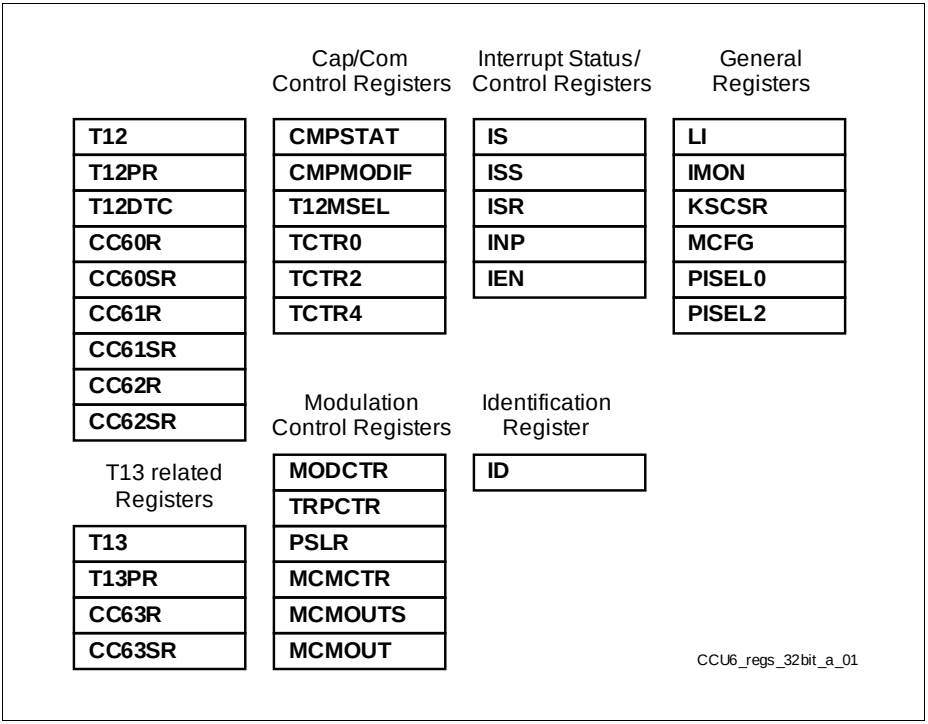

Figure 25-2 CCU6 Registers

Note: In the case of a write access to addresses inside the address range (that is covered by the same chip select signal), but that are not the addresses explicitly mentioned for the module, the write access is not taken into account for the

module. The same principle is valid for read accesses. In case of a read access to another address, the module does not react.

*Note: The exact register address is given by the relative address of the register (given in **Table 25-1**) plus the kernel base address (given in **Table 25-15**) of the kernel.*

25.2 Operating Timer T12

The timer T12 block is the main unit to generate the 3-phase PWM signals. A 16-bit counter is connected to 3 channel registers via comparators, that generate a signal when the counter contents match one of the channel register contents. A variety of control functions facilitate the adaptation of the T12 structure to different application needs.
Besides the 3-phase PWM generation, the T12 block offers options for individual compare and capture functions, as well as dead-time control and hysteresis-like compare mode.

This section provides information about:

- T12 overview (see **Section 25.2.1**)
- Counting scheme (see **Section 25.2.2**)
- Compare modes (see **Section 25.2.3**)
- Compare mode output path (see **Section 25.2.4**)
- Capture modes (see **Section 25.2.5**)
- Shadow transfer (see **Section 25.2.6**)
- T12 operating mode selection (see **Section 25.2.7**)
- T12 register description (see **Section 25.2.8**)

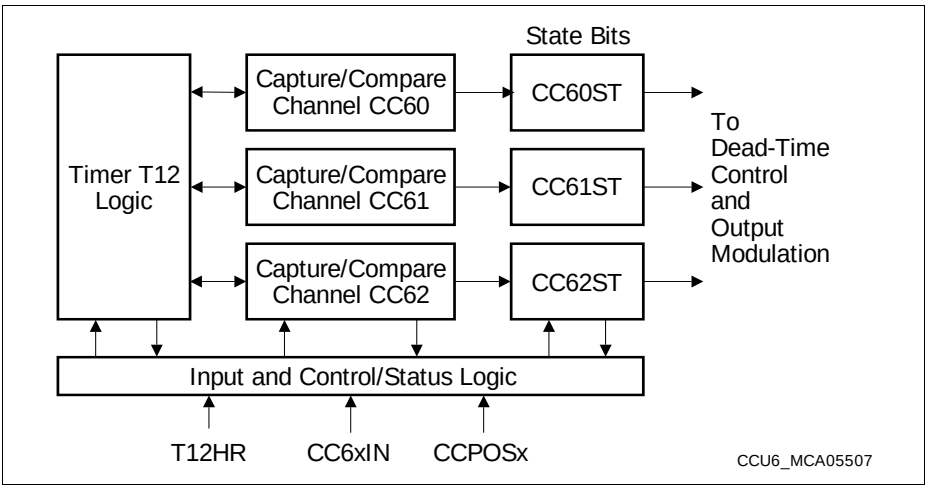

Figure 25-3 Overview Diagram of the Timer T12 Block

25.2.1 T12 Overview

Figure 25-4 shows a detailed block diagram of Timer T12. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISEL0**.

Timer T12 receives its input clock (f_{T12}) from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T12HR. These options are controlled via bit fields T12CLK and T12PRE (see **Table 25-2**). T12 can count up or down, depending on the selected operation mode. A direction flag, CDIR, indicates the current counting direction.

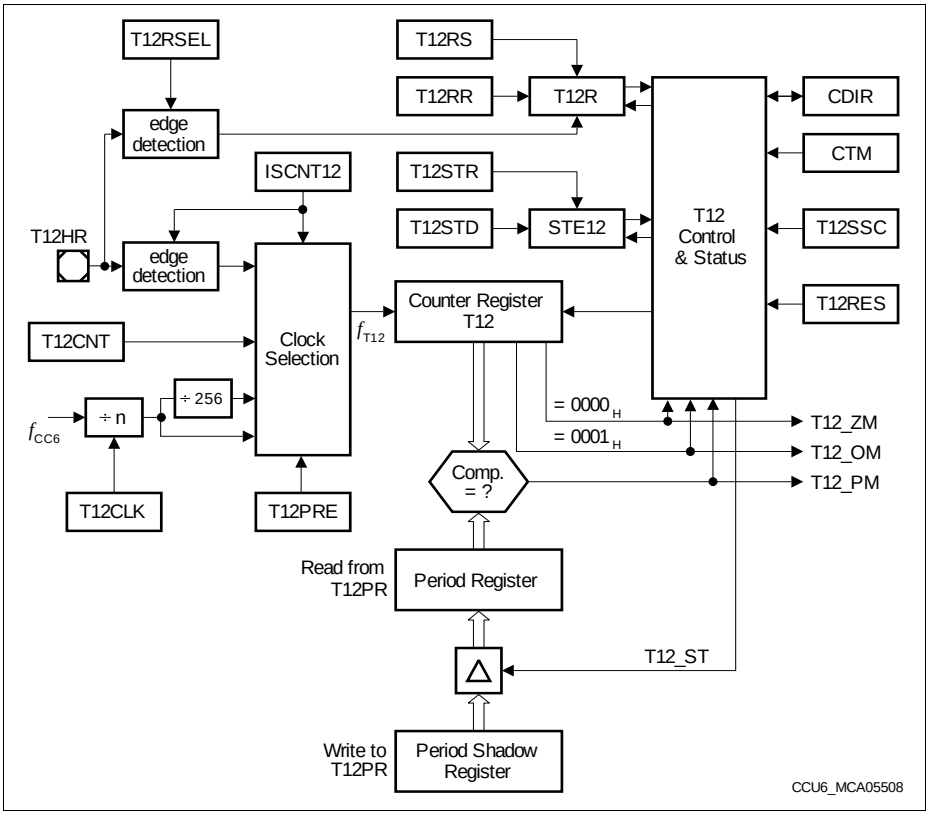

Figure 25-4 Timer T12 Logic and Period Comparators

Via a comparator, the T12 counter register **T12** is connected to a Period Register **T12PR**. This register determines the maximum count value for T12.

In Edge-Aligned mode, T12 is cleared to 0000_H after it has reached the period value defined by T12PR. In Center-Aligned mode, the count direction of T12 is set from ‘up’ to

‘down’ after it has reached the period value (please note that in this mode, T12 exceeds the period value by one before counting down). In both cases, signal T12_PM (T12 Period Match) is generated. The Period Register receives a new period value from its Shadow Period Register.
A read access to T12PR delivers the current period value at the comparator, whereas a write access targets the Shadow Period Register to prepare another period value. The transfer of a new period value from the Shadow Period Register into the Period Register (see **Section 25.2.6**) is controlled via the ‘T12 Shadow Transfer’ control signal, T12_ST. The generation of this signal depends on the operating mode and on the shadow transfer enable bit STE12. Providing a shadow register for the period value as well as for other values related to the generation of the PWM signal allows a concurrent update by software for all relevant parameters.
Two further signals indicate whether the counter contents are equal to 0000_H (T12_ZM = zero match) or 0001_H (T12_OM = one match). These signals control the counting and switching behavior of T12.

The basic operating mode of T12, either Edge-Aligned mode (**Figure 25-5**) or Center-Aligned mode (**Figure 25-6**), is selected via bit CTM. A Single-Shot control bit, T12SSC, enables an automatic stop of the timer when the current counting period is finished (see **Figure 25-7** and **Figure 25-8**).

The start or stop of T12 is controlled by the Run bit T12R that can be modified by bits in register **TCTR4**. The run bit can be set/cleared by software via the associated set/clear bits T12RS or T12RR, it can be set by a selectable edge of the input signal T12HR (**TCTR2**.T12RSEL), or it is cleared by hardware according to preselected conditions.
The timer T12 run bit T12R must not be set while the applied T12 period value is zero.
Timer T12 can be cleared via control bit T12RES. Setting this write-only bit does only clear the timer contents, but has no further effects, for example, it does not stop the timer.

The generation of the T12 shadow transfer control signal, T12_ST, is enabled via bit STE12. This bit can be set or reset by software indirectly through its associated set/clear control bits T12STR and T12STD.
While Timer T12 is running, write accesses to the count register T12 are not taken into account. If T12 is stopped and the Dead-Time counters are 0, write actions to register T12 are immediately taken into account.

25.2.2 T12 Counting Scheme

This section describes the clocking and counting capabilities of T12.

25.2.2.1 Clock Selection

In **Timer Mode** (**PISEL2**.ISCNT12 = 00_B), the input clock f_{T12} of Timer T12 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 25-2**. The prescaler of T12 is cleared while T12 is not running (**TCTR0**.T12R = 0) to ensure reproducible timings and delays.

Table 25-2 Timer T12 Input Frequency Options

T12CLK	Resulting Input Clock f_{T12} Prescaler Off (T12PRE = 0)	Resulting Input Clock f_{T12} Prescaler On (T12PRE = 1)
000_B	f_{CC6}	f_{CC6} / 256
001_B	f_{CC6} / 2	f_{CC6} / 512
010_B	f_{CC6} / 4	f_{CC6} / 1024
011_B	f_{CC6} / 8	f_{CC6} / 2048
100_B	f_{CC6} / 16	f_{CC6} / 4096
101_B	f_{CC6} / 32	f_{CC6} / 8192
110_B	f_{CC6} / 64	f_{CC6} / 16384
111_B	f_{CC6} / 128	f_{CC6} / 32768

In **Counter Mode**, timer T12 counts one step:

- If a 1 is written to **TCTR4**.T12CNT and **PISEL2**.ISCNT12 = 01_B
- If a rising edge of input signal T12HR is detected and **PISEL2**.ISCNT12 = 10_B
- If a falling edge of input signal T12HR is detected and **PISEL2**.ISCNT12 = 11_B

25.2.2.2 Edge-Aligned / Center-Aligned Mode

In **Edge-Aligned Mode** (CTM = 0), timer T12 is always counting upwards (CDIR = 0). When reaching the value given by the period register (period-match T12_PM), the value of T12 is cleared with the next counting step (saw tooth shape).

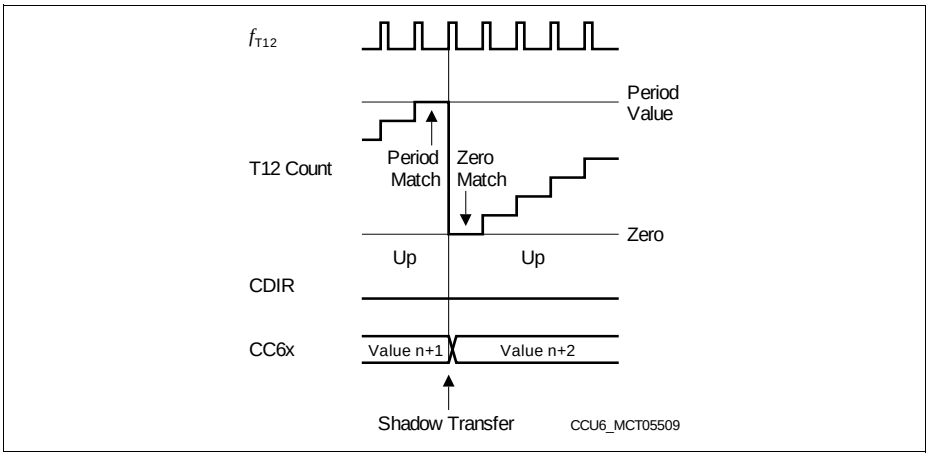

Figure 25-5 T12 Operation in Edge-Aligned Mode

As a result, in Edge-Aligned mode, the timer period is given by:

$T12_{PER}$ = <Period-Value> + 1; in T12 clocks (f_{T12}) (25.1)

In **Center-Aligned Mode** (CTM = 1), timer T12 is counting upwards or downwards (triangular shape). When reaching the value given by the period register (period-match T12_PM) while counting upwards (CDIR = 0), the counting direction control bit CDIR is changed to downwards (CDIR = 1) with the next counting step.
When reaching the value 0001_H (one-match T12_OM) while counting downwards, the counting direction control bit CDIR is changed to upwards with the next counting step.

As a result, in Center.Aligned mode, the timer period is given by:

$T12_{PER}$ = (<Period-Value> + 1) x 2; in T12 clocks (f_{T12}) (25.2)

- With the next clock event of f_{T12} the count direction is set to counting up (CDIR = 0) when the counter reaches 0001_H while counting down.
- With the next clock event of f_{T12} the count direction is set to counting down (CDIR = 1) when the Period-Match is detected while counting up.
- With the next clock event of f_{T12} the counter counts up while CDIR = 0 and it counts down while CDIR = 1.

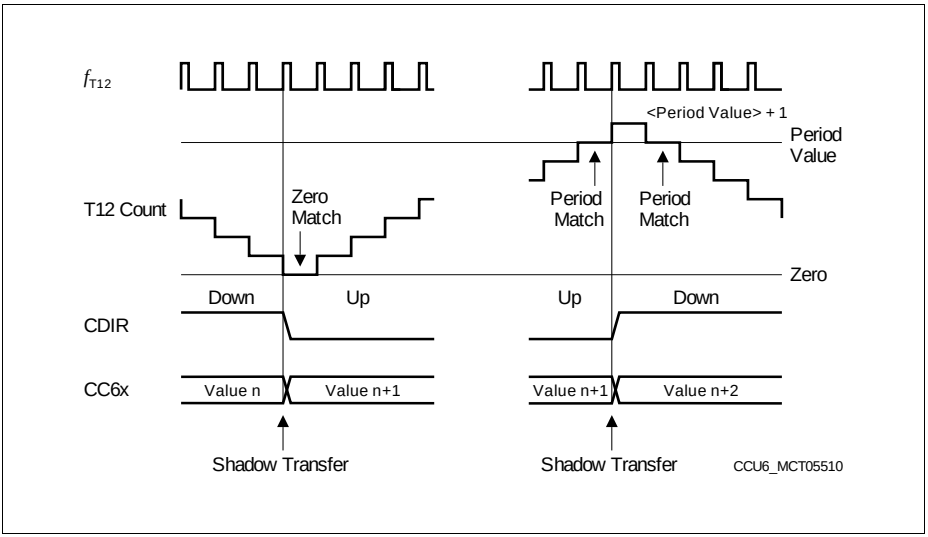

Figure 25-6 T12 Operation in Center-Aligned Mode

*Note: Bit CDIR changes with the next timer clock event after the one-match or the period-match. Therefore, the timer continues counting in the previous direction for one cycle before actually changing its direction (see **Figure 25-6**).*

25.2.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T12R is cleared by hardware. If bit T12SSC = 1, the timer T12 will stop when the current timer period is finished.

In Edge-Aligned mode, T12R is cleared when the timer becomes zero after having reached the period value (see **Figure 25-7**).

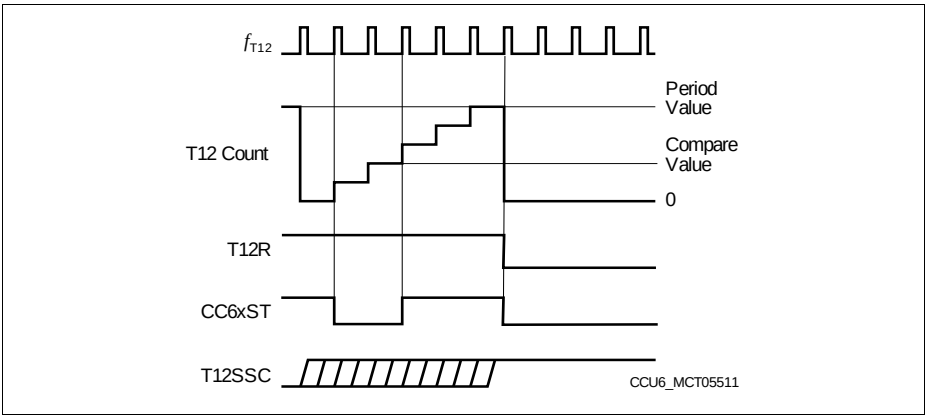

Figure 25-7 Single-Shot Operation in Edge-Aligned Mode

In Center-Aligned mode, the period is finished when the timer has counted down to zero (one clock cycle after the one-match while counting down, see **Figure 25-8**).

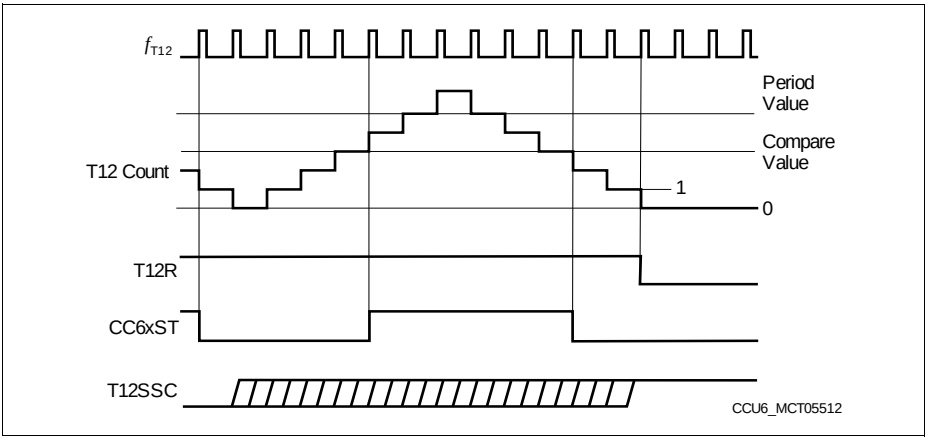

Figure 25-8 Single-Shot Operation in Center-Aligned Mode

25.2.3 T12 Compare Mode

Associated with Timer T12 are three individual capture/compare channels, that can perform compare or capture operations with regard to the contents of the T12 counter. The capture functions are explained in **Section 25.2.5**.

25.2.3.1 Compare Channels

In Compare Mode (see **Figure 25-9**), the three individual compare channels CC60 CC61, and CC62 can generate a three-phase PWM pattern.

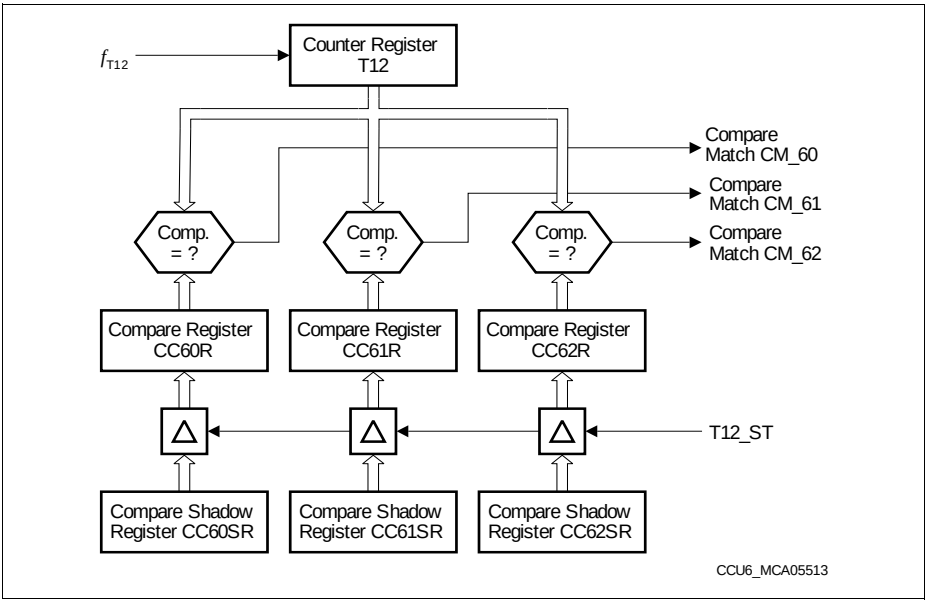

Figure 25-9 T12 Channel Comparators

Each compare channel is connected to the T12 counter register via its individual equal-to comparator, generating a match signal when the contents of the counter matches the contents of the associated compare register. Each channel consists of the comparator and a double register structure - the actual compare register CC6xR, feeding the comparator, and an associated shadow register CC6xSR, that is preloaded by software and transferred into the compare register when signal T12 shadow transfer, T12_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters of a three-phase PWM.

25.2.3.2 Channel State Bits

Associated with each (compare) channel is a State Bit, **CMPSTAT**.CC6xST, holding the status of the compare (or capture) operation (see **Figure 25-10**). In compare mode, the State Bits are modified according to a set of switching rules, depending on the current status of timer T12.

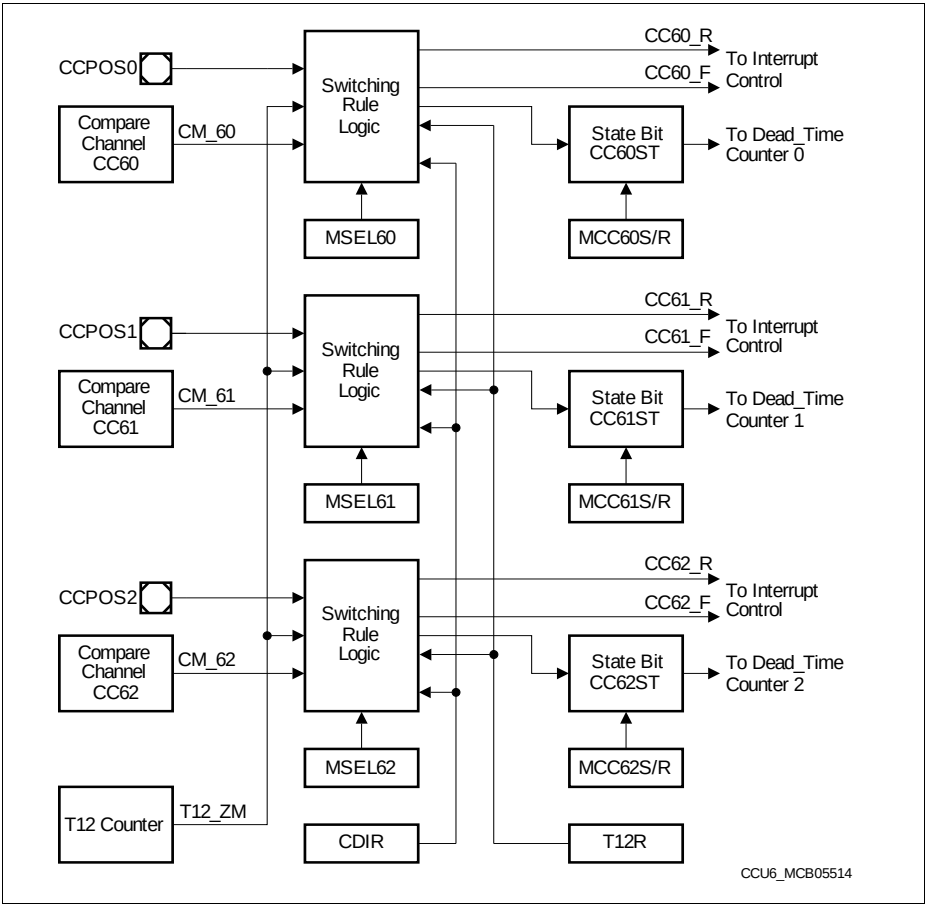

Figure 25-10 Compare State Bits for Compare Mode

The inputs to the switching rule logic for the CC6xST bits are the timer direction (CDIR), the timer run bit (T12R), the timer T12 zero-match signal (T12_ZM), and the actual individual compare-match signals CM_6x as well as the mode control bits, **T12MSEL**.MSEL6x.

In addition, each state bit can be set or cleared by software via the appropriate set and reset bits in register **CMPMODIF**, MCC6xS and MCC6xR. The input signals CCPOSx are used in hysteresis-like compare mode, whereas in normal compare mode, these inputs are ignored.

Note: In Hall Sensor, single shot or capture modes, additional/different rules are taken into account (see related sections).

A compare interrupt event CC6x_R is signaled when a compare match is detected while counting upwards, whereas the compare interrupt event CC6x_F is signaled when a compare match is detected while counting down. The actual setting of a State Bit has no influence on the interrupt generation in compare mode.

A modification of a State Bit CC6xST by the switching rule logic due to a compare action is only possible while Timer T12 is running (T12R = 1). If this is the case, the following switching rules apply for setting and clearing the State Bits in Compare Mode (illustrated in **Figure 25-11** and **Figure 25-12**):

A State Bit **CC6xST is set** to 1:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting up (i.e., when the counter is incremented above the compare value);
- with the next T12 clock (f_{T12}) after a zero-match AND a parallel compare-match when T12 is counting up.

A State Bit **CC6xST is cleared** to 0:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting down (i.e., when the counter is decremented below the compare value in center-aligned mode);
- with the next T12 clock (f_{T12}) after a zero-match AND NO parallel compare-match when T12 is counting up.

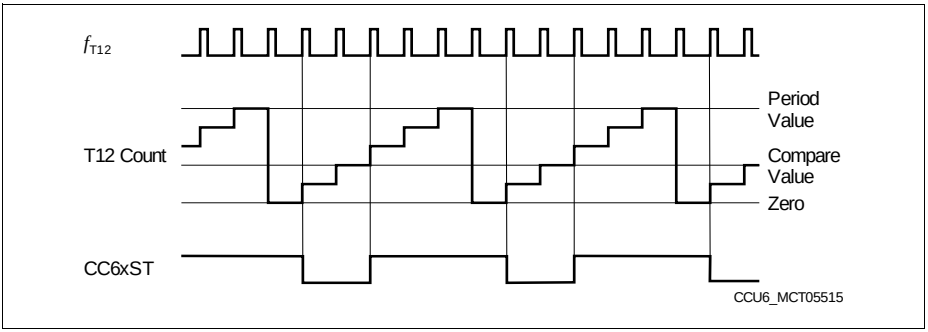

Figure 25-11 Compare Operation, Edge-Aligned Mode

Figure 25-13 illustrates some more examples for compare waveforms. It is important to note that in these examples, it is assumed that some of the compare values are changed

while the timer is running. This change is performed via a software preload of the Shadow Register, CC6xSR. The value is transferred to the actual Compare Register CC6xR with the T12 Shadow Transfer signal, T12_ST, that is assumed to be enabled.

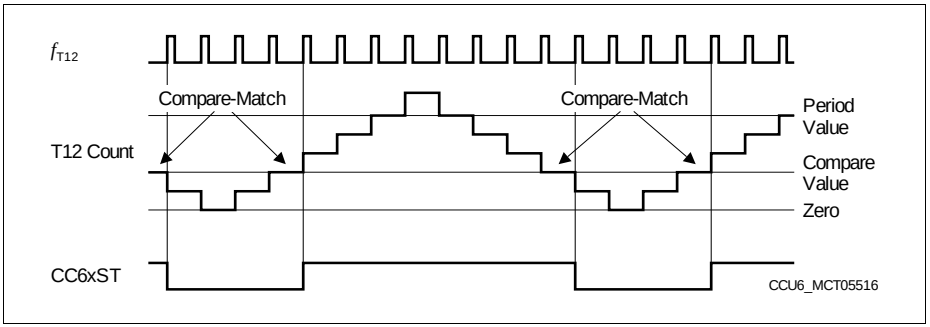

Figure 25-12 Compare Operation, Center-Aligned Mode

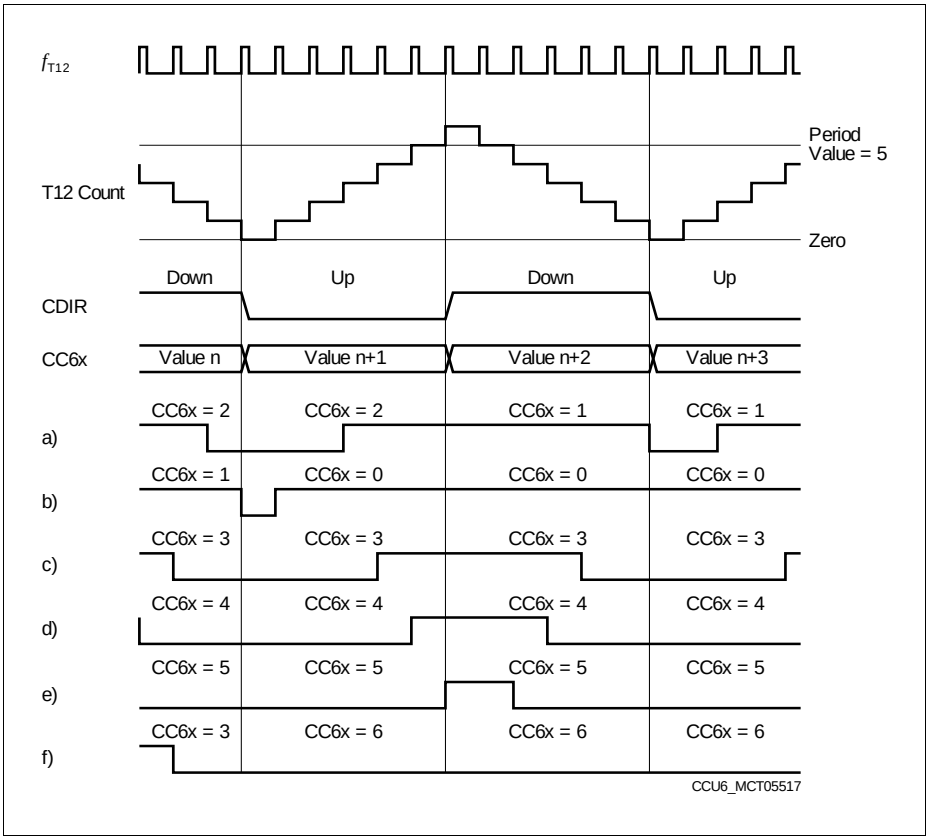

Figure 25-13 Compare Waveform Examples

Example b) illustrates the transition to a duty cycle of 100%. First, a compare value of 0001_H is used, then changed to 0000_H. Please note that a low pulse with the length of one T12 clock is still produced in the cycle where the new value 0000_H is in effect; this pulse originates from the previous value 0001_H. In the following timer cycles, the State Bit CC6xST remains at 1, producing a 100% duty cycle signal. In this case, the compare rule ‘zero-match AND compare-match’ is in effect.

Example f) shows the transition to a duty cycle of 0%. The new compare value is set to <Period-Value> + 1, and the State Bit CC6ST remains cleared.

Figure 25-14 illustrates an example for the waveforms of all three channels. With the appropriate dead-time control and output modulation, a very efficient 3-phase PWM signal can be generated.

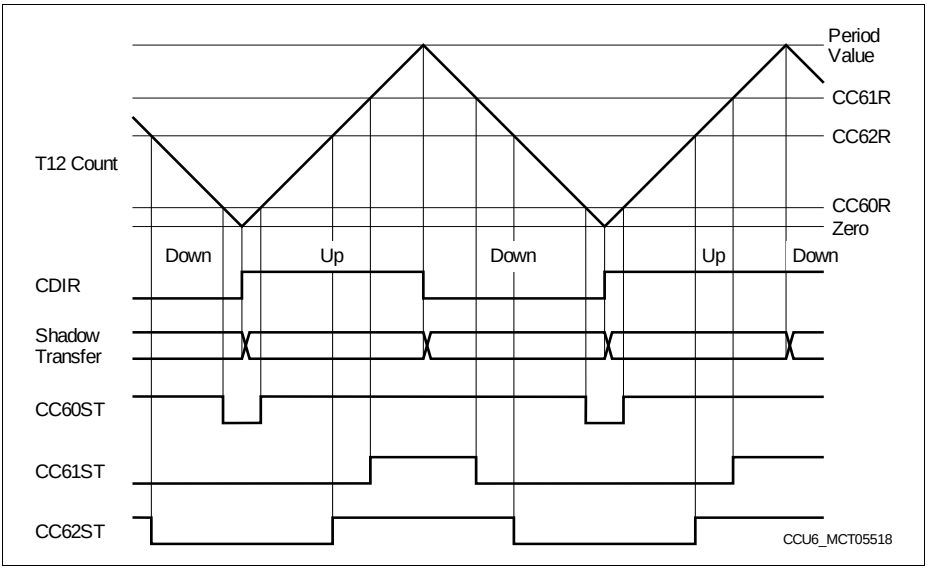

Figure 25-14 Three-Channel Compare Waveforms

25.2.3.3 Hysteresis-Like Control Mode

The hysteresis-like control mode (**T12MSEL**.MSEL6x = 1001_B) offers the possibility to switch off the PWM output if the input CCPOSx becomes 0 by clearing the State Bit CC6xST. This can be used as a simple motor control feature by using a comparator indicating, e.g., overcurrent. While CCPOSx = 0, the PWM outputs of the corresponding channel are driving their passive levels, because the setting of bit CC6xST is only possible while CCPOSx = 1.
As long as input CCPOSx is 0, the corresponding State Bit is held 0. When CCPOSx is at high level, the outputs can be in active state and are determined by bit CC6xST (see **Figure 25-10** for the state bit logic and **Figure 25-15** for the output paths).
The CCPOSx inputs are evaluated with f_{CC6}.

This mode can be used to introduce a timing-related behavior to a hysteresis controller. A standard hysteresis controller detects if a value exceeds a limit and switches its output according to the compare result. Depending on the operating conditions, the switching frequency and the duty cycle are not fixed, but change permanently.

If (outer) time-related control loops based on a hysteresis controller in an inner loop should be implemented, the outer loops show a better behavior if they are synchronized to the inner loops. Therefore, the hysteresis-like mode can be used, that combines timer-related switching with a hysteresis controller behavior. For example, in this mode, an output can be switched on according to a fixed time base, but it is switched off as soon as a falling edge is detected at input CCPOSx.

This mode can also be used for standard PWM with overcurrent protection. As long as there is no low level signal at pin CCPOSx, the output signals are generated in the normal manner as described in the previous sections. Only if input CCPOSx shows a low level, e.g. due to the detection of overcurrent, the outputs are shut off to avoid harmful stress to the system.

25.2.4 Compare Mode Output Path

Figure 25-15 gives an overview on the signal path from a channel State Bit to its output pin in its simplest form. As illustrated, a user has a variety of controls to determine the desired output signal switching behavior in relation to the current state of the State Bit, CC6xST. Please refer to **Section 25.2.4.3** for details on the output modulation.

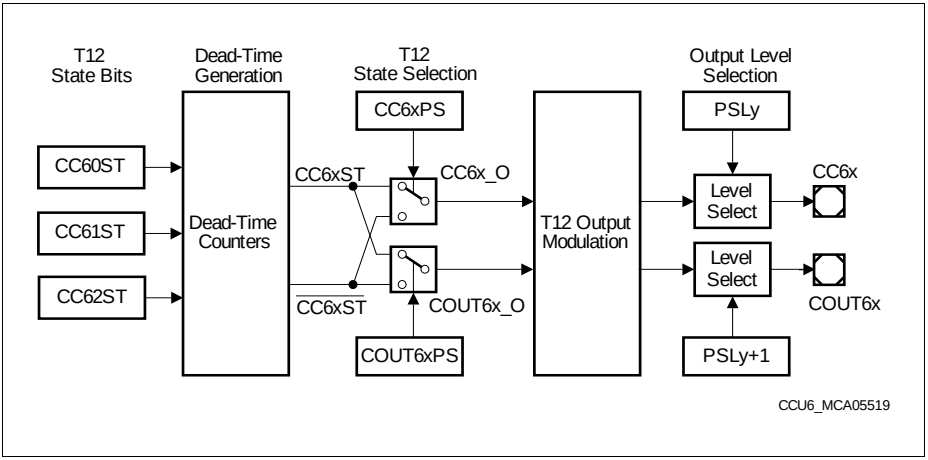

Figure 25-15 Compare Mode Simplified Output Path Diagram

The output path is based on signals that are defined as active or passive. The terms active and passive are not related to output levels, but to internal actions. This mainly applies for the modulation, where T12 and T13 signals are combined with the multi-channel signals and the trap function. The Output level Selection allows the user to define the output level at the output pin for the passive state (inverted level for the active state). It is recommended to configure this block in a way that an external power switch is switched off while the CCU6 delivers an output signal in the passive state.

25.2.4.1 Dead-Time Generation

The generation of (complementary) signals for the high-side and the low-side switches of one power inverter phase is based on the same compare channel. For example, if the high-side switch should be active while the T12 counter value is above the compare value (State Bit = 1), then the low-side switch should be active while the counter value is below the compare value (State Bit = 0).

In most cases, the switching behavior of the connected power switches is not symmetrical concerning the switch-on and switch-off times. A general problem arises if the time for switch-on is smaller than the time for switch-off of the power device. In this case, a short-circuit can occur in the inverter bridge leg, which may damage the complete system. In order to solve this problem by HW, this capture/compare unit

contains a programmable Dead-Time Generation Block, that delays the passive to active edge of the switching signals by a programmable time (the active to passive edge is not delayed).

The Dead-Time Generation Block, illustrated in **Figure 25-16**, is built in a similar way for all three channels of T12. It is controlled by bits in register **T12DTC**. Any change of a CC6xST State Bit activates the corresponding Dead-Time Counter, that is clocked with the same input clock as T12 (f_{T12}). The length of the dead-time can be programmed by bit field DTM. This value is identical for all three channels. Writing **TCTR4**.DTRES = 1 sets all dead-times to passive.

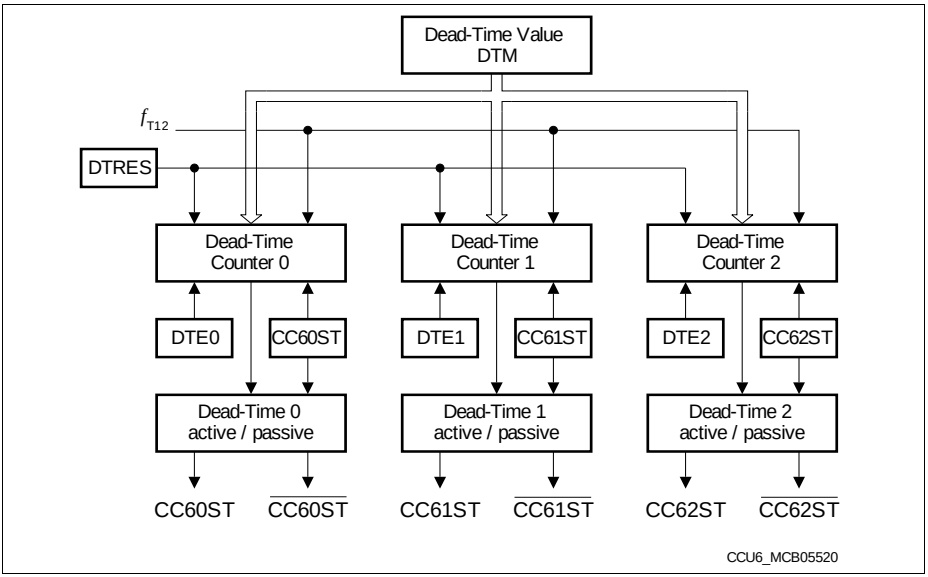

Figure 25-16 Dead-Time Generation Block Diagram

Each of the three dead-time counters has its individual dead-time enable bit, DTEx. An enabled dead-time counter generates a dead-time delaying the passive-to-active edge of the channel output signal. The change in a State Bit CC6xST is not taken into account while the dead-time generation of this channel is currently in progress (active). This avoids an unintentional additional dead-time if a State Bit CC6xST changes too early.
A disabled dead-time counter is always considered as passive and does not delay any edge of CC6xST.
Based on the State Bits CC6xST, the Dead-Time Generation Block outputs a direct signal CC6xST and an inverted signal $\overline{CC6xST}$ for each compare channel, each masked with the effect of the related Dead-Time Counters (waveforms illustrated in **Figure 25-17**).

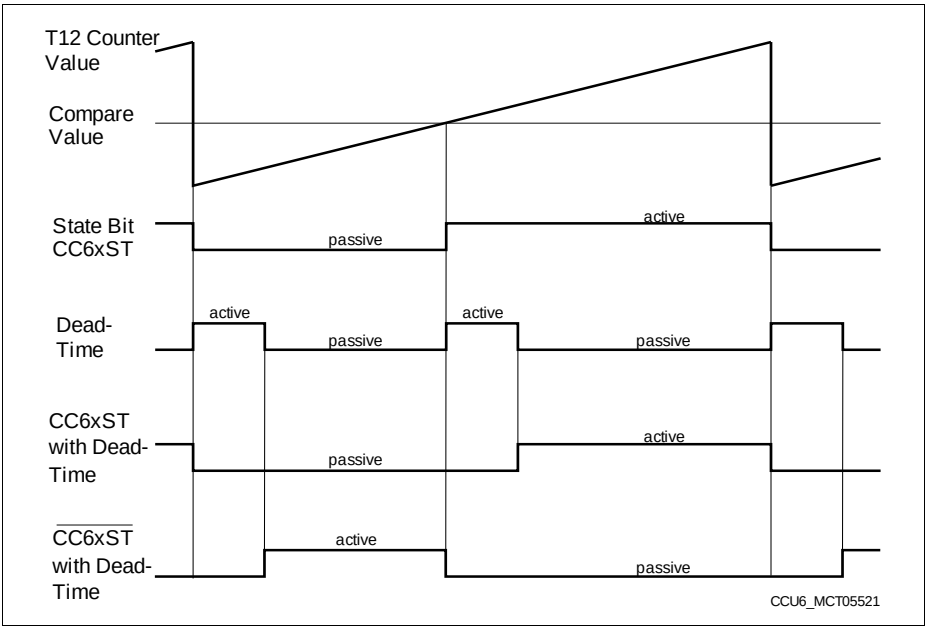

Figure 25-17 Dead-Time Generation Waveforms

25.2.4.2 State Selection

To support a wide range of power switches and drivers, the state selection offers the flexibility to define when an output can be active and can be modulated, especially useful for **complementary or multi-phase PWM** signals.

The state selection is based on the signals CC6xST and $\overline{\text{CC6xST}}$ delivered by the dead-time generator (see **Figure 25-15**). Both signals are never active at the same time, but can be passive at the same time. This happens during the dead-time of each compare channel after a change of the corresponding State Bit CC6xST.

The user can select independently for each output signal CC6xO and COUT6xO if it should be active before or after the compare value has been reached (see register **CMPSTAT**). With this selection, the active (conducting) phases of complementary power switches in a power inverter bridge leg can be positioned with respect to the compare value (e.g. signal CC6xO can be active before, whereas COUT6xO can be active after the compare value is reached). Like this, the output modulation, the trap logic and the output level selection can be programmed independently for each output signal, although two output signals are referring to the same compare channel.

25.2.4.3 Output Modulation and Level Selection

The last block of the data path is the Output Modulation block. Here, all the modulation sources and the trap functionality are combined and control the actual level of the output pins (controlled by the modulation enable bits T1xMODENy and MCMEN in register **MODCTR**). The following signal sources can be combined here **for each T12 output signal** (see **Figure 25-18** for compare channel CC60):

- A **T12 related compare signal** CC6x_O (for outputs CC6x) or COUT6x_O (for outputs COUT6x) delivered by the T12 block (state selection with dead-time) with an individual enable bit T12MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- The **T13 related compare signal** CC63_O delivered by the T13 state selection with an individual enable bit T13MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- A **multi-channel output signal** MCMPy (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x) with a common enable bit MCMEN
- The **trap state** TRPS with an individual enable bit TRPENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)

If one of the modulation input signals CC6x_O/COUT6x_O, CC63_O, or MCMPy of an output modulation block is enabled and is at passive state, the modulated is also in passive state, regardless of the state of the other signals that are enabled. Only if all enabled signals are in active state the modulated output shows an active state. If no modulation input is enabled, the output is in passive state.
If the Trap State is active (TRPS = 1), then the outputs that are enabled for the trap signal (by TRPENy = 1) are set to the passive state.

The output of each of the modulation control blocks is connected to a level select block that is configured by register **PSLR**. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit PSLy. If the modulated output signal is in the passive state, the level specified directly by PSLy is output. If it is in the active state, the inverted level of PSLy is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSLy bits have shadow registers to allow for updates without undesired pulses on the output lines. The bits related to CC6x and COUT6x (x = 0, 1, 2) are updated with the T12 shadow transfer signal (T12_ST). A read action returns the actually used values, whereas a write action targets the shadow bits. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Figure 25-18 shows the output modulation structure for compare channel CC60 (output signals CC60 and COUT60). A similar structure is implemented for the other two compare channels CC61 and CC62.

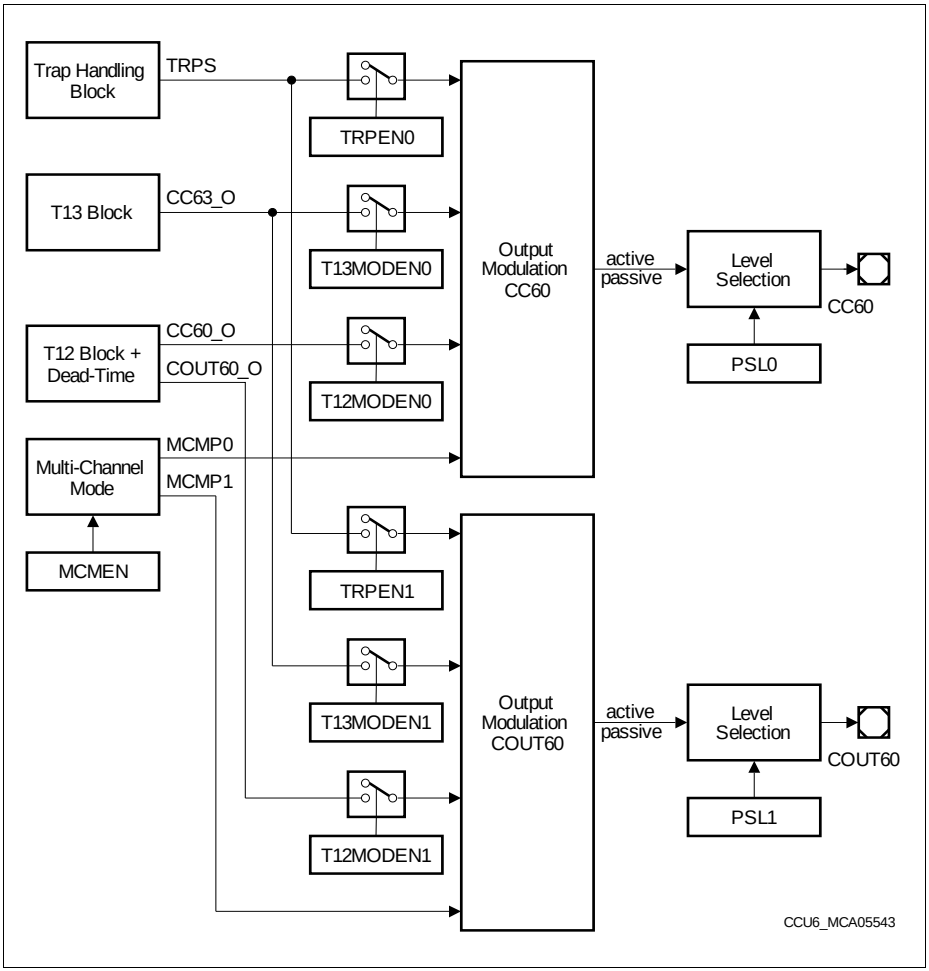

Figure 25-18 Output Modulation for Compare Channel CC60

25.2.5 T12 Capture Modes

Each of the three channels of the T12 Block can also be used to capture T12 time information in response to an external signal CC6xIN.
In capture mode, the interrupt event CC6x_R is detected when a rising edge is detected at the input CC6xIN, whereas the interrupt event CC6x_F is detected when a falling edge is detected.

There are a number of different modes for capture operation. In all modes, both of the registers of a channel are used. The selection of the capture modes is done via the **T12MSEL**.MSEL6x bit fields and can be selected individually for each of the channels.

Table 25-3 Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	CC6nSR Stored in	T12 Stored in
0100_B	1	CC6xIN	Rising	–	CC6xR
		CC6xIN	Falling	–	CC6xSR
0101_B	2	CC6xIN	Rising	CC6xR	CC6xSR
0110_B	3	CC6xIN	Falling	CC6xR	CC6xSR
0111_B	4	CC6xIN	Any	CC6xR	CC6xSR

Figure 25-19 illustrates **Capture Mode 1**. When a rising edge (0-to-1 transition) is detected at the corresponding input signal CC6xIN, the current contents of Timer T12 are captured into register CC6xR. When a falling edge (1-to-0 transition) is detected at the input signal CC6xIN, the contents of Timer T12 are captured into register CC6xSR.

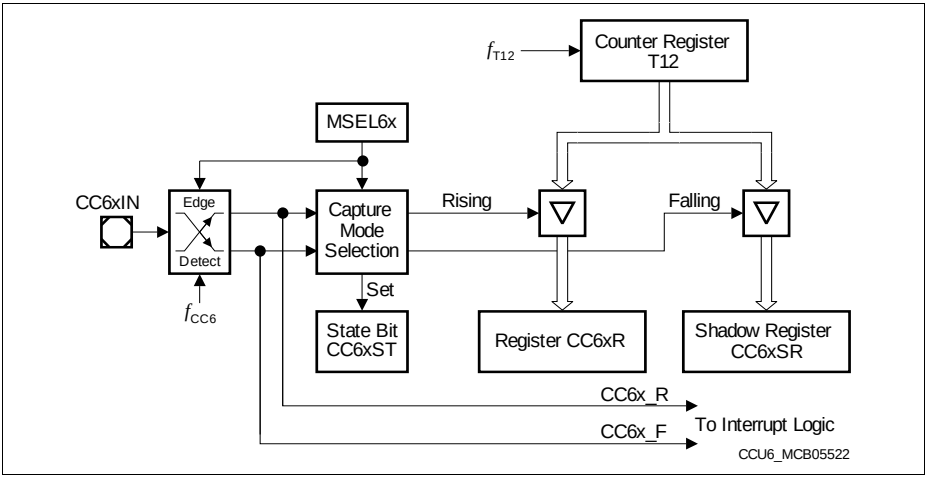

Figure 25-19 Capture Mode 1 Block Diagram

Capture Modes 2, 3 and 4 are shown in **Figure 25-20**. They differ only in the active edge causing the capture operation. In each of the three modes, when the selected edge is detected at the corresponding input signal CC6xIN, the current contents of the shadow register CC6xSR are transferred into register CC6xR, and the current Timer T12 contents are captured in register CC6xSR (simultaneous transfer). The active edge is a rising edge of CC6xIN for Capture Mode 2, a falling edge for Mode 3, and both, a rising or a falling edge for Capture Mode 4, as shown in **Table 25-3**. These capture modes are very useful in cases where there is little time between two consecutive edges of the input signal.

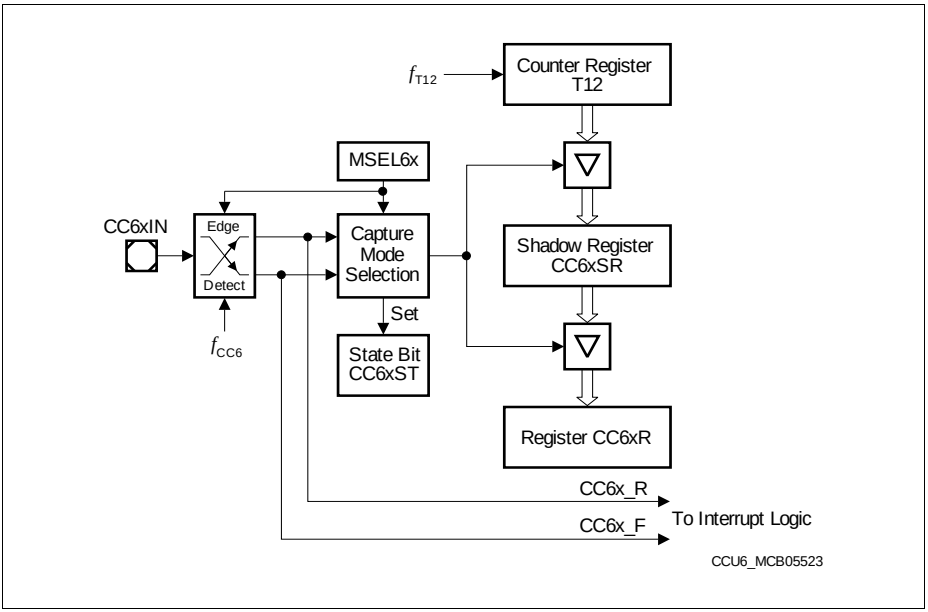

Figure 25-20 Capture Modes 2, 3 and 4 Block Diagram

Five further capture modes are called **Multi-Input Capture Modes**, as they use two different external inputs, signal CC6xIN and signal CCPOSx.

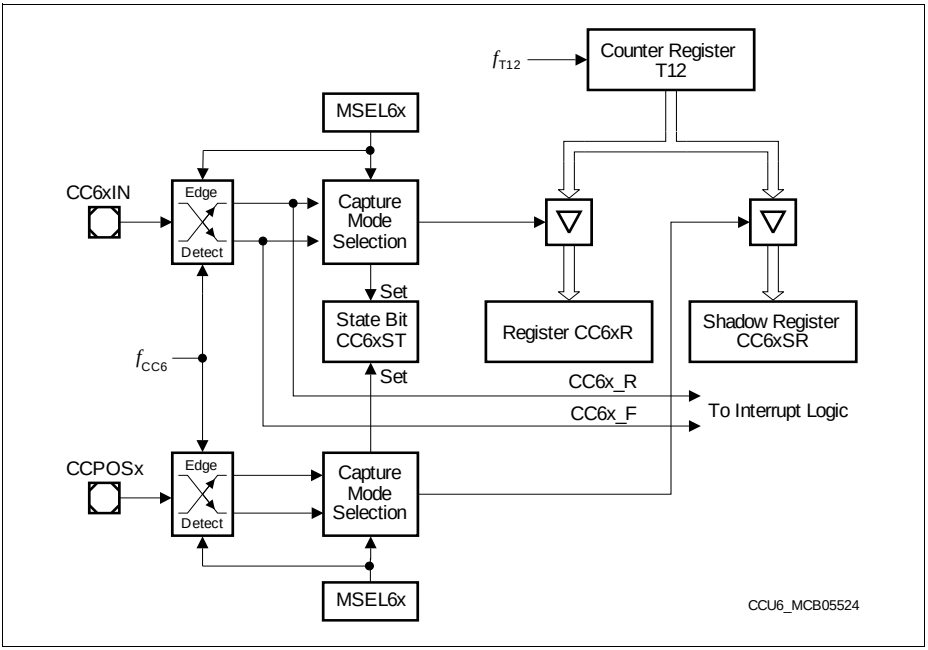

Figure 25-21 Multi-Input Capture Modes Block Diagram

In each of these modes, the current T12 contents are captured in register CC6xR in response to a selected event at signal CC6xIN, and in register CC6xSR in response to a selected event at signal CCPOSx. The possible events can be opposite input transitions, or the same transitions, or any transition at the two inputs. The different options are detailed in **Table 25-4**.

In each of the various capture modes, the Channel State Bit, CC6xST, is set to 1 when the selected capture trigger event at signal CC6xIN or CCPOSx has occurred. The State Bit is not cleared by hardware, but can be cleared by software.

In addition, appropriate signal lines to the interrupt logic are activated, that can generate an interrupt request to the CPU. Regardless of the selected active edge, all edges detected at signal CC6xIN can lead to the activation of the appropriate interrupt request line (see also **Section 25.9**).

Table 25-4 Multi-Input Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	T12 Stored in
1010_B	5	CC6xIN	Rising	CC6xR
		CCPOSx	Falling	CC6xSR
1011_B	6	CC6xIN	Falling	CC6xR
		CCPOSx	Rising	CC6xSR
1100_B	7	CC6xIN	Rising	CC6xR
		CCPOSx	Rising	CC6xSR
1101_B	8	CC6xIN	Falling	CC6xR
		CCPOSx	Falling	CC6xSR
1110_B	9	CC6xIN	Any	CC6xR
		CCPOSx	Any	CC6xSR
1111_B	–	reserved (no capture or compare action)		

25.2.6 T12 Shadow Register Transfer

A special shadow transfer signal (T12_ST) can be generated to facilitate updating the period and compare values of the compare channels CC60, CC61, and CC62 synchronously to the operation of T12. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0**.STE12 (set by writing 1 to the write-only bit **TCTR4**.T12STR, cleared by writing 1 to the write-only bit **TCTR4**.T12STD).

Figure 25-22 shows the shadow register structure and the shadow transfer signals, as well as on the read/write accessibility of the various registers.

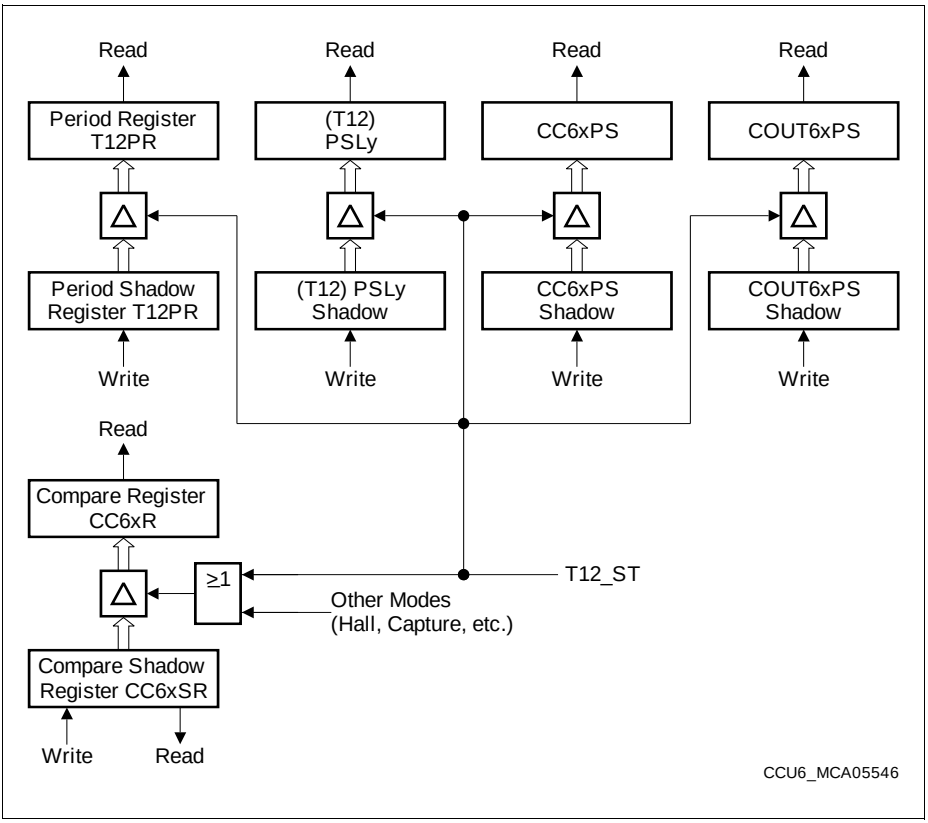

Figure 25-22 T12 Shadow Register Overview

A T12 shadow register transfer takes place (T12_ST active):

- while timer T12 is not running (T12R = 0), or
- STE12 = 1 and a Period-Match is detected while counting up, or
- STE12 = 1 and a One-Match is detected while counting down

When signal T12_ST is active, a shadow register transfer is triggered with the next cycle of the T12 clock. Bit STE12 is automatically cleared with the shadow register transfer.

25.2.7 Timer T12 Operating Mode Selection

The operating mode for the T12 channels are defined by the bit fields **T12MSEL**.MSEL6x.

Table 25-5 T12 Capture/Compare Modes Overview

MSEL6x	Selected Operating Mode
0000_B, 1111_B	Capture/Compare modes switched off
0001_B, 0010_B, 0011_B	Compare mode, see **Section 25.2.3** same behavior for all three codings
$01XX_B$	Double-Register Capture modes, see **Section 25.2.5**
1000_B	Hall Sensor Mode, see **Section 25.7** In order to properly enable this mode, all three MSEL6x fields have to be programmed to Hall Sensor mode.
1001_B	Hysteresis-like compare mode, see **Section 25.2.3.3**
1010_B 1011_B, 1100_B, 1101_B 1110_B	Multi-Input Capture modes, see **Section 25.2.5**

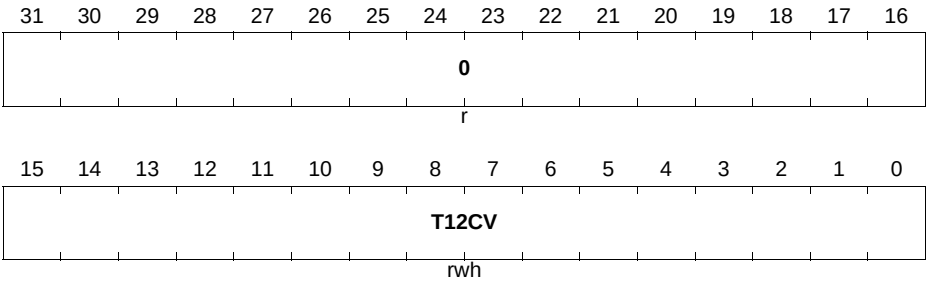
The clocking and counting scheme of the timers are controlled by the timer control registers **TCTR0** and **TCTR2**. Specific actions are triggered by write operations to register **TCTR4**.

25.2.8 T12 related Registers

25.2.8.1 T12 Counter Register

Register T12 represents the counting value of timer T12. It can only be written while the timer T12 is stopped. Write actions while T12 is running are not taken into account. Register T12 can always be read by SW.
In edge-aligned mode, T12 only counts up, whereas in center-aligned mode, T12 can count up and down.

T12
Timer T12 Counter Register **(20_H)** **Reset Value: 0000 0000_H**



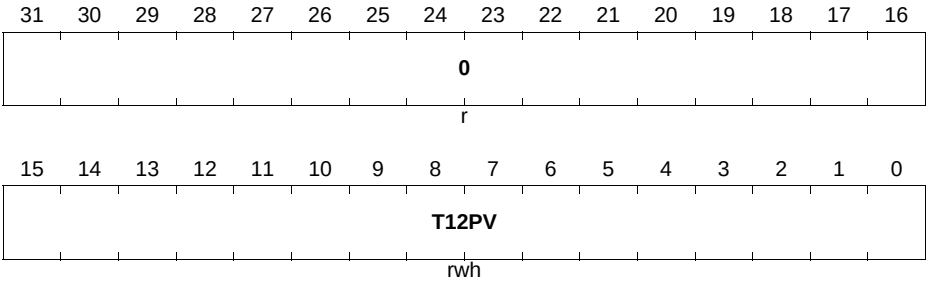
Field	Bits	Type	Description
T12CV	[15:0]	rwh	**Timer 12 Counter Value** This register represents the 16-bit counter value of Timer12.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

Note: While timer T12 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

25.2.8.2 Period Register

Register T12PR contains the period value for timer T12. The period value is compared to the actual counter value of T12 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE12. A read action by SW delivers the value that is currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T12-related values.

T12PR
Timer 12 Period Register **(24_H)** **Reset Value: 0000 0000_H**



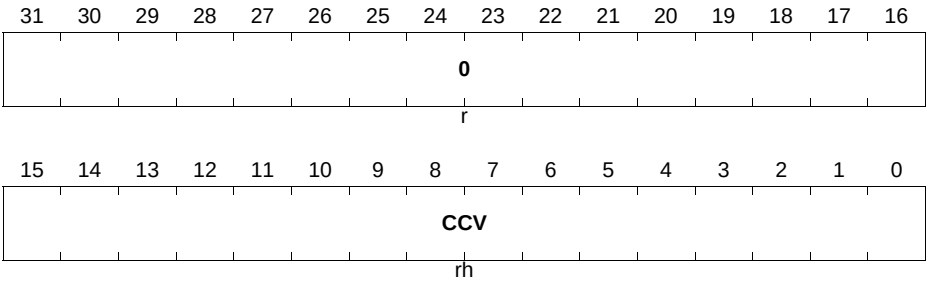
Field	Bits	Type	Description
T12PV	[15:0]	rwh	**T12 Period Value** The value T12PV defines the counter value for T12 leading to a period-match. When reaching this value, the timerT12 is set to zero (edge-aligned mode) or changes its count direction to down counting (center-aligned mode).
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.2.8.3 Capture/Compare Registers

In compare mode, the registers CC6xR (x = 0 - 2) are the actual compare registers for T12. The values stored in CC6xR are compared (all three channels in parallel) to the counter value of T12. In capture mode, the current value of the T12 counter register is captured by registers CC6xR if the corresponding capture event is detected.

CC6xR (x = 0-2)
Capture/Compare Register for Channel CC6x

(30_H + 4*x) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CCV	[15:0]	rh	**Capture/Compare Value** In compare mode, the bit fields CCV contain the values, that are compared to the T12 counter value. In capture mode, the captured value of T12 can be read from these registers.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.2.8.4 Capture/Compare Shadow Registers

The registers CC6xR can only be read by SW, the modification of the value is done by a shadow register transfer from register CC6xSR. The corresponding shadow registers CC6xSR can be read and written by SW. In capture mode, the value of the T12 counter register can also be captured by registers CC6xSR if the selected capture event is detected (depending on the selected capture mode).

CC6xSR (x=0-2)
Capture/Compare Shadow Reg. for Channel CC6x (40_H+4*x) **Reset Value: 0000 0000_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCS															
rwh															

Field	Bits	Type	Description
CCS	[15:0]	rwh	**Shadow Register for Channel x Capture/Compare Value** In compare mode, the bit fields contents of CCS are transferred to the bit fields CCV for the corresponding channel during a shadow transfer. In capture mode, the captured value of T12 can be read from these registers.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

Note: The shadow registers can also be written by SW in capture mode. In this case, the HW capture event wins over the SW write if both happen in the same cycle (the SW write is discarded).

25.2.8.5 Dead-time Control Register

Register T12DTC controls the dead-time generation for the timer T12 compare channels. Each channel can be independently enabled/disabled for dead-time generation. If enabled, the transition from passive state to active state is delayed by the value defined by bit field DTM.
The dead time counters are clocked with the same frequency as T12.
This structure allows symmetrical dead-time generation in center-aligned and in edge-aligned PWM mode. A duty cycle of 50% leads to CC6x, COUT6x switched on for: 0.5 * period - dead time.

Note: The dead-time counters are not reset by bit T12RES, but by bit DTRES.

T12DTC
Dead-Time Control Register for Timer12

(28_H) **Reset Value: 0000 0000$_H$**

r	rh	rh	rh	r	rw	rw	rw	rw							

Field	Bits	Type	Description
DTM	[7:0]	rw	**Dead-Time** Bit field DTM determines the programmable delay between switching from the passive state to the active state of the selected outputs. The switching from the active state to the passive state is not delayed.
DTE2, DTE1, DTE0	10, 9, 8	rw	**Dead Time Enable Bits** Bits DTE0..DTE2 enable and disable the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is disabled. The corresponding outputs switch from the passive state to the active state (according to the actual compare status) without any delay. 1_B Dead-Time Counter x is enabled. The corresponding outputs switch from the passive state to the active state (according to the compare status) with the delay programmed in bit field DTM.
DTR2, DTR1, DTR0	14, 13, 12	rh	**Dead Time Run Indication Bits** Bits DTR0..DTR2 indicate the status of the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is currently in the passive state. 1_B Dead-Time Counter x is currently in the active state.
0	11, [31:15]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.2.9 Capture/Compare Control Registers

25.2.9.1 Channel State Bits

The Compare State Register CMPSTAT contains status bits monitoring the current capture and compare state and control bits defining the active/passive state of the compare channels.

CMPSTAT
Compare State Register **(60_H)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
CC60ST, CC61ST, CC62ST, CC63ST [1]	0, 1, 2, 6	rh	**Capture/Compare State Bits** Bits CC6xST monitor the state of the capture/compare channels. Bits CC6xST (x = 0, 1, 2) are related to T12, bit CC63ST is related to T13. 0_B In compare mode, the timer count is less than the compare value. In capture mode, the selected edge has not yet been detected since the bit has been cleared by SW the last time. 1_B In compare mode, the counter value is greater than or equal to the compare value. In capture mode, the selected edge has been detected.
CCPOS60, CCPOS61, CCPOS62	3, 4, 5	rh	**Sampled Hall Pattern Bits** Bits CCPOS6x (x = 0, 1, 2) are indicating the value of the input Hall pattern that has been compared to the current and expected value. The value is sampled when the event HCRDY (Hall Compare Ready) occurs. 0_B The input CCPOSx has been sampled as 0. 1_B The input CCPOSx has been sampled as 1.
CC60PS, CC61PS, CC62PS, COUT60PS, COUT61PS, COUT62PS, COUT63PS [2]	8, 10, 12, 9, 11, 13, 14	rwh	**Passive State Select for Compare Outputs** Bits CC6xPS, COUT6xPS select the state of the corresponding compare channel, that is considered to be the passive state. During the passive state, the passive level (defined in register PSLR) is driven by the output pin. Bits CC6xPS, COUT6xPS (x = 0, 1, 2) are related to T12, bit CC63PS is related to T13. 0_B The corresponding compare signal is in passive state while CC6xST is 0. 1_B The corresponding compare signal is in passive state while CC6xST is 1. In capture mode, these bits are not used.

Field	Bits	Type	Description
T13IM 3)	15	rwh	**T13 Inverted Modulation** Bit T13IM inverts the T13 signal for the modulation of the CC6x and COUT6x (x = 0, 1, 2) signals. 0_B T13 output CC63_O is equal to CC63ST. 1_B T13 output CC63_O is equal to $\overline{\text{CC63ST}}$.
0	7, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

1) These bits are set and cleared according to the T12, T13 switching rules

2) These bits have shadow bits and are updated in parallel to the capture/compare registers of T12, T13 respectively. A read action targets the actually used values, whereas a write action targets the shadow bits.

3) This bit has a shadow bit and is updated in parallel to the compare and period registers of T13. A read action targets the actually used values, whereas a write action targets the shadow bit.

The Compare Status Modification Register CMPMODIF provides software-control (independent set and clear conditions) for the channel state bits CC6xST. This feature enables the user to individually change the status of the output lines by software, for example when the corresponding compare timer is stopped.

CMPMODIF
Compare State Modification Register

(64_H) **Reset Value: 0000 0000_H**

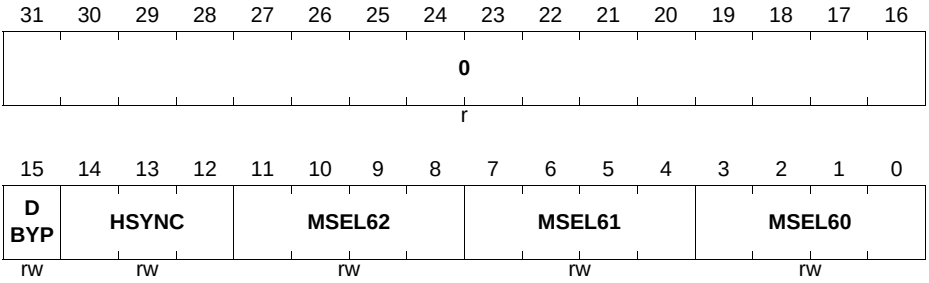
This feature allows the user to individually change the status of the output lines by SW, e.g. when the corresponding compare timer is stopped. This allows a bit manipulation of CC6xST-bits by a single data write action. The following functionality of a write access to bits concerning the same capture/compare state bit is provided: [MCC6xR, MCC6xS] = 00_B Bit CC6xST is not changed. 01_B Bit CC6xST is set. 10_B Bit CC6xST is cleared. 11_B reserved
0	[5:3], 7, [13:11], [31:15]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.2.9.2 T12 Mode Control Register

Register T12MSEL contains control bits to select the capture/compare functionality of the three channels of Timer T12.

T12MSEL
T12 Mode Select Register **(68_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
MSEL60, MSEL61, MSEL62	[3:0], [7:4], [11:8]	rw	**Capture/Compare Mode Selection** These bit fields select the operating mode of the three T12 capture/compare channels. Each channel (x = 0, 1, 2) can be programmed individually for one of these modes (except for Hall Sensor Mode). Coding see **Table 25-5**.
HSYNC	[14:12]	rw	**Hall Synchronization** Bit field HSYNC defines the source for the sampling of the Hall input pattern and the comparison to the current and the expected Hall pattern bit fields. Coding see **Table 25-11**.
DBYP	15	rw	**Delay Bypass** DBYP controls whether the source signal for the sampling of the Hall input pattern (selected by HSYNC) is delayed by the Dead-Time Counter 0. 0_B The bypass is not active. Dead-Time Counter 0 is generating a delay after the source signal becomes active. 1_B The bypass is active. Dead-Time Counter 0 is not used for a delay.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.2.9.3 Timer Control Registers

Register TCTR0 controls the basic functionality of both timers, T12 and T13.

Note: A write action to the bit fields T12CLK or T12PRE is only taken into account while the timer T12 is not running (T12R=0). A write action to the bit fields T13CLK or T13PRE is only taken into account while the timer T13 is not running (T13R=0).

TCTR0
Timer Control Register 0 **(70_H)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
T12CLK	[2:0]	rw	**Timer T12 Input Clock Select** Selects the input clock for timer T12 that is derived from the peripheral clock according to the equation $f_{T12} = f_{CC6} / 2^{<T12CLK>}$. 000_B $f_{T12} = f_{CC6}$ 001_B $f_{T12} = f_{CC6} / 2$ 010_B $f_{T12} = f_{CC6} / 4$ 011_B $f_{T12} = f_{CC6} / 8$ 100_B $f_{T12} = f_{CC6} / 16$ 101_B $f_{T12} = f_{CC6} / 32$ 110_B $f_{T12} = f_{CC6} / 64$ 111_B $f_{T12} = f_{CC6} / 128$
T12PRE	3	rw	**Timer T12 Prescaler Bit** In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T12. 0_B The additional prescaler for T12 is disabled. 1_B The additional prescaler for T12 is enabled.

Field	Bits	Type	Description
T12R	4	rh	**Timer T12 Run Bit[1)]** T12R starts and stops timer T12. It is set/cleared by SW by setting bits T12RR or T12RS or it is cleared by HW according to the function defined by bit field T12SSC. 0_B Timer T12 is stopped. 1_B Timer T12 is running.
STE12	5	rh	**Timer T12 Shadow Transfer Enable** Bit STE12 enables or disables the shadow transfer of the T12 period value, the compare values and passive state select bits and levels from their shadow registers to the actual registers if a T12 shadow transfer event is detected. Bit STE12 is cleared by hardware after the shadow transfer. A T12 shadow transfer event is a period-match while counting up or a one-match while counting down. 0_B The shadow register transfer is disabled. 1_B The shadow register transfer is enabled.
CDIR	6	rh	**Count Direction of Timer T12** This bit is set/cleared according to the counting rules of T12. 0_B T12 counts up. 1_B T12 counts down.
CTM	7	rw	**T12 Operating Mode** 0_B Edge-aligned Mode: T12 always counts up and continues counting from zero after reaching the period value. 1_B Center-aligned Mode: T12 counts down after detecting a period-match and counts up after detecting a one-match.

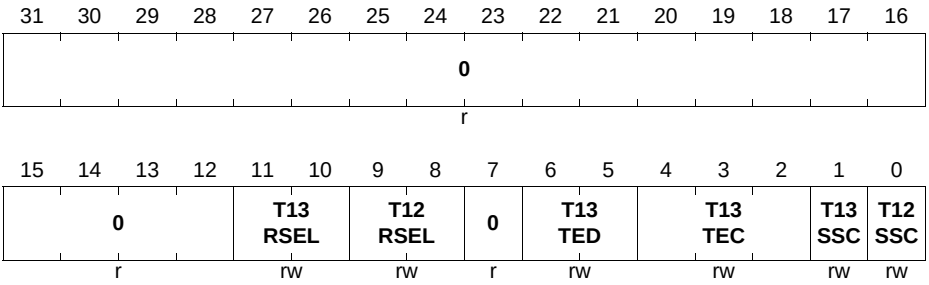
Field	Bits	Type	Description
T13CLK	[10:8]	rw	**Timer T13 Input Clock Select** Selects the input clock for timer T13 that is derived from the peripheral clock according to the equation $f_{T13} = f_{CC6} / 2^{<T13CLK>}$. 000_B $f_{T13} = f_{CC6}$ 001_B $f_{T13} = f_{CC6} / 2$ 010_B $f_{T13} = f_{CC6} / 4$ 011_B $f_{T13} = f_{CC6} / 8$ 100_B $f_{T13} = f_{CC6} / 16$ 101_B $f_{T13} = f_{CC6} / 32$ 110_B $f_{T13} = f_{CC6} / 64$ 111_B $f_{T13} = f_{CC6} / 128$
T13PRE	11	rw	**Timer T13 Prescaler Bit** In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T13. 0_B The additional prescaler for T13 is disabled. 1_B The additional prescaler for T13 is enabled.
T13R	12	rh	**Timer T13 Run Bit**[2)] T13R starts and stops timer T13. It is set/cleared by SW by setting bits T13RR orT13RS or it is set/cleared by HW according to the function defined by bit fields T13SSC, T13TEC and T13TED. 0_B Timer T13 is stopped. 1_B Timer T13 is running.
STE13	13	rh	**Timer T13 Shadow Transfer Enable** Bit STE13 enables or disables the shadow transfer of the T13 period value, the compare value and passive state select bit and level from their shadow registers to the actual registers if a T13 shadow transfer event is detected. Bit STE13 is cleared by hardware after the shadow transfer. A T13 shadow transfer event is a period-match. 0_B The shadow register transfer is disabled. 1_B The shadow register transfer is enabled.
0	[31:14]	r	**Reserved;** Returns 0 if read; should be written with 0.

1) A concurrent set/clear action on T12R (from T12SSC, T12RR or T12RS) will have no effect. The bit T12R will remain unchanged.

2) A concurrent set/cleared action on T13R (from T13SSC, T13TEC, T13RR or T13RS) will have no effect. The bit T12R will remain unchanged.

Register TCTR2 controls the single-shot and the synchronization functionality of both timers T12 and T13. Both timers can run in single-shot mode. In this mode they stop their counting sequence automatically after one counting period with a count value of zero. The single-shot mode and the synchronization feature of T13 to T12 allow the generation of events with a programmable delay after well-defined PWM actions of T12.

TCTR2
Timer Control Register 2 **(74_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
T12SSC	0	rw	**Timer T12 Single Shot Control** This bit controls the single shot-mode of T12. 0_B The single-shot mode is disabled, no HW action on T12R. 1_B The single shot mode is enabled, the bit T12R is cleared by HW if - T12 reaches its period value in edge-aligned mode - T12 reaches the value 1 while down counting in center-aligned mode. In parallel to the clear action of bit T12R, the bits CC6xST (x=0, 1, 2) are cleared.
T13SSC	1	rw	**Timer T13 Single Shot Control** This bit controls the single shot-mode of T13. 0_B No HW action on T13R 1_B The single-shot mode is enabled, the bit T13R is cleared by HW if T13 reaches its period value. In parallel to the clear action of bit T13R, the bit CC63ST is cleared.

Field	Bits	Type	Description
T13TEC	[4:2]	rw	**T13 Trigger Event Control** Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to following combinations: 000_B no action 001_B set T13R on a T12 compare event on channel 0 010_B set T13R on a T12 compare event on channel 1 011_B set T13R on a T12 compare event on channel 2 100_B set T13R on any T12 compare event (ch. 0, 1, 2) 101_B set T13R upon a period-match of T12 110_B set T13R upon a zero-match of T12 (while counting up) 111_B set T13R on any edge of inputs CCPOSx
T13TED	[6:5]	rw	**Timer T13 Trigger Event Direction**[1)] Bit field T13TED delivers additional information to control the automatic set of bit T13R in the case that the trigger action defined by T13TEC is detected. 00_B reserved, no action 01_B while T12 is counting up 10_B while T12 is counting down 11_B independent on the count direction of T12
T12RSEL	[9:8]	rw	**Timer T12 External Run Selection** Bit field T12RSEL defines the event of signal T12HR that can set the run bit T12R by HW. 00_B The external setting of T12R is disabled. 01_B Bit T12R is set if a rising edge of signal T12HR is detected. 10_B Bit T12R is set if a falling edge of signal T12HR is detected. 11_B Bit T12R is set if an edge of signal T12HR is detected.

Field	Bits	Type	Description
T13RSEL	[11:10]	rw	**Timer T13 External Run Selection** Bit field T13RSEL defines the event of signal T13HR that can set the run bit T13R by HW. 00_B The external setting of T13R is disabled. 01_B Bit T13R is set if a rising edge of signal T13HR is detected. 10_B Bit T13R is set if a falling edge of signal T13HR is detected. 11_B Bit T13R is set if an edge of signal T13HR is detected.
0	7, [31:12]	r	**Reserved;** Returns 0 if read; should be written with 0;

1) Example:
If the timer T13 is intended to start at any compare event on T12 (T13TEC=100) the trigger event direction can be programmed to
- counting up >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting up
- counting down >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting down
- independent from bit CDIR >> each T12 channel 0, 1, 2 compare match triggers T13R

The timer count direction is taken from the value of bit CDIR. As a result, if T12 is running in edge-aligned mode (counting up only), T13 can only be started automatically if bit field T13TED=01 or 11.

Register TCTR4 provides software-control (independent set and clear conditions) for the run bits T12R and T13R. Furthermore, the timers can be reset (while running) and bits STE12 and STE13 can be controlled by software. Reading these bits always returns 0.

TCTR4
Timer Control Register 4 **(78_H)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
T12RR	0	w	**Timer T12 Run Reset** Setting this bit clears the T12R bit. 0_B T12R is not influenced. 1_B T12R is cleared, T12 stops counting.
T12RS	1	w	**Timer T12 Run Set** Setting this bit sets the T12R bit. 0_B T12R is not influenced. 1_B T12R is set, T12 starts counting.
T12RES	2	w	**Timer T12 Reset** 0_B No effect on T12. 1_B The T12 counter register is cleared to zero. The switching of the output signals is according to the switching rules. Setting of T12RES has no impact on bit T12R.
DTRES	3	w	**Dead-Time Counter Reset** 0_B No effect on the dead-time counters. 1_B The three dead-time counter channels are cleared to zero.
T12CNT	5	w	**Timer T12 Count Event** 0_B No action 1_B If enabled (PISEL2), timer T12 counts one step.

Field	Bits	Type	Description
T12STR	6	w	**Timer T12 Shadow Transfer Request** 0_B No action 1_B STE12 is set, enabling the shadow transfer.
T12STD	7	w	**Timer T12 Shadow Transfer Disable** 0_B No action 1_B STE12 is cleared without triggering the shadow transfer.
T13RR	8	w	**Timer T13 Run Reset** Setting this bit clears the T13R bit. 0_B T13R is not influenced. 1_B T13R is cleared, T13 stops counting.
T13RS	9	w	**Timer T13 Run Set** Setting this bit sets the T13R bit. 0_B T13R is not influenced. 1_B T13R is set, T13 starts counting.
T13RES	10	w	**Timer T13 Reset** 0_B No effect on T13. 1_B The T13 counter register is cleared to zero. The switching of the output signals is according to the switching rules. Setting of T13RES has no impact on bit T13R.
T13CNT	13	w	**Timer T13 Count Event** 0_B No action 1_B If enabled (PISEL2), timer T13 counts one step.
T13STR	14	w	**Timer T13 Shadow Transfer Request** 0_B No action 1_B STE13 is set, enabling the shadow transfer.
T13STD	15	w	**Timer T13 Shadow Transfer Disable** 0_B No action 1_B STE13 is cleared without triggering the shadow transfer.
0	4, [12:11], [31:16]	r	**reserved;** returns 0 if read; should be written with 0;

Note: A simultaneous write of a 1 to bits that set and clear the same bit will trigger no action. The corresponding bit will remain unchanged.

25.3 Operating Timer T13

Timer T13 is implemented similarly to Timer T12, but only with one channel in compare mode. A 16-bit up-counter is connected to a channel register via a comparator, that generates a signal when the counter contents match the contents of the channel register. A variety of control functions facilitate the adaptation of the T13 structure to different application needs. In addition, T13 can be started synchronously to timer T12 events.

This section provides information about:

- T13 overview (see **Section 25.3.1**)
- Counting scheme (see **Section 25.3.2**)
- Compare mode (see **Section 25.3.3**)
- Compare output path (see **Section 25.3.4**)
- Shadow register transfer (see **Section 25.3.5**)
- T13 counter register description (see **Section 25.3.6**)

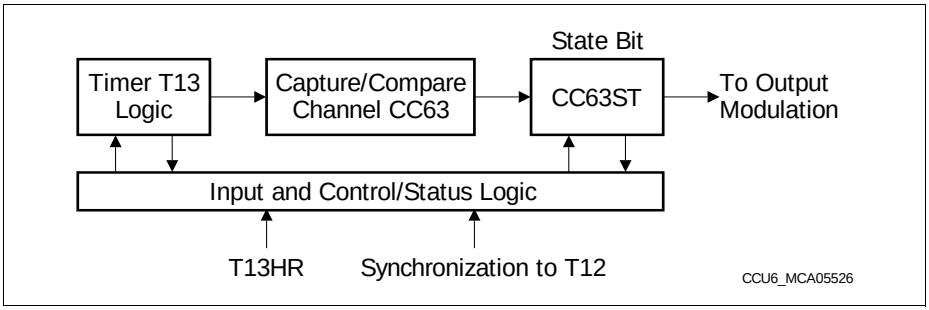

Figure 25-23 Overview Diagram of the Timer T13 Block

25.3.1 T13 Overview

Figure 25-24 shows a detailed block diagram of Timer T13. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISEL2**.
Timer T13 receives its input clock, f_{T13}, from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T13HR. T13 can only count up (similar to the Edge-Aligned mode of T12).

Via a comparator, the timer T13 Counter Register **T13** is connected to the Period Register **T13PR**. This register determines the maximum count value for T13. When T13 reaches the period value, signal T13_PM (T13 Period Match) is generated and T13 is cleared to 0000_H with the next T13 clock edge. The Period Register receives a new period value from its Shadow Period Register, T13PS, that is loaded via software. The transfer of a new period value from the shadow register into T13PR is controlled via the 'T13 Shadow Transfer' control signal, T13_ST. The generation of this signal depends on the associated control bit STE13. Providing a shadow register for the period value as

well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters (refer to **Table 25.3.5**).
Another signal indicates whether the counter contents are equal to 0000_H (T13_ZM).

A Single-Shot control bit, T13SSC, enables an automatic stop of the timer when the current counting period is finished (see **Figure 25-26**).

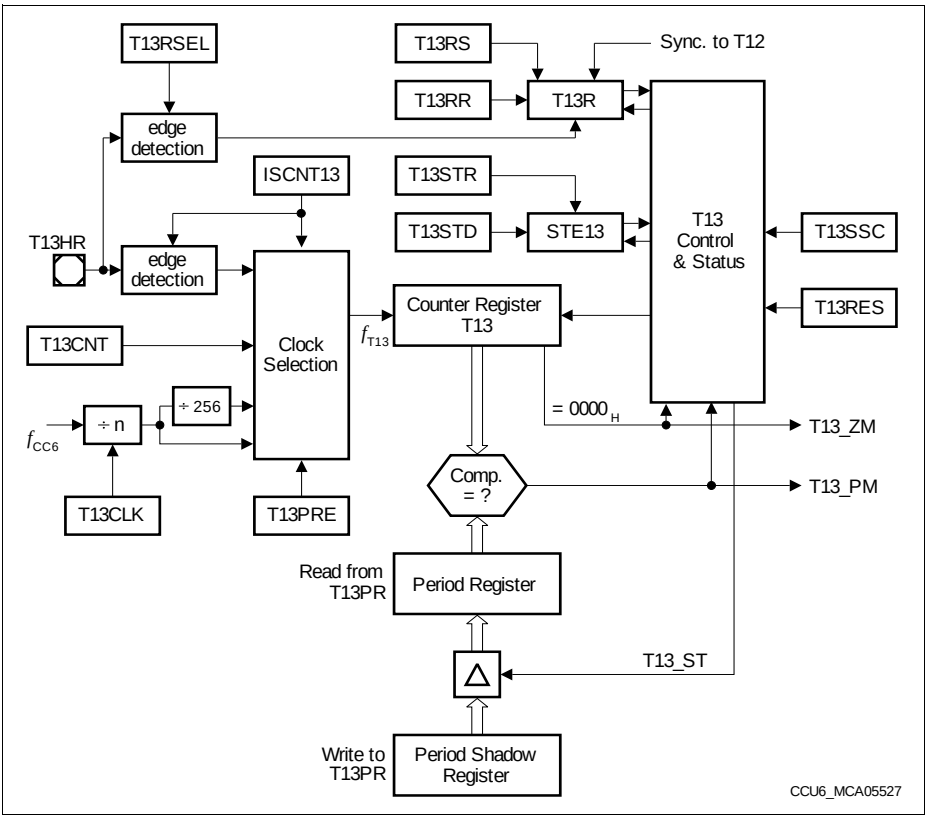

Figure 25-24 T13 Counter Logic and Period Comparators

The start or stop of T13 is controlled by the Run bit, T13R. This control bit can be set by software via the associated set/clear bits T13RS or T13RR in register **TCTR4**, or it is cleared by hardware according to preselected conditions (single-shot mode).
The timer T13 run bit T13R must not be set while the applied T13 period value is zero.
Bit T13R can be set automatically if an event of T12 is detected to synchronize T13 timings to T12 events, e.g. to generate a programmable delay via T13 after an edge of a T12 compare channel before triggering an AD conversion (T13 can trigger ADC

conversions).
Timer T13 can be cleared to 0000_H via control bit T13RES. Setting this write-only bit only clears the timer contents, but has no further effects, e.g., it does not stop the timer.

The generation of the T13 shadow transfer control signal, T13_ST, is enabled via bit STE13. This bit can be set or cleared by software indirectly through its associated set/reset control bits T13STR and T13STD.

Two bit fields, T13TEC and T13TED, control the synchronization of T13 to Timer T12 events. T13TEC selects the trigger event, while T13TED determines for which T12 count direction the trigger should be active.
While Timer T13 is running, write accesses to the count register T13 are not taken into account. If T13 is stopped, write actions to register T13 are immediately taken into account.

Note: The T13 Period Register and its associated shadow register are located at the same physical address. A write access to this address targets the Shadow Register, while a read access reads from the actual period register.

25.3.2 T13 Counting Scheme

This section describes the clocking and the counting capabilities of T13.

25.3.2.1 Clock Selection

In **Timer Mode** (**PISEL2**. ISCNT13 = 00_B), the input clock f_{T13} of Timer T13 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 25-6**. The prescaler of T13 is cleared while T13 is not running (**TCTR0**.T13R = 0) to ensure reproducible timings and delays.

Table 25-6 Timer T13 Input Clock Options

T13CLK	Resulting Input Clock f_{T13} Prescaler Off (T13PRE = 0)	Resulting Input Clock f_{T13} Prescaler On (T13PRE = 1)
000_B	f_{CC6}	f_{CC6} / 256
001_B	f_{CC6} / 2	f_{CC6} / 512
010_B	f_{CC6} / 4	f_{CC6} / 1024
011_B	f_{CC6} / 8	f_{CC6} / 2048
100_B	f_{CC6} / 16	f_{CC6} / 4096
101_B	f_{CC6} / 32	f_{CC6} / 8192
110_B	f_{CC6} / 64	f_{CC6} / 16384
111_B	f_{CC6} / 128	f_{CC6} / 32768

In **Counter Mode**, timer T13 counts one step:

- If a 1 is written to **TCTR4**.T13CNT and **PISEL2**.ISCNT13 = 01_B
- If a rising edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 10_B
- If a falling edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 11_B

25.3.2.2 T13 Counting

The period of the timer is determined by the value in the period Register T13PR according to the following formula:

$T13_{PER}$ = <Period-Value> + 1; in T13 clocks (f_{T13}) (25.3)

Timer T13 can only count up, comparable to the Edge-Aligned mode of T12. This leads to very simple ‘counting rule’ for the T13 counter:

- The counter is cleared with the next T13 clock edge if a Period-Match is detected. The counting direction is always upwards.

The behavior of T13 is illustrated in **Figure 25-25**.

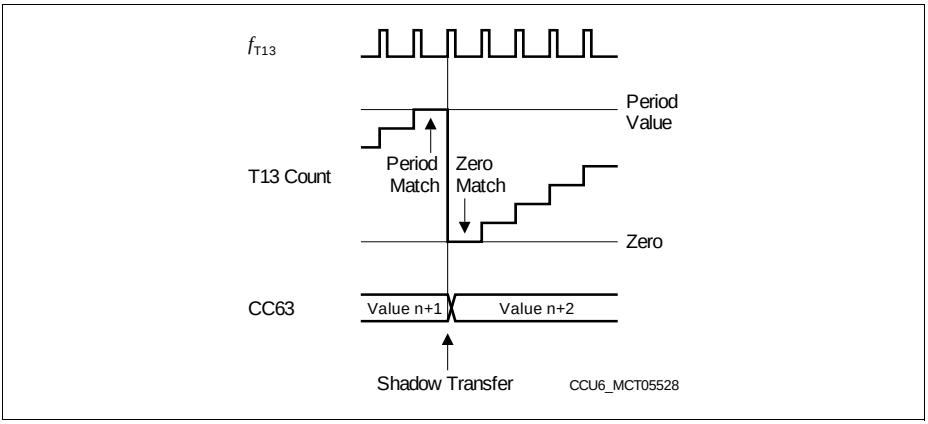

Figure 25-25 T13 Counting Sequence

25.3.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T13R is cleared by hardware. If bit T13SSC = 1, the timer T13 will stop when the current timer period is finished.

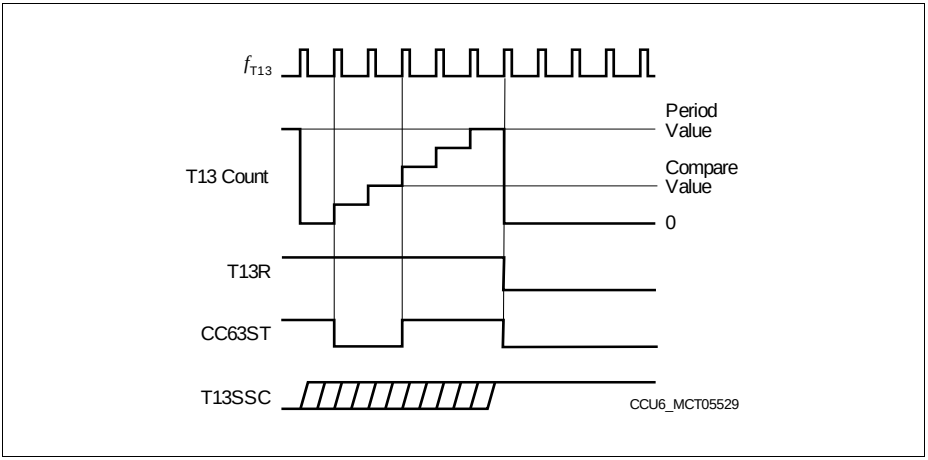

Figure 25-26 Single-Shot Operation of Timer T13

25.3.2.4 Synchronization to T12

Timer T13 can be synchronized to a T12 event. Bit fields T13TEC and T13TED select the event that is used to start Timer T13. The selected event sets bit T13R via HW, and T13 starts counting. Combined with the Single-Shot mode, this feature can be used to generate a programmable delay after a T12 event.

Figure 25-27 shows an example for the synchronization of T13 to a T12 event. Here, the selected event is a compare-match (compare value = 2) while counting up. The clocks of T12 and T13 can be different (other prescaler factor); the figure shows an example in which T13 is clocked with half the frequency of T12.

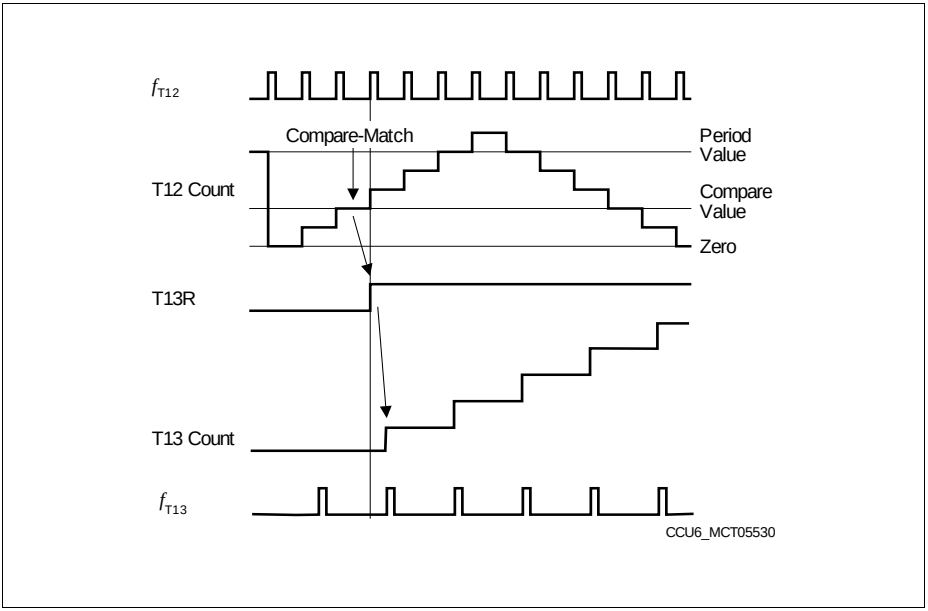

Figure 25-27 Synchronization of T13 to T12 Compare Match

Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to the combinations shown in **Table 25-7**. Bit field T13TED additionally specifies for which count direction of T12 the selected trigger event should be regarded (see **Table 25-8**).

Table 25-7 T12 Trigger Event Selection

T13TEC	Selected Event
000_B	None
001_B	T12 Compare Event on Channel 0 (CM_CC60)
010_B	T12 Compare Event on Channel 1 (CM_CC61)
011_B	T12 Compare Event on Channel 2 (CM_CC62)
100_B	T12 Compare Event on any Channel (0, 1, 2)
101_B	T12 Period-Match (T12_PM)
110_B	T12 Zero-Match while counting up (T12_ZM and CDIR = 0)
111_B	Any Hall State Change

Table 25-8 T12 Trigger Event Additional Specifier

T13TED	Selected Event Specifier
00_B	Reserved, no action
01_B	Selected event is active while T12 is counting up (CDIR = 0)
10_B	Selected event is active while T12 is counting down (CDIR = 1)
11_B	Selected event is active independently of the count direction of T12

25.3.3 T13 Compare Mode

Associated with Timer T13 is one compare channel, that can perform compare operations with regard to the contents of the T13 counter.

Figure 25-23 gives an overview on the T13 channel in Compare Mode. The channel is connected to the T13 counter register via an equal-to comparator, generating a compare match signal when the contents of the counter matches the contents of the compare register.

The channel consists of the comparator and a double register structure - the actual compare register, **CC63R**, feeding the comparator, and an associated shadow register, **CC63SR**, that is preloaded by software and transferred into the compare register when signal T13 shadow transfer, T13_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Associated with the channel is a State Bit, **CMPSTAT**.CC63ST, holding the status of the compare operation. **Figure 25-28** gives an overview on the logic for the State Bit.

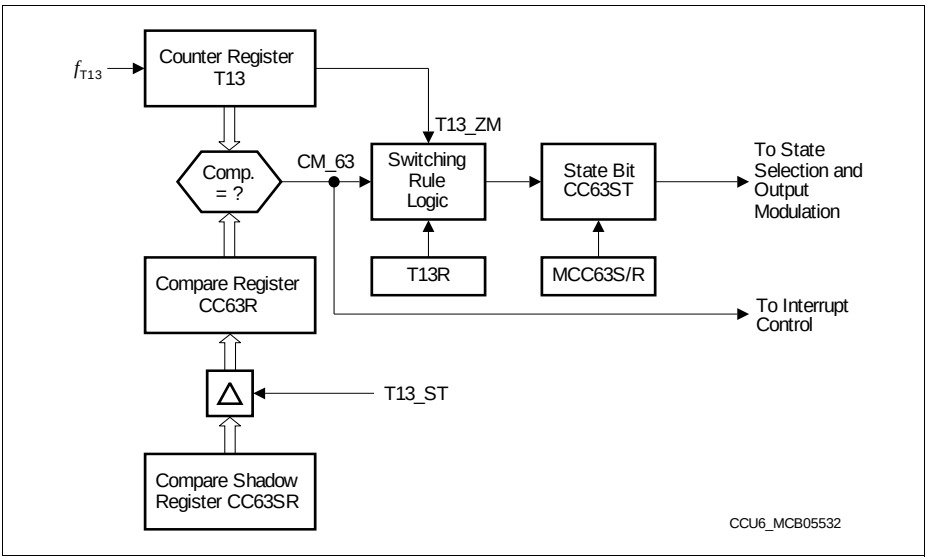

Figure 25-28 T13 State Bit Block Diagram

A compare interrupt event CM_63 is signaled when a compare match is detected. The actual setting of a State Bit has no influence on the interrupt generation.

The inputs to the switching rule logic for the CC63ST bit are the timer run bit (T13R), the timer zero-match signal (T13_ZM), and the actual individual compare-match signal CM_63. In addition, the state bit can be set or cleared by software via bits MCC63S and

MCC63R in register **CMPMODIF**.
A modification of the State Bit CC63ST by hardware is only possible while Timer T13 is running (T13R = 1). If this is the case, the following switching rules apply for setting and resetting the State Bit in Compare Mode:

State Bit **CC63ST is set** to 1

- with the next T13 clock (f_{T13}) after a compare-match (T13 is always counting up) (i.e., when the counter is incremented above the compare value);
- with the next T13 clock (f_{T13}) after a zero-match AND a parallel compare-match.

State Bit **CC63ST is cleared** to 0

- with the next T13 clock (f_{T13}) after a zero-match AND NO parallel compare-match.

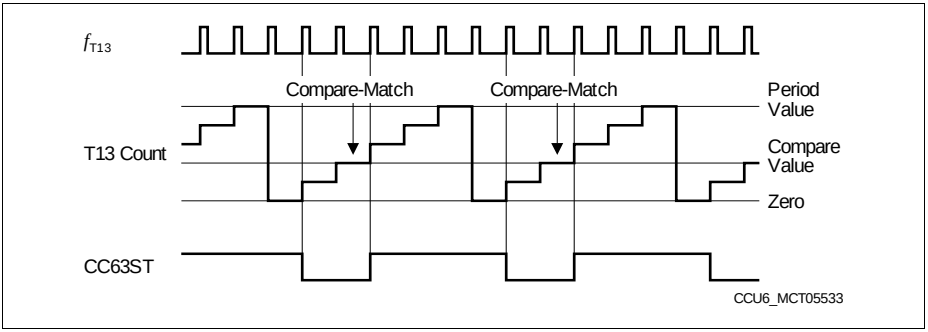

Figure 25-29 T13 Compare Operation

25.3.4 Compare Mode Output Path

Figure 25-30 gives an overview on the signal path from the channel State Bit CC63ST to its output pin COUT63. As illustrated, a user can determine the desired output behavior in relation to the current state of CC63ST. Please refer to **Section 25.2.4.3** for detailed information on the output modulation for T12 signals.

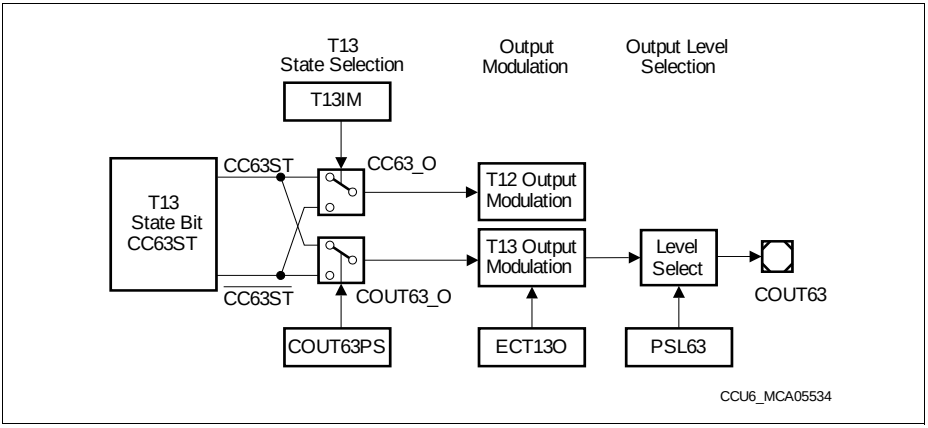

Figure 25-30 Channel 63 Output Path

The output line COUT63_O can generate a T13 PWM at the output pin COUT63. The signal CC63_O can be used to modulate the T12-related output signals with a T13 PWM. In order to decouple COUT63 from the internal modulation, the compare state leading to an active signal can be selected independently by bits T13IM and COUT63PS.

The last block of the data path is the Output Modulation block. Here, the modulation source T13 and the trap functionality are combined and control the actual level of the output pin COUT63 (see **Figure 25-31**):

- The **T13 related compare signal** COUT63_O delivered by the T13 state selection with the enable bit **MODCTR**.ECT13O
- The **trap state** TRPS with an individual enable bit **TRPCTR**.TRPEN13

If the modulation input signal COUT63_O is enabled (ECT13O = 1) and is at passive state, the modulated is also in passive state. If the modulation input is not enabled, the output is in passive state.
If the Trap State is active (TRPS = 1), then the output enabled for the trap signal (by TRPEN13 = 1) is set to the passive state.

The output of the modulation control block is connected to a level select block. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit **PSLR**.PSL63. If the modulated output signal is in the passive

state, the level specified directly by PSL63 is output. If it is in the active state, the inverted level of PSL63 is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSL63 bit has a shadow register to allow for updates with the T13 shadow transfer signal (T13_ST) without undesired pulses on the output lines. A read action returns the actually used value, whereas a write action targets the shadow bit. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

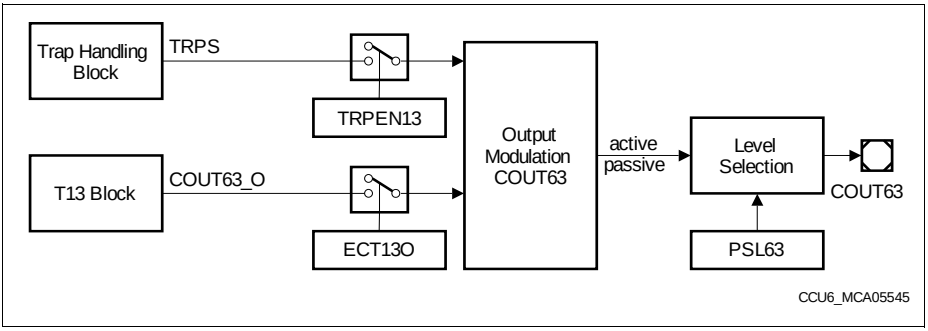

Figure 25-31 T13 Output Modulation

25.3.5 T13 Shadow Register Transfer

A special shadow transfer signal (T13_ST) can be generated to facilitate updating the period and compare values of the compare channel CC63 synchronously to the operation of T13. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0**.STE13 (set by writing 1 to the write-only bit **TCTR4**.T13STR, cleared by writing 1 to the write-only bit **TCTR4**.T13STD).
When signal T13_ST is active, a shadow register transfer is triggered with the next cycle of the T13 clock. Bit STE13 is automatically cleared with the shadow register transfer.
A T13 shadow register transfer takes place (T13_ST active):

- while timer T13 is not running (T13R = 0), or
- STE13 = 1 and a Period-Match is detected while T13R = 1

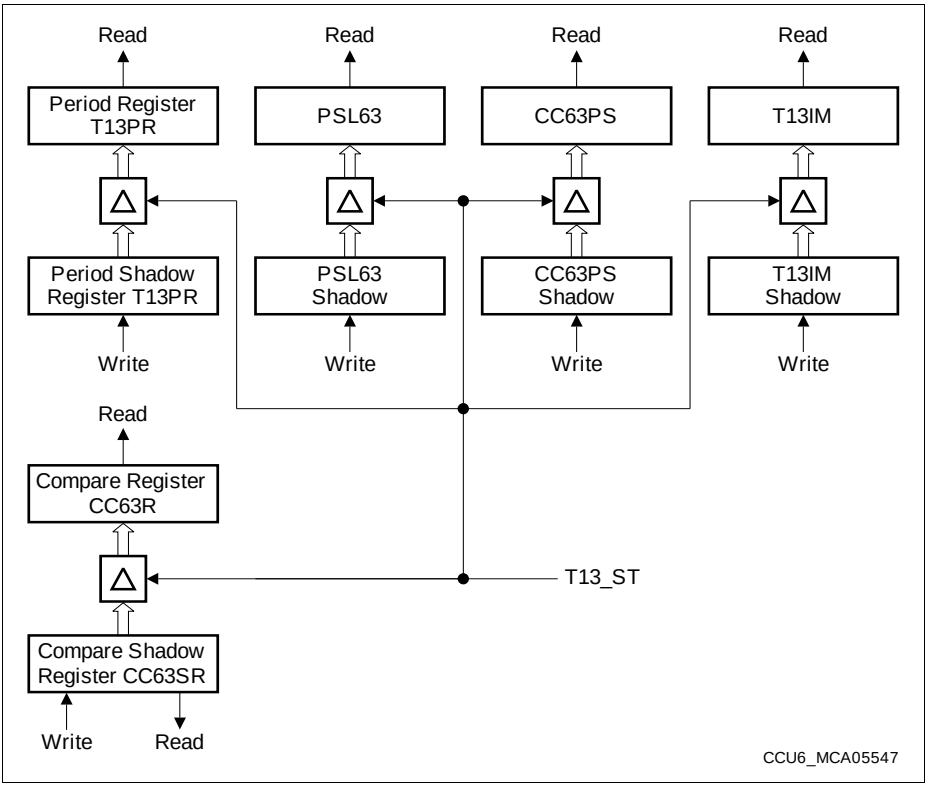

Figure 25-32 T13 Shadow Register Overview

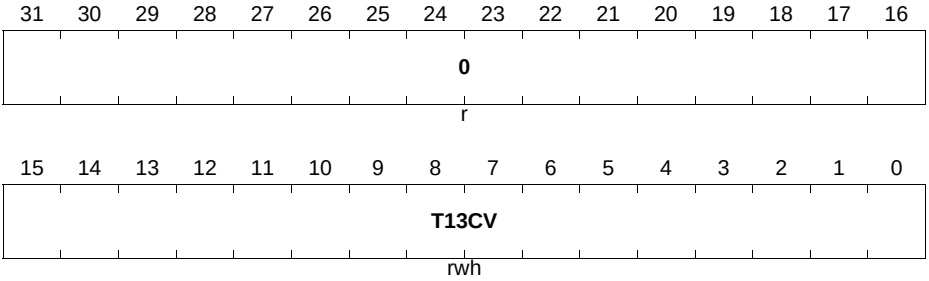
25.3.6 T13 related Registers

25.3.6.1 T13 Counter Register

The generation of the patterns for a single channel pulse width modulation (PWM) is based on timer T13. The registers related to timer T13 can be concurrently updated (with well-defined conditions) in order to ensure consistency of the PWM signal. T13 can be synchronized to several timer T12 events.
Timer T13 only supports compare mode on its compare channel CC63.
Register T13 represents the counting value of timer T13. It can only be written while the timer T13 is stopped. Write actions while T13 is running are not taken into account. Register T13 can always be read by SW.
Timer T13 only supports edge-aligned mode (counting up).

T13
Timer T13 Counter Register **(50_H)** **Reset Value: 0000 0000_H**



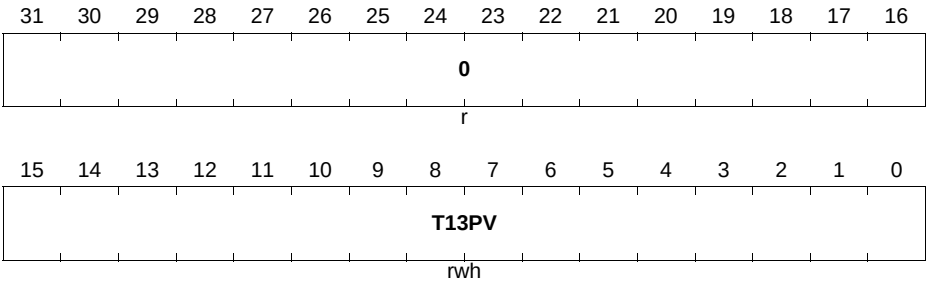
Field	Bits	Type	Description
T13CV	[15:0]	rwh	**Timer 13 Counter Value** This register represents the 16-bit counter value of Timer13.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

Note: While timer T13 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

25.3.6.2 Period Register

Register T13PR contains the period value for timer T13. The period value is compared to the actual counter value of T13 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE13. A read action by SW delivers the value currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T13-related values.

T13PR
Timer 13 Period Register **(54_H)** **Reset Value: 0000 0000_H**

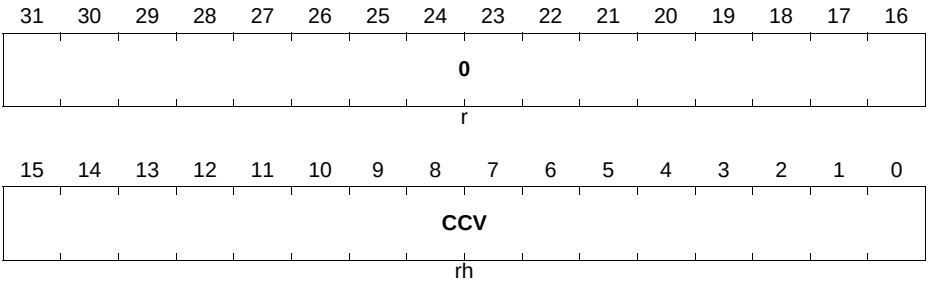


Field	Bits	Type	Description
T13PV	[15:0]	rwh	**T13 Period Value** The value T13PV defines the counter value for T13 leading to a period-match. When reaching this value, the timer T13 is set to zero.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.3.6.3 Compare Register

Registers CC63R is the actual compare register for T13. The values stored in CC63R is compared to the counter value of T13. The State Bit CC63ST is located in register **CMPSTAT**.

CC63R
Compare Register for T13 **(58_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CCV	[15:0]	rh	**Channel CC63 Compare Value** The bit field CCV contains the value, that is compared to the T13 counter value.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.3.6.4 Compare Shadow Register

The register CC63R can only be read by SW, the modification of the value is done by a shadow register transfer from register CC63SR. The corresponding shadow register CC63SR can be read and written by SW.

CC63SR
Compare Shadow Register for T13

($5C_H$) **Reset Value: 0000 0000$_H$**

CCS															
rw															

Field	Bits	Type	Description
CCS	[15:0]	rw	**Shadow Register for Channel CC63 Compare Value** The bit field contents of CCS is transferred to the bit field CCV during a shadow transfer.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.4 Synchronous Start Feature

The T12 and T13 timers can be started synchronously through the T12HR and T13HR inputs of all CCU6x kernels.

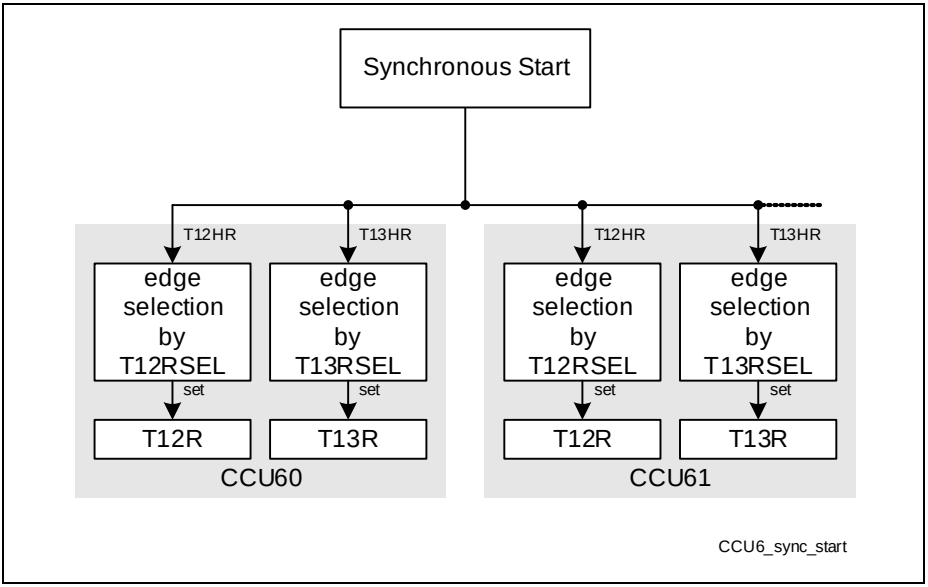

Figure 25-33 Synchronization Concept

25.5 Trap Handling

The trap functionality permits the PWM outputs to react on the state of the input signal CTRAP. This functionality can be used to switch off the power devices if the trap input becomes active (e.g. to perform an emergency stop). The trap handling and the effect on the output modulation are controlled by the bits in the trap control register **TRPCTR**. The trap flags TRPF and TRPS are located in register **IS** and can be set/cleared by SW by writing to registers **ISS** and **ISR**.
Figure 25-34 gives an overview on the trap function.

The Trap Flag TRPF monitors the trap input and initiates the entry into the Trap State. The Trap State Bit TRPS determines the effect on the outputs and controls the exit of the Trap State.
When a trap condition is detected ($\overline{\text{CTRAP}}$ = 0) and the input is enabled (TRPPEN = 1), both, the Trap Flag TRPF and the Trap State Bit TRPS, are set to 1 (trap state active). The output of the Trap State Bit TRPS leads to the Output Modulation Blocks (for T12 and for T13) and can there deactivate the outputs (set them to the passive state). Individual enable control bits for each of the six T12-related outputs and the T13-related output facilitate a flexible adaptation to the application needs.

There are a number of different ways to exit the Trap State. This offers SW the option to select the best operation for the application. Exiting the Trap State can be done either immediately when the trap condition is removed ($\overline{\text{CTRAP}}$ = 1 or TRPPEN = 0), or under software control, or synchronously to the PWM generated by either Timer T12 or Timer T13.

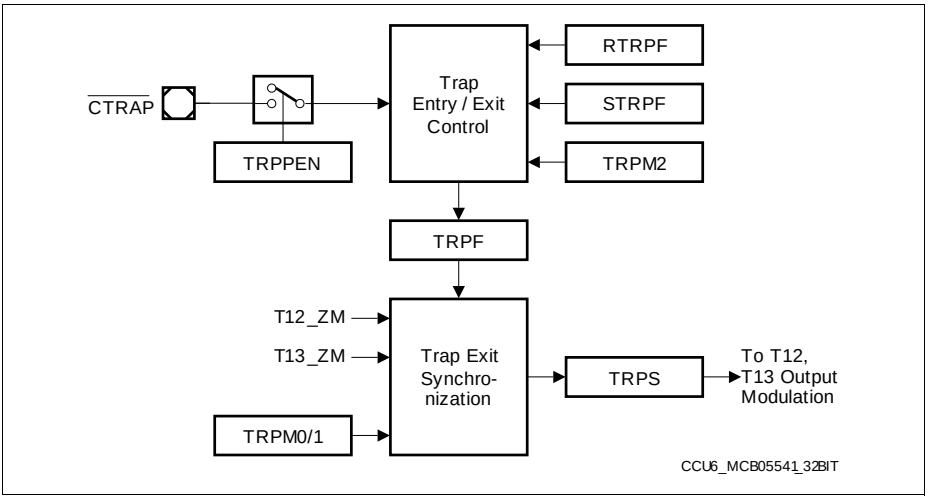

Figure 25-34 Trap Logic Block Diagram

Clearing of TRPF is controlled by the mode control bit TRPM2. If TRPM2 = 0, TRPF is automatically cleared by HW when $\overline{\text{CTRAP}}$ returns to the inactive level ($\overline{\text{CTRAP}}$ = 1) or if the trap input is disabled (TRPPEN = 0). When TRPM2 = 1, TRPF must be reset by SW after $\overline{\text{CTRAP}}$ has become inactive.

Clearing of TRPS is controlled by the mode control bits TRPM1 and TRPM0 (located in the Trap Control Register TRPCTR). A reset of TRPS terminates the Trap State and returns to normal operation. There are three options selected by TRPM1 and TRPM0. One is that the Trap State is left immediately when the Trap Flag TRPF is cleared, without any synchronization to timers T12 or T13. The other two options facilitate the synchronization of the termination of the Trap State to the count periods of either Timer T12 or Timer T13. **Figure 25-35** gives an overview on the associated operation.

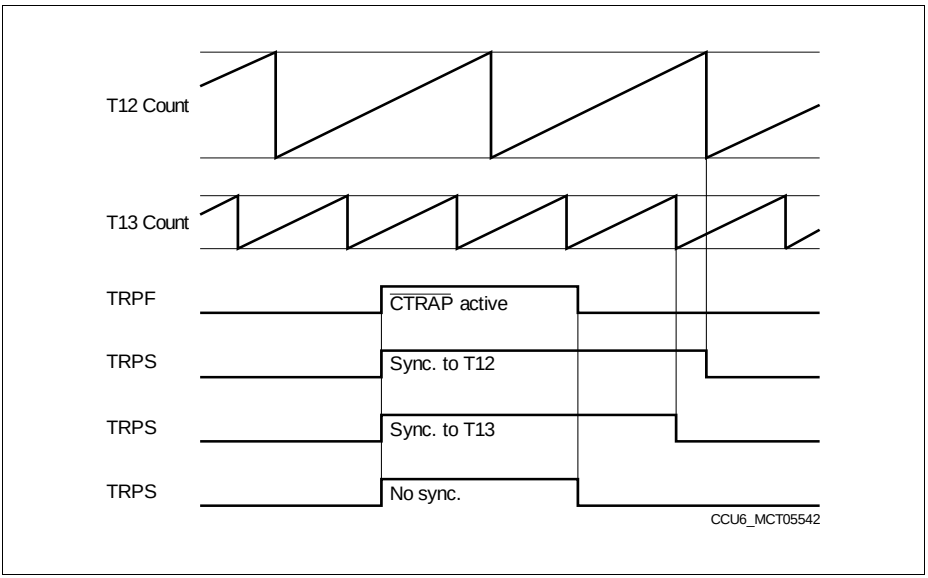

Figure 25-35 Trap State Synchronization (with TRPM2 = 0)

25.6 Multi-Channel Mode

The Multi-Channel mode offers the possibility to modulate all six T12-related output signals with one instruction. The bits in bit field **MCMOUT**.MCMP are used to specify the outputs that may become active. If Multi-Channel mode is enabled (bit **MODCTR**.MCMEN = 1), only those outputs may become active, that have a 1 at the corresponding bit position in bit field MCMP.
This bit field has its own shadow bit field **MCMOUTS**.MCMPS, that can be written by software. The transfer of the new value in MCMPS to the bit field MCMP can be triggered by, and synchronized to, T12 or T13 events. This structure permits the software to write the new value, that is then taken into account by the hardware at a well-defined moment and synchronized to a PWM signal. This avoids unintended pulses due to unsynchronized modulation sources.

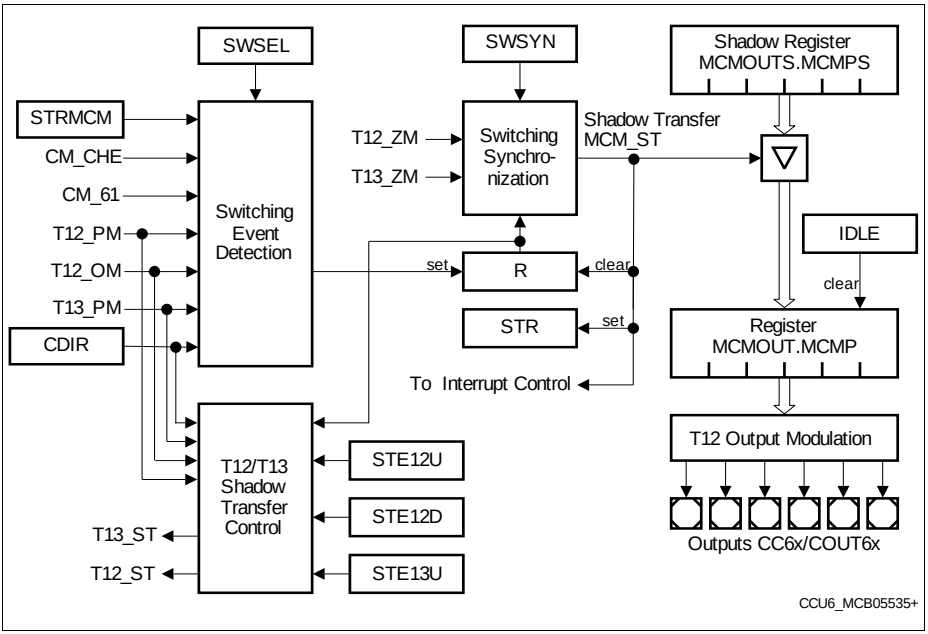

Figure 25-36 Multi-Channel Mode Block Diagram

Figure 25-36 shows the functional blocks for the Multi-Channel operation, controlled by bit fields in register **MCMCTR**. The event that triggers the update of bit field MCMP is chosen by SWSEL. In order to synchronize the update of MCMP to a PWM generated by T12 or T13, bit field SWSYN allows the selection of the synchronization event leading to the transfer from MCMPS to MCMP. Due to this structure, an update takes place with a new PWM period. A reminder flag R is set when the selected switching event occurs

(the event is not necessarily synchronous to the modulating PWM), and is cleared when the transfer takes place. This flag can be monitored by software to check for the status of this logic block. If the shadow transfer from MCMPS to MCMP takes place, bit **IS**.STR becomes set and an interrupt can be generated.
In addition to the Multi-Channel shadow transfer event MCM_ST, the shadow transfers for T12 (T12_ST) and T13 (T13_ST) can be generated to allow concurrent updates of applied duty cycles for T12 and/or T13 modulation and Multi-Channel patterns.

If it is explicitly desired, the update takes place immediately with the occurrence of the selected event when the direct synchronization mode is selected. The update can also be requested by software by writing to bit field MCMPS with the shadow transfer request bit STRMCM = 1. The option to trigger an update by SW is possible for all settings of SWSEL.
By using the direct mode and bit STRMCM = 1, the update takes place completely under software control.

Table 25-9 Multi-Channel Mode Switching Event Selection

SWSEL	Selected Event (see register MCMCTR)
000_B	No automatic event detection
001_B	Correct Hall Event (CM_CHE) detected at input signals CCPOSx without additional delay
010_B	T13 Period-Match (T13_PM)
011_B	T12 One-Match while counting down (T12_OM and CDIR = 1)
100_B	T12 Compare Channel 1 Event while counting up (CM_61 and CDIR = 0) to support the phase delay function by CC61 for block commutation mode.
101_B	T12 Period-Match while counting up (T12_PM and CDIR = 0)
110_B, 111_B	Reserved, no action

Table 25-10 Multi-Channel Mode Switching Synchronization

SWSYN	Synchronization Event (see register MCMCTR)
00_B	Direct Mode: the trigger event directly causes the shadow transfer
01_B	T13 Zero-Match (T13_ZM), the MCM shadow transfer is synchronized to a T13 PWM
10_B	T12 Zero-Match (T12_ZM), the MCM shadow transfer is synchronized to a T12 PWM
11_B	Reserved, no action

25.7 Hall Sensor Mode

For Brushless DC-Motors in block commutation mode, the Multi-Channel Mode has been introduced to provide efficient means for switching pattern generation. These patterns need to be output in relation to the angular position of the motor. For this, usually Hall sensors or Back-EMF sensing are used to determine the angular rotor position. The CCU6 provides three inputs, CCPOS0, CCPOS1, and CCPOS2, that can be used as inputs for the Hall sensors or the Back-EMF detection signals.

There is a strong correlation between the motor position and the output modulation pattern. When a certain position of the motor has been reached, indicated by the sampled Hall sensor inputs (the Hall pattern), the next, pre-determined Multi-Channel Modulation pattern has to be output. Because of different machine types, the modulation pattern for driving the motor can vary. Therefore, it is wishful to have a wide flexibility in defining the correlation between the Hall pattern and the corresponding Modulation pattern. Furthermore, a hardware mechanism significantly reduces the CPU for block-commutation.

The CCU6 offers the flexibility by having a register containing the currently assumed Hall pattern (CURH), the next expected Hall pattern (EXPH) and the corresponding output pattern (MCMP). A new Modulation pattern is output when the sampled Hall inputs match the expected ones (EXPH). To detect the next rotation phase (segment for block commutation), the CCU6 monitors the Hall inputs for changes. When the next expected Hall pattern is detected, the next corresponding Modulation pattern is output.

To increase for noise immunity (to a certain extend), the CCU6 offers the possibility to introduce a sampling delay for the Hall inputs. Some changes of the Hall inputs are not leading to the expected Hall pattern, because they are only short spikes due to noise. The Hall pattern compare logic compares the Hall inputs to the next expected pattern and also to the currently assumed pattern to filter out spikes.

For the Hall and Modulation output patterns, a double-register structure is implemented. While register **MCMOUT** holds the actually used values, its shadow register **MCMOUTS** can be loaded by software from a pre-defined table, holding the appropriate Hall and Modulation patterns for the given motor control.
A transfer from the shadow register into register MCMOUT can take place when a correct Hall pattern change is detected. Software can then load the next values into register MCMOUTS. It is also possible by software to force a transfer from MCMOUTS into MCMOUT.

Note: The Hall input signals CCPOSx and the CURH and EXPH bit fields are arranged in the following order:
CCPOS0 corresponds to CURH.0 (LSB) and EXPH.0 (LSB)
CCPOS1 corresponds to CURH.1 and EXPH.1
CCPOS2 corresponds to CURH.2 (MSB) and EXPH.2 (MSB)

25.7.1 Hall Pattern Evaluation

The Hall sensor inputs CCPOSx can be permanently monitored via an edge detection block (with the module clock f_{CC6}). In order to suppress spikes on the Hall inputs due to noise in rugged inverter environment, two optional noise filtering methods are supported by the Hall logic (both methods can be combined).

- Noise filtering with delay:
  For this function, the mode control bit fields MSEL6x for all T12 compare channels must be programmed to 1000_B and DBYP = 0. The selected event triggers Dead-Time Counter 0 to generate a programmable delay (defined by bit field DTM). When the delay has elapsed, the evaluation signal HCRDY becomes activated.
  Output modulation with T12 PWM signals is not possible in this mode.
- Noise filtering by synchronization to PWM:
  The Hall inputs are not permanently monitored by the edge detection block, but samples are taken only at defined points in time during a PWM period. This can be used to sample the Hall inputs when the switching noise (due to PWM) does not disturb the Hall input signals.

If neither the delay function of Dead-Time Counter 0 is not used for the Hall pattern evaluation nor the Hall mode for Brushless DC-Drive control is enabled, the timer T12 block is available for PWM generation and output modulation.

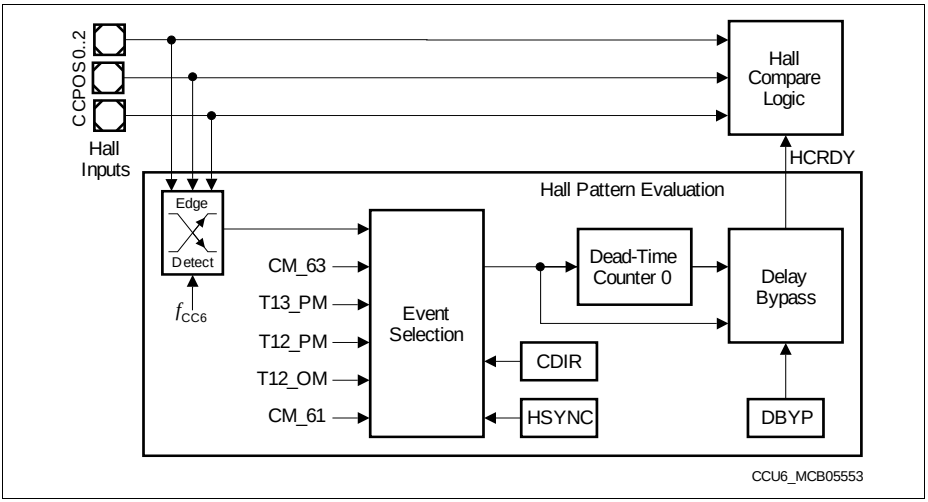

Figure 25-37 Hall Pattern Evaluation

If the evaluation signal HCRDY (Hall Compare Ready, see **Figure 25-38**) becomes activated, the Hall inputs are sampled and the Hall compare logic starts the evaluation of the Hall inputs.

Figure 25-37 illustrates the events for Hall pattern evaluation and the noise filter logic, Table 25-11 summarizes the selectable trigger input signals.

Table 25-11 Hall Sensor Mode Trigger Event Selection

HSYNC	Selected Event (see register T12MSEL)
000_B	Any edge at any of the inputs CCPOSx, independent from any PWM signal (permanent check).
001_B	A T13 Compare-Match (CM_63).
010_B	A T13 Period-Match (T13_PM).
011_B	Hall sampling triggered by HW sources is switched off.
100_B	A T12 Period-Match while counting up (T12_PM and CDIR = 0).
101_B	A T12 One-Match while counting down (T12_OM and CDIR = 1).
110_B	A T12 Compare-Match of compare channel CC61 while counting up (CM_61 and CDIR = 0).
111_B	A T12 Compare-Match of compare channel CC61 while counting down (CM_61 and CDIR = 1).

25.7.2 Hall Pattern Compare Logic

Figure 25-38 gives an overview on the double-register structure and the pattern compare logic. Software writes the next modulation pattern (MCMPS) and the corresponding current (CURHS) and expected (EXPHS) Hall patterns into the shadow register MCMOUTS. Register MCMOUT holds the actually used values CURH and EXPH. The modulation pattern MCMP is provided to the T12 Output Modulation block. The current (CURH) and expected (EXPH) Hall patterns are compared to the sampled Hall sensor inputs (visible in register **CMPSTAT**). Sampling of the inputs and the evaluation of the comparator outputs is triggered by the evaluation signal HCRDY (Hall Compare Ready), that is detailed in the next section.

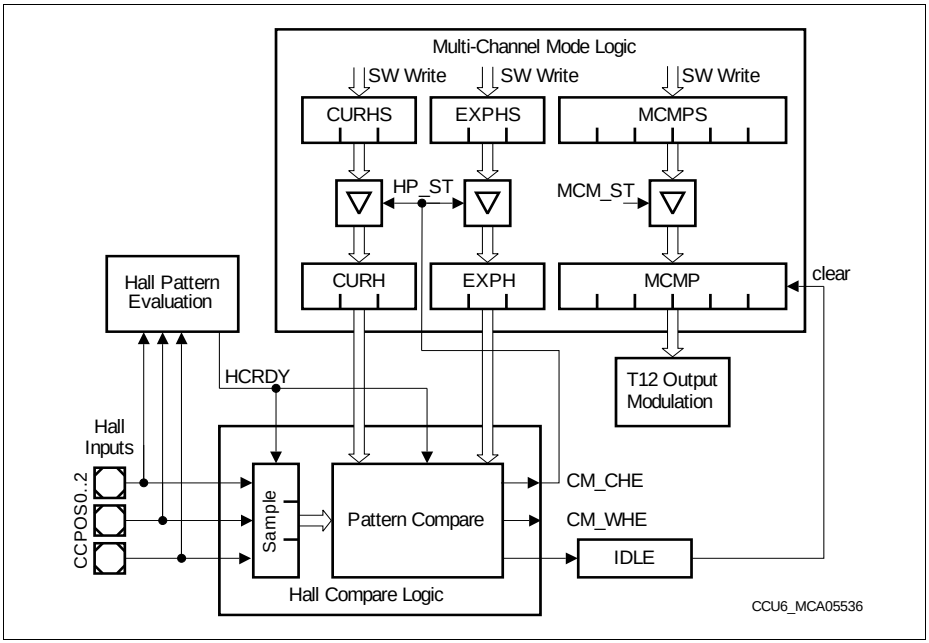

Figure 25-38 Hall Pattern Compare Logic

- If the sampled Hall pattern matches the value programmed in CURH, the detected transition was a spike (no Hall event) and no further actions are necessary.
- If the sampled Hall pattern matches the value programmed in EXPH, the detected transition was the expected event (correct Hall event CM_CHE) and the MCMP value has to change.
- If the sampled Hall pattern matches neither CURH nor EXPH, the transition was due to a major error (wrong Hall event CM_CWE) and can lead to an emergency shut down (IDLE).

At every correct Hall event (CM_CHE), the next Hall patterns are transferred from the shadow register MCMOUTS into MCMOUT (Hall pattern shadow transfer HP_ST), and a new Hall pattern with its corresponding output pattern can be loaded (e.g. from a predefined table in memory) by software into MCMOUTS. For the Modulation patterns, signal MCM_ST is used to trigger the transfer.
Loading this shadow register can also be done by writing MCMOUTS.STRHP = 1 (for EXPH and CURH) or MCMOUTS.STRMCMP = 1 (for MCMP).

25.7.3 Hall Mode Flags

Depending on the Hall pattern compare operation, a number of flags are set in order to indicate the status of the module and to trigger further actions and interrupt requests.

Flag **IS**.CHE (Correct Hall Event) is set by signal CM_CHE when the sampled Hall pattern matches the expected one (EXPH). This flag can also be set by SW by setting bit **ISS**.SCHE = 1. If enabled by bit **IEN**.ENCHE = 1, the set signal for CHE can also generate an interrupt request to the CPU. Bit field **INP**.INPCHE defines which service request output becomes activated in case of an interrupt request.To clear flag CHE, SW needs to write **ISR**.RCHE = 1.
Flag IS.WHE indicates a Wrong Hall Event. Its handling for flag setting and resetting as well as interrupt request generation are similar to the mechanism for flag CHE.
The implementation of flag STR is done in the same way as for CHE and WHE. This flag is set by HW by the shadow transfer signal MCM_ST (see also **Figure 25-36**).

Please note that for flags CHE, WHE, and STR, the interrupt request generation is triggered by the set signal for the flag. That means, a request can be generated even if the flag is already set. There is no need to clear the flag in order to enable further interrupt requests.

The implementation for the IDLE flag is different. It is set by HW through signal CM_WHE if enabled by bit ENIDLE. Software can also set the flag via bit SIDLE. As long as bit IDLE is set, the modulation pattern field MCMP is cleared to force the outputs to the passive state. Flag IDLE must be cleared by software by writing RIDLE = 1 in order to return to normal operation. To fully restart from IDLE mode, the transfer requests for the bit fields in register MCMOUTS to register MCMOUT have to be initiated by software via bits STRMCM and STRHP in register MCMOUTS. In this way, the release from IDLE mode is under software control, but can be performed synchronously to the PWM signal.

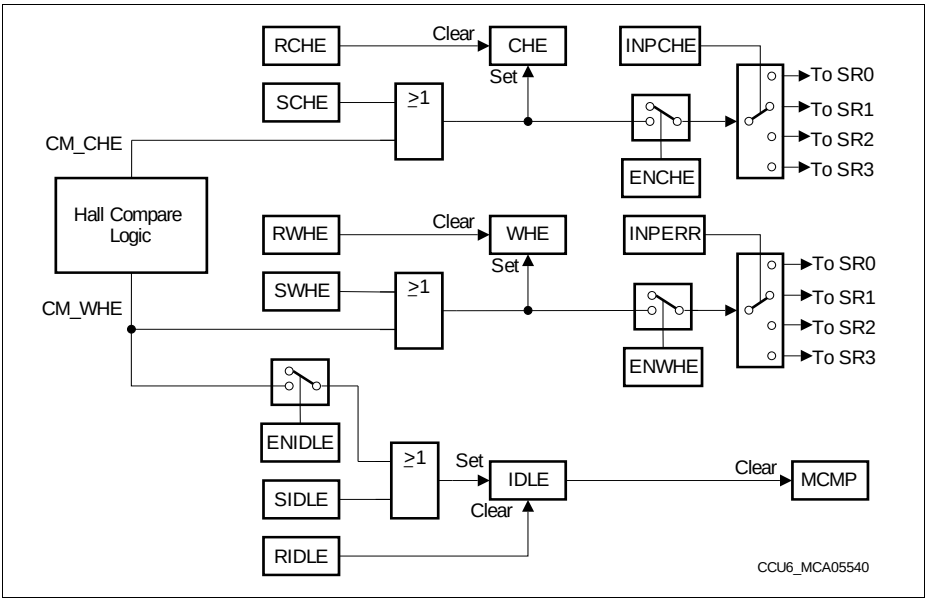

Figure 25-39 Hall Mode Flags

25.7.4 Hall Mode for Brushless DC-Motor Control

The CCU6 provides a mode for the Timer T12 Block especially targeted for convenient control of block commutation patterns for Brushless DC-Motors. This mode is selected by setting all **T12MSEL**.MSEL6x bit fields of the three T12 Channels to 1000_B.
In this mode, illustrated in **Figure 25-40**, channel CC60 is placed in capture mode to measure the time elapsed between the last two correct Hall events, channel CC61 in compare mode to provide a programmable phase delay between the Hall event and the application of a new PWM output pattern, and channel CC62 also in compare mode as first time-out criterion. A second time-out criterion can be built by the T12 period match event.

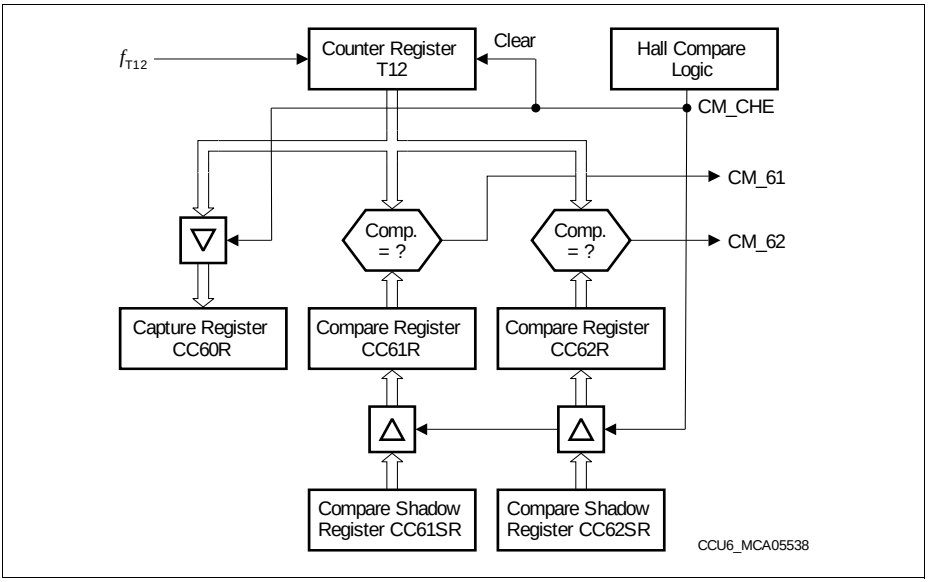

Figure 25-40 T12 Block in Hall Sensor Mode

The signal CM_CHE from the Hall compare logic is used to transfer the new compare values from the shadow registers CC6xSR into the actual compare registers CC6xR, performs the shadow transfer for the T12 period register, to capture the current T12 contents into register CC60R, and to clear T12.

Note: In this mode, the shadow transfer signal T12_ST is not generated. Not all shadow bits, such as the PSLy bits, will be transferred to their main registers. To program the main registers, SW needs to write to these registers while Timer T12 is stopped. In this case, a SW write actualizes both registers.

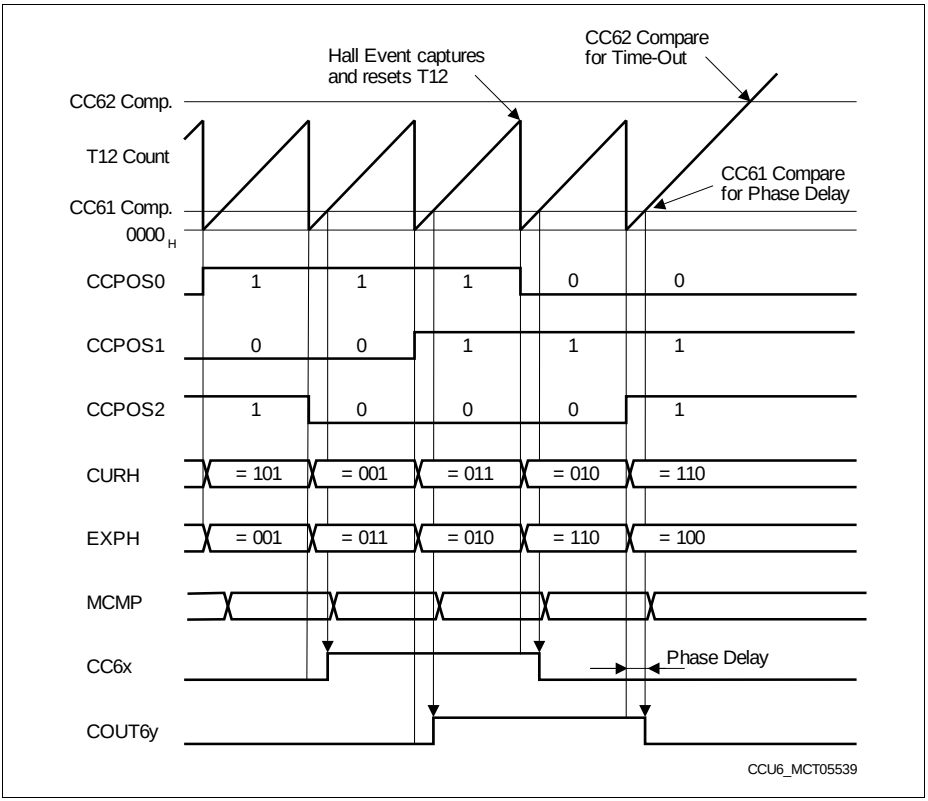

Figure 25-41 Brushless DC-Motor Control Example (all MSEL6x = 1000_B)

After the detection of an expected Hall pattern (CM_CHE active), the T12 count value is captured into channel CC60 (representing the actual rotor speed by measuring the elapsed time between the last two correct Hall events), and T12 is reset. When the timer reaches the compare value in channel CC61, the next multi-channel state is switched by triggering the shadow transfer of bit field MCMP (if enabled in bit field **SWEN**). This trigger event can be combined with the synchronization of the next multi-channel state to the PWM source (to avoid spikes on the output lines, see **Section 25.6**). This compare function of channel CC61 can be used as a phase delay from the position sensor input signals to the switching of the output signals, that is necessary if a sensorless back-EMF technique or Hall sensors are used. The compare value in channel CC62 can be used as a time-out trigger (interrupt), indicating that the actual motor speed is far below the desired destination value. An abnormal load change can be detected with this feature and PWM generation can be disabled.

25.8 Modulation Control Registers

25.8.1 Modulation Control

This register contains bits enabling the modulation of the corresponding output signal by PWM pattern generated by the timers T12 and T13. Furthermore, the multi-channel mode can be enabled as additional modulation source for the output signals.

MODCTR

0	6, 14, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.8.2 Trap Control Register

The register TRPCTR controls the trap functionality. It contains independent enable bits for each output signal and control bits to select the behavior in case of a trap condition. The trap condition is a low level on the $\overline{\text{CTRAP}}$ input pin, that is monitored (inverted level) by bit IS.TRPF. While TRPF=1 (trap input active), the trap state bit IS.TRPS is set to 1.

TRPCTR
Trap Control Register **(84_H)** **Reset Value: 0000 0000$_H$**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRPPEN	TRPEN13	TRPEN						0					TRPM2	TRPM1	TRPM0
rw	rw	rw						r					rw	rw	rw

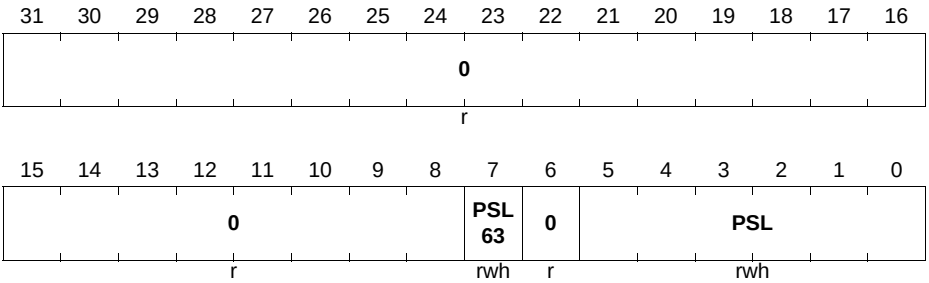
Field	Bits	Type	Description
TRPM1, TRPM0	1, 0	rw	**Trap Mode Control Bits 1, 0** These two bits define the behavior of the selected outputs when leaving the trap state after the trap condition has become inactive again. A synchronization to the timer driving the PWM pattern avoids unintended pulses when leaving the trap state. The combination [TRPM1, TRPM0] leads to: 00_B The trap state is left (return to normal operation) after TRPF has become 0 again when a zero-match of T12 (while counting up) is detected (synchronization to T12). 01_B The trap state is left (return to normal operation) after TRPF has become 0 again when a zero-match of T13 is detected (synchronization to T13). 10_B reserved 11_B The trap state is left (return to normal operation) immediately after TRPF has become 0 again without any synchronization to T12 or T13.
TRPM2	2	rw	**Trap Mode Control Bit 2** This bit defines how the trap flag TRPF can be cleared after the trap input condition ($\overline{\text{CTRAP}}$ = 0 and TRPPEN = 1) is no longer valid (either by $\overline{\text{CTRAP}}$ = 1 or by TRPPEN = 0). 0_B Automatic Mode: Bit TRPF is cleared by HW if the trap input condition is no longer valid. 1_B Manual Mode: Bit TRPF stays 0 after the trap input condition is no longer valid. It has to be cleared by SW by writing ISR.RTRPF = 1.

Field	Bits	Type	Description
TRPEN	[13:8]	rw	**Trap Enable Control** Setting a bit enables the trap functionality for the following corresponding output signals: TRPEN0 = TRPCTR.8 for output CC60 TRPEN1 = TRPCTR.9 for output COUT60 TRPEN2 = TRPCTR.10 for output CC61 TRPEN3 = TRPCTR.11 for output COUT61 TRPEN4 = TRPCTR.12 for output CC62 TRPEN5 = TRPCTR.13 for output COUT62 0_B The trap functionality of the corresponding output signal is disabled. The output state is independent from bit IS.TRPS. 1_B The trap functionality of the corresponding output signal is enabled. The output state is set to the passive while IS.TRPS=1.
TRPEN13	14	rw	**Trap Enable Control for Timer T13** 0_B The trap functionality for output COUT63 is disabled. The output state is independent from bit IS.TRPS. 1_B The trap functionality for output COUT63 is enabled. The output state is set to the passive while IS.TRPS=1.
TRPPEN	15	rw	**Trap Pin Enable** This bit enables the input (pin) function for the trap generation. An interrupt can only be generated if a falling edge is detected at pin $\overline{\text{CTRAP}}$ while TRPPEN = 1. 0_B The CCU6 trap functionality based on the input $\overline{\text{CTRAP}}$ is disabled. A CCU6 trap can only be generated by SW by setting bit TRPF. 1_B The CCU6 trap functionality based on the input $\overline{\text{CTRAP}}$ is enabled. A CCU6 trap can be generated by SW by setting bit TRPF or by $\overline{\text{CTRAP}}$=0.
0	[7:3], [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.8.3 Passive State Level Register

Register PSLR defines the passive state level of the PWM outputs of the module. The passive state level is the value that is driven during the passive state of the output. During the active state, the corresponding output pin drives the active state level, that is the inverted passive state level. The passive state level permits to adapt the driven output levels to the driver polarity (inverted, not inverted) of the connected power stage. The bits in this register have shadow bit fields to permit a concurrent update of all PWM-related parameters (bit field PSL is updated with T12_ST, whereas PSL63 is updated with T13_ST). The actually used values can be read (attribute “rh”), whereas the shadow bits can only be written (attribute “w”).

PSLR
Passive State Level Register **(88_H)** **Reset Value: $0000\ 0000_H$**



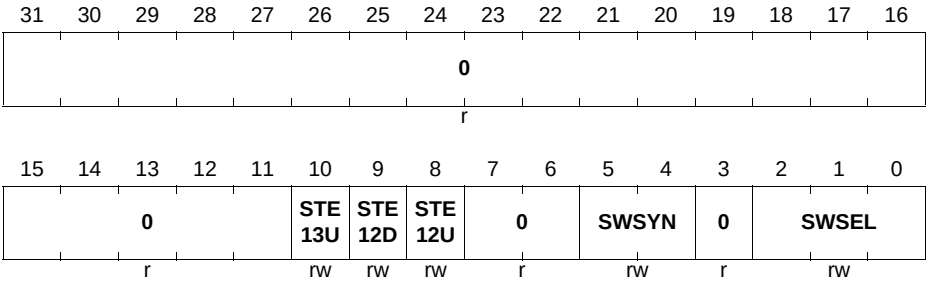
Field	Bits	Type	Description
PSL	[5:0]	rwh	**Compare Outputs Passive State Level** These bits define the passive level driven by the module outputs during the passive state. PSL0 = PSLR.0 for output CC60 PSL1 = PSLR.1 for output COUT60 PSL2 = PSLR.2 for output CC61 PSL3 = PSLR.3 for output COUT61 PSL4 = PSLR.4 for output CC62 PSL5 = PSLR.5 for output COUT62 0_B The passive level is 0. 1_B The passive level is 1.
PSL63	7	rwh	**Passive State Level of Output COUT63** This bit defines the passive level driven by the module output COUT63 during the passive state. 0_B The passive level is 0. 1_B The passive level is 1.
0	6, [31:8]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.8.4 Multi-Channel Mode Registers

Register MCMCTR contains control bits for the multi-channel functionality.

MCMCTR
Multi-Channel Mode Control Register

(94_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SWSEL	[2:0]	rw	**Switching Selection** Bit field SWSEL selects one of the following trigger request sources (next multi-channel event) for the shadow transfer MCM_ST from MCMPS to MCMP. The trigger request is stored in the reminder flag R until the shadow transfer is done and flag R is cleared automatically with the shadow transfer. The shadow transfer takes place synchronously with an event selected in bit field SWSYN. 000_B No trigger request will be generated 001_B Correct Hall pattern detected (CM_CHE) 010_B T13 period-match detected (while counting up) 011_B T12 one-match (while counting down) 100_B T12 channel 1 compare-match detected (phase delay function) 101_B T12 period match detected (while counting up) 110_B reserved, no trigger request will be generated 111_B reserved, no trigger request will be generated
SWSYN	[5:4]	rw	**Switching Synchronization** Bit field SWSYN defines the synchronization mechanism of the shadow transfer event MCM_ST if it has been requested before (flag R set by an event selected by SWSEL) and if MCMEN = 1. This feature permits the synchronization of the outputs to the PWM source, that is used for modulation (T12 or T13). 00_B Direct; the trigger event immediately leads to the shadow transfer 01_B A T13 zero-match triggers the shadow transfer 10_B A T12 zero-match (while counting up) triggers the shadow transfer 11_B reserved; no action
STE12U	8	rw	**Shadow Transfer Enable for T12 Upcounting** This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 period match is detected while counting up. 0_B No action 1_B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.

Field	Bits	Type	Description
STE12D	9	rw	**Shadow Transfer Enable for T12 Downcounting** This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 one match is detected while counting down. 0_B No action 1_B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.
STE13U	10	rw	**Shadow Transfer Enable for T13 Upcounting** This bit enables the shadow transfer T13_ST if flag MCMOUT.R is set or becomes set while a T13 period match is detected. 0_B No action 1_B The T13_ST shadow transfer mechanism is enabled if MCMEN = 1.
0	3, [7:6], [31:11]	r	**Reserved;** Returns 0 if read; should be written with 0.

Register MCMOUTS contains bits used as pattern input for the multi-channel mode and the Hall mode. This register is a shadow register (that can be read and written) for register MCMOUT, indicating the currently active signals.

MCMOUTS
Multi-Channel Mode Output Shadow Register

($8C_H$) **Reset Value: $0000\ 0000_H$**

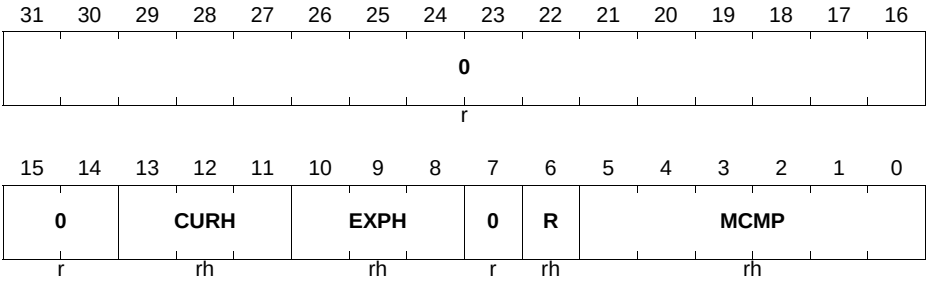
STRHP	0	CURHS			EXPHS			STRMCM	0	MCMPS					
w	r	rw			rw			w	r	rw					

Field	Bits	Type	Description
MCMPS	[5:0]	rw	**Multi-Channel PWM Pattern Shadow** Bit field MCMPS is the shadow bit field for bit field MCMP. The multi-channel shadow transfer is triggered by MCM_ST according to the transfer conditions defined by register MCMCTR.
STRMCM	7	w	**Shadow Transfer Request for MCMPS** Writing STRMCM = 1 leads to an immediate activation of MCM_ST to update bit field MCMP by the value of MCMPS. When read, this bit always delivers 0. 0_B No action. 1_B Bit field MCMP is updated.
EXPHS	[10:8]	rw	**Expected Hall Pattern Shadow** Bit field EXPHS is the shadow bit field for bit field EXPH. The shadow transfer takes place when a correct Hall event is detected (CM_CHE).
CURHS	[13:11]	rw	**Current Hall Pattern Shadow** Bit field CURHS is the shadow bit field for bit field CURH. The shadow transfer takes place when a correct Hall event is detected (CM_CHE).

Field	Bits	Type	Description
STRHP	15	w	**Shadow Transfer Request for the Hall Pattern** Writing STRHP = 1 leads to an immediate activation of HP_ST to update bit fields EXPH and CURH by EXPHS and CURHS. When read, this bit always delivers 0. 0_B No action. 1_B Bit fields EXPH and CURH are updated.
0	6, 14, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

MCMOUT
Multi-Channel Mode Output Register

(90_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
MCMP	[5:0]	rh	**Multi-Channel PWM Pattern** Bit field MCMP defines the output pattern for the multi-channel mode. If this mode is enabled by MODCTR.MCMEN = 1, the output state of all T12 related PWM outputs can be modified. This bit field is 0 while IS.IDLE = 1. MCMP0 = MCMOUT.0 for output CC60 MCMP1 = MCMOUT.1 for output COUT60 MCMP2 = MCMOUT.2 for output CC61 MCMP3 = MCMOUT.3 for output COUT61 MCMP4 = MCMOUT.4 for output CC62 MCMP5 = MCMOUT.5 for output COUT62 0_B The output is set to the passive state. A PWM generated by T12 or T13 are not taken into account. 1_B The output can be in the active state, depending on the enabled PWM modulation signals generated by T12, T13 and the trap state.
R	6	rh	**Reminder Flag** This flag indicates that the shadow transfer from MCMPS to MCMP has been requested by the selected trigger source. It is cleared when the shadow transfer takes place or while MCMEN=0. 0_B A shadow transfer MCM_ST is not requested. 1_B A shadow transfer MCM_ST is requested, but has not yet been executed, because the selected synchronization condition has not yet occurred.
EXPH	[10:8]	rh	**Expected Hall Pattern** Bit field EXPH is updated by a shadow transfer HP_ST from bit field EXPHS. If HCRDY = 1, EXPH is compared to the sampled CCPOSx inputs in order to detect the occurrence of the next desired (=expected) hall pattern or a wrong pattern. If the sampled hall pattern at the hall input pins is equal to bit field EXPH, a correct Hall event has been detected (CM_CHE).

Field	Bits	Type	Description
CURH	[13:11]	rh	**Current Hall Pattern** Bit field CURH is updated by a shadow transfer HP_ST from bit field CURHS. If HCRDY = 1, CURH is compared to the sampled CCPOSx inputs in order to detect a spike. If the sampled Hall pattern at the Hall input pins is equal to bit field CURH, no Hall event has been detected. If the sampled Hall input pattern is neither equal to CURH nor equal to EXPH, the Hall event was not the desired one and may be due to a fatal error (e.g. blocked rotor, etc.). In this case, a wrong Hall event has been detected (CM_WHE).
0	7, [31:14]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.9 Interrupt Handling

This section describes the interrupt handling of the CCU6 module.

25.9.1 Interrupt Structure

The HW interrupt event or the SW setting of the corresponding interrupt set bit (in register ISS) sets the event indication flags (in register IS) and can trigger the interrupt generation. The interrupt pulse is generated independently from the interrupt status flag in register IS (it is not necessary to clear the related status bit to be able to generate another interrupt). The interrupt flag can be cleared by SW by writing to the corresponding bit in register ISR.

If enabled by the related interrupt enable bit in register IEN, an interrupt pulse can be generated on one of the four service request outputs (SR0 to SR3) of the module. If more than one interrupt source is connected to the same interrupt node pointer (in register INP), the requests are logically OR-combined to one common service request output (see **Figure 25-42**).

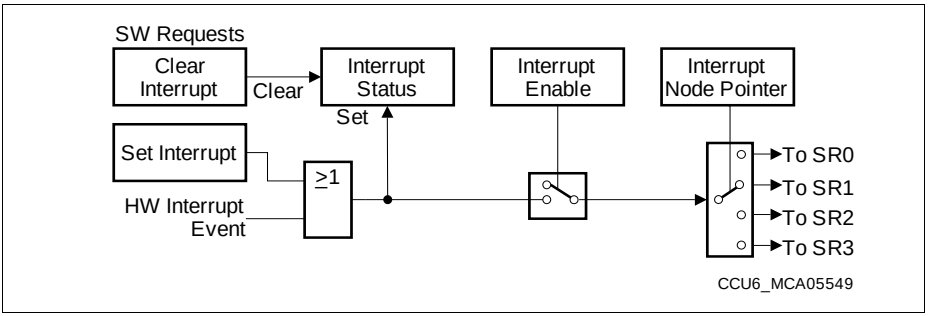


Figure 25-42 General Interrupt Structure

The available interrupt events in the CCU6 are shown in **Figure 25-43**.

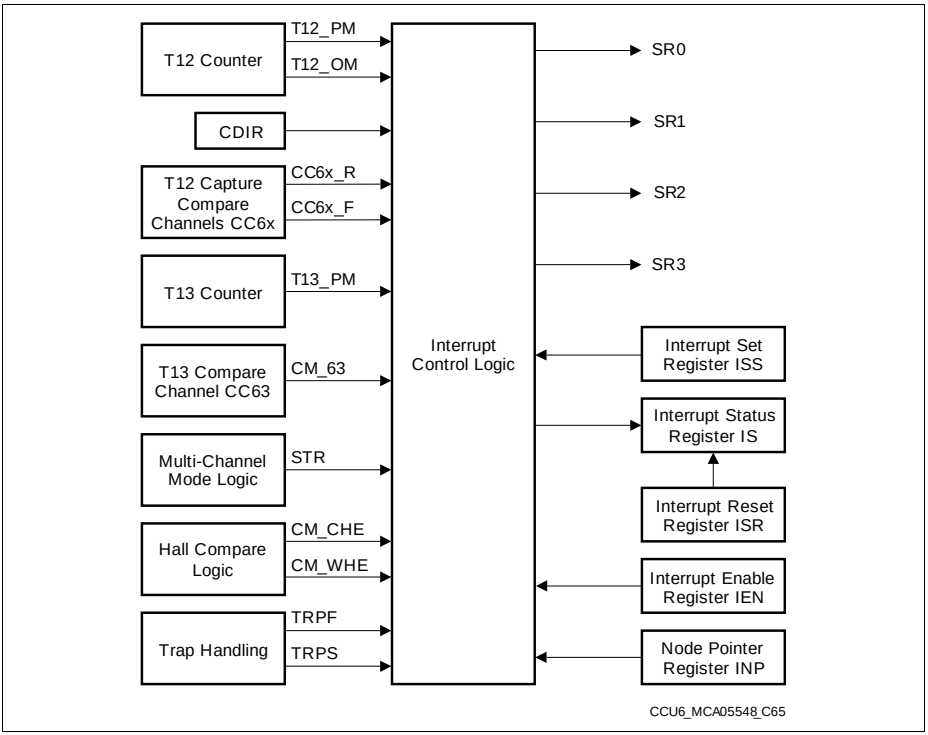

Figure 25-43 Interrupt Sources and Events

25.9.2 Interrupt Registers

25.9.2.1 Interrupt Status Register

Register IS contains the individual interrupt request bits. This register can only be read, write actions have no impact on the contents of this register. The SW can set or clear the bits individually by writing to the registers ISS (to set the bits) or to register ISR (to clear the bits).

The interrupt generation is independent from the value of the bits in register IS, e.g. the interrupt will be generated (if enabled) even if the corresponding bit is already set. The trigger for an interrupt generation is the detection of a set condition (by HW or SW) for the corresponding bit in register IS.

In compare mode (and hall mode), the timer-related interrupts are only generated while the timer is running (T1xR=1). In capture mode, the capture interrupts are also generated while the timer T12 is stopped.

Note: Not all bits in register IS can generate an interrupt. Other status bits have been added, that have a similar structure for their set and clear actions. It is recommended that SW checks the interrupt bits bit-wisely (instead of common OR over the bits).

IS
Interrupt Status Register **($A0_H$)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
ICC60R, ICC61R, ICC62R	0, 2, 4	rh	**Capture, Compare-Match Rising Edge Flag** This bit indicates that event CC6x_R has been detected. This event occurs in compare mode when a compare-match is detected while T12 is counting up (CM_6x and CDIR = 0) and in capture mode when a rising edge is detected at the related input CC6xIN. 0_B The event has not yet been detected. 1_B The event has been detected.
ICC60F, ICC61F, ICC62F	1, 3, 5	rh	**Capture, Compare-Match Falling Edge Flag** This bit indicates that event CC6x_F has been detected. This event occurs in compare mode when a compare-match is detected while T12 is counting down (CM_6x and CDIR = 1) and in capture mode when a falling edge is detected at the related input CC6xIN. 0_B The event has not yet been detected. 1_B The event has been detected.
T12OM	6	rh	**Timer T12 One-Match Flag** This bit indicates that a timer T12 one-match while counting down (T12_OM and CDIR = 1) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T12PM	7	rh	**Timer T12 Period-Match Flag** This bit indicates that a timer T12 period-match while counting up (T12_PM and CDIR = 0) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T13CM	8	rh	**Timer T13 Compare-Match Flag** This bit indicates that a timer T13 compare-match (CM_63) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T13PM	9	rh	**Timer T13 Period-Match Flag** This bit indicates that a timer T13 period-match (T13_PM) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.

Field	Bits	Type	Description
TRPF	10	rh	**Trap Flag** This bit indicates if a trap condition (input $\overline{\text{CTRAP}}$ = 0 or by SW) is / has been detected. If TRPM2= 0, it becomes cleared automatically if $\overline{\text{CTRAP}}$ = 1 or TRPPEN = 0, whereas if TRPM2 = 1, it has to be cleared by writing RTRPF = 1. 0_B The trap condition has not been detected. 1_B The trap condition is / has been detected.
TRPS	11	rh	**Trap State**[1)] This bit indicates the actual trap state. It is set if TRPF = 1 and becomes cleared according to the mode selected in register TRPCTR. 0_B The trap state is not active. 1_B The trap state is active.
CHE	12	rh	**Correct Hall Event** This bit indicates that a correct Hall event (CM_CHE) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
WHE	13	rh	**Wrong Hall Event** This bit indicates that a wrong Hall event (CM_WHE) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
IDLE	14	rh	**IDLE State** If enabled by ENIDLE = 1, this bit is set together with bit WHE and it has to be cleared by SW. 0_B No action. 1_B Bit field MCMP is cleared, the selected outputs are set to passive state.
STR	15	rh	**Multi-Channel Mode Shadow Transfer Request** This bit indicates that a shadow transfer from MCMPS to MCMP (MCM_ST) has taken place. 0_B The event has not yet been detected. 1_B The event has been detected.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

1) During the trap state, the selected outputs are set to the passive state. The logic level driven during the passive state is defined by the corresponding bit in register PSLR. Bits TRPS=1 and TRPF=0 can occur if the trap condition is no longer active but the selected synchronization has not yet taken place.

25.9.2.2 Interrupt Status Set Register

Register ISS contains individual interrupt request set bits to generate a CCU6 interrupt request by software. Writing a 1 sets the bit(s) in register IS at the corresponding bit position(s) and can generate an interrupt event (if available and enabled).
All bit positions read as 0.

ST12PM	7	w	**Set Timer T12 Period-Match Flag** 0_B No action 1_B Bit T12PM will be set.
ST13CM	8	w	**Set Timer T13 Compare-Match Flag** 0_B No action 1_B Bit T13CM will be set.

Field	Bits	Type	Description
ST13PM	9	w	**Set Timer T13 Period-Match Flag** 0_B No action 1_B Bit T13PM will be set.
STRPF	10	w	**Set Trap Flag** 0_B No action 1_B Bits TRPF and TRPS will be set.
SWHC	11	w	**Software Hall Compare** 0_B No action 1_B The Hall compare action is triggered.
SCHE	12	w	**Set Correct Hall Event Flag** 0_B No action 1_B Bit CHE will be set.
SWHE	13	w	**Set Wrong Hall Event Flag** 0_B No action 1_B Bit WHE will be set.
SIDLE	14	w	**Set IDLE Flag** 0_B No action 1_B Bit IDLE will be set.
SSTR	15	w	**Set STR Flag** 0_B No action 1_B Bit STR will be set.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.9.2.3 Status Reset Register

Register ISR contains bits to individually clear the interrupt event flags by software. Writing a 1 clears the bit(s) in register IS at the corresponding bit position(s).
All bit positions read as 0.

ISR
Interrupt Status Reset Register **($A8_H$)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
ENCC60R, ENCC61R, ENCC62R	0, 2, 4	rw	**Capture, Compare-Match Rising Edge Interrupt Enable for Channel CC6x** 0_B No interrupt will be generated if the set condition for bit CC6xR in register IS occurs. 1_B An interrupt will be generated if the set condition for bit CC6xR in register IS occurs. The service request output that will be activated is selected by bit field INPCC6x.
ENCC60F, ENCC61F, ENCC62F	1, 3, 5	rw	**Capture, Compare-Match Falling Edge Interrupt Enable for Channel CC6x** 0_B No interrupt will be generated if the set condition for bit CC6xF in register IS occurs. 1_B An interrupt will be generated if the set condition for bit CC6xF in register IS occurs. The service request output that will be activated is selected by bit field INPCC6x.

Field	Bits	Type	Description
ENT12OM	6	rw	**Enable Interrupt for T12 One-Match** 0_B No interrupt will be generated if the set condition for bit T12OM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T12OM in register IS occurs. The service request output that will be activated is selected by bit field INPT12.
ENT12PM	7	rw	**Enable Interrupt for T12 Period-Match** 0_B No interrupt will be generated if the set condition for bit T12PM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T12PM in register IS occurs. The service request output that will be activated is selected by bit field INPT12.
ENT13CM	8	rw	**Enable Interrupt for T13 Compare-Match** 0_B No interrupt will be generated if the set condition for bit T13CM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T13CM in register IS occurs. The service request output that will be activated is selected by bit field INPT13.
ENT13PM	9	rw	**Enable Interrupt for T13 Period-Match** 0_B No interrupt will be generated if the set condition for bit T13PM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T13PM in register IS occurs. The service request output that will be activated is selected by bit field INPT13.
ENTRPF	10	rw	**Enable Interrupt for Trap Flag** 0_B No interrupt will be generated if the set condition for bit TRPF in register IS occurs. 1_B An interrupt will be generated if the set condition for bit TRPF in register IS occurs. The service request output that will be activated is selected by bit field INPERR.

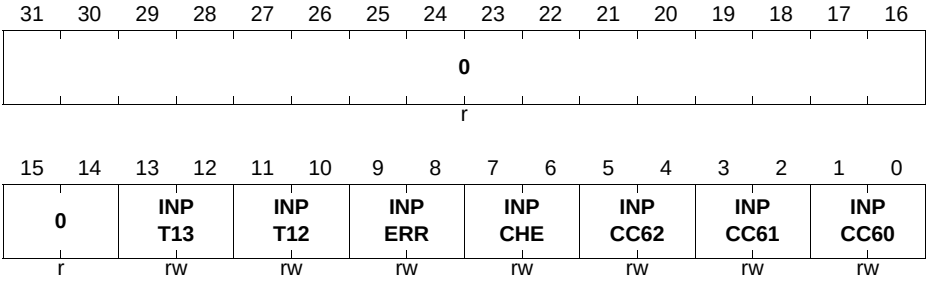
Field	Bits	Type	Description
ENCHE	12	rw	**Enable Interrupt for Correct Hall Event** 0_B No interrupt will be generated if the set condition for bit CHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit CHE in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
ENWHE	13	rw	**Enable Interrupt for Wrong Hall Event** 0_B No interrupt will be generated if the set condition for bit WHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit WHE in register IS occurs. The service request output that will be activated is selected by bit field INPERR.
ENIDLE	14	rw	**Enable Idle** This bit enables the automatic entering of the idle state (bit IDLE will be set) after a wrong hall event has been detected (bit WHE is set). During the idle state, the bit field MCMP is automatically cleared. 0_B The bit IDLE is not automatically set when a wrong hall event is detected. 1_B The bit IDLE is automatically set when a wrong hall event is detected.
ENSTR	15	rw	**Enable Multi-Channel Mode Shadow Transfer Interrupt** 0_B No interrupt will be generated if the set condition for bit STR in register IS occurs. 1_B An interrupt will be generated if the set condition for bit STR in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
0	11, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.9.2.5 Interrupt Node Pointer Register

Register INP contains the interrupt node pointers allowing a flexible interrupt handling. These bit fields define which service request output will be activated if the corresponding interrupt event occurs and the interrupt generation for this event is enabled.

INP

Interrupt Node Pointer Register **(AC_H)** **Reset Value: 0000 3940$_H$**



Field	Bits	Type	Description
INPCC60, INPCC61, INPCC62	[1:0], [3:2], [5:4]	rw	**Interrupt Node Pointer for Channel CC6x Interrupts** This bit field defines the service request output activated due to a set condition for bit CC6xR (if enabled by bit ENCC6xR) or for bit CC6xF (if enabled by bit ENCC6xF). 00_B Service request output SR0 is selected. 01_B Service request output SR1 is selected. 10_B Service request output SR2 is selected. 11_B Service request output SR3 is selected.
INPCHE	[7:6]	rw	**Interrupt Node Pointer for the CHE Interrupt** This bit field defines the service request output activated due to a set condition for bit CHE (if enabled by bit ENCHE) of for bit STR (if enabled by bit ENSTR). Coding see INPCC6x.
INPERR	[9:8]	rw	**Interrupt Node Pointer for Error Interrupts** This bit field defines the service request output activated due to a set condition for bit TRPF (if enabled by bit ENTRPF) or for bit WHE (if enabled by bit ENWHE). Coding see INPCC6x.
INPT12	[11:10]	rw	**Interrupt Node Pointer for Timer12 Interrupts** This bit field defines the service request output activated due to a set condition for bit T12OM (if enabled by bit ENT12OM) or for bit T12PM (if enabled by bit ENT12PM). Coding see INPCC6x.

Field	Bits	Type	Description
INPT13	[13:12]	rw	**Interrupt Node Pointer for Timer13 Interrupt** This bit field defines the service request output activated due to a set condition for bit T13CM (if enabled by bit ENT13CM) or for bit T13PM (if enabled by bit ENT13PM). Coding see INPCC6x.
0	[31:14]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.10 General Module Operation

This section provides information about the:

- Input Selection (see **Section 25.10.1**)
- Input Monitoring (see **Section 25.10.2**)
- OCDS Suspend Functionality (see **Section 25.10.3**)
- OCDS Trigger Bus (OTGB) Interface (see **Section 25.10.4**)
- General Register Description (see **Section 25.10.5**)
- BPI Register Description (see **Section 25.10.6**)

25.10.1 Input Selection

Each CCU6 input signal can be selected from a vector of four or eight possible inputs by programming the port input select registers **PISEL0** and **PISEL2**. This permits to adapt the pin functionality of the device to the application requirements.
The output pins for the module output signals are chosen in the ports.

Naming convention:
The input vector CC60IN[D:A] for input signal CC60IN is composed of the signals CC60INA to CC60IND.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they affect the module internal logic. The resulting delay of $2/f_{CC6}$ and for asynchronous signals an additional uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation. An edge of an input signal can only be correctly detected if the high phase and the low phase of the input signal are both longer than $1/f_{CC6}$.

25.10.2 Input Monitoring

A selected event which occurs at each CCU6 input signal can be monitored through **IMON**.x. Every input signal can be included for the detection of a lost bit event (**IMON**.LBE) if enabled through its individual lost indicator enable bits (**LI**.yEN). The lost bit event occurs if a selected event occurs again with the previous event captured (IMON.x remains set) and its lost indicator is enabled for at least one of the monitored input signals. The lost bit event can be enabled (**LI**.LBEEN) for an interrupt to be generated at one of the SRx line, selected through **LI**.INPLBE. The LBE output signal of the kernel can be connected to a capture input to indicate when does the lost bit event happens.

The lost bit event can be used as a kind of interrupt or event watchdog to monitor if an action related to an event has been processed before a second event of the same type occurs. Like this, if a certain event is treated by an interrupt that should be monitored, the related indication flag has to be cleared by SW. If the SW has not yet cleared the flag and the event occurs again, the event is considered as being lost and another interrupt can be generated to inform the system about the loss. This can be also used to indicate that input events occur too often and the main task has not enough time to treat them.

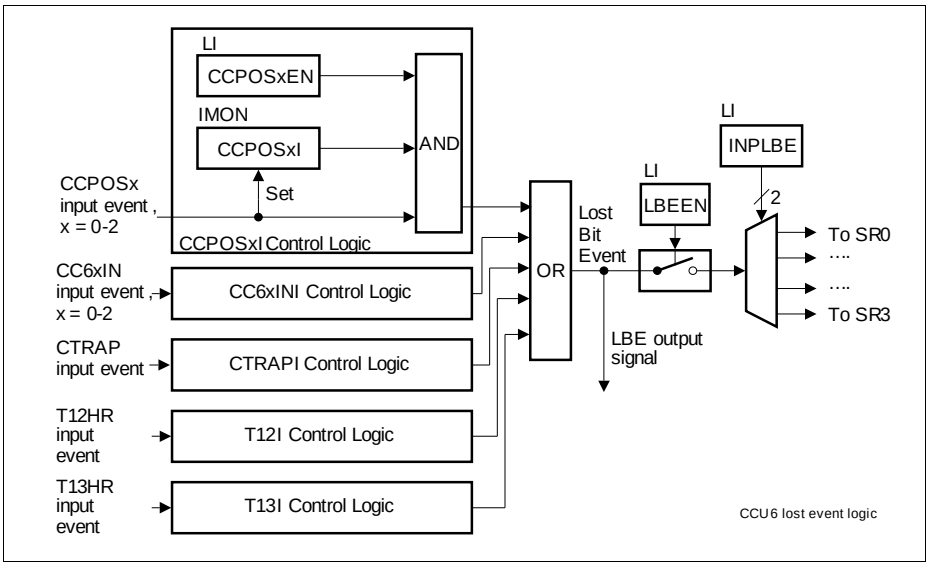


Figure 25-44 Lost Event Logic

25.10.3 OCDS Suspend

The behavior of CCU6 upon an OCDS suspend request is controlled by the **OCS** register. CCU6 supports both Hard Suspend Mode and Soft Suspend Mode.

Hard Suspend Mode

In Hard Suspend Mode the CCU6 kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a CCU6 kernel reset might not be sufficient to bring the system into a defined state.

Soft Suspend Mode

In Soft Suspend Mode CCU6 may finalize specific actions before it enters the suspended state with **OCS**.SUSSTA set. This can be advantageous for applications (e.g. motor control) where critical system states could occur if the kernel clock would be switched off immediately upon an OCDS suspend request.

Soft Suspend mode does not influence the kernel clock. Reading and writing of registers is possible without the side effects that may occur when reading/writing registers in Hard Suspend Mode.

For CCU6, two basic soft suspend options (**Stop Mode 0**, **Stop Mode 1**) are available, selected via bit field **OCS**.SUS.

In addition, the internal functional blocks (T12, T13, Hall logic, Trap logic) may individually be programmed via their Sensitivity Bits in register **KSCSR** to accept or ignore a suspend request. If the request sensitivity is disabled, the block continues normal operation. If the request sensitivity is enabled, the block operates as specified for the selected stop mode. The mapping of the CCU6 functional blocks to their Sensitivity Bits is shown in **Table 25-12**.

Stop Mode 0

In Stop Mode 0, if selected to be stopped, the Hall and Trap logic stops immediately, while Timer T12 and/or T13 continues normal operation (if running) until it reaches the end of the PWM period; then it stops (same stop condition as in single shot mode). When Timer T12 stops, the capture inputs CC6xIN are frozen.

Stop Mode 1

In Stop Mode 1, if selected to be stopped, the internal functional blocks (T12, T13, Hall logic, Trap logic) will stop immediately upon a suspend request.

If the sensitivity bits for Timer T12 or T13 are set, the corresponding output lines enabled for the trap condition are set to their passive values (similar to a trap condition).

Table 25-12 summarizes the reaction of the CCU6 functional blocks to OCDS suspend requests.

Table 25-12 CCU6 Functional Blocks

Block	Reaction to OCDS Suspend Request	Sensitivity Bit
0	**Timer T12:** if bit SB0 = 1_B, - in **Stop Mode 0** Timer T12 continues (if running) until the end of the PWM period. Then it stops and the CCxIN input stages are frozen. - in **Stop Mode 1** Timer T12 stops immediately and the CC6xIN input stages are frozen. Output lines CC6x, COUT6x with enabled trap functionality are set to their passive states.	KSCSR.SB0
1	**Timer T13:** if bit SB1 = 1_B, - in **Stop Mode 0** Timer T13 continues (if running) until the end of the PWM period. Then it stops. - in **Stop Mode 1** Timer T13 stops immediately. If trap functionality for COUT63 is enabled, it is set to the passive state.	KSCSR.SB1
2	**Hall Logic:** if bit SB2 = 1_B, the hall logic is stopped immediately and the CCPOSx input stages are frozen (same behavior for Stop Mode 0 and 1).	KSCSR.SB2
3	**Trap Logic:** if bit SB3 = 1_B, the trap logic is stopped immediately and the CTRAP input stage is frozen (same behavior for Stop Mode 0 and 1).	KSCSR.SB3

25.10.4 OCDS Trigger Bus (OTGB) Interface

The CCU6 kernel provides a set of 16 internal status signals that are combined to a Trigger Set. The CCU6 Trigger Set is shown in **Table 25-13**. It is output on OTGB0 or OTGB1 controlled by the **OCS** register.

Table 25-13 TS16_CCU6 Trigger Set CCU6

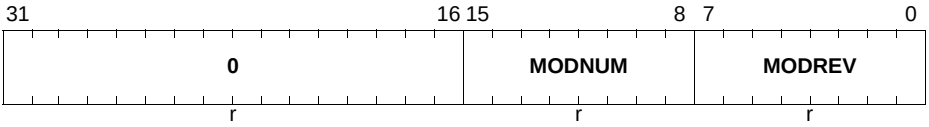
Bits	Name	Description
0	T12pre	T12 prescaler output
1	T13pre	T13 prescaler output
2	T12_cm0	T12 compare match channel 0
3	T12_cm1	T12 compare match channel 1
4	T12_cm2	T12 compare match channel 2
5	T12_pm	T12 period match
6	T12_om	T12 one match
7	T12_cdir	T12 count direction
8	T12_zm	T12 zero match
9	T13_cm	T13 compare match
10	T13_pm	T13 period match
11	T13_zm	T13 zero match
12	mcm_st	MCM shadow transfer
13	che	Correct Hall event
14	whe	Wrong Hall event
15	trpf	Trap flag

25.10.5 General Registers

25.10.5.1 ID Register

The CCU6 Module Identification Register ID contains read-only information about the module identification number and its revision.

ID
Module Identification Register **(08_H)** **Reset Value: 0000 54XX$_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision), 02_H, 03_H, ... up to FF_H.
MODNUM	[15:8]	r	**Module Number Value** This bit field defines the module identification number for the CCU6: 54_H
0	[31:16]	r	**Reserved** Read as 0.

25.10.5.2 Port Input Select Registers

Registers PISEL0 and PISEL2 contain bit fields selecting the actual input signal for the module inputs.

PISEL0
Port Input Select Register 0 **(10_H)** **Reset Value: 0000 0000_H**

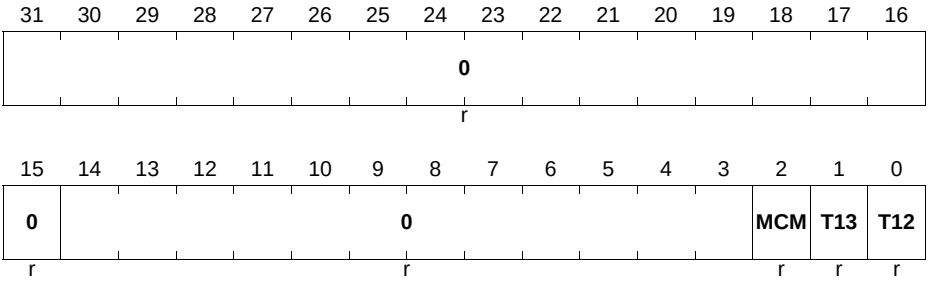
The T12 prescaler is not taken into account. 10_B The timer T12 is counting each rising edge detected in the selected T12HR signal. 11_B The timer T12 is counting each falling edge detected in the selected T12HR signal.
ISCNT13	[5:4]	rw	**Input Select for T13 Counting Input** This bit field defines the input event leading to a counting action of T13. 00_B The T13 prescaler generates the counting events. Bit TCTR4.T13CNT is not taken into account. 01_B Bit TCTR4.T13CNT written with 1 is a counting event. The T13 prescaler is not taken into account. 10_B The timer T13 is counting each rising edge detected in the selected T13HR signal. 11_B The timer T13 is counting each falling edge detected in the selected T13HR signal.
T12EXT	6	rw	**Extension for T12HR Inputs** This bit extends the 2-bit field IST12HR. 0_B One of the signals T12HR[D:A] is selected. 1_B One of the signals T12HR[H:E] is selected.

Field	Bits	Type	Description
T13EXT	7	rw	**Extension for T13HR Inputs** This bit extends the 2-bit field IST13HR. 0_B One of the signals T13HR[D:A] is selected. 1_B One of the signals T13HR[H:E] is selected.
0	[31:8]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.10.5.3 Module Configuration Register

The module configuration register contains bits describing the functionality that is available in the CCU6 module.

MCFG
Module Configuration Register (04_H) Reset Value: 0000 0007$_H$



Field	Bits	Type	Description
T12	0	r	**T12 Available** This bit indicates if the T12 block is available. 0_B The T12 block is not available. A write access to T12PR is ignored. 1_B The T12 block is available. A write access to T12PR is executed.
T13	1	r	**T13 Available** This bit indicates if the T13 block is available. 0_B The T13 block is not available. A write access to T13PR is ignored. 1_B The T13 block is available. A write access to T13PR is executed.
MCM	2	r	**Multi-Channel Mode Available** This bit indicates if the multi-channel mode functionality is available. 0_B The multi-channel mode functionality is not available. A write access to MCMOUTS is ignored. 1_B The multi-channel mode functionality is available. A write access to MCMOUTS is executed.
0	[31:3]	r	**Reserved;** read as 0; should be written with 0.

25.10.5.4 Input Monitoring Register

The input monitoring register monitors the occurrence of a selected event for the input signals. If a hardware event triggers the setting of bit IMON.x and the same bit is written with 1 via software at the same time, then the corresponding bit is cleared (software overrules hardware). The lost bit event is indicated if an event is detected again at one or more input signals with its lost indicator enabled.

Note: The register is only applicable in capture modes if the edges are selected through T12MSEL.MSEL6x.

IMON
Input Monitoring Register **(98_H)** **Reset Value: 0000 0000$_H$**

r						rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
LBE	0	rwh	**Lost Bit Event** This bit determines if a lost bit event has occurred. A lost bit event occurs when a selected event occurs again with the previous event captured (IMON.x remains set) and its lost indicator is enabled, for at least one of the monitored input signals. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B The lost bit event has not occurred. 1_B The lost bit event has occurred.
CCPOSxI (x = 0 -2)	x + 1	rwh	**Event indication for input signal CCPOSx** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B A selected event has not occurred. 1_B Edge detection indicates a selected event has occurred. *Note: The dedicated edge is indicated for a selected event if Hysteretic-like Control or Capture modes are initialized in T12MSEL.MSEL6x. If these modes are not selected, then all edges will be indicated as an event for the inputs.*
CC6xINI (x = 0 -2)	x + 4	rwh	**Event indication for input signal CC6xIN** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B A selected event has not occurred. 1_B Edge detection indicates a selected event has occurred.
CTRAPI	7	rwh	**Event indication for input signal CTRAP** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.

Field	Bits	Type	Description
T12HRI	8	rwh	**Event indication for input signal T12HR** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.
T13HRI	9	rwh	**Event indication for input signal T13HR** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.
0	[31:10]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.10.5.5 Lost Indicator Register

The lost indicator register has the lost indicator enable bits for its detected event at the input signals. The lost bit event can then be enabled as an output signal through one of the service request lines.

LI
Lost Indicator Register **($9C_H$)** **Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
CCPOSxEN (x = 0 -2)	x + 1	rw	**Lost Indicator Enable for input signal CCPOSx** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
CC6xINEN (x = 0 -2)	x + 4	rw	**Lost Indicator Enable for input signal CC6xIN** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.

Field	Bits	Type	Description
CTRAPEN	7	rw	**Lost Indicator Enable for input signal CTRAP** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
T12HREN	8	rw	**Lost Indicator Enable for input signal T12HR** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
T13HREN	9	rw	**Lost Indicator Enable for input signal T13HR** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
LBEEN	13	rw	**Interrupt Enable for Lost Bit Event** This bit determines if a SRx line is activated if lost bit event is detected. 0_B Lost bit event is disabled for the activation of a SRx line. 1_B Lost bit event is enabled for the activation of a SRx line.
INPLBE	[15:14]	rw	**Interrupt Node Pointer for lost bit event** This bit field defines which service request output line is selected to output an lost event alert for an enabled lost bit event. 00_B Service request output SR0 is selected. 01_B Service request output SR1 is selected. 10_B Service request output SR2 is selected. 11_B Service request output SR3 is selected.
0	0, [12:10], [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.10.5.6 Kernel State Control Sensitivity Register

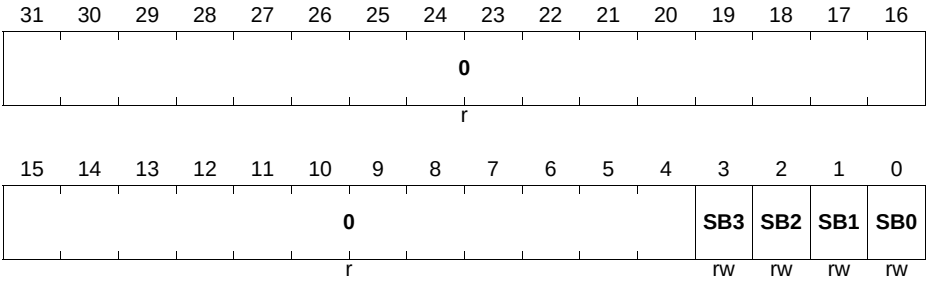
The kernel state control sensitivity register bits define which internal block is affected by Stop Modes 0 and 1, as described in section **Soft Suspend Mode**.

The Kernel State Control Sensitivity Register (KSCSR) is cleared by Debug Reset.

The register can only be written while the OCDS is enabled (OCDS enable = ´1´).

KSCSR
Kernel State Control Sensitivity Register

(1C$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SB0, **SB1,** **SB2,** **SB3**	0, 1, 2, 3	rw	**Sensitivity Block x** This bit defines if block x of the CCU6 kernel is sensitive to Stop Mode 0 or Stop Mode 1. The functional definition of the blocks is given in **Table 25-12**. 0_B Block x is not sensitive to Stop Mode 0 or Stop Mode 1. It continues normal operation without respecting the defined stop condition. 1_B Block x is sensitive to Stop Mode 0 or Stop Mode 1. It is respecting the defined stop condition.
0	[31:4]	r	**Reserved;** Returns 0 if read; should be written with 0.

25.10.6 BPI Registers

This section describes the registers of the BPI (Bus Peripheral Interface). **Figure 25-45** shows all registers associated with the BPI for one CCU6 kernel.

BPI Registers Overview

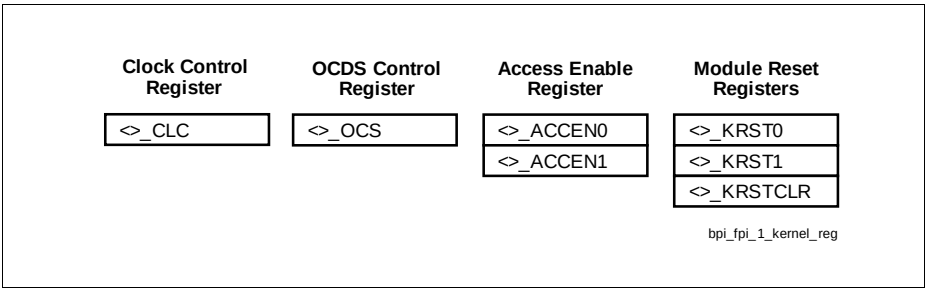


Figure 25-45 BPI Registers

Table 25-14 gives an overview of the BPI registers, including their access modes and reset class.

Table 25-14 Registers Overview - BPI Registers

Register Short Name	Description	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
CLC	Clock Control Register	00_H	U, SV	SV, E, P	Application Reset	25-130
-	Kernel Registers	-	-	-	-	-
OCS	OCDS Control and Status Register	$E8_H$	U, SV	SV, P	Debug Reset	25-131
KRSTCLR	Reset Status Clear Register	EC_H	U, SV	SV, E, P	Application Reset	25-137
KRST1	Reset Control Register 1	$F0_H$	U, SV	SV, E, P	Application Reset	25-136
KRST0	Reset Control Register 0	$F4_H$	U, SV	SV, E, P	Application Reset	25-135

Table 25-14 Registers Overview - BPI Registers

Register Short Name	Description	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
ACCEN1	Access Enable Register 1	$F8_H$	U, SV	SV, SE	Application Reset	25-134
ACCEN0	Access Enable Register 0	FC_H	U, SV	SV, SE	Application Reset	25-133

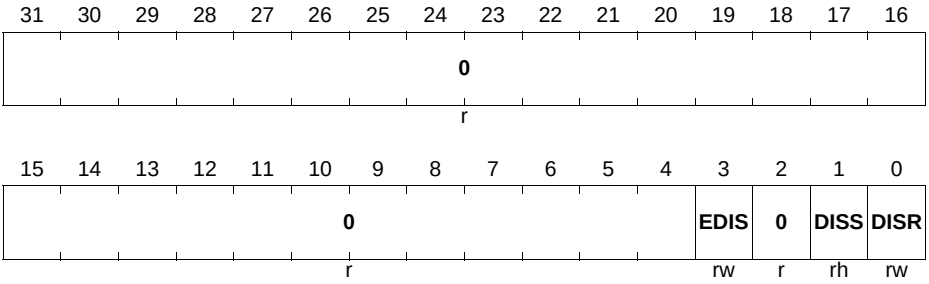
Note: Register bits marked “r” in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

25.10.6.1 System Registers

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the CCU6. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{CCU6} module clock signal and Sleep Mode for the module.

CLC
Clock Control Register (00_H) Reset Value: $0000\ 0003_H$



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested. 1_B Module disable is requested.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module is enabled. 1_B Module is disabled.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered upon a request.

Field	Bits	Type	Description
0	[31:16], [15:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: Upon an accepted Sleep Mode request (with EDIS = '1'), or upon a disable request (DISR = '1'), the CCU6 kernel clock is switched off immediately. Therefore, software should ensure that the system controlled by the CCU6 kernel has reached a safe state before triggering a Sleep Mode or module disable request.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status Register ($E8_H$) Reset Value: 0000 0000$_H$

SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend, Stop Mode 0 3_H Soft suspend, Stop Mode 1 **others**, reserved Effects of soft suspend options on CCU6 Functional Blocks are described in section **Soft Suspend Mode**
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:4], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ..., EN31 -> TAG ID 011111_B.

1) The BPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

ACCEN0
Access Enable Register 0 **(FC_H)** **Reset Value: FFFF FFFF$_H$**

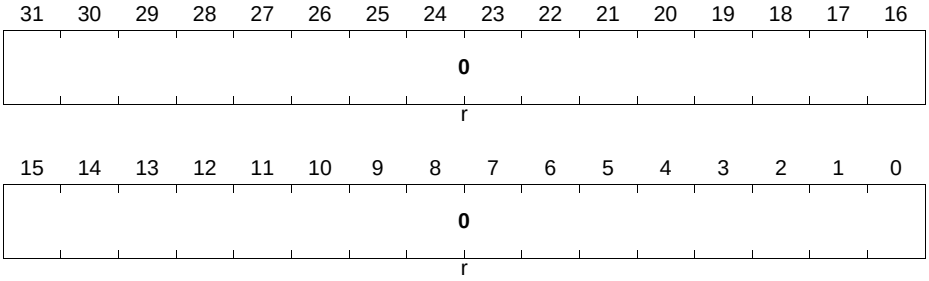
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ..., EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

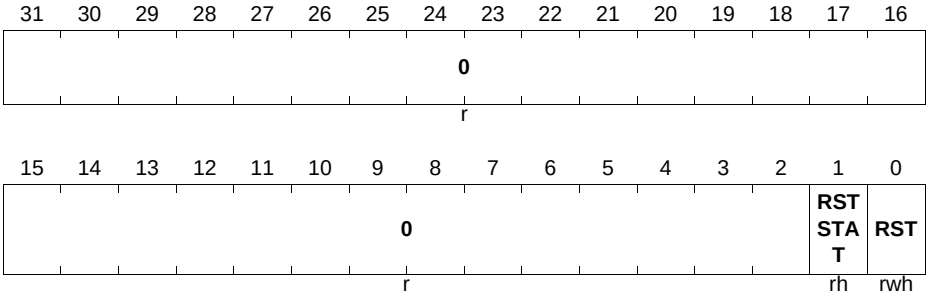
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI in the same clock cycle the RST bit is re-set by the BPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the CLR bit in the related KRSTCLR register.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge

*Note: A kernel reset, initiated via registers KRST0/KRST1, does not affect the port logic. Because register **PSLR** is set to its default value, the passive level 0 is selected for the outputs CC60..CC62 and COUT60..COUT63 upon a kernel reset. Therefore, software must ensure appropriate levels for the external system at the port pins in case they are different from the default values selected via PSLR.*

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**

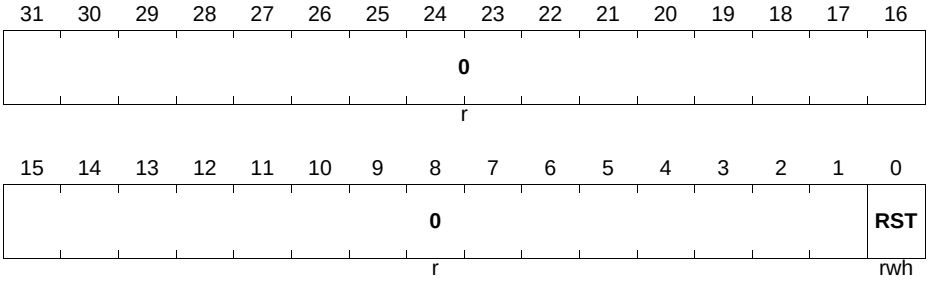


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (KRSTx1.RST and KRSTx0.RST) related to the module kernel that should be reset. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: 0000 0000$_H$**



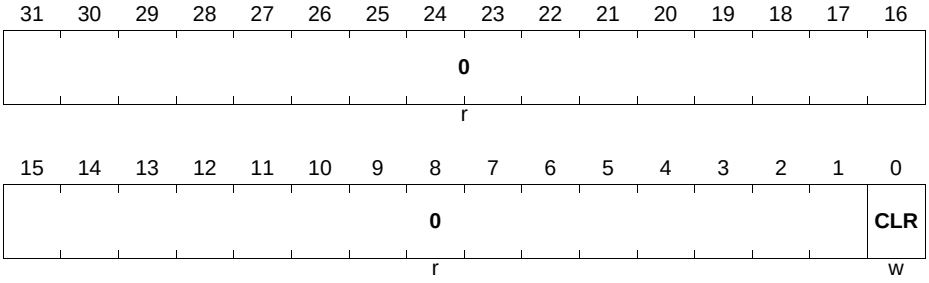
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear Register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

25.11 Implementation

This chapter describes the implementation of the CCU6 module in the TC21x/TC22x/TC23x device.

- Address map (see **Section 25.11.1**)
- Module output select (see **Section 25.11.2**)
- Synchronous start (see **Section 25.11.3**)
- Digital Connections (see **Section 25.11.4**)

25.11.1 Address Map

There are two CCU6 kernels in the TC21x/TC22x/TC23x, namely CCU60 and CCU61. The CCU6061 module consists of CCU60 and CCU61 kernels .

Table 25-15 Registers Address Space

Module	Base Address	End Address	Note
CCU60	F000 2A00$_H$	F000 2AFF$_H$	CCU6061 module includes CCU60 and CCU61 kernels
CCU61	F000 2B00$_H$	F000 2BFF$_H$	CCU6061 module includes CCU60 and CCU61 kernels

Table 25-16 Registers Overview - CCU6 Module Registers

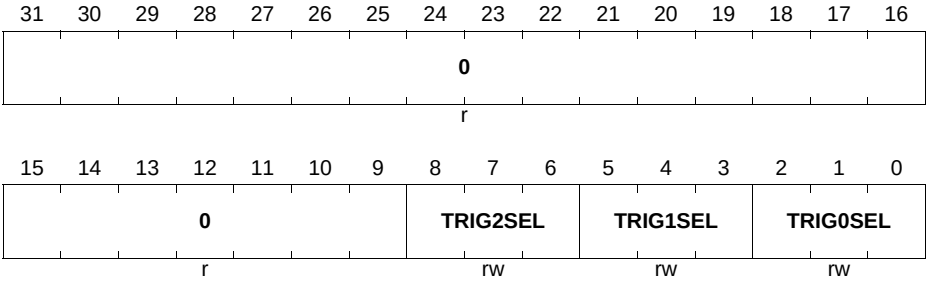
Register Short Name	Register Long Name	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
CCU6061 Module Registers (only available in the address range of CCU60)						
CCU60_MOSEL	CCU60 Module Output Select Register	0C$_H$	U, SV	U, SV, P	Application Reset	25-139

25.11.1.1 Module Registers

Module Output Select Register

MOSEL contains bit fields to select the output signal from module CCU6061 for the trigger signals to the A/D converters in the VADC module.

CCU60_MOSEL
CCU60 Module Output Select Register($0C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TRIG0SEL	[2:0]	rw	**Output Trigger Select for CCU6061 TRIG0** This bit field defines the output signal from the CCU6061 module used as the trigger signal to the VADC inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC60 is selected. 011_B The signal CCU61_CC60 is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
TRIG1SEL	[5:3]	rw	**Output Trigger Select for CCU6061 TRIG1** This bit field defines the output signal from the CCU6061 module used as the trigger signal to the VADC inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC61 is selected. 011_B The signal CCU61_CC61 is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
TRIG2SEL	[8:6]	rw	**Output Trigger Select for CCU6061 TRIG2** This bit field defines the output signal from the CCU6061 module used as the trigger signal to the VADC inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC62 is selected. 011_B The signal CCU61_CC62 is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
0	[31:9]	r	**Reserved** Returns 0 if read, should be written with 0.

*Note: CCU60_MOSEL is located in the address space of kernel CCU60. Therefore, when a reset of kernel CCU60 is triggered via registers CCU60_**KRST0** and CCU60_**KRST1**, register CCU60_MOSEL is also reset.*

*CCU60_MOSEL is **not** reset when a reset of kernel CCU61 is triggered via registers CCU61_KRST0 and CCU61_KRST1.*
*Because CCU60_MOSEL controls both signals from kernel CCU60 and CCU61, the output signals TRIG0..2 will be set to their inactive levels during **any** kernel reset of CCU60 as well as of CCU61 (see also **Figure 25-46**).*
Depending on the application, it may make sense to always reset both kernels in this case.

25.11.2 Module Output Select

For CCU6061 module, there are 3 trigger signals which are selectable from the output signals of the CCU60 and CCU61 kernels.

Each of the trigger signals (TRIG0, TRIG1, TRIG2) of the module is routed to each converter of the VADC module, as follows:

- TRIG0 of CCU6061 is routed to inputs BGREQGTC and GxREQGTC, x = 0, 1
- TRIG1 of CCU6061 is routed to inputs BGREQGTD and GxREQGTD, x = 0, 1
- TRIG2 of CCU6061 is routed to inputs BGREQGTE and GxREQGTE, x = 0, 1

Note: For ADAS devices, x = 0..3

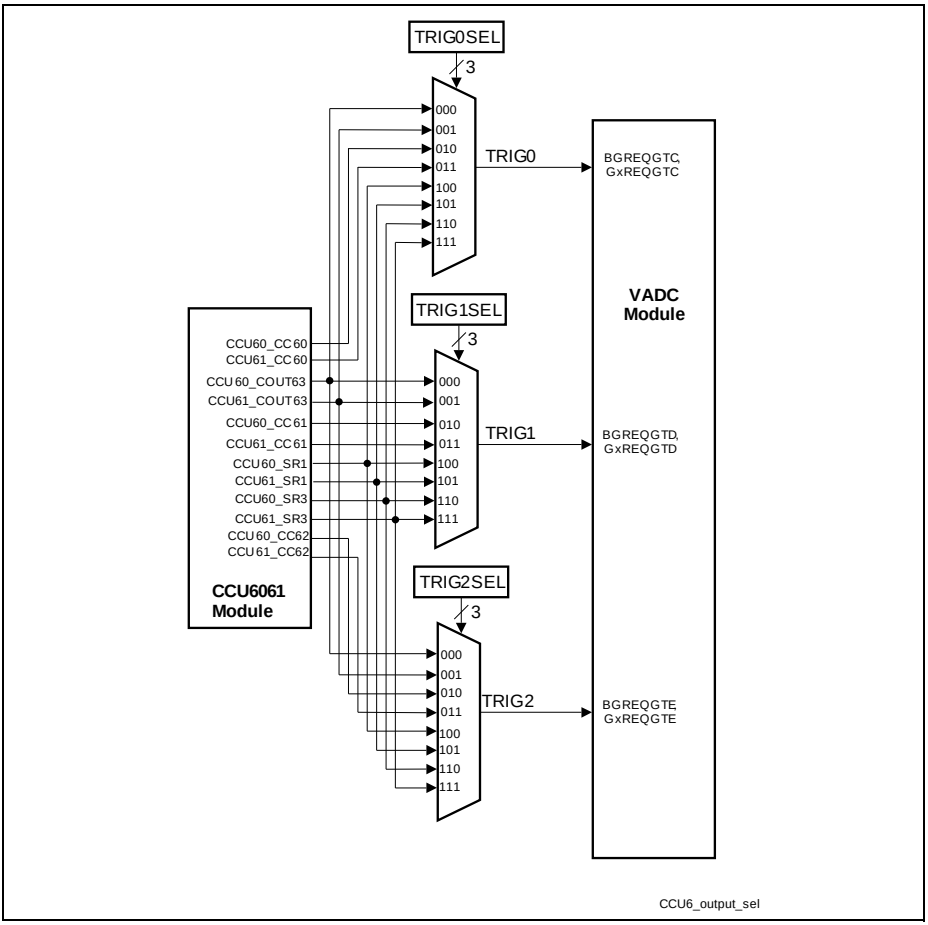


Figure 25-46 Output select trigger TC21x/TC22x/TC23x

25.11.3 Synchronous Start

Synchronous start of the capture/compare timers is supported by control bit SYSCON.CCTRIG0 in the SCU module. Bit SYSCON.CCTRIG0 is connected to the T12HR and T13HR inputs of the CCU60 and CCU61 kernels.

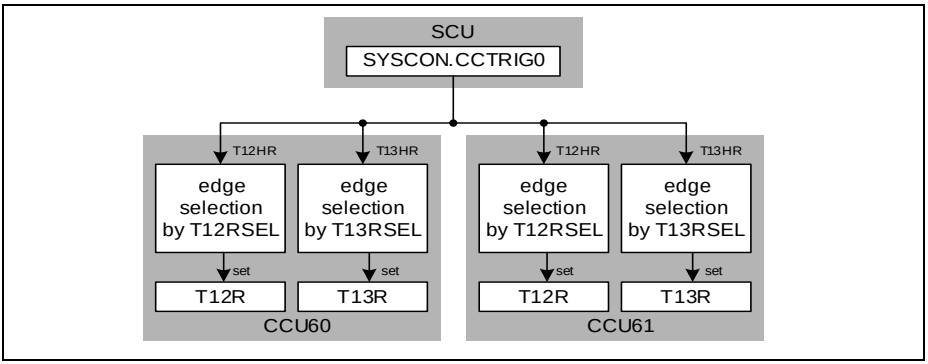

Figure 25-47 Synchronization Concept in TC21x/TC22x/TC23x

25.11.4 Digital Connections

The following tables show the digital connections of the CCU6x module with other modules or pins in the TC21x/TC22x/TC23x device.
Each input signal can be selected among 4 or 8 possible input lines, e.g. the input vector for input signal CC60IN is composed of CC60IN[D:A], whereas the input vectors for T12HR and T13HR are composed of T12HR[H:A] and T13HR[H:A]. The following sections refer to the interface signals.

The CCU6x module is clocked with the SPB_Bus clock, so $f_{CC6} = f_{SPB}$.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they can affect the module internal logic. The resulting delay of $2/f_{CC6}$ and an uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation.
An edge of an input signal can only be correctly detected if both, the high phase and the low phase of the input signal are each longer than $1/f_{CC6}$.

25.11.4.1 Connections of CCU60

This table describes the module interconnections of CCU60.

Note: Signals that are not available in the 100- and 80-pin package variant are specifically marked, see footnote [1].

Note: Signals that are not available in the 80-pin package variant are specifically marked, see footnote [2].

Table 25-17 CCU60 Digital Connections in TC21x/TC22x/TC23x

26 General Purpose Timer Unit (GPT12)

The General Purpose Timer Unit blocks GPT1 and GPT2 have very flexible multifunctional timer structures which may be used for timing, event counting, pulse width measurement, pulse generation, frequency multiplication, and other purposes.

They incorporate five 16-bit timers that are grouped into the two timer blocks GPT1 and GPT2. Each timer in each block may operate independently in a number of different modes such as Gated Timer or Counter Mode, or may be concatenated with another timer of the same block.

Each block has alternate input/output functions and specific interrupts (service requests) associated with it. Input signals can be selected from several sources by register PISEL.

The GPT12 module is clocked with clock f_{GPT}.

Block GPT1 contains three timers/counters: The core timer T3 and the two auxiliary timers T2 and T4. The maximum resolution is $f_{GPT}/4$. The auxiliary timers of GPT1 may optionally be configured as reload or capture registers for the core timer. These registers are listed in **Section 26.1.6.1**.

The following list summarizes the supported features:

- $f_{GPT}/4$ maximum resolution
- 3 independent timers/counters
- Timers/counters can be concatenated
- 4 operating modes:
  - Timer Mode
  - Gated Timer Mode
  - Counter Mode
  - Incremental Interface Mode
- Reload and Capture functionality
- Separate interrupts

Block GPT2 contains two timers/counters: The core timer T6 and the auxiliary timer T5. The maximum resolution is $f_{GPT}/2$. An additional Capture/Reload register (CAPREL) supports capture and reload operation with extended functionality. These registers are listed in **Section 26.2.7.1**.

The following list summarizes the supported features:

- $f_{GPT}/2$ maximum resolution
- 2 independent timers/counters
- Timers/counters can be concatenated
- 3 operating modes:
  - Timer Mode
  - Gated Timer Mode
  - Counter Mode
- Extended capture/reload functions via 16-bit capture/reload register CAPREL
- Separate interrupts

26.1 Timer Block GPT1

All three timers of block GPT1 (T2, T3, T4) can run in one of 4 basic modes: Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode. All timers can count up or down. Each timer of GPT1 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T3 is indicated by the Output Toggle Latch T3OTL, whose state may be output on the associated pin T3OUT (alternate pin function). The auxiliary timers T2 and T4 may additionally be concatenated with the core timer T3 (through T3OTL) or may be used as capture or reload registers for the core timer T3.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T2, T3, or T4. When any of the timer registers is written to by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupt requests of GPT1 are signalled on service request lines SR0, SR1, and SR2.

The input and output lines of GPT1 are connected to pins. The control registers for the port functions are located in the respective port modules.

*Note: The timing requirements for external input signals can be found in **Section 26.1.5**, **Section 26.5.2** summarizes the module interface signals, including pins and interrupt request signals.*

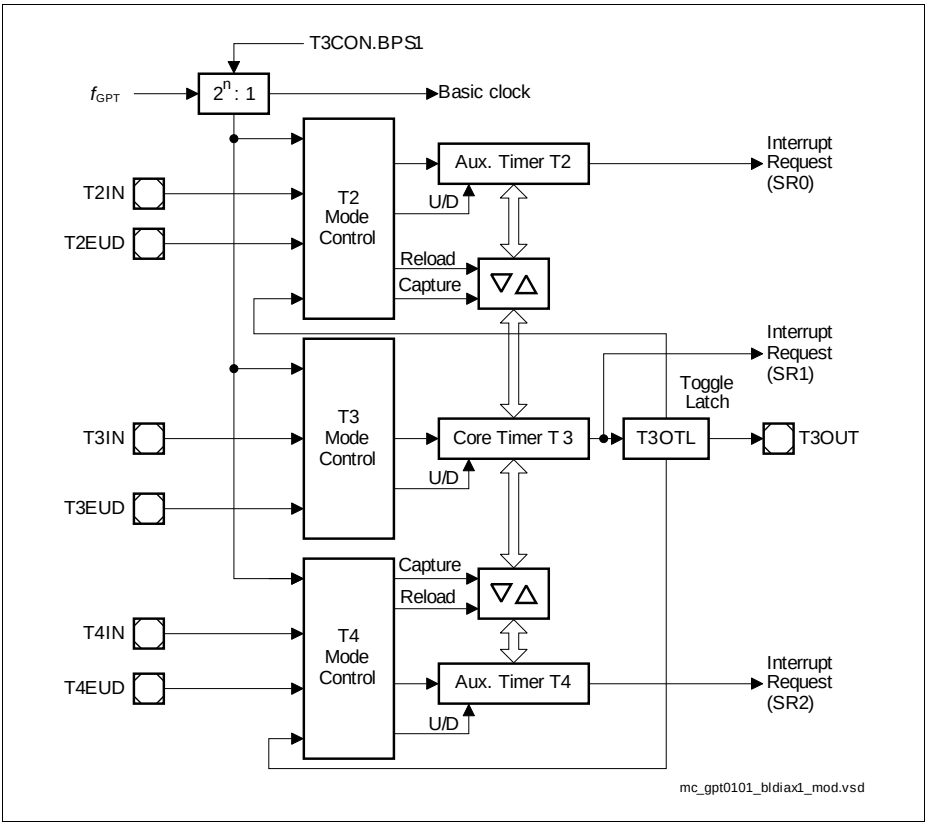

Figure 26-1 GPT1 Block Diagram

26.1.1 GPT1 Core Timer T3 Control

The current contents of the core timer T3 are reflected by its count register T3. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T3 is configured and controlled via its control register T3CON.

Timer T3 Run Control

The core timer T3 can be started or stopped by software through bit T3R (Timer T3 Run Bit). This bit is relevant in all operating modes of T3. Setting bit T3R will start the timer, clearing bit T3R stops the timer.

In Gated Timer Mode, the timer will only run if T3R = 1 and the gate is active (high or low, as programmed).

Note: When bit T2RC or T4RC in timer control register T2CON or T4CON is set, bit T3R will also control (start and stop) the auxiliary timer(s) T2 and/or T4.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in **Table 26-6**. The count direction can be changed regardless of whether or not the timer is running.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

Timer T3 Output Toggle Latch

The overflow/underflow signal of timer T3 is connected to a block named ‘Toggle Latch’, shown in the Timer Mode diagrams. **Figure 26-2** illustrates the details of this block. An overflow or underflow of T3 will clock two latches: The first latch represents bit T3OTL in control register T3CON. The second latch is an internal latch toggled by T3OTL’s output. Both latch outputs are connected to the input control blocks of the auxiliary timers T2 and T4. The output level of the shadow latch will match the output level of T3OTL, but is delayed by one clock cycle. When the T3OTL value changes, this will result in a temporarily different output level from T3OTL and the shadow latch, which can trigger the selected count event in T2 and/or T4.

When software writes to T3OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timers carry the same level and no edge will be detected. Bit T3OE (overflow/underflow output enable) in register T3CON enables the state of T3OTL to be monitored via an external pin T3OUT. When T3OTL is linked to an external port pin (must be configured as output), T3OUT can be used to control external HW. If T3OE = 1, pin T3OUT outputs the state of T3OTL. If T3OE = 0, pin T3OUT outputs a high level (as long as the T3OUT alternate function is selected for the port pin).

The trigger signals can serve as an input for the counter function or as a trigger source for the reload function of the auxiliary timers T2 and T4.

As can be seen from **Figure 26-2**, when latch T3OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T2/T4 in this case.

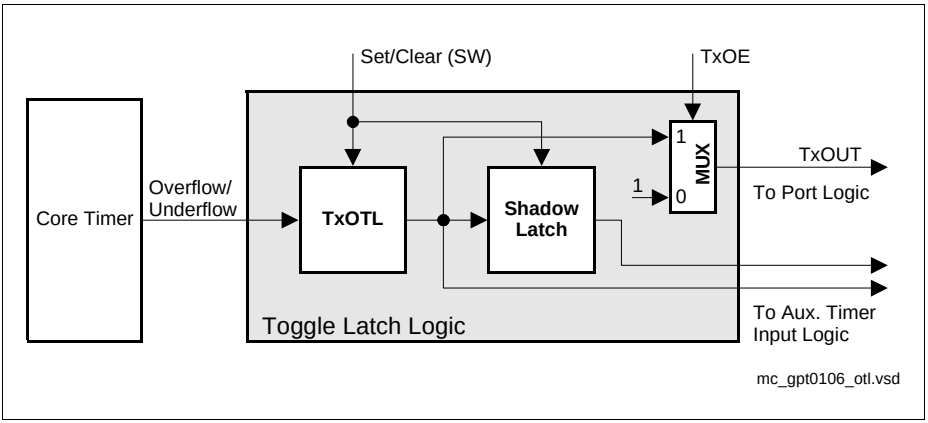

Figure 26-2 Block Diagram of the Toggle Latch Logic of Core Timer T3 (x = 3)

26.1.2 GPT1 Core Timer T3 Operating Modes

Timer T3 can operate in one of several modes.

Timer T3 in Timer Mode

Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 000_B. In Timer Mode, T3 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS1 and T3I in register T3CON. Please see **Section 26.1.5** for details on the input clock options.

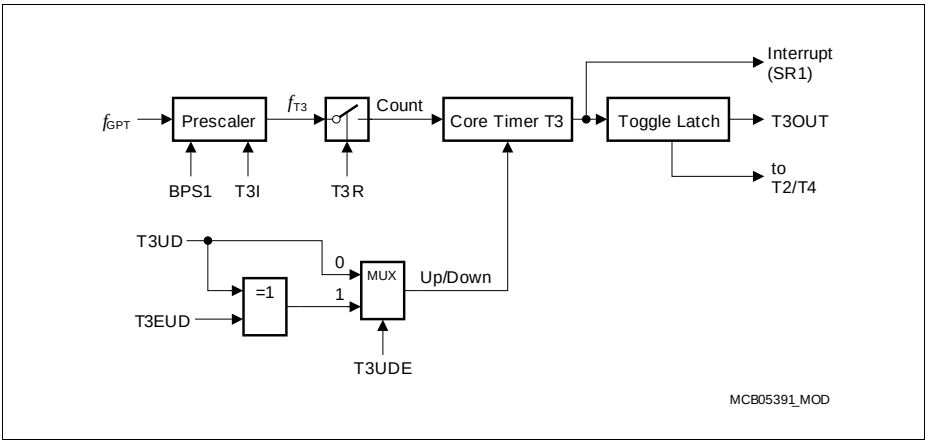

Figure 26-3 Block Diagram of Core Timer T3 in Timer Mode

Timer T3 in Gated Timer Mode

Gated Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 010_B or 011_B. Bit T3M.0 (T3CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see **Section 26.1.5**). However, the input clock to the timer in this mode is gated by the external input pin T3IN (Timer T3 External Input).

To enable this operation, the associated pin T3IN must be configured as input.

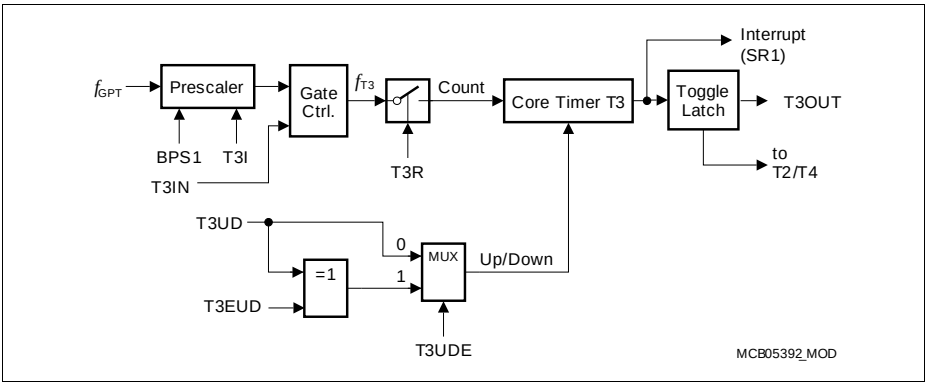

Figure 26-4 Block Diagram of Core Timer T3 in Gated Timer Mode

If T3M = 010_B, the timer is enabled when T3IN shows a low level. A high level at this line stops the timer. If T3M = 011_B, line T3IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T3R. The timer will only run if T3R is 1 and the gate is active. It will stop if either T3R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T3IN does not cause a service request via SR1.

Timer T3 in Counter Mode

Counter Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 001_B. In Counter Mode, timer T3 is clocked by a transition at the external input pin T3IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T3I in control register T3CON selects the triggering transition (see **Table 26-8**).

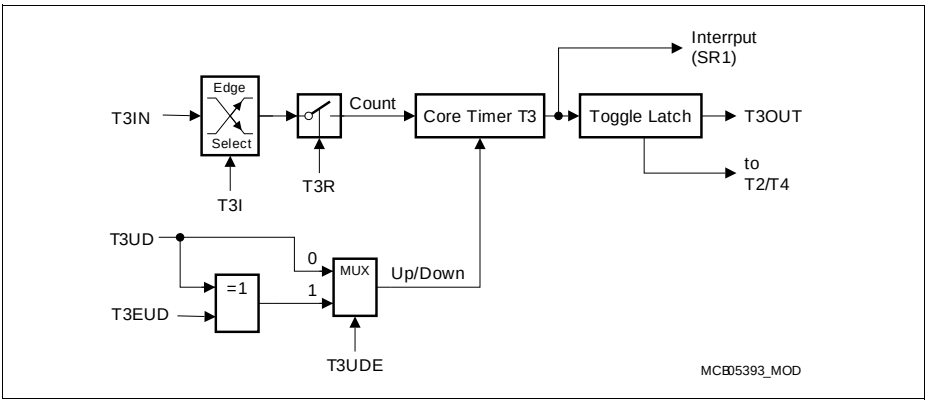

Figure 26-5 Block Diagram of Core Timer T3 in Counter Mode

For Counter Mode operation, pin T3IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T3IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 26.1.5**.

Timer T3 in Incremental Interface Mode

Incremental Interface Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with core timer T3 (T3IN, T3EUD) are used to interface to an incremental encoder. T3 is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

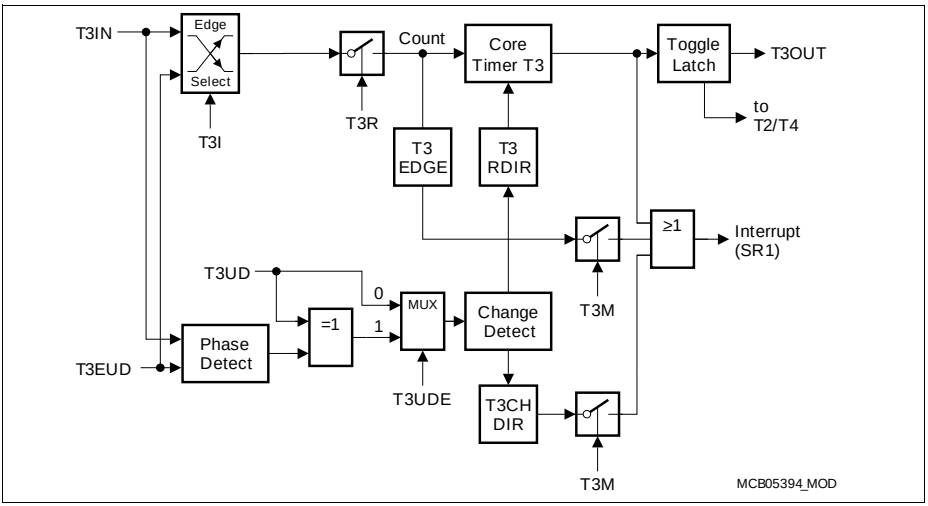

Figure 26-6 Block Diagram of Core Timer T3 in Incremental Interface Mode

Bitfield T3I in control register T3CON selects the triggering transitions (see **Table 26-10**). The sequence of the transitions of the two input signals is evaluated and generates count pulses as well as the direction signal. So T3 is modified automatically according to the speed and the direction of the incremental encoder and, therefore, its contents always represent the encoder's current position.

The service request generation can be selected: In Rotation Detection Mode (T3M = 110_B), a service request is generated each time the count direction of T3 changes. In Edge Detection Mode (T3M = 111_B), a service request is generated each time a count edge for T3 is detected. Count direction, changes in the count direction, and count requests are monitored by status bits T3RDIR, T3CHDIR, and T3EDGE in register T3CON.

The incremental encoder can be connected directly to the TC21x/TC22x/TC23x without external interface logic. In a standard system, however, comparators will be employed to convert the encoder's differential outputs (such as A, $\overline{A}$) to digital signals (such as A). This greatly increases noise immunity.

Note: The third encoder output T0, that indicates the mechanical zero position, may be connected to an external interrupt input and trigger a reset of timer T3.
*If input T4IN is available, T0 can be connected there and clear T3 automatically without requiring an interrupt (see bit CLRT3EN in register **T4CON**).*

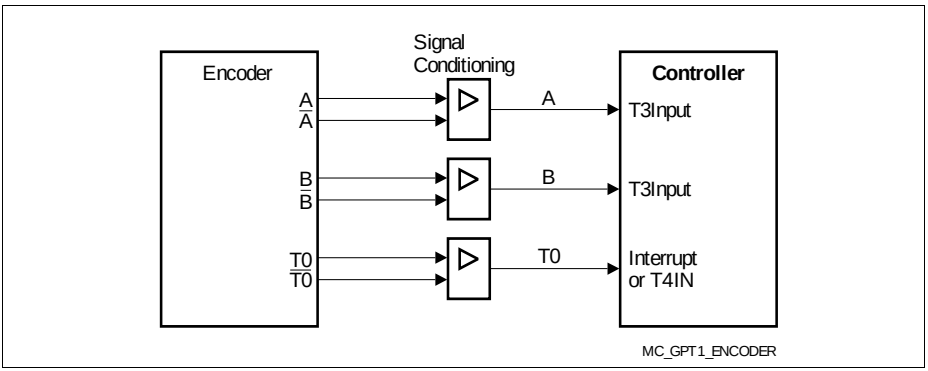

Figure 26-7 Connection of the Encoder to the TC21x/TC22x/TC23x

For Incremental Interface Mode operation, the following conditions must be met:

- Bitfield T3M must be 110_B or 111_B.
- Both pins T3IN and T3EUD must be configured as input.
- Pin T4IN must be configured as input, if used for T0.
- Bit T3UDE must be 1 to enable automatic external direction control.

The maximum count frequency allowed in Incremental Interface Mode depends on the selected prescaler value. To ensure that a transition of any input signal is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 26.1.5**.

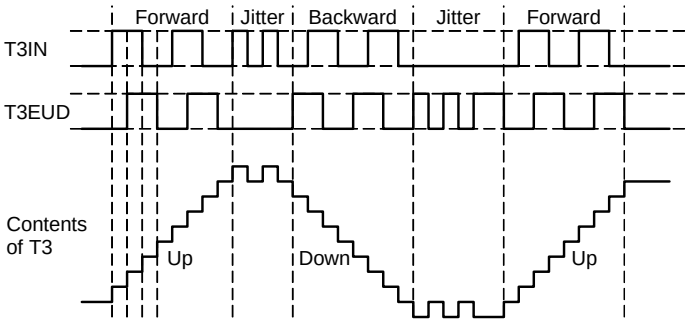
As in Incremental Interface Mode two input signals with a 90° phase shift are evaluated, their maximum input frequency can be half the maximum count frequency.

In Incremental Interface Mode, the count direction is automatically derived from the sequence in which the input signals change, which corresponds to the rotation direction of the connected sensor. **Table 26-1** summarizes the possible combinations.

Table 26-1 GPT1 Core Timer T3 (Incremental Interface Mode) Count Direction

Level on Respective other Input	T3IN Input		T3EUD Input	
	Rising ↑	**Falling ↓**	**Rising ↑**	**Falling ↓**
High	Down	Up	Up	Down
Low	Up	Down	Down	Up

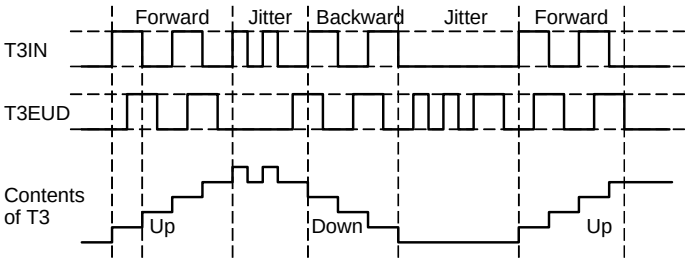
Figure 26-8 and **Figure 26-9** give examples of T3's operation, visualizing count signal generation and direction control. They also show how input jitter is compensated, which might occur if the sensor rests near to one of its switching points.



Note: This example shows the timer behaviour assuming that T3 counts upon any transition on any input (T3IN and T3EUD), i.e. T3I = 011_B.

MCT04373

Figure 26-8 Evaluation of Incremental Encoder Signals, 2 Count Inputs



Note: This example shows the timer behaviour assuming that T3 counts upon any transition on input T3IN, i.e. T3I = 001_B.

MCT04374

Figure 26-9 Evaluation of Incremental Encoder Signals, 1 Count Input

Note: Timer T3 operating in Incremental Interface Mode automatically provides information on the sensor's current position. Dynamic information (speed,

acceleration, deceleration) may be obtained by measuring the incoming signal periods (see ***"Combined Capture Modes" on Page 26-58****).*

26.1.3 GPT1 Auxiliary Timers T2/T4 Control

Auxiliary timers T2 and T4 have exactly the same functionality. They can be configured for Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode with the same options for the timer frequencies and the count signal as the core timer T3. In addition to these 4 counting modes, the auxiliary timers can be concatenated with the core timer, or they may be used as reload or capture registers in conjunction with the core timer. The start/stop function of the auxiliary timers can be remotely controlled by the T3 run control bit. Several timers may thus be controlled synchronously.

The current contents of an auxiliary timer are reflected by its count register T2 or T4, respectively. These registers can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timers T2 and T4 are determined by their control registers T2CON and T4CON, that are organized identically. Note that functions which are present in all 3 timers of block GPT1 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timers have no output toggle latch and no alternate output function.

Timer T2/T4 Run Control

Each of the auxiliary timers T2 and T4 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T2R or T4R). In this case it is required that the respective control bit TxRC = 0.
- Through the core timer's run bit (T3R). In this case the respective remote control bit must be set (TxRC = 1).

The selected run bit is relevant in all operating modes of T2/T4. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T3R will start/stop timer T3 and the selected auxiliary timer(s) synchronously.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) is controlled in the same way, either by software or by the external input pin TxEUD. Please refer to the description in **Table 26-6**.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

26.1.4 GPT1 Auxiliary Timers T2/T4 Operating Modes

The operation of the auxiliary timers in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timers T2 and T4 in Timer Mode

Timer Mode for an auxiliary timer Tx is selected by setting its bitfield TxM in register TxCON to 000_B.

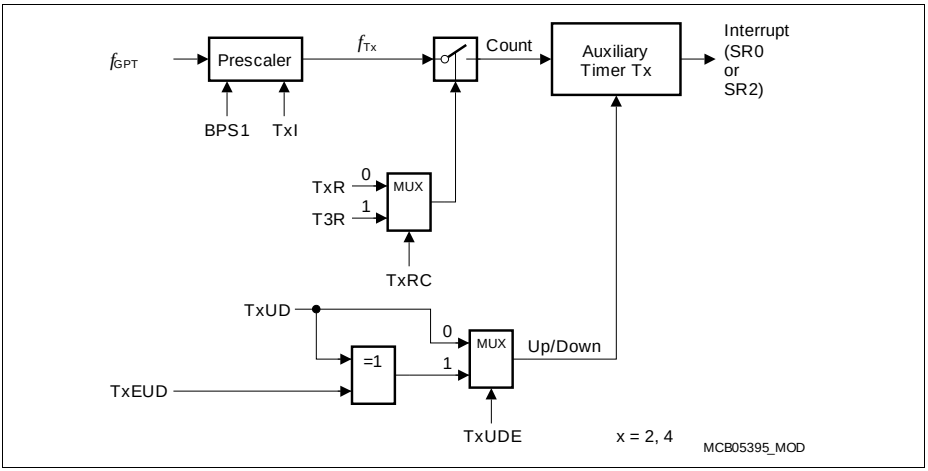


Figure 26-10 Block Diagram of an Auxiliary Timer in Timer Mode

Timers T2 and T4 in Gated Timer Mode

Gated Timer Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 010_B or 011_B. Bit TxM.0 (TxCON.3) selects the active level of the gate input.

Note: A transition of the gate signal at TxIN does not cause a service request. Service requests of timer T2 are handled via SR0, and service requests of timer T4 are handled via SR2.

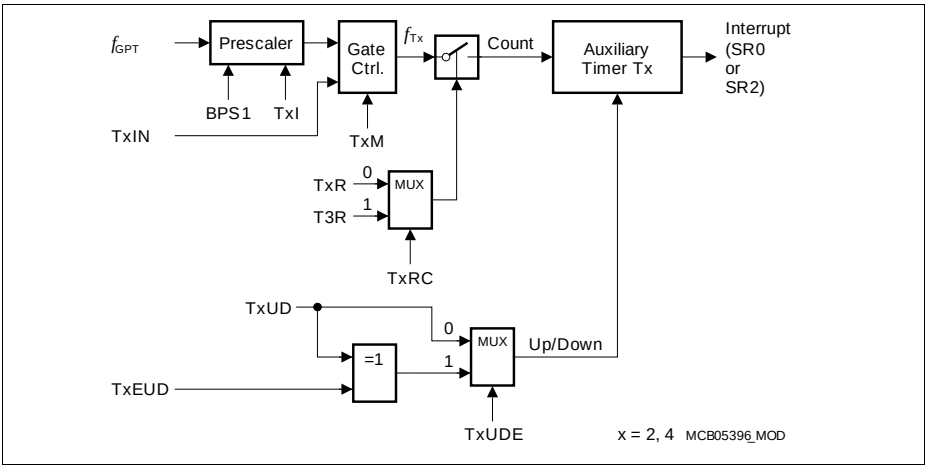

Figure 26-11 Block Diagram of an Auxiliary Timer in Gated Timer Mode

Note: There is no output toggle latch for T2 and T4.
Start/stop of an auxiliary timer can be controlled locally or remotely.

Timers T2 and T4 in Counter Mode

Counter Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 001_B. In Counter Mode, an auxiliary timer can be clocked either by a transition at its external input line TxIN, or by a transition of timer T3's toggle latch T3OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield TxI in control register TxCON selects the triggering transition (see **Table 26-9**).

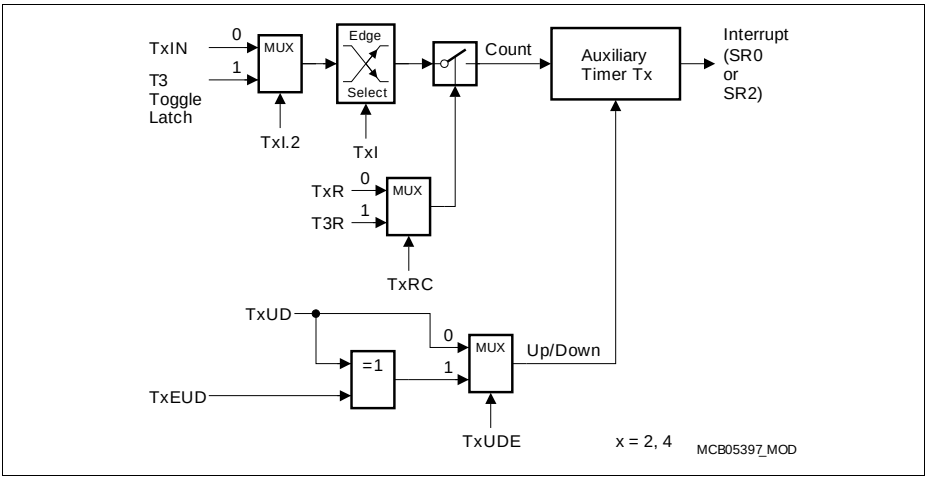

Figure 26-12 Block Diagram of an Auxiliary Timer in Counter Mode

Note: Only state transitions of T3OTL which are caused by the overflows/underflows of T3 will trigger the counter function of T2/T4. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

For counter operation, pin TxIN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 26.1.5**.

Timer Concatenation

Using the toggle bit T3OTL as a clock source for an auxiliary timer in Counter Mode concatenates the core timer T3 with the respective auxiliary timer. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T3OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T3OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T3. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T3OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T3. This configuration forms a 33-bit timer (16-bit core timer + T3OTL + 16-bit auxiliary timer).
  As long as bit T3OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T3, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

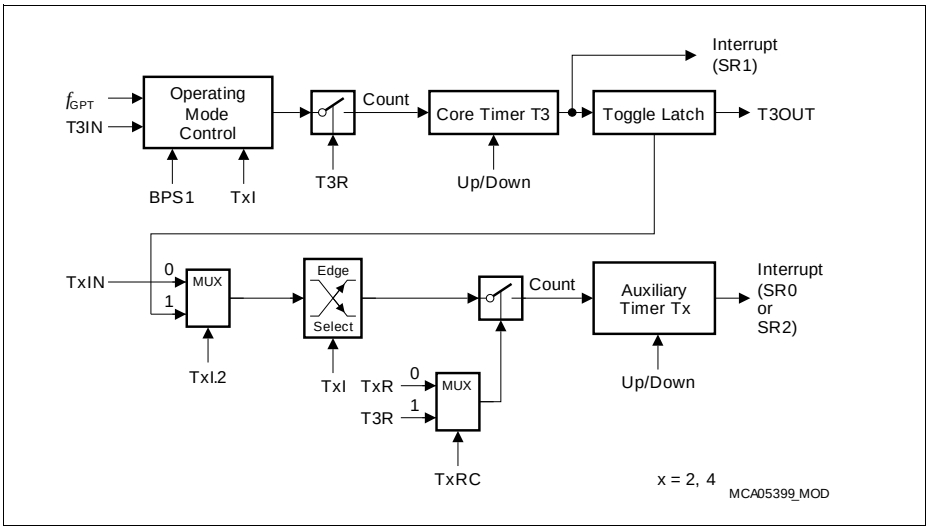

Figure 26-13 Concatenation of Core Timer T3 and an Auxiliary Timer

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT1 timers, represented by TIMER_HIGH (for auxiliary timer, here T2) and TIMER_LOW (for core timer T3). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T2
- TIMER_LOW = T3
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see **Table 26-2**
- TIMER_HIGH = T2
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T3

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of module clock cycles corresponding to two basic clock cycles is shown in **Table 26-2**.

Table 26-2 Number of Module Clock Cycles to Wait for Two Basic Clock Cycles

Block Prescaler	BPS1 = 01_B	BPS1 = 00_B	BPS1 = 11_B	BPS1 = 10_B
Number of Module clocks	8	16	32	64

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS1 and the Individual Prescalers TxI (see **Table 26-7**), the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time.

Timers T2 and T4 in Incremental Interface Mode

Incremental Interface Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with an auxiliary timer Tx (TxIN, TxEUD) are used to interface to an incremental encoder. Tx is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

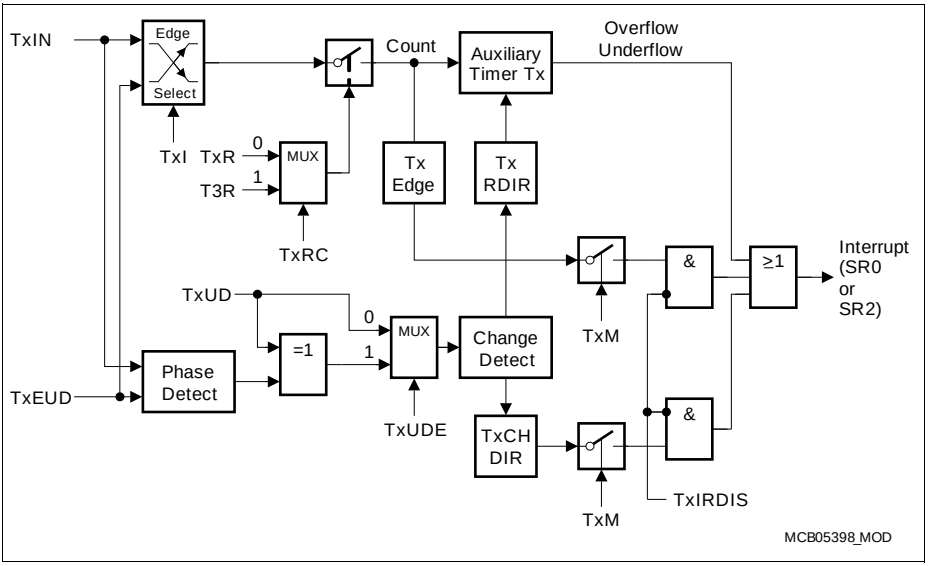

Figure 26-14 Block Diagram of an Auxiliary Timer in Incremental Interface Mode

The operation of the auxiliary timers T2 and T4 in Incremental Interface Mode and the interrupt generation are the same as described for the core timer T3. The descriptions, figures and tables apply accordingly.

Note: Timers T2 and T4 operating in Incremental Interface Mode automatically provide information on the sensor's current position. For dynamic information (speed, acceleration, deceleration) see ***"Combined Capture Modes" on Page 26-58****).*

Timers T2 and T4 in Reload Mode

Reload Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 100_B. In Reload Mode, the core timer T3 is reloaded with the contents of an auxiliary timer register, triggered by one of two different signals. The trigger signal is selected the same way as the clock source for Counter Mode (see **Table 26-9**), i.e. a transition of the auxiliary timer's input TxIN or the toggle latch T3OTL may trigger the reload.

Note: When programmed for Reload Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.
The timer input pin TxIN must be configured as input if it shall trigger a reload operation.

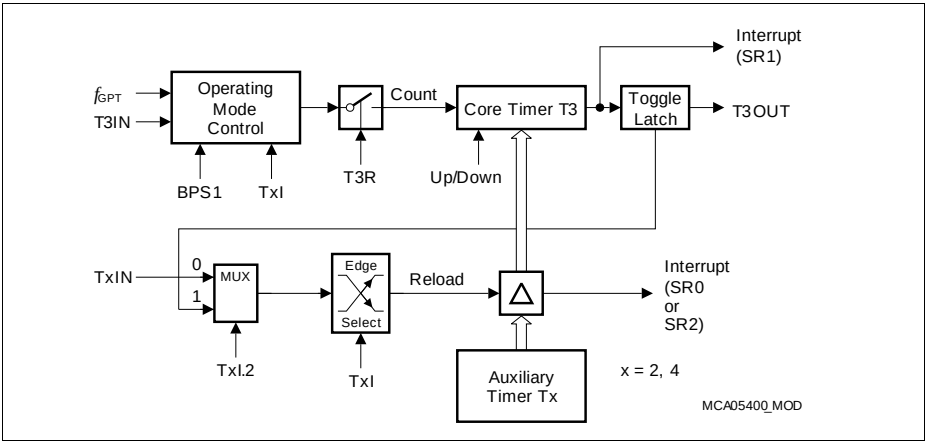

Figure 26-15 GPT1 Auxiliary Timer in Reload Mode

Upon a trigger signal, T3 is loaded with the contents of the respective timer register (T2 or T4) and the respective service request SR0 or SR2 is activated.

Note: When a T3OTL transition is selected for the trigger signal, service request SR1 will also become active, indicating T3's overflow or underflow. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

To ensure that a transition of the reload input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 26.1.5**.

The Reload Mode triggered by the T3 toggle latch can be used in a number of different configurations. The following functions can be performed, depending on the selected active transition:

- If both a positive and a negative transition of T3OTL are selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer each time it overflows or underflows. This is the standard Reload Mode (reload on overflow/underflow).
- If either a positive or a negative transition of T3OTL is selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer on every second overflow or underflow.
- Using this “single-transition” mode for both auxiliary timers allows to perform very flexible Pulse Width Modulation (PWM). One of the auxiliary timers is programmed to reload the core timer on a positive transition of T3OTL, the other is programmed for a reload on a negative transition of T3OTL. With this combination the core timer is alternately reloaded from the two auxiliary timers.

Figure 26-16 shows an example for the generation of a PWM signal using the “single-transition” reload mechanism. T2 defines the high time of the PWM signal (reloaded on positive transitions) and T4 defines the low time of the PWM signal (reloaded on negative transitions). The PWM signal can be output on pin T3OUT if T3OE = 1. With this method, the high and low time of the PWM signal can be varied in a wide range.

Note: The output toggle latch T3OTL is accessible via software and may be changed, if required, to modify the PWM signal.
However, this will NOT trigger the reloading of T3.

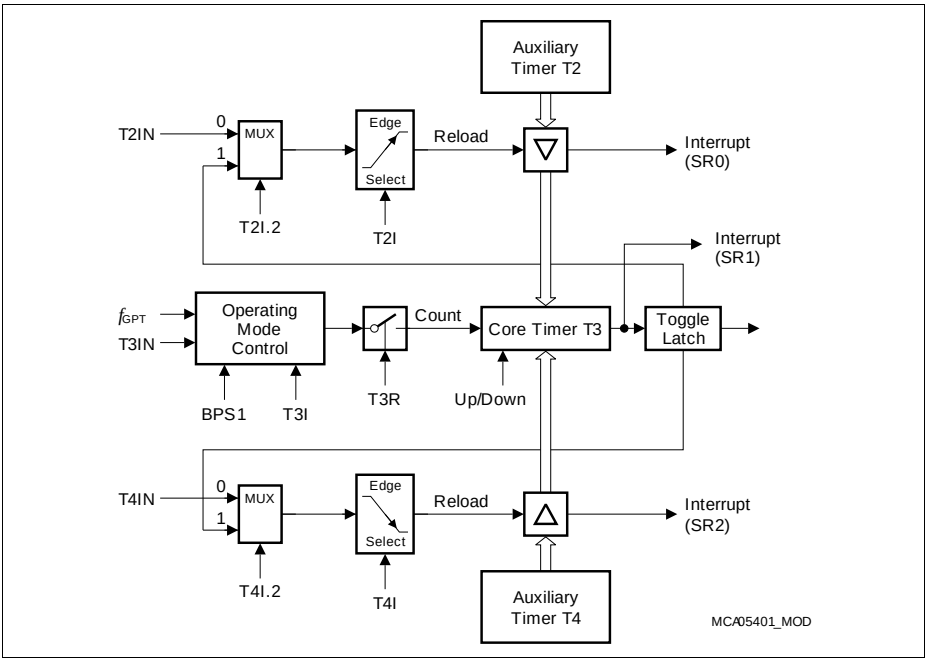

Figure 26-16 GPT1 Timer Reload Configuration for PWM Generation

Note: Although possible, selecting the same reload trigger event for both auxiliary timers should be avoided. In such a case, both reload registers would try to load the core timer at the same time. If this combination is selected, T2 is disregarded and the contents of T4 is reloaded.

The implementation of the GPT1 finite state machine may require special consideration in following cases.

In Case 1, when T2 or T4 are used to reload T3 on overflow/underflow, and T3 is read by software on the fly, the following unexpected values may be read from T3:

- When T3 is counting up, 0000_H or 0001_H may be read from T3 directly after an overflow, although the reload value in T2/T4 is higher (0001_H may be read in particular if BPS1 = 01_B and T3I = 000_B).
- When T3 is counting down, $FFFF_H$ or $FFFE_H$ may be read from T3 directly after an underflow, although the reload value in T2/T4 is lower ($FFFE_H$ may be read in particular if BPS1 = 01_B and T3I = 000_B).

Note: All timings derived from T3 in this configuration (e.g. distance between service requests, PWM waveform on T3OUT, etc.) are accurate except for the specific case described below.

Recommendation:

- When T3 counts up, and T3_value < reload value is read from T3, T3_value should be replaced with the reload value for further calculations.
- When T3 counts down, and T3_value > reload value is read from T3, T3_value should be replaced with the reload value for further calculations.

Alternatively, if the intention is to identify the overflow/underflow of T3, the T3 service request (SR1) may be used.

In Case 2, when T2 is used to reload T3 in the configuration with BPS1 = 01_B and T3I = 000_B (i.e. fastest configuration/highest resolution of T3), the reload of T3 is performed with a delay of one basic clock cycle.

Recommendation:

To compensate the delay and achieve correct timing,

- increment the reload value in T2 by 1 when T3 is configured to count up,
- decrement the reload value in T2 by 1 when T3 is configured to count down.

Alternatively, use T4 instead of T2 as reload register for T3. In this configuration the reload of T3 is not delayed, i.e. the effect described above does not occur with T4.

Timers T2 and T4 in Capture Mode

Capture Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 101_B. In Capture Mode, the contents of the core timer T3 are latched into an auxiliary timer register in response to a signal transition at the respective auxiliary timer's external input pin TxIN. The capture trigger signal can be a positive, a negative, or both a positive and a negative transition.

The two least significant bits of bitfield TxI select the active transition (see **Table 26-9**). Bit 2 of TxI is irrelevant for Capture Mode and must be cleared (TxI.2 = 0).

Note: When programmed for Capture Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.

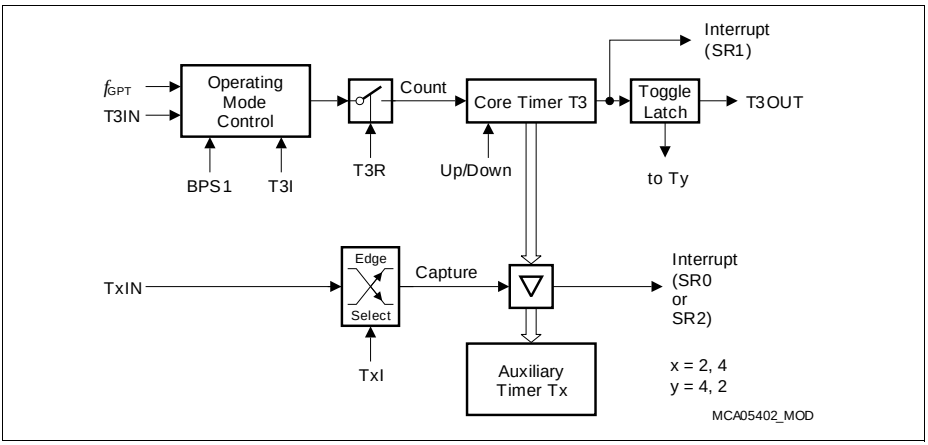

Figure 26-17 GPT1 Auxiliary Timer in Capture Mode

Upon a trigger (selected transition) at the corresponding input pin TxIN the contents of the core timer T3 are loaded into the auxiliary timer register Tx and the associated service request (SR0 or SR2) will be activated.

For Capture Mode operation, the respective timer input pin TxIN must be configured as input. To ensure that a transition of the capture input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 26.1.5**.

26.1.5 GPT1 Clock Signal Control

All actions within the timer block GPT1 are triggered by transitions of its basic clock. This basic clock is derived from the module clock f_{GPT} by a basic block prescaler, controlled by bitfield BPS1 in register T3CON (see **Figure 26-1**). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT1's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode or Incremental Interface Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 26-3 Basic Clock Selection for Block GPT1

Block Prescaler[1)]	BPS1 = 01_B	BPS1 = 00_B[2)]	BPS1 = 11_B	BPS1 = 10_B
Prescaling Factor for GPT1: F(BPS1)	F(BPS1) = 4	F(BPS1) = 8	F(BPS1) = 16	F(BPS1) = 32
Maximum External Count Frequency	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$	$f_{GPT}/64$
Input Signal Stable Time	4 x t_{GPT}	8 x t_{GPT}	16 x t_{GPT}	32 x t_{GPT}

1) Please note the non-linear encoding of bitfield BPS1.

2) Default after reset.

Note: The GPT1 block uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T2, T3, T4), these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT1 state machine has 8 states (4 states when BPS1 = 01_B) and processes the timers in the order T3 - T2 (all actions except capture) - T4 - T2 (capture).

Note: When initializing the GPT1 block after reset, and the block prescaler BPS1 in register T3CON needs to be set to a value different from its default value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, incremental interface, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur during the first basic clock cycle.
In this case, or when changing BPS1 during operation of the GPT1 block, disable related interrupts before modification of BPS1, and afterwards clear the corresponding service request flags and re-initialize those registers (T2, T3, T4) that might be affected by a count/capture/reload event.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT1 timer is derived from the GPT1 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS1) \times 2^{<TxI>}} \qquad r_{Tx}[\mu s] = \frac{F(BPS1) \times 2^{<TxI>}}{f_{GPT}[MHz]} \tag{26.1}$$

The effective count frequency depends on the common module clock prescaler factor F(BPS1) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 26-7** summarizes the resulting overall divider factors for a GPT1 timer that result from these cascaded prescalers.

Table 26-4 lists GPT1 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor and the module clock f_{GPT}. Note that some numbers may be rounded.

Table 26-4 GPT1 Timer Parameters

Module Clock f_{GPT} = 10 MHz			Overall Prescaler Factor	Module Clock f_{GPT} = 40 MHz		
Frequency	**Resolution**	**Period**		**Frequency**	**Resolution**	**Period**
2.5 MHz	400 ns	26.21 ms	4	10.0 MHz	100 ns	6.55 ms
1.25 MHz	800 ns	52.43 ms	8	5.0 MHz	200 ns	13.11 ms
625.0 kHz	1.6 µs	104.9 ms	16	2.5 MHz	400 ns	26.21 ms
312.5 kHz	3.2 µs	209.7 ms	32	1.25 MHz	800 ns	52.43 ms
156.25 kHz	6.4 µs	419.4 ms	64	625.0 kHz	1.6 µs	104.9 ms
78.125 kHz	12.8 µs	838.9 ms	128	312.5 kHz	3.2 µs	209.7 ms
39.06 kHz	25.6 µs	1.678 s	256	156.25 kHz	6.4 µs	419.4 ms
19.53 kHz	51.2 µs	3.355 s	512	78.125 kHz	12.8 µs	838.9 ms
9.77 kHz	102.4 µs	6.711 s	1024	39.06 kHz	25.6 µs	1.678 s
4.88 kHz	204.8 µs	13.42 s	2048	19.53 kHz	51.2 µs	3.355 s
2.44 kHz	409.6 µs	26.84 s	4096	9.77 kHz	102.4 µs	6.711 s

External Count Clock Input

The external input signals of the GPT1 block are sampled with the GPT1 basic clock (see **Figure 26-1**). To ensure that a signal is recognized correctly, its current level (high or

low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods is required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 26-5 summarizes the resulting requirements for external GPT1 input signals.

Table 26-5 GPT1 External Input Signal Limits

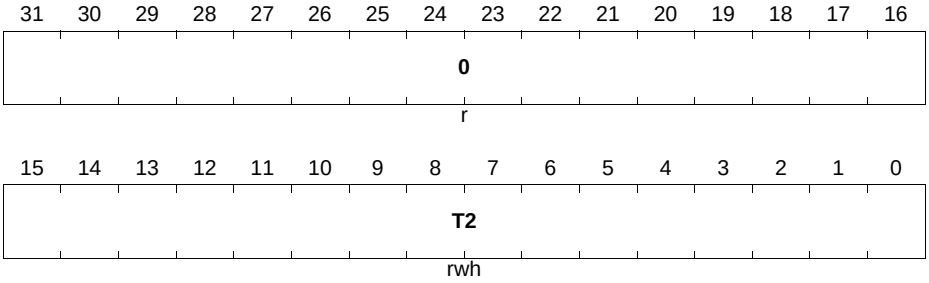
GPT1 Basic Clock = 10 MHz		Input Freq. Factor	GPT1 Divider BPS1	Input Phase Duration	GPT1 Basic Clock = 40 MHz	
Max. Input Frequency	**Min. Level Hold Time**				**Max. Input Frequency**	**Min. Level Hold Time**
1.25 MHz	400 ns	$f_{GPT}/8$	01_B	4 x t_{GPT}	5.0 MHz	100 ns
625.0 kHz	800 ns	$f_{GPT}/16$	00_B	8 x t_{GPT}	2.5 MHz	200 ns
312.5 kHz	1.6 µs	$f_{GPT}/32$	11_B	16 x t_{GPT}	1.25 MHz	400 ns
156.25 kHz	3.2 µs	$f_{GPT}/64$	10_B	32 x t_{GPT}	625.0 kHz	800 ns

These limitations are valid for all external input signals to GPT1, including the external count signals in Counter Mode and Incremental Interface Mode, the gate input signals in Gated Timer Mode, and the external direction signals.

26.1.6 GPT1 Registers

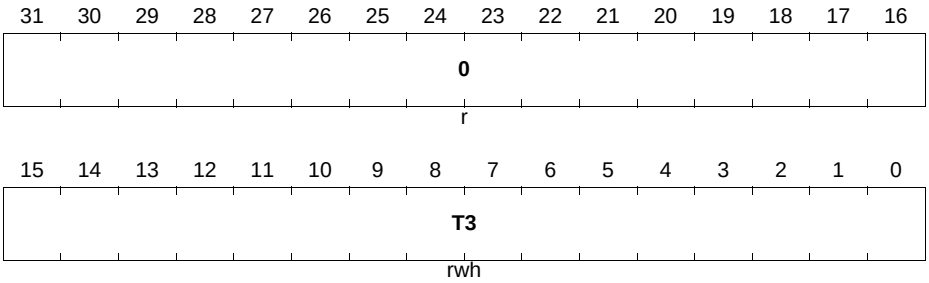
26.1.6.1 GPT1 Timer Registers

T2
Timer T2 Register **(34_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
T2	[15:0]	rwh	**Timer T2** Contains the current value of Timer T2.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

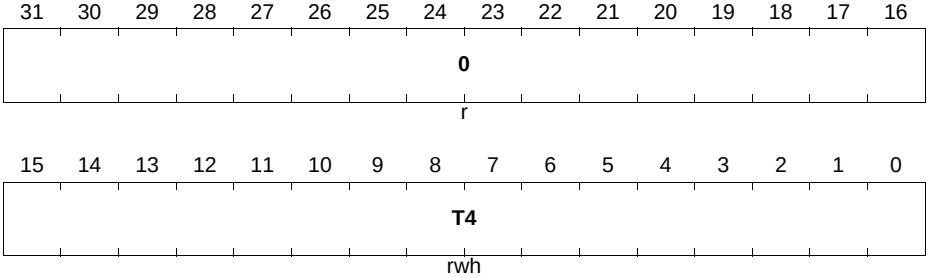
T3
Timer T3 Register **(38_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
T3	[15:0]	rwh	**Timer T3** Contains the current value of Timer T3.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

T4

Timer T4 Register **($3C_H$)** **Reset Value: 0000 0000$_H$**

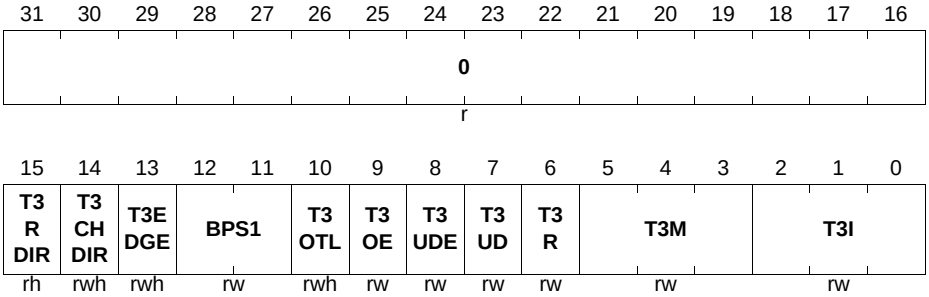


Field	Bits	Type	Description
T4	[15:0]	rwh	**Timer T4** Contains the current value of Timer T4.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

26.1.6.2 GPT1 Timer Control Registers

GPT1 Core Timer T3 Control Register

T3CON
Timer T3 Control Register **(14_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T3I	[2:0]	rw	**Timer T3 Input Parameter Selection** Depends on the operating mode, see respective sections for encoding: **Table 26-7** for Timer Mode and Gated Timer Mode **Table 26-8** for Counter Mode **Table 26-10** for Incremental Interface Mode

TxI = 100_B	64	128	256	512
TxI = 101_B	128	256	512	1024
TxI = 110_B	256	512	1024	2048
TxI = 111_B	512	1024	2048	4096

1) Please note the non-linear encoding of bitfield BPS1.

Encoding of GPT1 Input Edge Selection in Counter Mode

Table 26-8 GPT1 Core Timer T3 Input Edge Selection (Counter Mode)

TxI	Triggering Edge for Counter Increment/Decrement
000_B	None. Counter T3 is disabled
001_B	Positive transition (rising edge) on T3IN
010_B	Negative transition (falling edge) on T3IN
011_B	Any transition (rising or falling edge) on T3IN
$1XX_B$	Reserved. Do not use this combination

Table 26-9 GPT1 Auxiliary Timers T2/T4 Input Edge Selection

T2I/T4I	Triggering Edge for Counter Increment/Decrement, Capture[1] or Reload
$X00_B$	None. Counter Tx is disabled
001_B	Positive transition (rising edge) on TxIN
010_B	Negative transition (falling edge) on TxIN
011_B	Any transition (rising or falling edge) on TxIN
101_B	Positive transition (rising edge) of T3 toggle latch T3OTL[2]
110_B	Negative transition (falling edge) of T3 toggle latch T3OTL[2]
111_B	Any transition (rising or falling edge) of T3 toggle latch T3OTL[2]

1) For Capture Mode, only settings TxI = 0XX may be used.

2) Not for Capture Mode.

Encoding of Input Edge Selection in Incremental Interface Mode

Table 26-10 GPT1 Timer Tx Input Edge Selection (Incremental Interface Mode)

TxI	Triggering Edge for Counter Increment/Decrement
000_B	None. Counter Tx stops.
001_B	Any transition (rising or falling edge) on TxIN.
010_B	Any transition (rising or falling edge) on TxEUD.
011_B	Any transition (rising or falling edge) on any Tx input (TxIN or TxEUD).
$1XX_B$	Reserved. Do not use this combination.

26.2 Timer Block GPT2

Both timers of block GPT2 (T5, T6) can run in one of 3 basic modes: Timer Mode, Gated Timer Mode, or Counter Mode. All timers can count up or down. Each timer of GPT2 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T6 is indicated by the Output Toggle Latch T6OTL, whose state may be output on the associated pin T6OUT (alternate pin function). The auxiliary timer T5 may additionally be concatenated with core timer T6 (through T6OTL).

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, or by GPT1 timer's T3 input lines T3IN and T3EUD. The reload function is triggered by an overflow or underflow of timer T6.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T5 or T6. When any of the timer registers is written by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupt requests of GPT2 are signalled on service request lines SR3, SR4, and SR5.

The input and output lines of GPT2 are connected to pins. The control registers for the port functions are located in the respective port modules.

*Note: The timing requirements for external input signals can be found in **Section 26.2.6**, **Section 26.5.2** summarizes the module interface signals, including pins and interrupt request signals.*

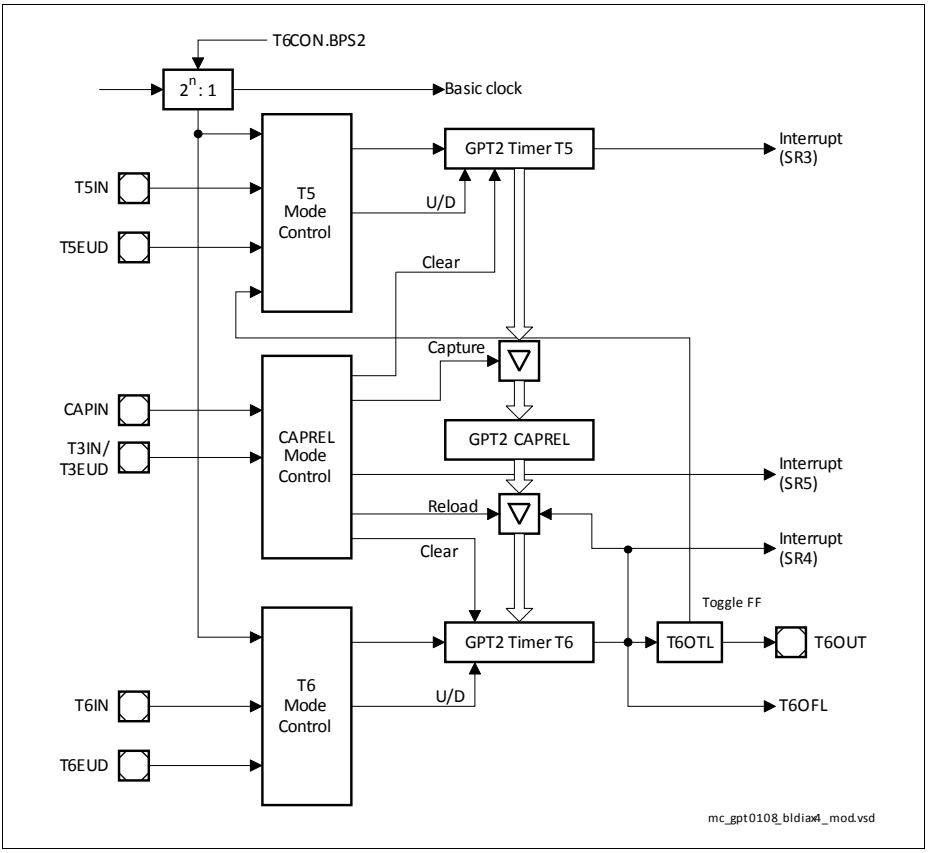

Figure 26-18 GPT2 Block Diagram

26.2.1 GPT2 Core Timer T6 Control

The current contents of the core timer T6 are reflected by its count register T6. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T6 is configured and controlled via its control register T6CON.

Timer T6 Run Control

The core timer T6 can be started or stopped by software through bit T6R (timer T6 run bit). This bit is relevant in all operating modes of T6. Setting bit T6R will start the timer, clearing bit T6R stops the timer.

In Gated Timer Mode, the timer will only run if T6R = 1 and the gate is active (high or low, as programmed).

Note: When bit T5RC in timer control register T5CON is set, bit T6R will also control (start and stop) the Auxiliary Timer T5.

Count Direction Control

The count direction of the GPT2 timers (core timer and auxiliary timer) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in **Table 26-15**. The count direction can be changed regardless of whether or not the timer is running.

Timer T6 Output Toggle Latch

The overflow/underflow signal of timer T6 is connected to a block named ‘Toggle Latch’, shown in the Timer Mode diagrams. **Figure 26-19** illustrates the details of this block. An overflow or underflow of T6 will clock two latches: The first latch represents bit T6OTL in control register T6CON. The second latch is an internal latch toggled by T6OTL’s output. Both latch outputs are connected to the input control block of the auxiliary timer T5. The output level of the shadow latch will match the output level of T6OTL, but is delayed by one clock cycle. When the T6OTL value changes, this will result in a temporarily different output level from T6OTL and the shadow latch, which can trigger the selected count event in T5.

When software writes to T6OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timer carry the same level and no edge will be detected. Bit T6OE (overflow/underflow output enable) in register T6CON enables the state of T6OTL to be monitored via an external pin T6OUT. When T6OTL is linked to an external port pin (must be configured as output), T6OUT can be used to control external HW. If T6OE = 1, pin T6OUT outputs the state of T6OTL. If T6OE = 0, pin T6OUT outputs a high level (while it selects the timer output signal).

As can be seen from **Figure 26-19**, when latch T6OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T5 in this case.

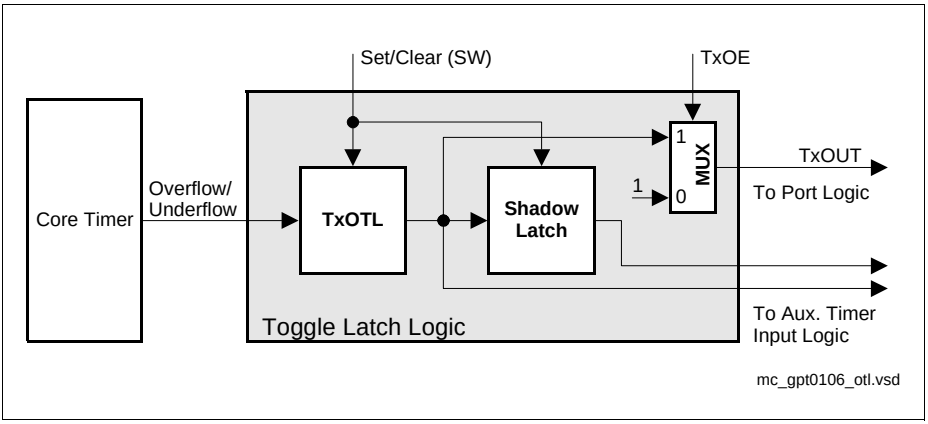

Figure 26-19 Block Diagram of the Toggle Latch Logic of Core Timer T6 (x = 6)

26.2.2 GPT2 Core Timer T6 Operating Modes

Timer T6 can operate in one of several modes.

Timer T6 in Timer Mode

Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 000_B. In this mode, T6 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS2 and T6I in register T6CON. Please see **Section 26.2.6** for details on the input clock options.

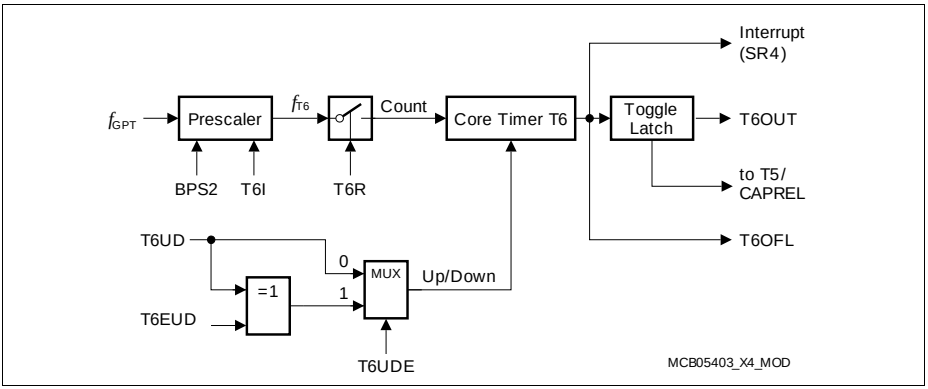

Figure 26-20 Block Diagram of Core Timer T6 in Timer Mode

Timer 6 in Gated Timer Mode

Gated Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 010_B or 011_B. Bit T6M.0 (T6CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see **Section 26.2.6**). However, the input clock to the timer in this mode is gated by the external input pin T6IN (Timer T6 External Input).
To enable this operation, the associated pin T6IN must be configured as input.

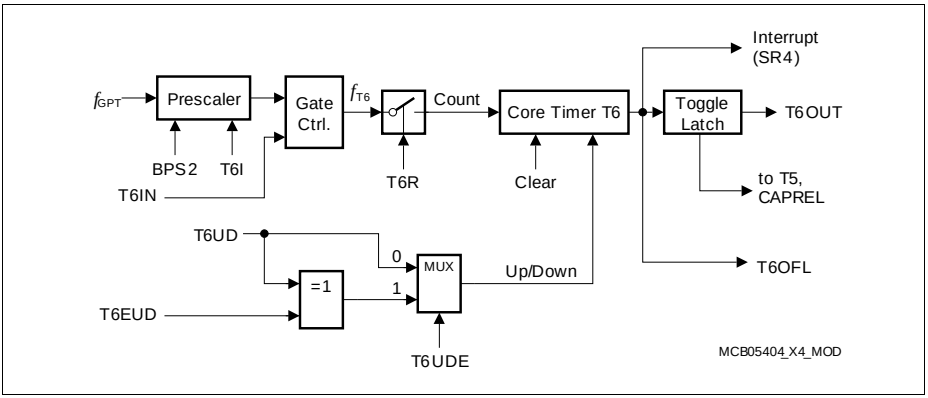

Figure 26-21 Block Diagram of Core Timer T6 in Gated Timer Mode

If T6M = 010_B, the timer is enabled when T6IN shows a low level. A high level at this line stops the timer. If T6M = 011_B, line T6IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T6R. The timer will only run if T6R is 1 and the gate is active. It will stop if either T6R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T6IN does not cause a service request.

Timer 6 in Counter Mode

Counter Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 001_B. In Counter Mode, timer T6 is clocked by a transition at the external input pin T6IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T6I in control register T6CON selects the triggering transition (see **Table 26-17**).

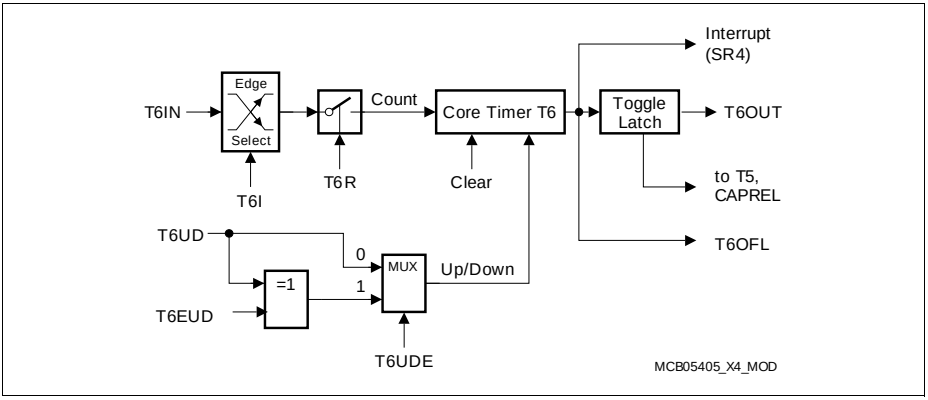

Figure 26-22 Block Diagram of Core Timer T6 in Counter Mode

For Counter Mode operation, pin T6IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T6IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 26.2.6**.

26.2.3 GPT2 Auxiliary Timer T5 Control

Auxiliary timer T5 can be configured for Timer Mode, Gated Timer Mode, or Counter Mode with the same options for the timer frequencies and the count signal as the core timer T6. In addition to these 3 counting modes, the auxiliary timer can be concatenated with the core timer. The contents of T5 may be captured to register CAPREL upon an external or an internal trigger. The start/stop function of the auxiliary timer can be remotely controlled by the T6 run control bit. Both timers may thus be controlled synchronously.

The current contents of the auxiliary timer are reflected by its count register T5. This register can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timer T5 are determined by its control register T5CON. Some bits in this register also control the function of the CAPREL register. Note that functions which are present in all timers of block GPT2 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timer has no output toggle latch and no alternate output function.

Timer T5 Run Control

The auxiliary timer T5 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T5R). In this case it is required that the respective control bit T5RC = 0.
- Through the core timer's run bit (T6R). In this case the respective remote control bit must be set (T5RC = 1).

The selected run bit is relevant in all operating modes of T5. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T6R will start/stop timer T6 and the auxiliary timer T5 synchronously.

26.2.4 GPT2 Auxiliary Timer T5 Operating Modes

The operation of the auxiliary timer in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timer T5 in Timer Mode

Timer Mode for the auxiliary timer T5 is selected by setting its bitfield T5M in register T5CON to 000_B.

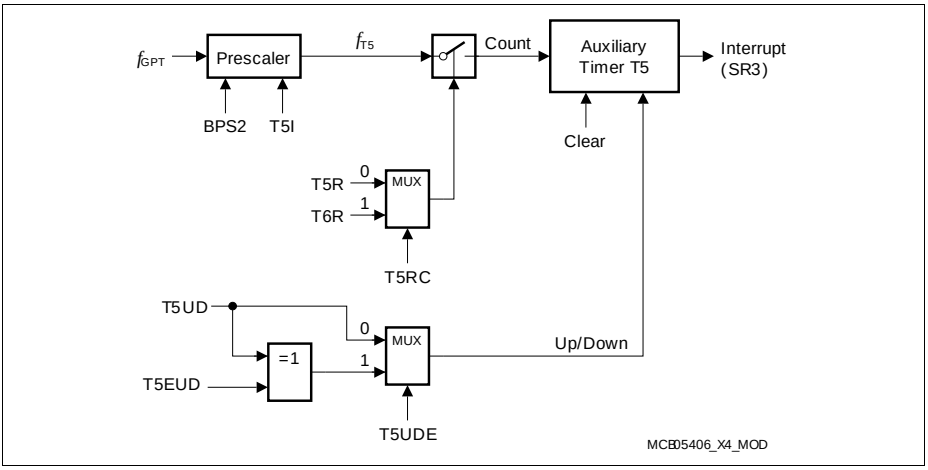

Figure 26-23 Block Diagram of Auxiliary Timer T5 in Timer Mode

Timer T5 in Gated Timer Mode

Gated Timer Mode for the auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 010_B or 011_B. Bit T5M.0 (T5CON.3) selects the active level of the gate input.

Note: A transition of the gate signal at line T5IN does not cause a service request.

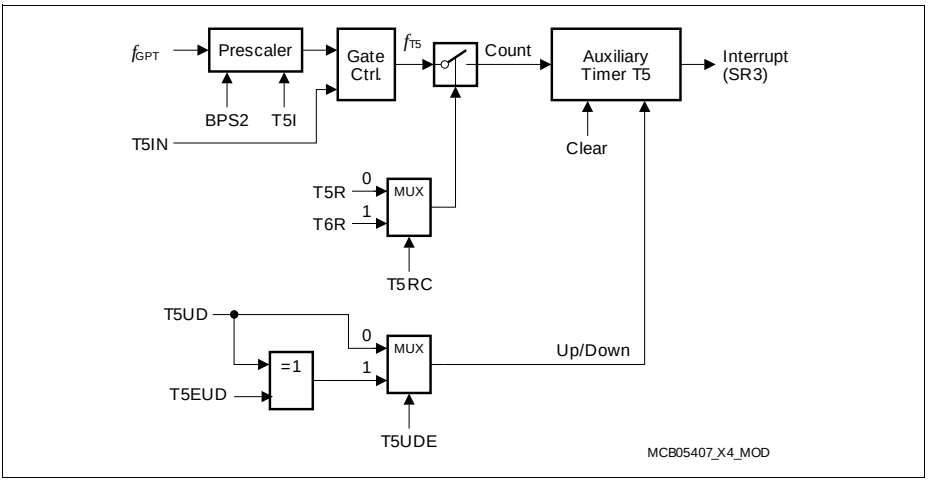

Figure 26-24 Block Diagram of Auxiliary Timer T5 in Gated Timer Mode

Note: There is no output toggle latch for T5.
Start/stop of the auxiliary timer can be controlled locally or remotely.

Timer T5 in Counter Mode

Counter Mode for auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 001_B. In Counter Mode, the auxiliary timer can be clocked either by a transition at its external input line T5IN, or by a transition of timer T6's toggle latch T6OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield T5I in control register T5CON selects the triggering transition (see **Table 26-18**).

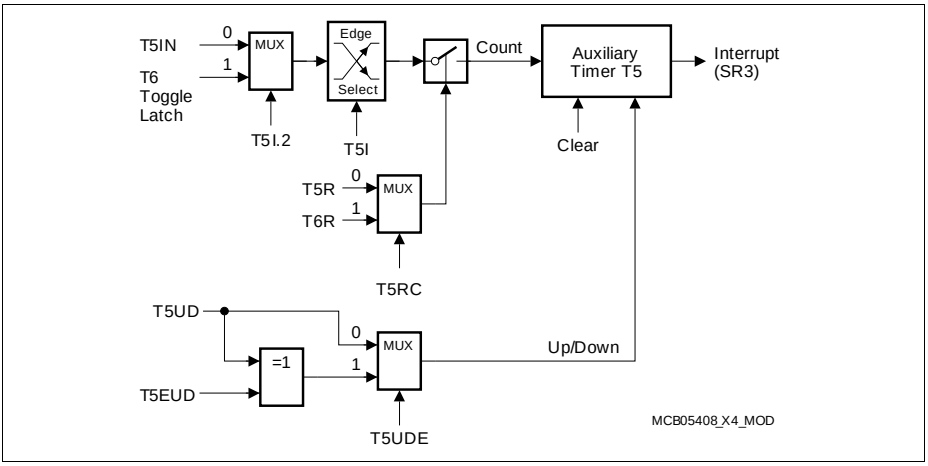

Figure 26-25 Block Diagram of Auxiliary Timer T5 in Counter Mode

Note: Only state transitions of T6OTL which are caused by the overflows/underflows of T6 will trigger the counter function of T5. Modifications of T6OTL via software will NOT trigger the counter function of T5.

For counter operation, pin T5IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T5IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 26.2.6**.

Timer Concatenation

Using the toggle bit T6OTL as a clock source for the auxiliary timer in Counter Mode concatenates the core timer T6 with the auxiliary timer T5. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T6OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T6OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T6. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T6OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T6. This configuration forms a 33-bit timer (16-bit core timer + T6OTL + 16-bit auxiliary timer).
  As long as bit T6OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T6, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

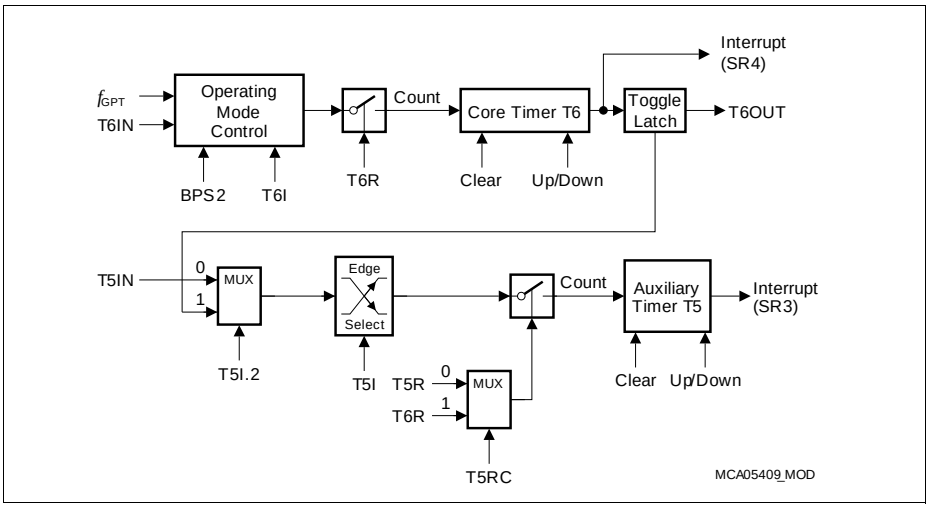

Figure 26-26 Concatenation of Core Timer T6 and Auxiliary Timer T5

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT2 timers, represented by TIMER_HIGH (for auxiliary timer T5) and TIMER_LOW (for core timer T6). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T5
- TIMER_LOW = T6
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see **Table 26-11**
- TIMER_HIGH = T5
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T6

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of module clock cycles corresponding to two basic clock cycles is shown in **Table 26-11**.

Table 26-11 Number of Module Clock Cycles to Wait for Two Basic Clock Cycles

Block Prescaler	BPS2 = 01_B	BPS2 = 00_B	BPS2 = 11_B	BPS2 = 10_B
Number of module clocks	4	8	16	32

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS2 and the Individual Prescalers TxI (see **Table 26-16**), the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time. E.g. in order to run T6 at f_{SYS}/512, select BPS2 = 00_B, T6I = 111_B, and insert 8 NOPs (or other instructions) to ensure the required waiting time before reading TIMER_HIGH the second time.

26.2.5 GPT2 Register CAPREL Operating Modes

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, by GPT1 timer's T3 input lines T3IN and T3EUD, or by read accesses to GPT1 timers. The reload function is triggered by an overflow or underflow of timer T6.

The capture trigger signal can also be used to clear the contents of timers T5 and T6 individually.

The functions of register CAPREL are controlled via several bit(field)s in the timer control registers T5CON and T6CON.

Capture/Reload Register CAPREL in Capture Mode

Capture Mode for register CAPREL is selected by setting bit T5SC in control register T5CON (set bitfield CI in register T5CON to a non-zero value to select a trigger signal). In Capture Mode, the contents of the auxiliary timer T5 are latched into register CAPREL in response to a signal transition at the selected external input pin(s). Bit CT3 selects the external input line CAPIN or the input lines T3IN and/or T3EUD of GPT1 timer T3 as the source for a capture trigger. Either a positive, a negative, or both a positive and a negative transition at line CAPIN can be selected to trigger the capture function, or transitions on input T3IN or input T3EUD or both inputs, T3IN and T3EUD. The active edge is controlled by bitfield CI in register T5CON. **Table 26-19** summarizes these options.

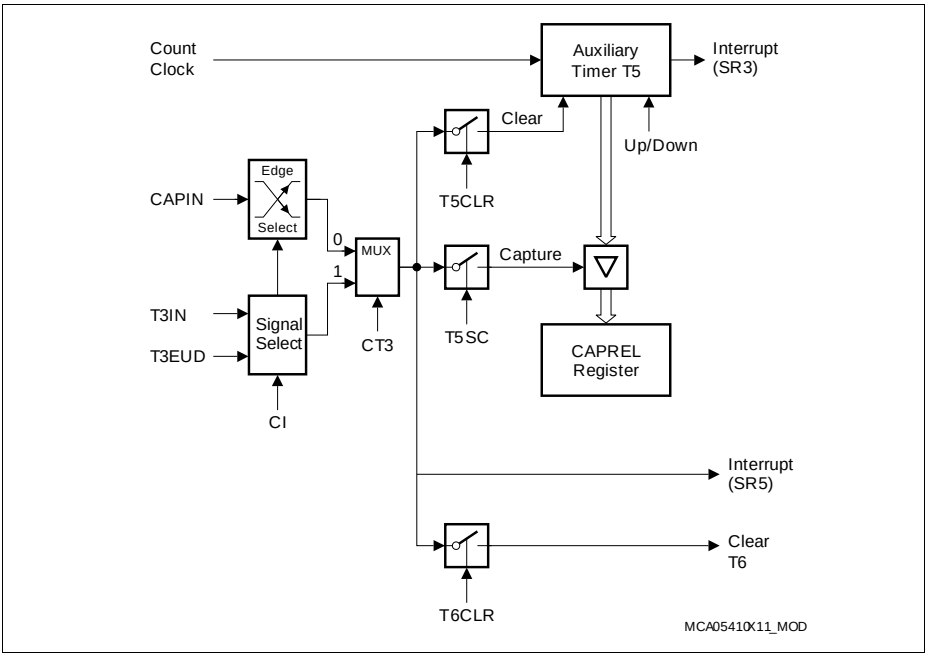

Figure 26-27 Capture/Reload Register CAPREL in Capture Mode

When a selected trigger is detected, the contents of the auxiliary timer T5 are latched into register CAPREL and the service request is activated. The same event can optionally clear timer T5 and/or timer T6. This option is enabled by bit T5CLR in register T5CON and bit T6CLR in register T6CON, respectively. If TxCLR = 0 the contents of timer Tx is not affected by a capture. If TxCLR = 1 timer Tx is cleared after the current timer T5 value has been latched into register CAPREL.

Note: Bit T5SC only controls whether or not a capture is performed. If T5SC is cleared the external input pin(s) can still be used to clear timer T5 and/or T6, or as external interrupt input(s). This interrupt is signalled by the CAPREL interrupt request SR5.

When capture triggers T3IN or T3EUD are enabled (CT3 = 1), register CAPREL captures the contents of T5 upon transitions of the selected input(s). These values can be used to measure T3's input signals. This is useful, for example, when T3 operates in Incremental Interface Mode, in order to derive dynamic information (speed, acceleration) from the input signals.

For Capture Mode operation, the selected pins CAPIN, T3IN, or T3EUD must be configured as input. To ensure that a transition of a trigger input signal applied to one of

these inputs is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 26.2.6**.

Capture/Reload Register CAPREL in Reload Mode

Reload Mode for register CAPREL is selected by setting bit T6SR in control register T6CON. In Reload Mode, the core timer T6 is reloaded with the contents of register CAPREL, triggered by an overflow or underflow of T6. This will not activate the service request SR5 associated with the CAPREL register. However, service request SR4 will be activated, indicating the overflow/underflow of T6.

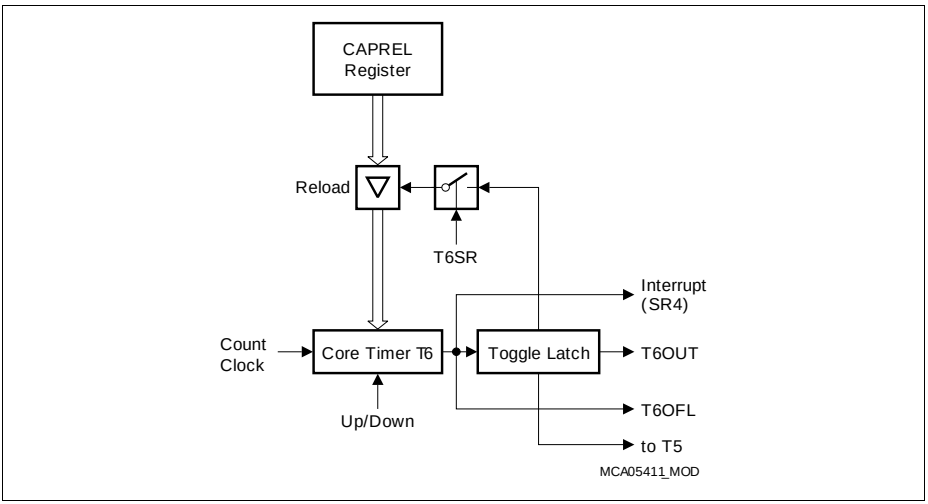

Figure 26-28 Capture/Reload Register CAPREL in Reload Mode

Capture/Reload Register CAPREL in Capture-And-Reload Mode

Since the reload function and the capture function of register CAPREL can be enabled individually by bits T5SC and T6SR, the two functions can be enabled simultaneously by setting both bits. This feature can be used to generate an output frequency that is a multiple of the input frequency.

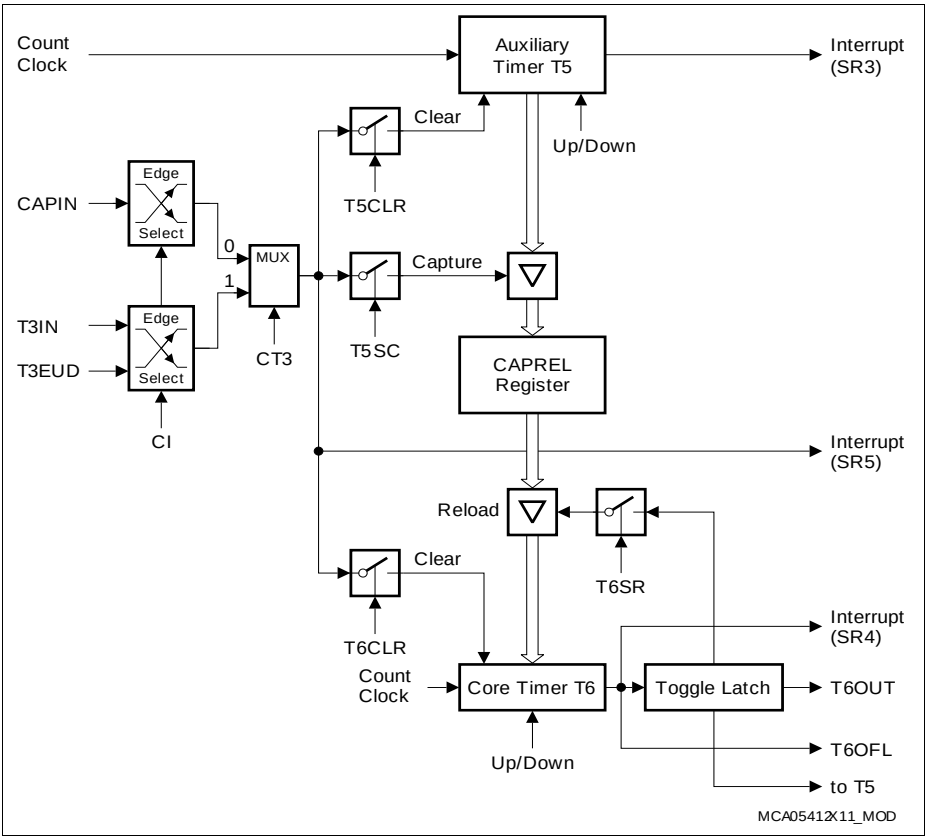

Figure 26-29 Capture/Reload Register CAPREL in Capture-And-Reload Mode

This combined mode can be used to detect consecutive external events which may occur aperiodically, but where a finer resolution, that means, more ‘ticks’ within the time between two external events is required.

For this purpose, the time between the external events is measured using timer T5 and the CAPREL register. Timer T5 runs in Timer Mode counting up with a frequency of e.g. $f_{GPT}/32$. The external events are applied e.g. to pin CAPIN (or other pins supporting

capture mode, see **Table 26-19**). When an external event occurs, the contents of timer T5 are latched into register CAPREL and timer T5 is cleared (T5CLR = 1). Thus, register CAPREL always contains the correct time between two events, measured in timer T5 increments. Timer T6, which runs in Timer Mode counting down with a frequency of e.g. $f_{GPT}/4$, uses the value in register CAPREL to perform a reload on underflow. This means, the value in register CAPREL represents the time between two underflows of timer T6, now measured in timer T6 increments. Since (in this example) timer T6 runs 8 times faster than timer T5, it will underflow 8 times within the time between two external events. Thus, the underflow signal of timer T6 generates 8 'ticks'. Upon each underflow, the interrupt request SR4 will be activated and bit T6OTL will be toggled. The state of T6OTL may be output on pin T6OUT. This signal on T6OUT has 8 times more transitions than the signal which is applied to the selected input (CAPIN in this example).

*Note: The underflow signal of Timer T6 can furthermore be used to clock functional units in other modules, e.g. one or more of the timers of the capture/compare units CCU6 (connections see **Section 26.5.2**). This gives the user the possibility to set compare events based on a finer resolution than that of the external events. This connection is accomplished via signal T6OFL.*

Capture Correction

A certain deviation of the output frequency is generated by the fact that timer T5 will count actual time units (e.g. T5 running at 1 MHz will count up to the value $64_H/100_D$ for a 10 kHz input signal), while T6OTL will only toggle upon an underflow of T6 (i.e. the transition from 0000_H to $FFFF_H$). In the above mentioned example, T6 would count down from 64_H, so the underflow would occur after 101 timing ticks of T6. The actual output frequency then is 79.2 kHz, instead of the expected 80 kHz.

This deviation can be compensated for by using T6 overflows. In this case, T5 counts down and T6 counts up. Upon a signal transition at the selected input pin(s), e.g. on CAPIN, the count value in T5 is captured into CAPREL and T5 is cleared to 0000_H. In its next clock cycle, T5 underflows to $FFFF_H$, and continues to count down with the following clocks. T6 is reloaded from CAPREL upon an overflow, and continues to count up with its following clock cycles (8 times faster in the above example). In this case, T5 and T6 count the same number of steps with their respective internal count frequency.

In the above example, T5 running at 1 MHz will count down to the value $FF9C_H/-100_D$ for a 10 kHz input signal applied e.g. at CAPIN, while T6 counts up from $FF9C_H$ through $FFFF_H$ to 0000_H. So the overflow occurs after 100 timing ticks of T6, and the actual output frequency at T6OUT then is the expected 80 kHz.

However, in this case CAPREL does not directly contain the time between two external events, but rather its 2's complement. Software will have to convert this value, if it is required for the operation.

Combined Capture Modes

For incremental interface applications in particular, several timer features can be combined to obtain dynamic information such as speed, acceleration, or deceleration. The current position itself can be obtained directly from the timer register (T2, T3, T4).

The time information to determine the dynamic parameters is generated by capturing the contents of the free-running timer T5 into register CAPREL. Two trigger sources for this event can be selected:

- Capture trigger on sensor signal transitions
- Capture trigger on position read operations

Capturing on sensor signal transitions is available for timer T3 inputs. This mode is selected by setting bit CT3 and selecting the intended signal(s) via bitfield CI in register T5CON. CAPREL then indicates the time between two selected transitions (measured in T5 counts).

Capturing on position read operations is available for timers T2, T3, and T4. This mode is selected by clearing bit CT3 and selecting the rising edge via bitfield CI in register T5CON. Bitfield ISCAPIN in register PISEL then selects either a read access from T3 or a read access from any of T2 or T3 or T4. CAPREL then indicates the time between two read accesses.

In general, GPT12 has no destructive read mechanisms, except for this special operation mode ‘capture on position read operations’, where register CAPREL is intentionally updated after a read of T3 or T2/T4 (and T5 or T6 are optionally cleared). In this case, also the associated service request flag in register SRC_GPT120CIRQ is set.

Note: If mode ‘capturing on position read operations’ is selected, and the corresponding timer (T3, or any of T2, T3, T4) is read by a debugger, a capture event may be triggered (T5 is captured into CAPREL, and T5 or T6 may optionally be cleared (if T5CLR = 1 or T6CLR = 1)).

These operating modes directly support the measurement of position and rotational speed. Acceleration and deceleration can then be determined by evaluating subsequent speed measurements.

26.2.6 GPT2 Clock Signal Control

All actions within the timer block GPT2 are triggered by transitions of its basic clock. This basic clock is derived from the module clock f_{GPT} by a basic block prescaler, controlled by bitfield BPS2 in register T6CON (see **Figure 26-18**). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT2's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 26-12 Basic Clock Selection for Block GPT2

Block Prescaler[1]	BPS2 = 01_B	BPS2 = 00_B[2]	BPS2 = 11_B	BPS2 = 10_B
Prescaling Factor for GPT2: F(BPS2)	F(BPS2) = 2	F(BPS2) = 4	F(BPS2) = 8	F(BPS2) = 16
Maximum External Count Frequency	$f_{GPT}/4$	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$
Input Signal Stable Time	2 x t_{GPT}	4 x t_{GPT}	8 x t_{GPT}	16 x t_{GPT}

1) Please note the non-linear encoding of bitfield BPS2.

2) Default after reset.

Note: The GPT2 module uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T5, T6) and register CAPREL, these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT2 state machine has 4 states (2 states when BPS2 = 01_B) and processes T6 before T5.

Note: When initializing the GPT2 block after reset, and the block prescaler BPS2 in register T6CON needs to be set to a value different from its default value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur during the first basic clock cycle.
In this case, or when changing BPS2 during operation of the GPT2 block, disable related interrupts before modification of BPS2, and afterwards clear the corresponding service request flags and re-initialize those registers (T5, T6, CAPREL) that might be affected by a count/capture/reload event.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT2 timer is derived from the GPT2 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS2) \times 2^{<TxI>}} \qquad r_{Tx}[\mu s] = \frac{F(BPS2) \times 2^{<TxI>}}{f_{GPT}[MHz]} \tag{26.2}$$

The effective count frequency depends on the common module clock prescaler factor F(BPS2) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 26-16** summarizes the resulting overall divider factors for a GPT2 timer that result from these cascaded prescalers.

Table 26-13 lists GPT2 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor and the module clock f_{GPT}. Note that some numbers may be rounded.

Table 26-13 GPT2 Timer Parameters

Module Clock f_{GPT} = 10 MHz			Overall Prescaler Factor	Module Clock f_{GPT} = 40 MHz		
Frequency	Resolution	Period		Frequency	Resolution	Period
5.0 MHz	200 ns	13.11 ms	2	20.0 MHz	50 ns	3.28 ms
2.5 MHz	400 ns	26.21 ms	4	10.0 MHz	100 ns	6.55 ms
1.25 MHz	800 ns	52.43 ms	8	5.0 MHz	200 ns	13.11 ms
625.0 kHz	1.6 µs	104.9 ms	16	2.5 MHz	400 ns	26.21 ms
312.5 kHz	3.2 µs	209.7 ms	32	1.25 MHz	800 ns	52.43 ms

External Count Clock Input

The external input signals of the GPT2 block are sampled with the GPT2 basic clock (see **Figure 26-18**). To ensure that a signal is recognized correctly, its current level (high or

low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods are required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 26-14 summarizes the resulting requirements for external GPT2 input signals.

Table 26-14 GPT2 External Input Signal Limits

GPT2 Basic Clock = 10 MHz		Input Freq. Factor	GPT2 Divider BPS2	Input Phase Duration	GPT2 Basic Clock = 40 MHz	
Max. Input Frequency	**Min. Level Hold Time**				**Max. Input Frequency**	**Min. Level Hold Time**
2.5 MHz	200 ns	$f_{GPT}/4$	01_B	2 x t_{GPT}	10.0 MHz	50 ns
1.25 MHz	400 ns	$f_{GPT}/8$	00_B	4 x t_{GPT}	5.0 MHz	100 ns
625.0 kHz	800 ns	$f_{GPT}/16$	11_B	8 x t_{GPT}	2.5 MHz	200 ns
312.5 kHz	1.6 µs	$f_{GPT}/32$	10_B	16 x t_{GPT}	1.25 MHz	400 ns

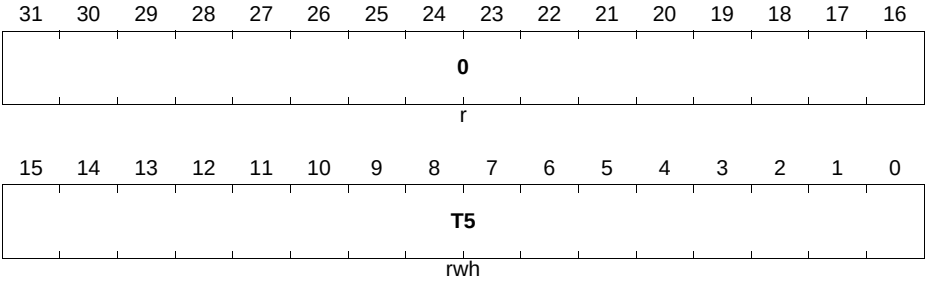
These limitations are valid for all external input signals to GPT2, including the external count signals in Counter Mode and the gate input signals in Gated Timer Mode.

26.2.7 GPT2 Registers

26.2.7.1 GPT2 Timer Registers

T5

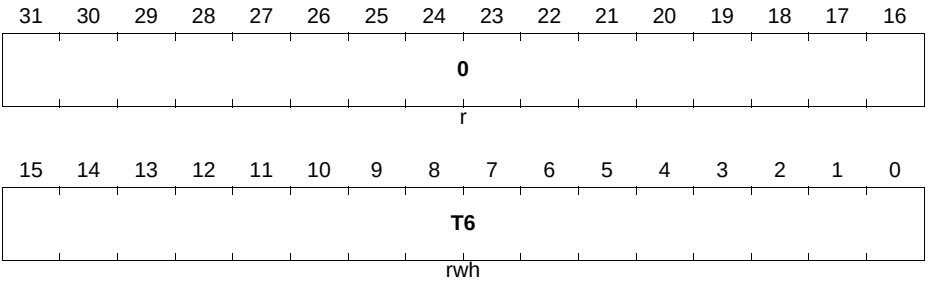
Timer T5 Register **(40_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
T5	[15:0]	rwh	**Timer T5** Contains the current value of Timer T5.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

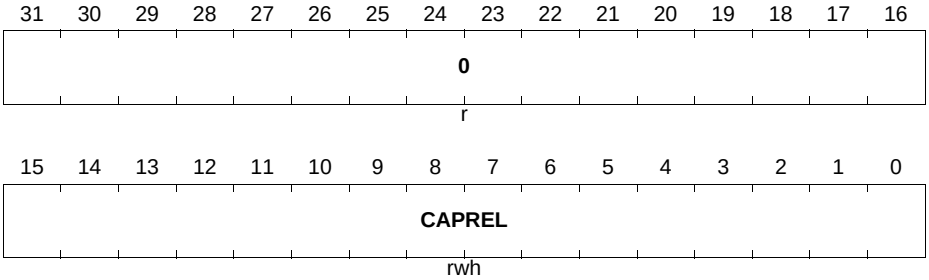
T6

Timer T6 Register **(44_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
T6	[15:0]	rwh	**Timer T6** Contains the current value of Timer T6.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

CAPREL
Capture and Reload Register **(30_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CAPREL	[15:0]	rwh	**Current reload value or Captured value**
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

26.2.7.2 GPT2 Timer Control Registers

GPT2 Core Timer T6 Control Register

T6CON
Timer T6 Control Register **(20_H)** **Reset Value: 0000 0000_H**

TxI = 011_B	16	32	64	128
TxI = 100_B	32	64	128	256
TxI = 101_B	64	128	256	512
TxI = 110_B	128	256	512	1024
TxI = 111_B	256	512	1024	2048

1) Please note the non-linear encoding of bitfield BPS2.

Encoding of GPT2 Input Edge Selection in Counter Mode

Table 26-17 GPT2 Core Timer T6 (Counter Mode) Input Edge Selection

T6I	Triggering Edge for Counter Increment/Decrement
000_B	None. Counter T6 is disabled
001_B	Positive transition (rising edge) on T6IN
010_B	Negative transition (falling edge) on T6IN
011_B	Any transition (rising or falling edge) on T6IN
$1XX_B$	Reserved. Do not use this combination

Table 26-18 GPT2 Auxiliary Timer T5 (Counter Mode) Input Edge Selection

T5I	Triggering Edge for Counter Increment/Decrement
$X00_B$	None. Counter T5 is disabled
001_B	Positive transition (rising edge) on T5IN
010_B	Negative transition (falling edge) on T5IN
011_B	Any transition (rising or falling edge) on T5IN
101_B	Positive transition (rising edge) of T6 toggle latch T6OTL
110_B	Negative transition (falling edge) of T6 toggle latch T6OTL
111_B	Any transition (rising or falling edge) of T6 toggle latch T6OTL

Encoding of GPT2 Input Selection for Capture and Timer Clear Function

Table 26-19 CAPREL Register Input Edge Selection

CT3	CI	Triggering Signal/Edge for Capture Mode and/or T5/T6 Clear
X	00_B	None. Capture Mode is disabled.
0	01_B	Positive transition (rising edge) on CAPIN, or read operation on selected GPT1 timers[1)].
0	10_B	Negative transition (falling edge) on CAPIN.
0	11_B	Any transition (rising or falling edge) on CAPIN.
1	01_B	Any transition (rising or falling edge) on T3IN.
1	10_B	Any transition (rising or falling edge) on T3EUD.
1	11_B	Any transition (rising or falling edge) on T3IN or T3EUD.

1) Rising edge must be selected for triggering the capture/clear operation by the internal GPT1 read signals (see bit field ISCAPIN in register **PISEL** and description in section **"Combined Capture Modes" on Page 26-58**).

26.3 GPT12 Kernel Register Overview

Table 26-20 summarizes the GPT12 kernel registers and the module external registers and defines their addresses and reset values.

BPI registers are included in a separate Table 26-21.

Table 26-20 Register Overview of GPT12

Register Short Name	Register Long Name	Offset Addr.[1]	Access Mode		Reset	Page Num.
			Read	Write		
PISEL	Port Input Select Register	04_H	U, SV	U, SV, P	Application Reset	26-73
ID	Identification Register	08_H	U, SV	BE	Application Reset	26-75
T2CON	Timer T2 Control Register	10_H	U, SV	U, SV, P	Application Reset	26-32
T3CON	Timer T3 Control Register	14_H	U, SV	U, SV, P	Application Reset	26-30
T4CON	Timer T4 Control Register	18_H	U, SV	U, SV, P	Application Reset	26-34
T5CON	Timer T5 Control Register	1C	U, SV	U, SV, P	Application Reset	26-66
T6CON	Timer T6 Control Register	20_H	U, SV	U, SV, P	Application Reset	26-64
CAPREL	Capture and Reload Register	30_H	U, SV	U, SV, P	Application Reset	26-63
T2	Timer T2 Register	34_H	U, SV	U, SV, P	Application Reset	26-28
T3	Timer T3 Register	38_H	U, SV	U, SV, P	Application Reset	26-28
T4	Timer T4 Register	$3C_H$	U, SV	U, SV, P	Application Reset	26-29
T5	Timer T5 Register	40_H	U, SV	U, SV, P	Application Reset	26-62
T6	Timer T6 Register	44_H	U, SV	U, SV, P	Application Reset	26-62

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

26.4 General Module Operation

This section provides information about the:

- Input Selection (see **Section 26.4.1**)
- OCDS Suspend Functionality (see **Section 26.4.2**)
- Miscellaneous GPT12 Register Description (see **Section 26.4.3**)
- BPI Register Description (see **Section 26.4.4**)

26.4.1 Input Selection

Each GPT12 input signal can be selected from a vector of two or four possible inputs by programming the port input select register **PISEL**. This permits to adapt the pin functionality of the device to the application requirements.
The output pins for the module output signals are chosen in the ports.

Naming convention (example):
The input vector T3IN[D:A] for input signal T3IN is composed of the signals T3INA to T3IND.

*Note: All functional inputs of the GPT12 module are synchronized to the internal basic clock of the GPT1 and GPT2 block, respectively. An edge of an input signal can only be correctly recognized if the high phase and the low phase are longer than one basic clock period. See **Table 26-5** for GPT1 external input signal limits, and **Table 26-14** for GPT2 external input signal limits.*

26.4.2 OCDS Suspend

The behavior of GPT12 upon an OCDS suspend request is controlled by the **OCS** register. GPT12 supports only Hard Suspend Mode.

Hard Suspend Mode

In Hard Suspend Mode the GPT12 kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a GPT12 kernel reset might not be sufficient to bring the system into a defined state.

26.4.3 Miscellaneous GPT12 Registers

26.4.3.1 Port Input Select Register

Register PISEL contains bit fields selecting the actual input signal for the module inputs.

PISEL
Port Input Select Register **(04_H)** **Reset Value: $0000\ 0000_H$**

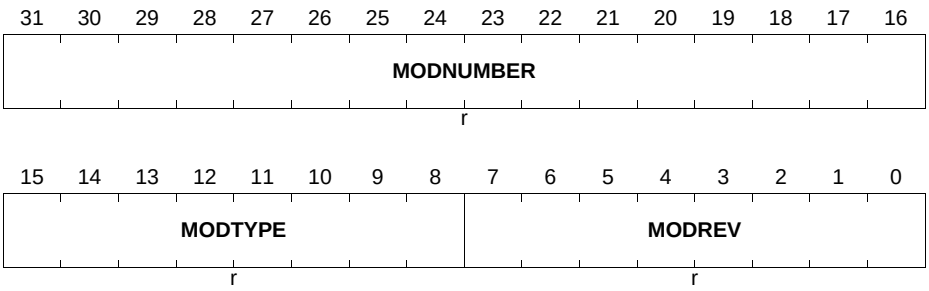
ISCAPIN	[15:14]	rw	**Input Select for CAPIN** 00_B Signal CAPINA is selected 01_B Signal CAPINB is selected 10_B Signal CAPINC (Read trigger from T3) is selected 11_B Signal CAPIND (Read trigger from T2 or T3 or T4) is selected
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

26.4.3.2 Identification Register

The GPT12 Module Identification Register ID contains read-only information about the module identification number and its revision.

ID
Identification Register **(08_H)** **Reset Value: 0068 C0XX$_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field indicates the revision number of the TC21x/TC22x/TC23x module (01_H = first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines a 32-bit module
MODNUMBER	[31:16]	r	**Module Number** This bit field defines the module identification number. For the GPT12 module the module identification number is 68_H.

26.4.4 BPI Registers

This section describes the registers of the BPI (Bus Peripheral Interface). **Figure 26-30** shows all registers associated with the BPI of a GPT12 module.

BPI Registers Overview

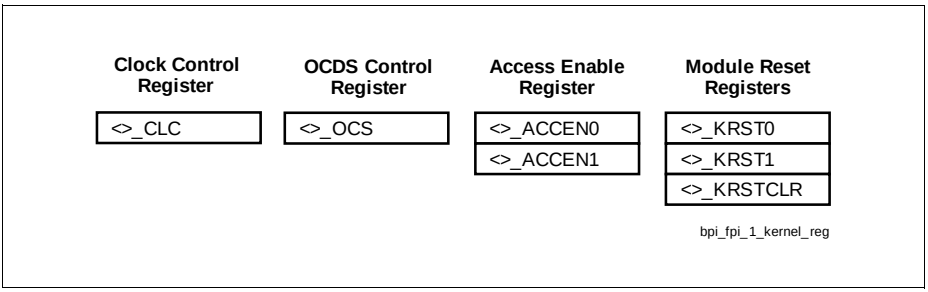


Figure 26-30 BPI Registers

Table 26-21 gives an overview of the BPI registers, including their access modes and reset class.

Table 26-21 Registers Overview - BPI Registers

Register Short Name	Description	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
CLC	Clock Control Register	00_H	U, SV	SV, E, P	Application Reset	26-78
-	Kernel Registers	-	-	-	-	-
OCS	OCDS Control and Status Register	$E8_H$	U, SV	SV, P	Debug Reset	26-79
KRSTCLR	Reset Status Clear Register	EC_H	U, SV	SV, E, P	Application Reset	26-84
KRST1	Reset Control Register 1	$F0_H$	U, SV	SV, E, P	Application Reset	26-83
KRST0	Reset Control Register 0	$F4_H$	U, SV	SV, E, P	Application Reset	26-82
ACCEN1	Access Enable Register 1	$F8_H$	U, SV	SV, SE	Application Reset	26-81
ACCEN0	Access Enable Register 0	FC_H	U, SV	SV, SE	Application Reset	26-80

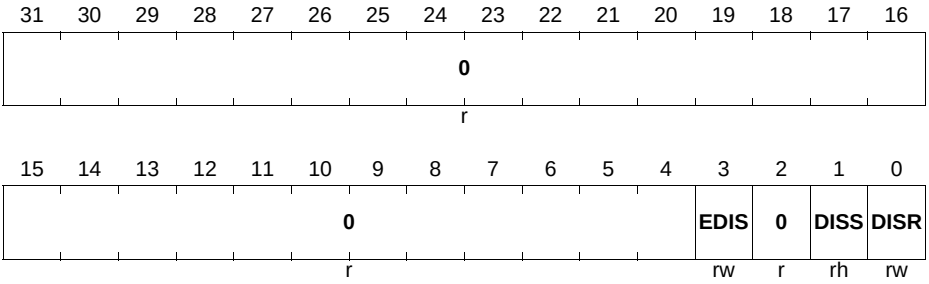
Note: Register bits marked “r” in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

26.4.4.1 System Registers

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the GPT12 module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{GPT} module clock signal and Sleep Mode for the module.

CLC
Clock Control Register (00_H) Reset Value: $0000\ 0003_H$



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested. 1_B Module disable is requested.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module is enabled. 1_B Module is disabled.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered upon a request.

Field	Bits	Type	Description
0	[31:16], [15:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: Upon an accepted Sleep Mode request (with EDIS = '1'), or upon a disable request (DISR = '1'), the GPT12 kernel clock is switched off immediately. Therefore, software should ensure that the system controlled by the GPT12 kernel has reached a safe state before triggering a Sleep Mode or module disable request.

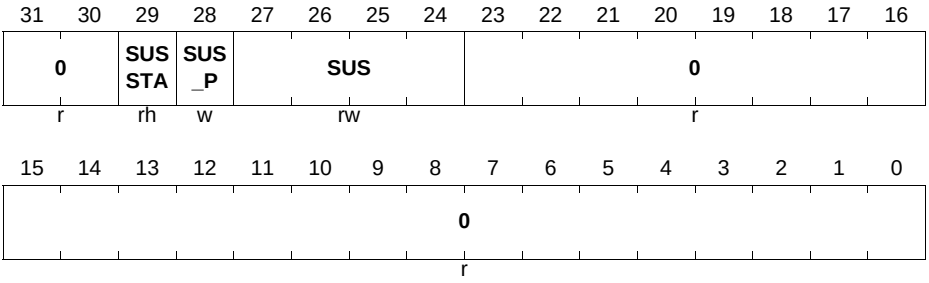
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status Register ($E8_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.

Field	Bits	Type	Description
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0
Access Enable Register 0 **(FC_H)** **Reset Value: $FFFF\ FFFF_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN31	**EN30**	**EN29**	**EN28**	**EN27**	**EN26**	**EN25**	**EN24**	**EN23**	**EN22**	**EN21**	**EN20**	**EN19**	**EN18**	**EN17**	**EN16**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN15	**EN14**	**EN13**	**EN12**	**EN11**	**EN10**	**EN9**	**EN8**	**EN7**	**EN6**	**EN5**	**EN4**	**EN3**	**EN2**	**EN1**	**EN0**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn **(n = 0-31)**	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

1) The BPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1

Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

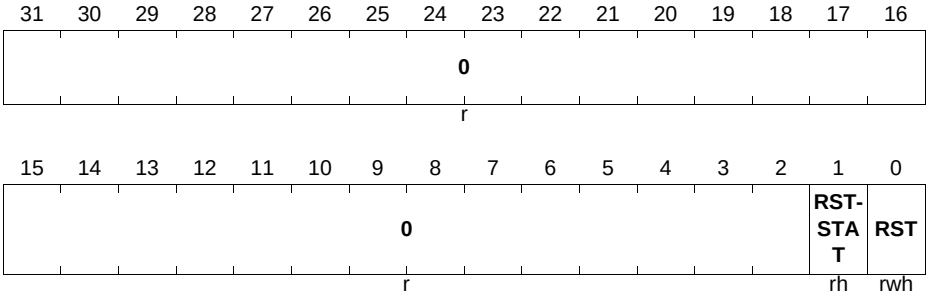
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI in the same clock cycle the RST bit is re-set by the BPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000_H**

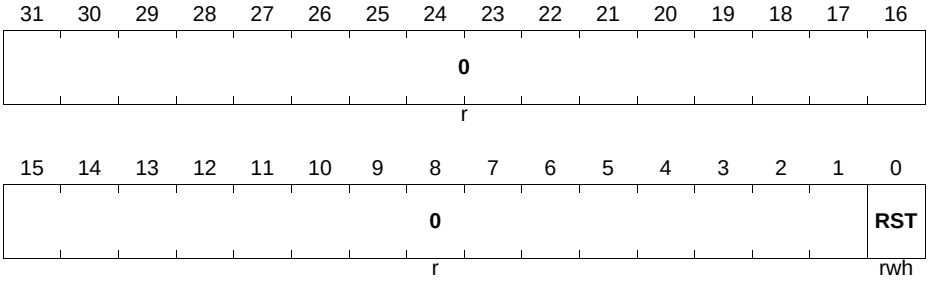


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed.
RSTSTAT	1	rw	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: 0000 0000_H**



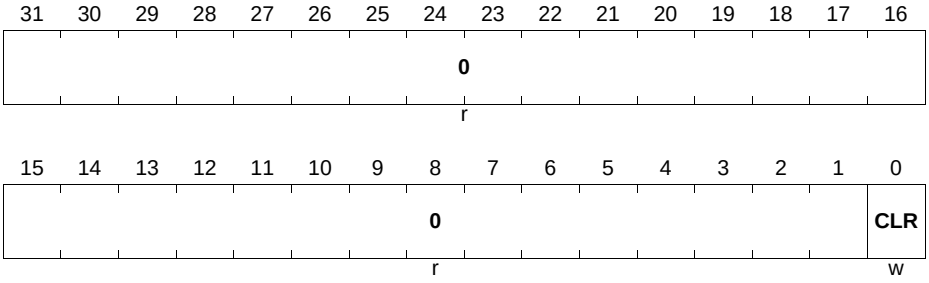
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear Register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

26.5 Implementation of the GPT12 Module

This chapter describes the implementation of the GPT12 module in the TC21x/TC22x/TC23x device.

26.5.1 Address Map

There is one GPT12 kernel implemented in the TC21x/TC22x/TC23x, namely GPT120.

Table 26-22 Registers Address Space

Module	Base Address	End Address	Note
GPT120	F000 2E00$_H$	F000 2EFF$_H$	

26.5.2 Module Connections

The following table shows the digital connections of the GPT12 module with other modules or pins in the TC21x/TC22x/TC23x device.

The GPT12 module is clocked with the SPB_Bus clock, so $f_{GPT} = f_{SPB}$.

Note: Signals that are not available in the 100- and 80-pin package variant are specifically marked, see footnote [1].

Note: Signals that are not available in the 80-pin package variant are specifically marked, see footnote [2].

27 Versatile Analog-to-Digital Converter (VADC)

The TC21x/TC22x/TC23x provides a series of analog input channels connected to a cluster of Analog/Digital Converters using the Successive Approximation Register (SAR) principle to convert analog input values (voltages) to discrete digital values.
The TC21x/TC22x/TC23x is based on individual SAR converters with dedicated Sample&Hold units.
The number of analog input channels and ADCs depends on the chosen product type (please refer to **"Product-Specific Configuration" on Page 27-167**).

Each converter of the ADC cluster can operate independent of the others, controlled by a dedicated set of registers and triggered by a dedicated group request source. The results of each channel can be stored in a dedicated channel-specific result register or in a group-specific result register.

A background request source can access all analog input channels that are not assigned to any group request source. These conversions are executed with low priority. The background request source can, therefore, be regarded as an additional background converter.

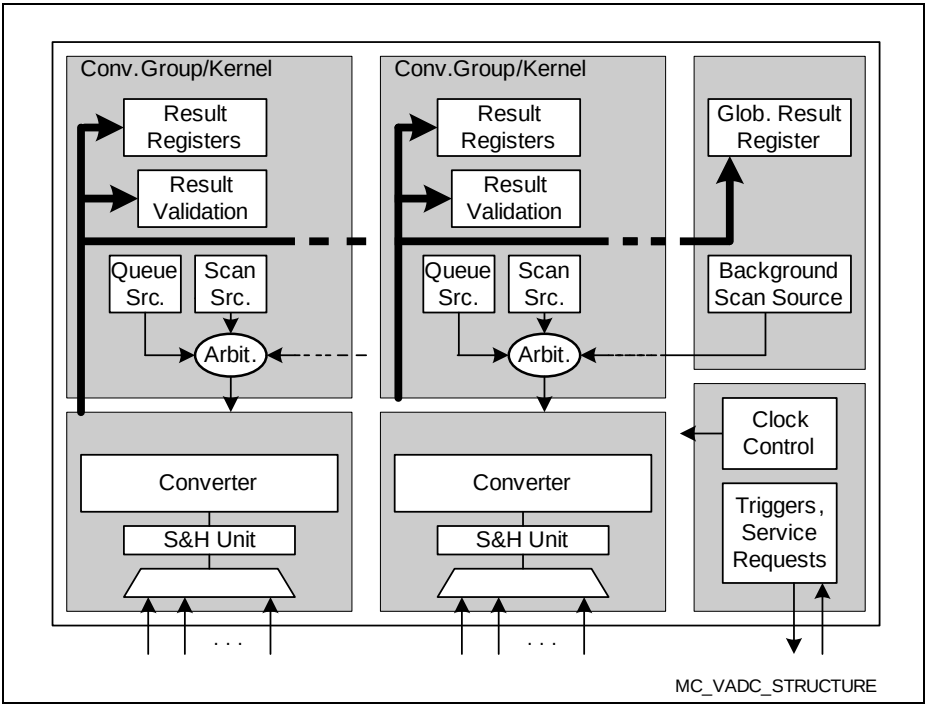

Figure 27-1 ADC Structure Overview

You will find the following major sections within this chapter:

Feature List

The following features describe the functionality of the ADC cluster:

- Nominal analog supply voltage 5.0 V, operation at 3.3 V with reduced performance
- Input voltage range from 0 V up to analog supply voltage
- Standard (V_{AREF}) and alternate (CH0) reference voltage source selectable for each channel to support ratiometric measurements and different signal scales
- 2 independent converters with up to 12+2 analog input channels (4 converters in the ADAS device, see **"Product-Specific Configuration" on Page 27-167**)
- External analog multiplexer control, including adjusted sample time and scan support
- Conversion speed and sample time adjustable to adapt to sensors and reference
- Conversion time below 1 µs (depending on result width and sample time)
- Flexible source selection and arbitration
  - Programmable arbitrary conversion sequence (single or repeated)
  - Configurable auto scan conversion (single or repeated) on each converter
  - Configurable auto scan conversion (single or repeated) in the background (all converters)
  - Conversions triggered by software, timer events, or external events
  - Cancel-inject-restart mode for reduced conversion delay on priority channels
- Powerful result handling
  - Selectable result width of 8/10/12 bits
  - Fast Compare Mode
  - Independent result registers
  - Configurable limit checking against programmable border values
  - Data rate reduction through adding a selectable number of conversion results

  - FIR/IIR filter with selectable coefficients
- Flexible service request generation based on selectable events
- Built-in safety features
  - Configurable register access protection supports safety applications
  - Broken wire detection with programmable default levels
  - Multiplexer test mode to verify signal path integrity
- Support of suspend and power saving modes

Table 27-1 Abbreviations used in ADC chapter

Abbreviation	Meaning
ADAS	Advanced Driver Assistance System
ADC	Analog to Digital Converter
DMA	Direct Memory Access (controller)
DNL	Differential Non-Linearity (error)
INL	Integral Non-Linearity (error)
LSB_n	Least Significant Bit: finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2^n equally distributed steps)
SCU	System Control Unit of the device
TUE	Total Unadjusted Error

27.1 Introduction and Basic Structure

The Versatile Analog to Digital Converter module (VADC) of the TC21x/TC22x/TC23x comprises a set of converter blocks that can be operated either independently or via a common request source that emulates a background converter. Each converter block is equipped with a dedicated input multiplexer and dedicated request sources, which together build separate groups, each assigned to a kernel.

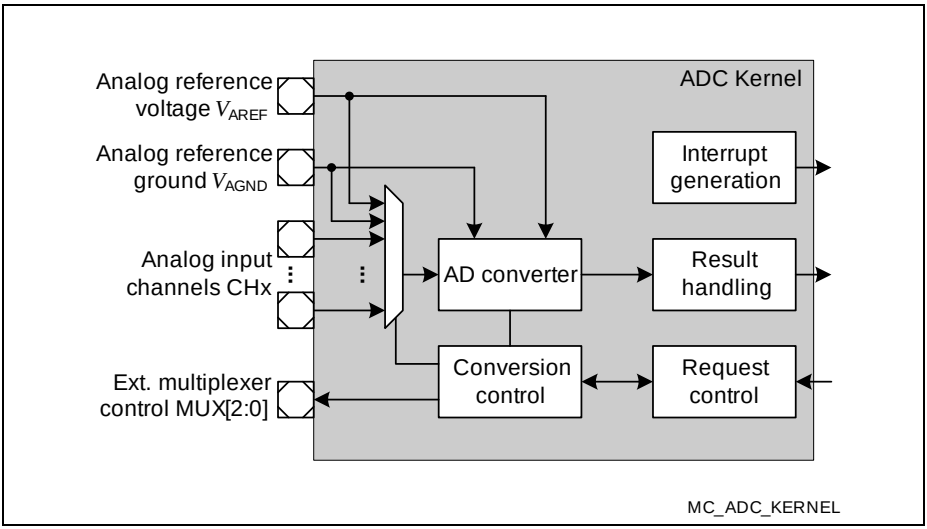

Figure 27-2 ADC Kernel Block Diagram

This basic structure supports application-oriented programming and operating while still providing general access to all resources. The almost identical converter groups allow a flexible assignment of functions to channels.

A set of functional units (described further down in this section) can be configured according to the requirements of a given application. These units build a path from the input signals to the digital results.

Each kernel provides a dedicated Sample&Hold unit connected to the input multiplexer and the converter.

The basic module clock f_{ADC} is connected to the system clock signal f_{SPB}.

Conversion Modes and Request Sources

Analog/Digital conversions can be requested by several request sources (2 group request sources and the background request source) and can be executed in several conversion modes. The request sources can be enabled concurrently with configurable priorities.

- **Fixed Channel Conversion (single or continuous)**
  A specific channel source requests conversions of one selectable channel (once or repeatedly)
- **Auto Scan Conversion (single or continuous)**
  A channel scan source (request source 1 or 2) requests auto scan conversions of a configurable linear sequence of all available channels (once or repeatedly)
- **Channel Sequence Conversion (single or continuous)**
  A queued source (request source 0 or 3) requests a sequence of conversions of up to 8 arbitrarily selectable channels (once or repeatedly)

The conversion modes can be used concurrently by the available request sources, i.e. conversions in different modes can be enabled at the same time. Each source can be enabled separately and can be triggered by external events, such as edges of PWM or timer signals, or pin transitions.

Request Source Control

Because all request sources can be enabled at the same time, an arbiter resolves concurrent conversion requests from different sources. Each source can be triggered by external signals, by on-chip signals, or by software.

Requests with higher priority can either cancel a running lower-priority conversion (cancel-inject-repeat mode) or be converted immediately after the currently running conversion (wait-for-start mode). If the target result register has not been read, a conversion can be deferred (wait-for-read mode).

Certain channels can also be synchronized with other ADC kernels, so several signals can be converted in parallel.

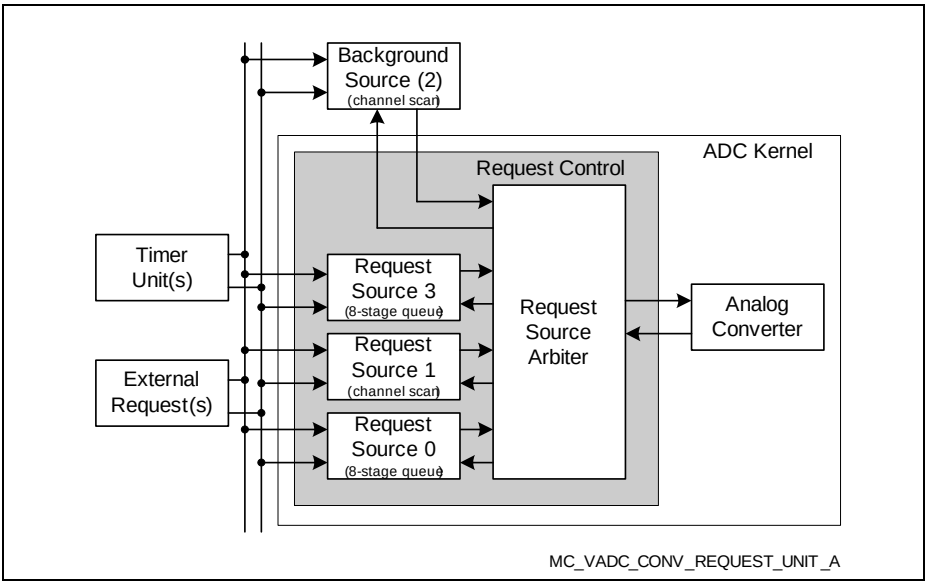

Figure 27-3 Conversion Request Unit

Input Channel Selection

The analog input multiplexer selects one of the available analog inputs (CH0 - CHx[1)]) to be converted. Three sources can select a linear sequence, an arbitrary sequence, or a specific channel. The priorities of these sources can be configured.

Additional external analog multiplexers can be controlled automatically, if more separate input channels are required than are built in (see **Section 27.12**).

*Note: Not all analog input channels are necessarily available in all packages, due to pin limitations. Please refer to the implementation description in **Section 27.14**.*

Conversion Control

Conversion parameters, such as sample phase duration or result resolution can be configured for 4 input classes (2 group-specific classes, 2 global classes). Each channel can be individually assigned to one of these input classes.

Each channel can select either the standard reference voltage or the alternate reference voltage (restrictions see **"Product-Specific Configuration" on Page 27-167**).

1) The availablity of input channels depends on the package of the used product type. A summary can be found in **Section 27.14.3**.

The input channels can, thus, be adjusted to the type of sensor (or other analog sources) connected to the ADC.

This unit also controls the built-in multiplexer and external analog multiplexers, if selected.

Analog/Digital Converter

The selected input channel is converted to a digital value by first sampling the voltage on the selected input and then generating the selected number of result bits.

For 12-bit conversions, post-calibration is executed after converting the channel.

For broken wire detection (see **Section 27.11.1**), the converter network can be preloaded before sampling the selected input channel.

Result Handling

The conversion results of each analog input channel can be directed to one of 16 group-specific result registers and one global result register to be stored there. A result register can be used by a group of channels or by a single channel.

The wait-for-read mode avoids data loss due to result overwrite by blocking a conversion until the previous result has been read.

Data reduction (e.g. for digital anti-aliasing filtering) can automatically add up to 4 conversion results before issuing a service request.

Alternatively, an FIR or IIR filter can be enabled that preprocesses the conversion results before sending them to the result register.

Also, result registers can be concatenated to build FIFO structures that store a number of conversion results without overwriting previous data. This increases the allowed CPU latency for retrieving conversion data from the ADC.

Service Request Generation

Several ADC events can issue service requests to CPU or DMA:

- **Source events** indicate the completion of a conversion sequence in the corresponding request source. This event can be used to trigger the setup of a new sequence.
- **Channel events** indicate the completion of a conversion for a certain channel. This can be combined with limit checking, so interrupt are generated only if the result is within a defined range of values.
- **Result events** indicate the availability of new result data in the corresponding result register. If data reduction mode is active, events are generated only after a complete accumulation sequence.

Each event can be assigned to one of eight service request nodes. This allows grouping the requests according to the requirements of the application.

Safety Features

Safety-aware applications are supported with mechanisms that help to ensure the integrity of a signal path.

Broken-wire-detection (BWD) preloads the converter network with a selectable level before sampling the input channel. The result will then reflect the preload value if the input signal is no more connected. If buffer capacitors are used, a certain number of conversions may be required to reach the failure indication level.

Pull Down Diagnostics (PDD) connects an additional strong pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper connection of a signal source (sensor) to the multiplexer.

Multiplexer Diagnostics (MD) connects a weak pull-up or pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper operation of the multiplexer.

Converter Diagnostics (CD) connects an alternate signal to the converter. A subsequent conversion can then confirm the proper operation of the converter.

Automatic Test Conversions can be scheduled using request source 3. This queued request source can execute an arbitrary test sequence. Please refer to **Section 27.11.4**.

27.2 Electrical Models

Each conversion of an analog input voltage to a digital value consists of two consecutive phases:

- During the sample phase, the input voltage is sampled and stored.
  The **Input Signal Path** is a simplified model for this.
- During the conversion phase the stored voltage is converted to a digital result.
  The **Reference Voltage Path** is a simplified model for this.

Input Signal Path

The ADC of the TC21x/TC22x/TC23x uses a switched capacitor field represented by C_{AINSW} (small parasitic capacitances are present at each input pin). During the sample phase, the capacitor field C_{AINSW} is connected to the selected analog input CHx via the input multiplexer (modeled by ideal switches and series resistors R_{AIN}).

The switch to CHx is closed during the sample phase and connects the capacitor field to the input voltage V_{AINx}.

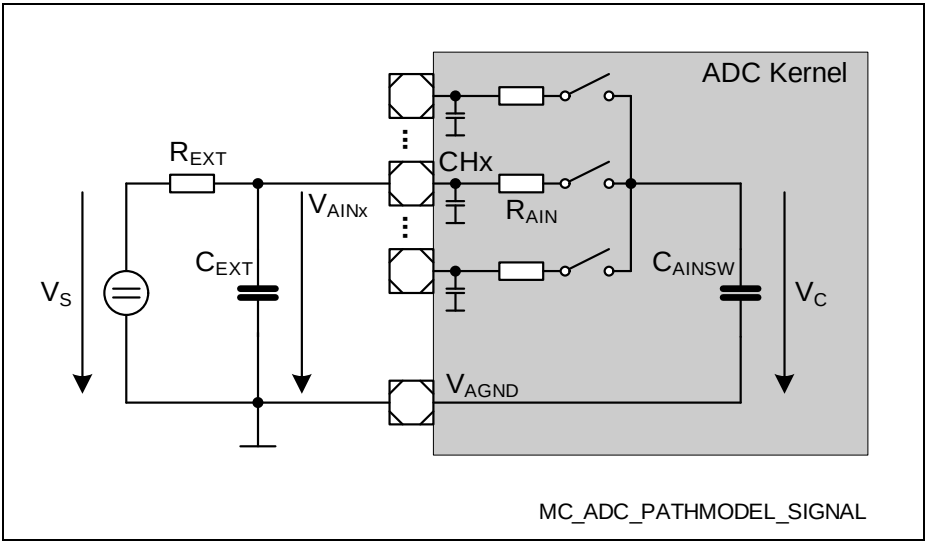

Figure 27-4 Signal Path Model

A simplified model for the analog input signal path is given in **Figure 27-4**. An analog voltage source (value V_S) with an internal impedance of R_{EXT} delivers the analog input that should be converted.

During the sample phase the corresponding switch is closed and the capacitor field C_{AINSW} is charged. Due to the low-pass behavior of the resulting RC combination, the

voltage V_C to be actually converted does not immediately follow V_S. The value R_{EXT} of the analog voltage source and the desired precision of the conversion strongly define the required length of the sample phase.

To reduce the influence of R_{EXT} and to filter input noise, it is recommended to introduce a fast external blocking capacitor C_{EXT} at the analog input pin of the ADC. Like this, mainly C_{EXT} delivers the charge during the sample phase. This structure allows a significantly shorter sample phase than without a blocking capacitor, because the low-pass time constant defining the sample time is mainly given by the values of R_{AIN} and C_{AINSW}.

The resulting low-pass filter of R_{EXT} (usually a parameter of the signal source) and C_{EXT} should be dimensioned according to the application's requirements:

- For quickly changing dynamic signals, a smaller capacitor allows V_{AINx} to follow V_S between two sample phases of the same analog input channel.
- For high-precision conversions, an external blocking capacitor C_{EXT} in the range of at least $2^n \times C_{AINSW}$ keeps the voltage change of V_{AINx} during the sample phase below 1 LSB_n. This voltage change is due to the charge redistribution between C_{EXT} and C_{AINSW}.

Leakage current through the analog input structure of the ADC can generate a voltage drop over R_{EXT}, introducing an error. The ADC input leakage current increases at high temperature and if the input voltage level is close to the analog supply ground V_{SS} or to the analog power supply V_{DDPA}. The input leakage current of an ADC channel can be reduced by avoiding input voltages close to the supplies.

An overload condition (input voltage exceeds the supply range) at adjacent analog inputs injects an additional leakage current (defined by a coupling factor) .

The capacitor C_{AINSW} is automatically precharged to a voltage of approximately half the standard reference voltage V_{AREF} to minimize the average difference between V_{AINx} and V_C at the beginning of a sample phase. Due to varying parameters and parasitic effects, the precharge voltage of C_{AINSW} is typically smaller than V_{AREF} / 2.

Reference Voltage Path

During the conversion phase, parts of the capacitor field (represented by C_{AREFSW}) are switched to a reference input (V_{AREF} or CH0) or to V_{AGND}. Using CH0 as alternate reference source allows conversions of 5.0 V and 3.3 V based analog input signals with the same ADC kernel.

Stable and noise-free reference and analog supply voltages support accurate conversion results. Because noise can also be introduced from other modules (e.g. switching pins), it is strongly recommended to carefully decouple analog from digital signal domains.

The switching of parts of C_{AREFSW} requires a dynamic current at the selected reference input. The impedance R_{REFEXT} of the reference voltage source V_R has to be low enough to supply the reference current during the conversion phase. An external blocking capacitor C_{REFEXT} can supply the peak currents and minimize the current to be delivered by the reference source.

The reference current I_{AREF} introduces a voltage drop at R_{REFEXT} that should not be neglected for the calculation of the overall accuracy. The average reference current during a conversion depends on the reference voltage level and the time t_{CONV} between two conversion starts: $I_{AREF} = C_{AREFSW} \times V_{AREF} / t_{CONV}$.

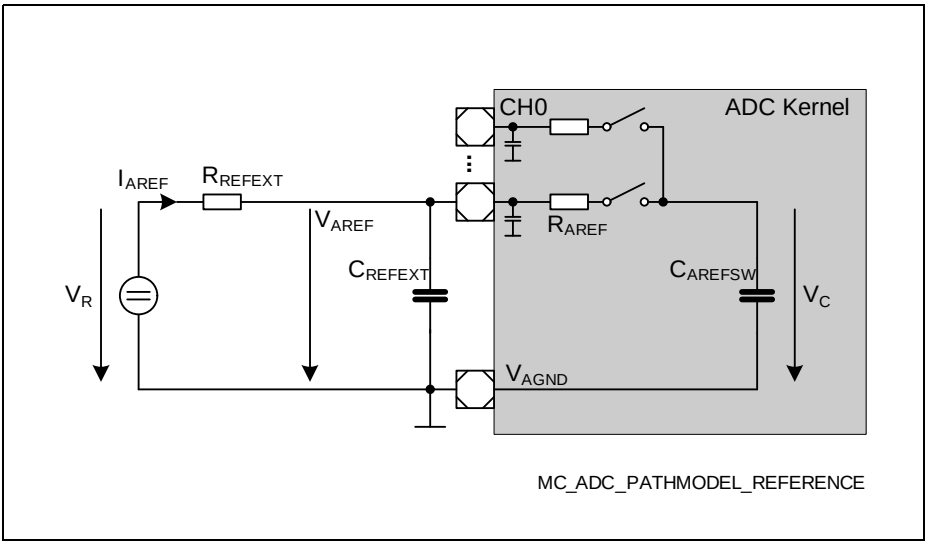

Figure 27-5 Reference Path Model

Reference Signal Connection

The reference voltages (V_{AREF}, V_{AGND}) have a strong influence on the digital result of a conversion. It is, therefore, recommended to carefully avoid noise of these inputs. The recommended filter structures (see figure) help to cancel high-frequency noise.

- Capacitors (C_{REFEXT}) between corresponding reference pins (V_{AREF}, V_{AGND}) provide peak currents for the conversion steps[1)]
- Capacitors (C_N) between reference ground and signal ground (V_{AGND}, V_{SS}) and the inductance of the connections attenuate noise
- Use low-ESR capacitors connected closely to the pins
- Connect reference pins via separate lines to star points close to the sensor supply
- Additional resistors in the reference lines (R_F) must be able to carry the average reference current, to avoid inaccuracy due to voltage drop
- The reference ground lines are connected to the signal ground in many applications

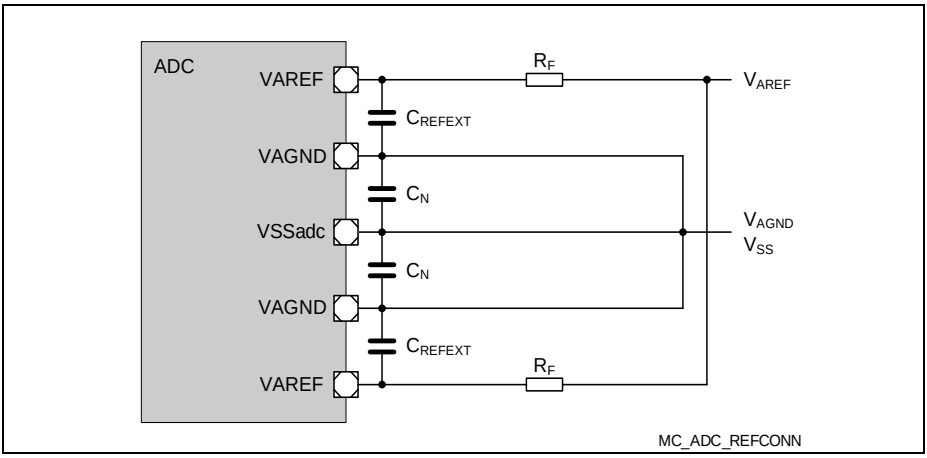

Figure 27-6 Connection of Reference Signals

Due to the charge redistribution between C_{REFEXT} and C_{AREFSW}, the voltage V_{AREF} decreases during the conversion phase. The error introduced by this effect is limited by the external blocking capacitor. $C_{REFEXT} \geq 2^n \times C_{AREFSW}$ limits this error to 1/2 LSB_n (double C_{REFEXT} to limit the error to 1/4 LSB_n).

Assuming 12-bit conversions and C_{AREFSW} = 30 pF leads to:
$C_{REFEXT} > 2^{12} \times 30$ pF = 123 nF, 100 nF are a good approximation.

The noise filtering capacitor C_N depends on the board properties (e.g. 100 nF).

1) The required capacitor value here depends on the resolution and accuracy.

Transfer Characteristics and Error Definitions

The transfer characteristic of the ADC describes the association of analog input voltages to the 2^n discrete digital result values (n bits resolution). Each digital result value (in the range of 0 to 2^n-1) represents an input voltage range defined by the reference voltage range divided by 2^n. This range (called quantization step or code width) represents the granularity (called LSB_n) of the ADC. The discrete character of the digital result generates a system-inherent quantization uncertainty of ±0.5 LSB_n for each conversion result.
The ideal transfer curve has the first digital transition (between 0 and 1) when the analog input reaches 0.5 LSB_n. The quantization steps are equally distributed over the input voltage range.
Analog input voltages below or above the reference voltage limits lead to a saturation of the digital result at 0 or 2^n-1.

The real transfer curve can exhibit certain deviations from the ideal transfer curve:

- The **offset error** is the deviation of the real transfer line from the ideal transfer line at the lowest code. This refers to best-fit lines through all possible codes, for both cases.
- The **gain error** is the deviation of the slope of the real transfer line from the slope of the ideal transfer line. This refers to best-fit lines through all possible codes, for both cases.
- The **differential non-linearity error** (DNL) is the deviation of the real code width (variation of the analog input voltage between two adjacent digital conversion results) from the ideal code width.
- The **integral non-linearity error** (INL) is the deviation of the real transfer curve from an adjusted ideal transfer curve (same offset and gain error as the real curve, but equal code widths).
- The **total unadjusted error** (TUE) describes the maximum deviation between a real conversion result and the ideal transfer characteristics over a given measurement range. Since some of these errors noted above can compensate each other, the TUE value generally is much less than the sum of the individual errors.
  The TUE also covers production process variations and internal noise effects (if switching noise is generated by the system, this generally leads to an increased TUE value).

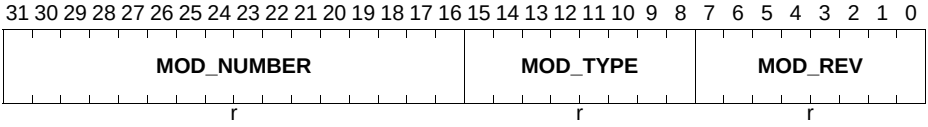
27.3 Configuration of General Functions

While many parameters can be selected individually for each channel, source, or group, some adjustments are valid for the whole ADC cluster.

27.3.1 Module Identification

The module identification register indicates the version of the ADC module that is used in the TC21x/TC22x/TC23x.

ID
Module Identification Register (0008$_H$) Reset Value: 00C5 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision** Indicates the revision number of the implementation. This information depends on the design step.
MOD_TYPE	[15:8]	r	**Module Type** This internal marker is fixed to C0$_H$.
MOD_NUMBER	[31:16]	r	**Module Number** Indicates the module identification number (00C5$_H$ = SARADC).

27.3.2 System Registers

A set of standardized registers provides general access to the module and controls basic system functions.

The Clock Control Register **CLC** allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. Register **CLC** controls the module clock signal and the reactivity to the sleep mode signal.

CLC
Clock Control Register **(0000_H)** **Reset Value: 0000 0003_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. Also the analog section is disabled by clearing ANONS. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	r	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
0	2	r	**Reserved, write 0, read as 0**
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	[31:4]	r	**Reserved, write 0, read as 0**

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging) and includes the module-related control bits for the OCDS Trigger Bus (OTGB).

The OCDS Control and Status (OCS) register is cleared by Debug Reset.
The OCS register can only be written when the OCDS is enabled.
If OCDS is being disabled, the OCS register value will not change.
When OCDS is disabled the OCS suspend control is ineffective.
Write access is 32 bit wide only and requires Supervisor Mode.

OCS

Individual Module Reset

The Kernel Reset Registers **KRST0/KRST1** are used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. The RST bits will be cleared by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Registers 0 and 1 each include bit RST. To trigger a module reset, both RST bits must be set. They will be cleared automatically with the end of the BPI kernel reset sequence.

1) The Access Enable functionality controls only write transactions to registers CLC, OCS, KRSTx, and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0

27.3.3 General Clocking Scheme and Control

The A/D Converters of the TC21x/TC22x/TC23x are supplied with a global clock signal from the system f_{ADC}. Two clock signals are derived from this input and are distributed to all converters. The global configuration register defines common clock bases for all converters of the cluster. This ensures deterministic behavior of converters that shall operate in parallel.

The analog converter clock f_{ADCI} determines the performance of the converters and must be selected to comply with the specification given in the Data Sheet.

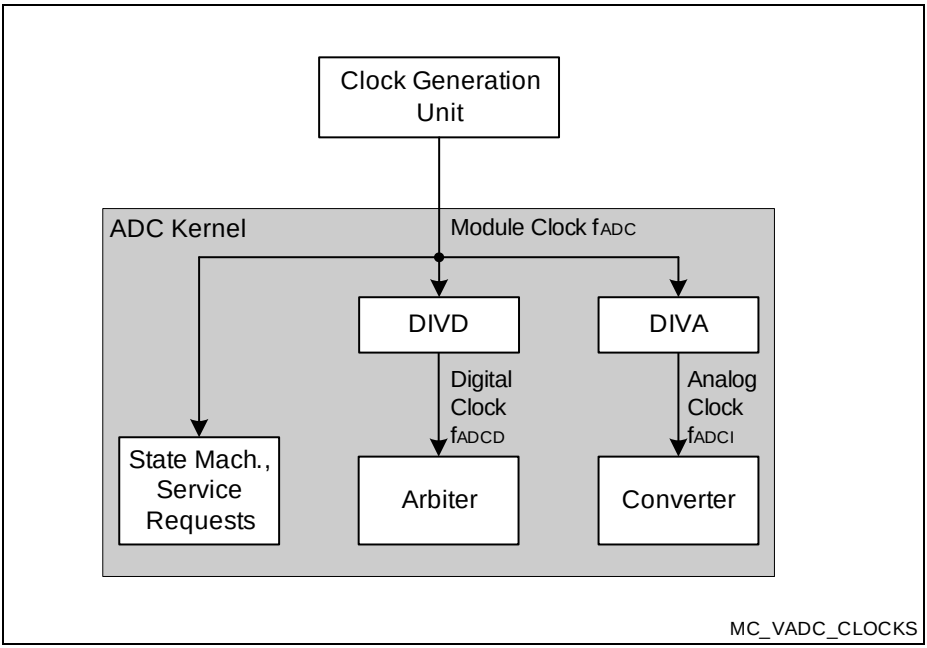

Figure 27-7 Clock Signal Summary

Global Configuration

The global configuration register GLOBCFG provides global control and configuration options that are valid for all converters of the cluster.

27.3.4 Register Access Control

Several protection schemes are provided to prevent unintended write access to control bitfields of the VADC.

- The registers of the VADC are protected by the general access control mechanism that is configured by register **ACCEN0**.
- A specific register access control scheme provides a versatile protection scheme against unintended corruption of register contents. Registers ACCPROT0/1 allow the restriction of write accesses for several groups of registers. The registers to be protected can be selected by the user. **Table 27-3** lists the registers that belong to each register group.
  Registers ACCPROT0/1 themselves are protected by the Safety Endinit feature.
- Groups of bitfields within a register may also be protected by an associated write control bit. This write control bit (xxWC) must be written with 1 along with the write access to the intended bitfield(s).

27.4 Analog Module Activation and Control

The analog converter of the ADC is the functional block that generates the digital result values from the selected input voltage. It draws a permanent current during its operation and can be deactivated between conversions to reduce the consumed overall energy.

Note: After reset the analog converters are off. They must be enabled before triggering any action involving a converter.

The accuracy of the conversions is improved by calibrating the analog converter to compensate process, temperature, and voltage variations.

27.4.1 Analog Converter Control

The operating mode is determined by bitfield **GxARBCFG (x = 0 - 3)**.ANONS:

- ANONS = 11_B: **Normal Operation**
  The converter is active, conversions are started immediately.
  Requires no wakeup time.
- ANONS = 10_B or 01_B: **Reserved**
- ANONS = 00_B: **Converter switched Off** (default after reset)
  The converter is switched off. Furthermore, digital logic blocks are set to their initial state. If the arbiter is currently running, it completes the actual arbitration round and then stops.
  Before starting a conversion, select the active mode for ANONS.
  Requires the wakeup time (see below).

Wakeup Time from Analog Powerdown

When the converter is activated, it needs a certain wakeup time to settle before a conversion can be properly executed. This wakeup time can be established by waiting the required period before starting a conversion, or by adding it to the intended sample time.

The wakeup time is approximately 15 µs.
Exact numbers can be found in the respective Data Sheets.

Note: The wakeup time is also required after initially enabling the converter.

27.4.2 Calibration

Calibration automatically compensates deviations caused by process, temperature, and voltage variations. This ensures precise results throughout the operation time.

An initial start-up calibration is required once after a reset for all calibrated converters and is triggered globally. All calibrated converters must be enabled (ANONS = 11_B) before initiating the start-up calibration. Conversions may be started after the initial calibration sequence. This is indicated by bit CAL = 0_B.

After that, postcalibration cycles will compensate the effects of drifting parameters.

27.5 Conversion Request Generation

The conversion request unit of a group autonomously handles the generation of conversion requests. Three request sources (2 group-specific sources and the background source) can generate requests for the conversion of an analog channel. The arbiter resolves concurrent requests and selects the channel to be converted next.

Upon a trigger event, the request source requests the conversion of a certain analog input channel or a sequence of channels.

- **Software triggers**
  directly activate the respective request source.
- **External triggers**
  synchronize the request source activation with external events, such as a trigger pulse from a timer generating a PWM signal or from a port pin.

Application software selects the trigger type and source, the channel(s) to be converted, and the request source priority. A request source can also be activated directly by software without requiring an external trigger.

The arbiter regularly scans the request sources for pending conversion requests and selects the conversion request with the highest priority. This conversion request is then forwarded to the converter to start the sampling and conversion of the requested channel.

Each request source can operate in single-shot or in continuous mode:

- **In single-shot mode**,
  the programmed conversion (sequence) is requested once after being triggered. A subsequent conversion (sequence) must be triggered again.
- **In continuous mode**,
  the programmed conversion (sequence) is automatically requested repeatedly after being triggered once.

For each request source of a group, external triggers are generated from one of 15 selectable trigger inputs (REQTRx[O:A]) and from one of 16 selectable gating inputs (REQGTx[P:A])[1)]. The available trigger signals for the TC21x/TC22x/TC23x are listed in **Section 27.14.4**.

*Note: **Figure 27-3 "Conversion Request Unit" on Page 27-6** summarizes the request sources.*

1) The selected gating input can be used as a trigger signal (REQTRxP).

Two types of requests sources are available:

- **A queued source** can issue conversion requests for an arbitrary sequence of input channels. The channel numbers for this sequence can be freely programmed[1]. This supports application-specific conversion sequences that cannot be covered by a channel scan source. Also, multiple conversions of the same channel within a sequence are supported.
  A queued source converts a series of input channels permanently or on a regular time base. For example, if programmed with medium priority, some input channels can be converted upon a specified event (e.g. synchronized to a PWM). Conversions of lower priority sources are suspended in the meantime.
  – Request source 0 is a group-specific 8-stage queued source.
  – Request source 3 is a group-specific 8-stage queued source with test features.
- **A channel scan source** can issue conversion requests for a coherent sequence of input channels. This sequence begins with the highest enabled channel number and continues towards lower channel numbers. All available channels[1] can be enabled for the scan sequence. Each channel is converted once per sequence.
  A scan source converts a series of input channels permanently or on a regular time base. For example, if programmed with low priority, some input channels can be scanned in a background task to update information that is not time-critical.
  – Request source 1 is a group-specific channel scan source.
  – Request source 2 is a global channel scan source (background source).
  The background source can request conversions of all channels of all groups.

1) The availablity of input channels depends on the package of the used product type. A summary can be found in **Section 27.14.3**.
The background source can only request non-priority channels, i.e. channels that are not selected in registers GxCHASS. Priority channels are reserved for the group-specific request sources 0 and 1.

27.5.1 Queued Request Source Handling

A queued request source supports short conversion sequences (up to 8) of arbitrary channels (contrary to a scan request source with a fixed conversion order for the enabled channels). The programmed sequence is stored in a queue buffer (based on a FIFO mechanism). The requested channel numbers are entered via the queue input, while queue stage 0 defines the channel to be converted next.

A conversion request is only issued to the request source arbiter if a valid entry is stored in queue stage 0.

If the arbiter aborts a conversion triggered by a queued request source due to higher priority requests, the corresponding conversion parameters are automatically saved in the backup stage. This ensures that an aborted conversion is not lost but takes part in the next arbitration round (before stage 0).

The trigger and gating unit generates trigger events from the selected external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Trigger events start a queued sequence and can be generated either via software or via the selected hardware triggers. The occurrence of a trigger event is indicated by bit QSRx.EV. This flag is cleared when the corresponding conversion is started or by writing to bit QMRx.CEV.

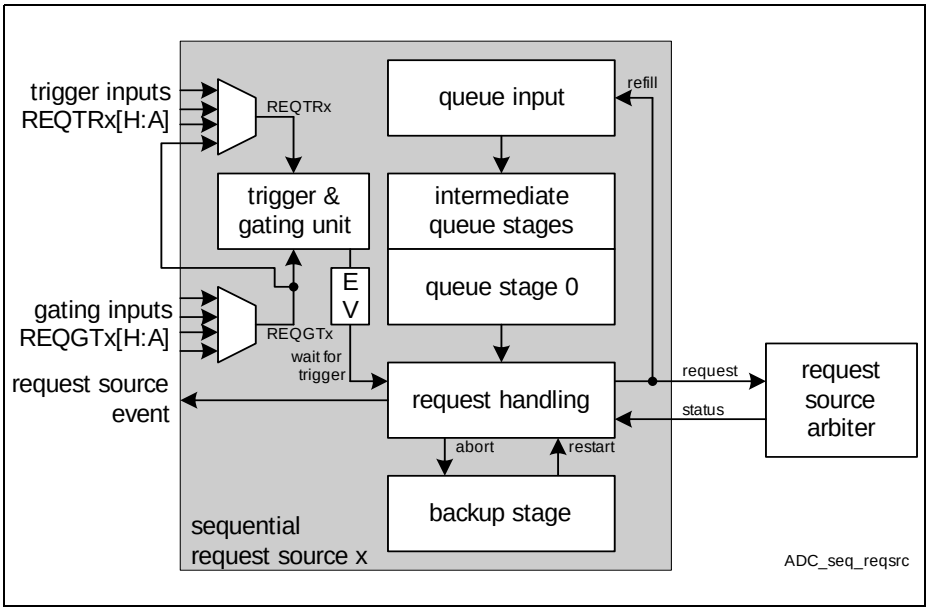

Figure 27-8 Queued Request Source

A sequence is defined by entering conversion requests into the queue input register (**GxQINR0 (x = 0 - 3)**). Each entry selects the channel to be converted and can enable an external trigger, generation of an interrupt, and an automatic refill (i.e. copy this entry to the top of the queue after conversion). The entries are stored in the queue buffer stages.

The content of stage 0 (**GxQ0R0 (x = 0 - 3)**) selects the channel to be converted next. When the requested conversion is started, the contents of this queue stage is invalidated and copied to the backup stage. Then the next queue entry can be handled (if available).

Note: The contents of the queue stages cannot be modified directly, but only by writing to the queue input or by flushing the queue.
*The current status of the queue is shown in register **GxQSR0 (x = 0 - 3)**.*
If all queue entries have automatic refill selected, the defined conversion sequence can be repeated without re-programming.

Properties of the Queued Request Source

Queued request source 0 provides 8 buffer stages and can handle sequences of up to 8 input channel entries. It supports short application-specific conversion sequences, especially for timing-critical sequences containing also multiple conversions of the same channel.

Queued Source Operation

Configure the queued request source by executing the following actions:

- Define the sequence by writing the entries to the queue input **GxQINR0 (x = 0 - 3)**. Initialize the complete sequence before enabling the request source, because with enabled refill feature, software writes to QINRx are not allowed.
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper transitions by programming **GxQCTRL0 (x = 0 - 3)**.
  Enable the trigger and select the gating mode by programming bitfield ENGT in register **GxQMR0 (x = 0 - 3)**.[1)]
- Enable the corresponding arbitration slot (0) to accept conversion requests from the queued source (see register **GxARBPR (x = 0 - 3)**).

Start a queued sequence by generating a trigger event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- Generate a software trigger event by setting GxQMR0.TREV = 1.

1) To avoid unexpected signal transitions, select/enable the trigger and/or gate inputs before activating the corresponding request source. If PDOUT signals from the ERU are used, first initialize the ERU.

- Write a new entry to the queue input of an empty queue. This leads to a (new) valid queue entry that is forwarded to queue stage 0 and starts a conversion request (if enabled by GxQMR0.ENGT and without waiting for an external trigger).

Note: If the refill mechanism is activated, a processed entry is automatically reloaded into the queue. This permanently repeats the respective sequence (autoscan). In this case, do not write to the queue input while the queued source is running. Write operations to a completely filled queue are ignored.

Stop or abort an ongoing queued sequence by executing the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the queue entries, but only prevents issuing conversion requests to the arbiter.
- Disable the corresponding arbitration slot (0) in the arbiter. This does not modify the queue entries, but only prevents the arbiter from accepting requests from the request handling block.
- Disable the queued source by clearing bitfield ENGT = 00_B.
  - Invalidate the next pending queue entry by setting bit GxQMR0.CLRV = 1. If the backup stage contains a valid entry, this one is invalidated, otherwise stage 0 is invalidated.
  - Remove all entries from the queue by setting bit GxQMR0.FLUSH = 1.

Queue Request Source Events and Service Requests

A request source event of a queued source occurs when a conversion is finished. A source event service request can be generated based on a request source event according to the structure shown in **Figure 27-9**. If a request source event is detected, it sets the corresponding indication flag in register **GxSEFLAG (x = 0 - 3)**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect. The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **GxSEFCLR (x = 0 - 3)**.
The interrupt enable bit is taken from stage 0 for a normal sequential conversion, or from the backup stage for a repeated conversion after an abort.

The service request output line SRx that is selected by the request source event interrupt node pointer bitfields in register **GxSEVNP (x = 0 - 3)** becomes activated each time the related request source event is detected (and enabled by GxQ0R0.ENSI, or GxQBUR0.ENSI respectively) or the related bit position in register **GxSEFLAG (x = 0 - 3)** is written with a 1 (this write action simulates a request source event).

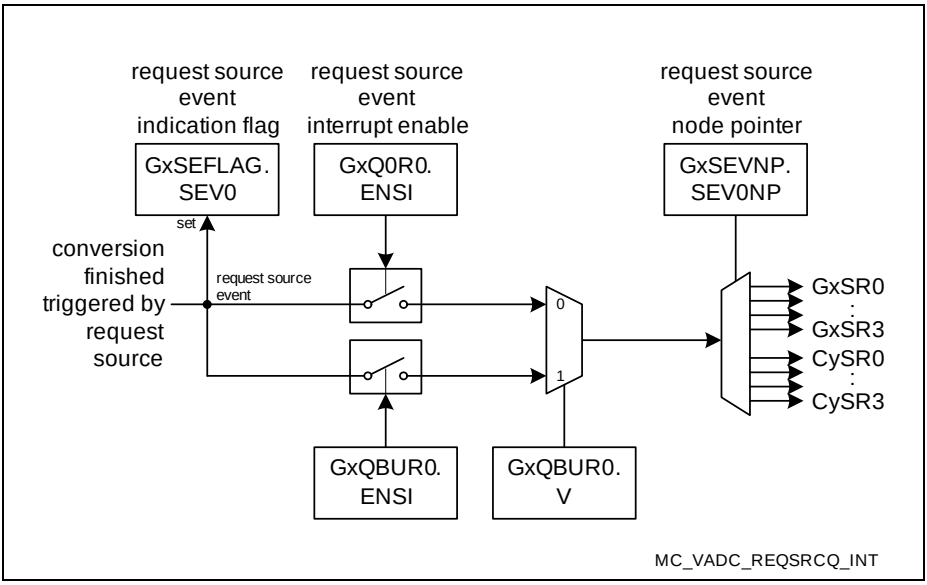

Figure 27-9 Interrupt Generation of a Queued Request Source

The control register of the queue source selects the external gate and/or trigger signals. Write control bits allow separate control of each function with a simple write access.

Field	Bits	Type	Description
FILL	[3:0]	rh	**Filling Level for Queue 3** Indicates the number of valid queue entries. It is incremented each time a new entry is written to QINR3 or by an enabled refill mechanism. It is decremented each time a requested conversion has been started. A new entry is ignored if the filling level has reached its maximum value. 0000_B There is 1 (if EMPTY = 0) or no (if EMPTY = 1) valid entry in the queue 0001_B There are 2 valid entries in the queue 0010_B There are 3 valid entries in the queue … 0111_B There are 8 valid entries in the queue others: Reserved
0	4	r	**Reserved, write 0, read as 0**
EMPTY	5	rh	**Queue Empty** 0_B There are valid entries in the queue (see FILL) 1_B No valid entries (queue is empty)
0	6	r	**Reserved, write 0, read as 0**

Field	Bits	Type	Description
REQGT	7	rh	**Request Gate Level** Monitors the level at the selected REQGT input. 0_B The gate input is low 1_B The gate input is high
EV	8	rh	**Event Detected** Indicates that an event has been detected while at least one valid entry has been in the queue (queue register 0 or backup stage). Once set, this bit is cleared automatically when the requested conversion is started. 0_B No trigger event 1_B A trigger event has been detected
0	[31:9]	r	**Reserved, write 0, read as 0**

The Queue Input Register is the entry point for conversion requests of a queued request source. QINR3 contains additional control bits to select the test functions. Please refer to **Section 27.11.4**.

*Note: The test functions selected via GxQINR3 only become active if enabled in register **GLOBTE**.*

0	[30:29]	r	**Reserved, write 0, read as 0**
COV	31	w	**Clear Overflow Flag** 0_B No action 1_B Clear bits OV and Q3ACT

1) Write zero to bitfield TSCSET, to disable the trigger sequence counter and start the sequence in queue 3 with each incoming trigger.

*Note: For more information, please see **Section 27.11.4**.*

27.5.2 Channel Scan Request Source Handling

The VADC provides two types of channel scan sources:

- Source 1: Group scan source
  This scan source can request all channels of the corresponding group.
- Source 2: Background scan source
  This scan source can request all channels of all groups.
  Priority channels selected in registers **GxCHASS (x = 0 - 3)** cannot take part in background conversion sequences.

Both sources operate in the same way and provide the same register interface. The background source provides more request/pending bits because it can request all channels of all groups.

Each analog input channel can be included in or excluded from the scan sequence by setting or clearing the corresponding channel select bit in register **GxASSEL (x = 0 - 3)** or **BRSSELx (x = 0 - 3)**. The programmed register value remains unchanged by an ongoing scan sequence. The scan sequence starts with the highest enabled channel number and continues towards lower channel numbers.

Upon a load event, the request pattern is transferred to the pending bits in register **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)**. The pending conversion requests indicate which input channels are to be converted in an ongoing scan sequence. Each conversion start that was triggered by the scan request source, automatically clears the corresponding pending bit. If the last conversion triggered by the scan source is finished and all pending bits are cleared, the current scan sequence is considered finished and a request source event is generated.

A conversion request is only issued to the request source arbiter if at least one pending bit is set.

If the arbiter aborts a conversion triggered by the scan request source due to higher priority requests, the corresponding pending bit is automatically set. This ensures that an aborted conversion is not lost but takes part in the next arbitration round.

The trigger and gating unit generates load events from the selected external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Load events start a scan sequence and can be generated either via software or via the selected hardware triggers. The request source event can also generate an automatic load event, so the programmed sequence is automatically repeated.

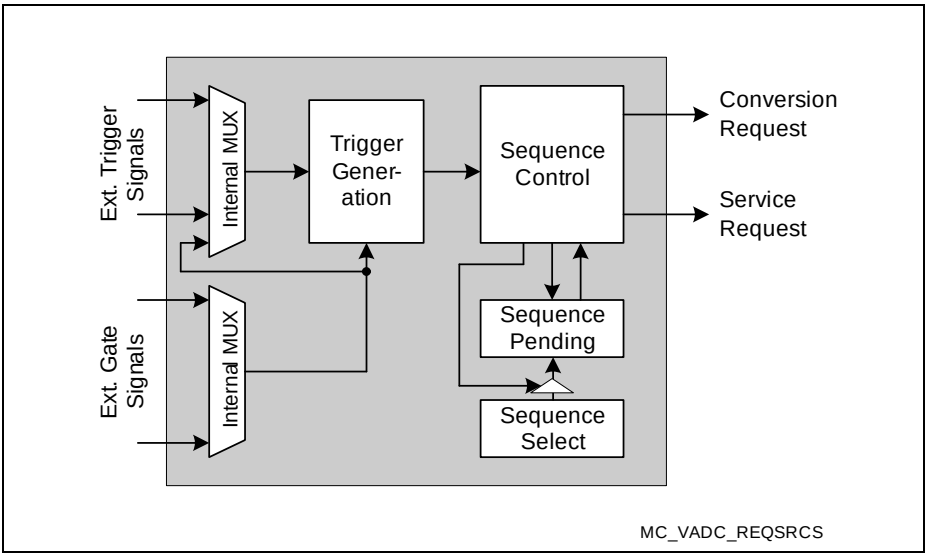

Figure 27-10 Scan Request Source

Scan Source Operation

Configure the scan request source by executing the following actions:

- Select the input channels for the sequence by programming **GxASSEL (x = 0 - 3)** or **BRSSELx (x = 0 - 3)**
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper signal transitions by programming **GxASCTRL (x = 0 - 3)** or **BRSCTRL**. Enable the trigger and select the gating mode by programming **GxASMR (x = 0 - 3)** or **BRSMR**.[1)]
- Define the load event operation (handling of pending bits, autoscan mode) by programming **GxASMR (x = 0 - 3)** or **BRSMR**.
  A load event with bit LDM = 0 copies the content of **GxASSEL (x = 0 - 3)** or **BRSSELx (x = 0 - 3)** to **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)** (overwrite mode). This starts a new scan sequence and aborts any pending conversions from a previous scan sequence.
  A load event with bit LDM = 1 OR-combines the content of **GxASSEL (x = 0 - 3)** or **BRSSELx (x = 0 - 3)** to **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)** (combine mode). This starts a scan sequence that includes pending conversions from a prvious scan sequence.
- Enable the corresponding arbitration slot (1) to accept conversion requests from the channel scan source (see register **GxARBPR (x = 0 - 3)**).

Start a channel scan sequence by generating a load event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- Generate a software load event by setting LDEV = 1 (**GxASMR (x = 0 - 3)** or **BRSMR**).
- Generate a load event by writing the scan pattern directly to the pending bits in **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)**. The pattern is copied to **GxASSEL (x = 0 - 3)** or **BRSSELx (x = 0 - 3)** and a load event is generated automatically.
  In this case, a scan sequence can be defined and started with a single data write action, e.g. under PEC control (provided that the pattern fits into one register).

Note: If autoscan is enabled, a load event is generated automatically each time a request source event occurs when the scan sequence has finished. This permanently repeats the defined scan sequence (autoscan).

Stop or abort an ongoing scan sequence by executing the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the conversion pending bits, but only prevents issuing conversion requests to the arbiter.

1) To avoid unexpected signal transitions, select/enable the trigger and/or gate inputs before activating the corresponding request source. If PDOUT signals from the ERU are used, first initialize the ERU.

- Disable the corresponding arbitration slot (1 or 2) in the arbiter. This does not modify the contents of the conversion pending bits, but only prevents the arbiter from accepting requests from the request handling block.
- Disable the channel scan source by clearing bitfield ENGT = 00_B. Clear the pending request bits by setting bit CLRPND = 1 (**GxASMR (x = 0 - 3)** or **BRSMR**).

Scan Request Source Events and Service Requests

A request source event of a scan source occurs if the last conversion of a scan sequence is finished (all pending bits = 0). A request source event interrupt can be generated based on a request source event. If a request source event is detected, it sets the corresponding indication flag in register **GxSEFLAG (x = 0 - 3)**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect.

The service request output SRx that is selected by the request source event interrupt node pointer bitfields in register **GxSEVNP (x = 0 - 3)** becomes activated each time the related request source event is detected (and enabled by ENSI) or the related bit position in register **GxSEFLAG (x = 0 - 3)** is written with a 1 (this write action simulates a request source event).

The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **GxSEFCLR (x = 0 - 3)**.[1)]

1) Please refer to **"Service Request Generation" on Page 27-153**.

Registers of Group Scan Source

There is a separate register set for each group scan source. These sources can be operated independently.

The control register of the autoscan source selects the external gate and/or trigger signals.
Write control bits allow separate control of each function with a simple write access.

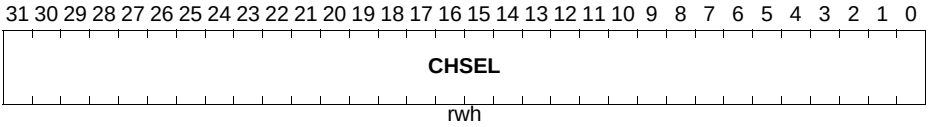
The Channel Select Register selects the channels to be converted by the group scan request source. Its bits are used to update the pending register, when a load event occurs.

The number of valid channel bits depends on the channels available in the respective product type (please refer to **“Product-Specific Configuration” on Page 27-167**).

GxASSEL (x = 0 - 3)
Autoscan Source Channel Select Register, Group x

($x * 0400_H + 0528_H$) **Reset Value: $0000\ 0000_H$**



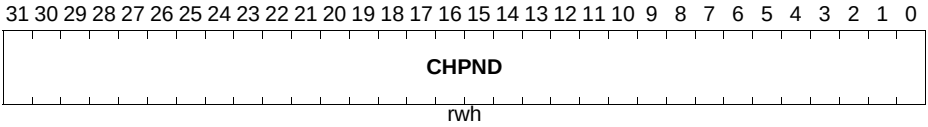
Field	Bits	Type	Description
CHSEL	[31:0]	rwh	**Channel Selection** Each bit (when set) enables the corresponding input channel of the respective group to take part in the scan sequence. 0_B Ignore this channel 1_B This channel is part of the scan sequence

Note: Register GxASSEL is also updated when writing a pattern to register GxASPND.

The Channel Pending Register indicates the channels to be converted in the current conversion sequence. They are updated from the select register, when a load event occurs.

GxASPND (x = 0 - 3)
Autoscan Source Pending Register, Group x

($x * 0400_H + 052C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CHPND	[31:0]	rwh	**Channels Pending** Each bit (when set) request the conversion of the corresponding input channel of the respective group. 0_B Ignore this channel 1_B Request conversion of this channel

Note: Writing to register GxASPND automatically updates register GxASSEL.

Registers of Background Scan Source

There is a single register set for the background scan source. This source is common for the complete VADC.

The control register of the background request source selects the external gate and/or trigger signals.
Write control bits allow separate control of each function with a simple write access.

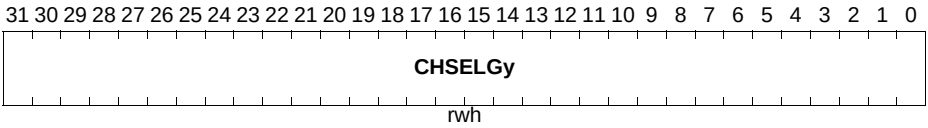
(0180_H + x * 0004_H) **Reset Value: 0000 0000_H**

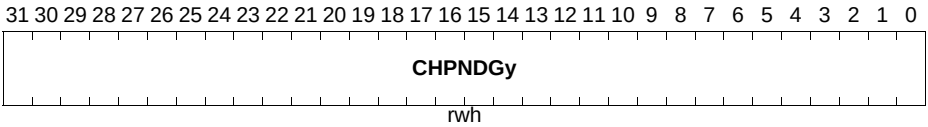


Field	Bits	Type	Description
CHSELGy	[31:0]	rwh	**Channel Selection Group x** Each bit (when set) enables the corresponding input channel of the respective group to take part in the background scan sequence. 0_B Ignore this channel 1_B This channel is part of the scan sequence

The Channel Pending Registers indicate the channels to be converted in the current conversion sequence. They are updated from the select registers, when a load event occurs.

BRSPNDx (x = 0 - 3)
Background Request Source Pending Register, Group x

($01C0_H$ + x * 0004_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CHPNDGy	[31:0]	rwh	**Channels Pending Group x** Each bit (when set) request the conversion of the corresponding input channel of the respective group. 0_B Ignore this channel 1_B Request conversion of this channel

Note: Writing to any of registers BRSPNDx automatically updates the corresponding register BRSSELx and generates a load event that copies all bits from all registers BRSSELx to BRSPNDx.
Use this shortcut only when writing the last word of the request pattern.

27.6 Request Source Arbitration

The request source arbiter regularly polls the request sources, one after the other, for pending conversion requests. Each request source is assigned to a certain time slot within an arbitration round, called arbitration slot. The duration of an arbitration slot is user-configurable via register GLOBCFG, see **Global Configuration**.

The priority of each request source is user-configurable via register **GxARBPR (x = 0 - 3)**, so the arbiter can select the next channel to be converted, in the case of concurrent requests from multiple sources, according to the application requirements.

An unused arbitration slot is considered empty and does not take part in the arbitration. After reset, all slots are disabled and must be enabled (register **GxARBPR (x = 0 - 3)**) to take part in the arbitration process.

Figure 27-11 summarizes the arbitration sequence. An arbitration round consists of one arbitration slot for each available request source. The synchronization source is always evaluated in the last slot and has a higher priority than all other sources. At the end of each arbitration round, the arbiter has determined the highest priority conversion request.

If a conversion is started in an arbitration round, this arbitration round does not deliver an arbitration winner. In the TC21x/TC22x/TC23x, the following request sources are available:

- Arbitration slot 0: **Group Queued source**, 8-stage sequences in arbitrary order
- Arbitration slot 1: **Group Scan source**, sequences in defined order within group
- Arbitration slot 2: **Background Scan source**, sequences in defined order, all groups
- Arbitration slot 3: **Group Queued source**, 8-stage sequences in arbitrary order, automatic control of test features
- Last arbitration slot: **Synchronization source**, synchronized conversion requests from another ADC kernel (always handled with the highest priority in a synchronization slave kernel).

Note: If request source 3 is not used, the shortest possible arbitration round of 4 arbitration slots (ARBRND = 00_B) can be selected. This provides the fastest arbiter operation.
To use request source 3, the arbitration round must be increased to 8 slots (ARBRND = 01_B). In this case, slots 0 … 3 are used for sources 0 … 3 and slot 7 is the synchronization slot (slots 4 … 6 are unused).
***Figure 27-11** shows the shortest possible arbitration round of 4 slots.*

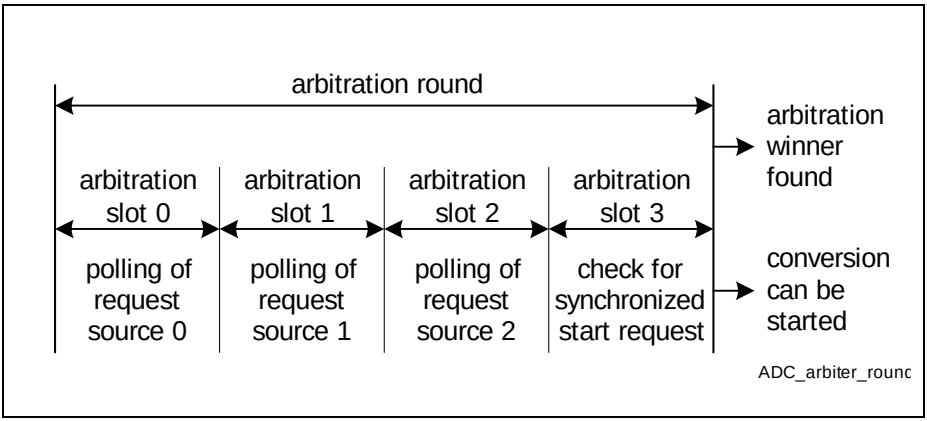


Figure 27-11 Arbitration Round with 4 Arbitration Slots

27.6.1 Arbiter Operation and Configuration

The timing of the arbiter (i.e. of an arbitration round) is determined by the number of arbitration slots within an arbitration round and by the duration of an arbitration slot.

An arbitration round consist of 4…20 arbitration slots (defined by bitfield **GxARBCFG (x = 0 - 3)**.ARBRND). 4 or 8 slots are sufficient for the TC21x/TC22x/TC23x (depending on the usage of source 3), more can be programmed to obtain the same arbiter timing for different products.

The duration of an arbitration slot is configurable t_{Slot} = (DIVD+1) / f_{ADC}.
The duration of an arbitration round, therefore, is t_{ARB} = 4 × t_{Slot} (or 8 × t_{Slot}).

The period of the arbitration round introduces a timing granularity to detect an incoming conversion request signal and the earliest point to start the related conversion. This granularity can introduce a jitter of maximum one arbitration round. The jitter can be reduced by minimizing the period of an arbitration round.

To achieve a reproducible reaction time (constant delay without jitter) between the trigger event of a conversion request (e.g. by a timer unit or due to an external event) and the start of the related conversion, mainly the following two options exist. For both options, the converter has to be idle and other conversion requests must not be pending for at least one arbiter round before the trigger event occurs:

- If bit **GxARBCFG (x = 0 - 3)**.ARBM = 0, the **arbiter runs permanently**. In this mode, synchronized conversions of more than one ADC kernel are possible.[1)]
  The trigger for a conversion request has to be generated synchronously to the arbiter timing. Incoming triggers should have exactly n-times the granularity of the arbiter (n = 1, 2, 3,...). In order to allow some flexibility, the duration of an arbitration slot can be programmed in cycles of f_{ADC}.
- If bit **GxARBCFG (x = 0 - 3)**.ARBM = 1, the **arbiter stops after an arbitration round** when no conversion request have been found pending any more. The arbiter is started again if at least one enabled request source indicates a pending conversion request. The trigger for a conversion request does not need to be synchronous to the arbiter timing.
  In this mode, parallel conversions are not possible for synchronization slave kernels.

Each request source has a configurable priority, so the arbiter can resolve concurrent conversion requests from different sources. The request with the highest priority is selected for conversion. These priorities can be adapted to the requirements of a given application (see register **GxARBPR (x = 0 - 3)**).

The **Conversion Start Mode** determines the handling of the conversion request that has won the arbitration.

1) For more information, please refer to **"Synchronization of Conversions" on Page 27-132**.

The Arbitration Configuration Register selects the timing and the behavior of the arbiter.

GxARBCFG (x = 0 - 3)

ARBRND	[5:4]	rw	**Arbitration Round Length** Defines the number of arbitration slots per arb. round (arbitration round length = t_{ARB}).[1)] 00_B 4 arbitration slots per round ($t_{ARB} = 4 / f_{ADCD}$) 01_B 8 arbitration slots per round ($t_{ARB} = 8 / f_{ADCD}$) 10_B 16 arbitration slots per round ($t_{ARB} = 16 / f_{ADCD}$) 11_B 20 arbitration slots per round ($t_{ARB} = 20 / f_{ADCD}$)
0	6	r	**Reserved, write 0, read as 0**

Field	Bits	Type	Description
ARBM	7	rw	**Arbitration Mode** 0_B The arbiter runs permanently. This setting is required for a synchronization slave (see **Section 27.10.1**) and for equidistant sampling using the signal ARBCNT (see **Section 27.10.2**). 1_B The arbiter only runs if at least one conversion request of an enabled request source is pending. This setting ensures a reproducible latency from an incoming request to the conversion start, if the converter is idle. Synchronized conversions are not supported.
0	[15:8]	r	**Reserved, write 0, read as 0**
ANONS	[17:16]	rh	**Analog Converter Control Status** Defined by bitfield ANONC in a stand-alone kernel or a kernel in master mode. In slave mode, this bitfield is defined by bitfield ANONC of the respective master kernel. See also **Section 27.4.1**. 00_B Analog converter off 01_B Reserved 10_B Reserved 11_B Normal operation (permanently on)
CSRC	[19:18]	rh	**Currently Converted Request Source** Indicates the arbitration slot number of the current (BUSY = 1) or of the last (BUSY = 0) conversion. This bitfield is updated when a conversion is started. 00_B Current/last conversion for request source 0 01_B Current/last conversion for request source 1 10_B Current/last conversion for background source 11_B Current/last conversion for request source 3 or synchronization request (slave converter) [2)]
CHNR	[24:20]	rh	**Channel Number** Indicates the current or last converted analog input channel. This bitfield is updated when a conversion is started.

Field	Bits	Type	Description
SYNRUN	25	rh	**Synchronous Conversion Running** Indicates that a synchronized (= parallel) conversion is currently running. 0_B Normal conversion or no conversion running 1_B A synchronized conversion is running (cannot be cancelled by higher priority requests!)
0	[27:26]	r	**Reserved, write 0, read as 0**
CAL	28	rh	**Start-Up Calibration Active Indication** Indicates the start-up calibration phase of the corresponding analog converter. 0_B Completed or not yet started 1_B Start-up calibration phase is active (set one clock cycle after setting bit SUCAL) *Note: Start conversions only after the start-up calibration phase is complete.*[3]
CALS	29	rh	**Start-Up Calibration Started** Indicates that the start-up calibration has begun. 0_B Requested but not yet started 1_B Start-up calibration has begun *Note: Bit CALS is cleared when setting bit SUCAL and is set together with bit CAL.*
BUSY	30	rh	**Converter Busy Flag** 0_B Not busy 1_B Converter is busy with a conversion
SAMPLE	31	rh	**Sample Phase Flag** 0_B Converting or idle 1_B Input signal is currently sampled

1) The default setting of 4 arbitration slots is sufficient for correct arbitration of request sources 0 … 2. To include request source 3 select 8 arbitration slots. The duration of an arbitration round can be increased if required to synchronize requests.

2) If request source 3 is available/active and/or synchronized conversions are configured.

3) The completion of the start-up calibration is indicated by CAL = 0 AND CALS = 1.
CAL = CALS = 0 indicates that the start-up calibration was requested but has not yet begun.
CAL = CALS = 1 indicates an ongoing calibration phase.

The Arbitration Priority Register defines the request source priority and the conversion start mode for each request source.

Note: Only change priority and conversion start mode settings of a request source while this request source is disabled, and a currently running conversion requested by this source is finished.

Pending conversion requests from the associated request source are disregarded. 1_B The corresponding arbitration slot is enabled. Pending conversion requests from the associated request source are arbitrated.
0	[31:28]	r	**Reserved, write 0, read as 0**

27.6.2 Conversion Start Mode

When the arbiter has selected the request to be converted next, the handling of this channel depends on the current activity of the converter:

- Converter is currently idle: the conversion of the arbitration winner is started immediately.
- Current conversion has same or higher priority: the current conversion is completed, the conversion of the arbitration winner is started after that.
- Current conversion has lower priority: the action is user-configurable:
  - **Wait-for-start mode**: the current conversion is completed, the conversion of the arbitration winner is started after that. This mode provides maximum throughput, but can produce a jitter for the higher priority conversion.
    Example in **Figure 27-12**:
    Conversion A is requested (t1) and started (t2). Conversion B is then requested (t3), but started only after completion of conversion A (t4).
  - **Cancel-inject-repeat mode**: the current conversion is aborted, the conversion of the arbitration winner is started after the abortion (3 f_{ADC} cycles).
    The aborted conversion request is restored in the corresponding request source and takes part again in the next arbitration round. This mode provides minimum jitter for the higher priority conversions, but reduces the overall throughput.
    Example in **Figure 27-12**:
    Conversion A is requested (t6) and started (t7). Conversion B is then requested (t8) and started (t9), while conversion A is aborted but requested again. When conversion B is complete (t10), conversion A is restarted.
    Exception: If both requests target the same result register with wait-for-read mode active (see **Section 27.9.3**), the current conversion cannot be aborted.

Note: A cancelled conversion can be repeated automatically in each case, or it can be discarded if it was cancelled. This is selected for each source by bit RPTDIS in the corresponding source's mode register.

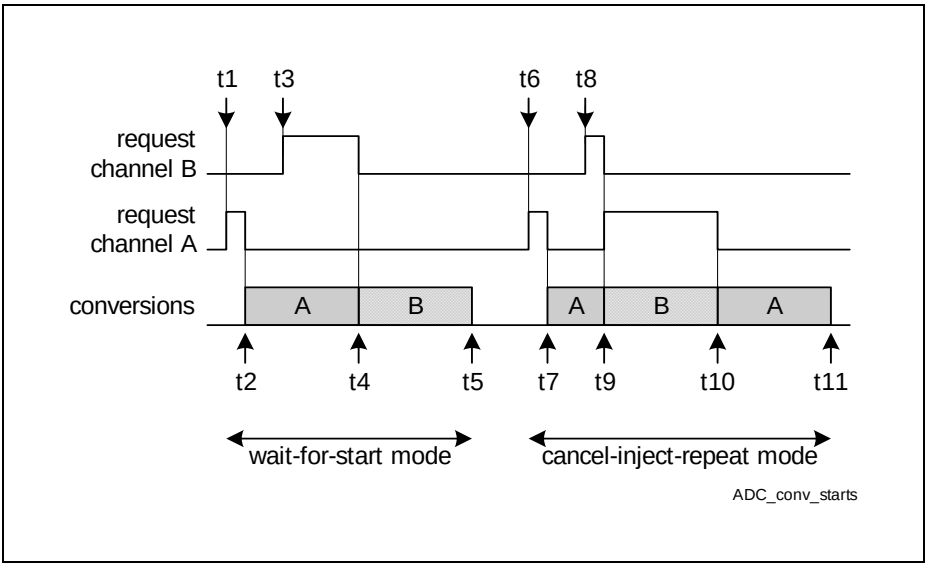

Figure 27-12 Conversion Start Modes

The conversion start mode can be individually programmed for each request source by bits in register **GxARBPR (x = 0 - 3)** and is applied to all channels requested by the source. In this example, channel A is issued by a request source with a lower priority than the request source requesting the conversion of channel B.

27.7 Analog Input Channel Configuration

For each analog input channel a number of parameters can be configured that control the conversion of this channel. The channel control registers define the following parameters:

- **Channel Parameters**: The sample time for this channel and the data width of the result are defined via input classes. Each channel can select one of two classes of its own group or one of two global classes.
- **Reference selection**: an alternate reference voltage can be selected for most channels (exceptions are marked in **Section 27.14.3**)
- **Result target**: The conversion result values are stored either in a group-specific result register or in the global result register. The group-specific result registers are selected in several ways:
  - channel-specific, selected by bitfield RESREG in register **G0CHCTRy (y = 0 - 11)** etc., with bitfield SRCRESREG = 0000_B
  - source-specific, selected by bitfield SRCRESREG in register **GxQCTRL0 (x = 0 - 3)**, **GxASCTRL (x = 0 - 3)** or **BRSCTRL** with bitfield SRCRESREG ≠ 0000_B
- **Result position**: The result values can be stored left-aligned or right-aligned. The exact position depends also on the configured result width and on the data accumulation mode.
  See also **Figure 27-19 “Result Storage Options” on Page 27-121**.
- **Compare with Standard Conversions (Limit Checking)**: Channel events can be generated whenever a new result value becomes available. Channel event generation can be restricted to values that lie inside or outside a user-configurable band.
  In Fast Compare Mode, channel events can be generated depending on the transitions of the (1-bit) result.
- **Broken Wire Detection**: This safety feature can detect a missing connection to an analog signal source (sensor).
- **Synchronization of Conversions**: Synchronized conversions are executed at the same time on several converters.

The **Alias Feature** redirects conversion requests for channels CH0 and/or CH1 to other channels.

27.7.1 Channel Parameters

Each analog input channel is configured by its associated channel control register.

*Note: For the safety feature “Broken Wire Detection”, refer to **Section 27.11.1**.*

The following features can be defined for each channel:

- The conversion class defines the result width and the sample time
- Generation of channel events and the result value band, if used
- Target of the result defining the target register and the position within the register

1) While BNDSELX ≠ 0000_B, bitfields BNDSELU and BNDSELL are concatenated and select the corresponding result register as lower boundary.

2) The boundary band is defined as the area where the result is less than or equal to the selected upper boundary and greater than or equal to the selected lower boundary, see **Section 27.7.4**.

3) The result is bit FCR in the selected result register.

4) Some channels cannot select an alternate reference.

Input Class Registers

The group-specific input class registers define the sample time and data conversion mode for each channel of the respective group that selects them via bitfield ICLSEL in its channel control register GxCHCTRx.

The global input class registers define the sample time and data conversion mode for each channel of any group that selects them via bitfield ICLSEL in its channel control register GxCHCTRx.

27.7.2 Alias Feature

The Alias Feature redirects conversion requests for channels CH0 and/or CH1 to other channel numbers. This feature can be used to trigger conversions of the same input channel by independent events and to store the conversion results in different result registers.

- The same signal can be measured twice without the need to read out the conversion result to avoid data loss. This allows triggering both conversions quickly one after the other and being independent from CPU/DMA service request latency.
- The sensor signal is connected to only one analog input (instead of two analog inputs). This saves input pins in low-cost applications and only the leakage of one input has to be considered in the error calculation.
- Even if the analog input CH0 is used as alternative reference (see **Figure 27-13**), the internal trigger and data handling features for channel CH0 can be used.
- The channel settings for both conversions can be different (boundary values, service requests, etc.).

In typical low-cost AC-drive applications, only one common current sensor is used to determine the phase currents. Depending on the applied PWM pattern, the measured value has different meanings and the sample points have to be precisely located in the PWM period. **Figure 27-13** shows an example where the sensor signal is connected to one input channel (CHx) but two conversions are triggered for two different channels (CHx and CH0). With the alias feature, a conversion request for CH0 leads to a conversion of the analog input CHx instead of CH0, but taking into account the settings for CH0. Although the same analog input (CHx) has been measured, the conversion results can be stored and read out from the result registers RESx (conversion triggered for CHx) and RESy (conversion triggered for CH0). Additionally, different interrupts or limit boundaries can be selected, enabled or disabled.

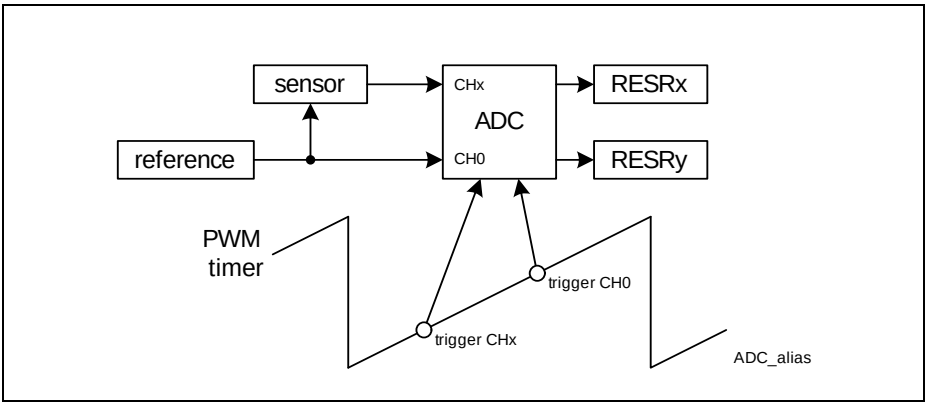

Figure 27-13 Alias Feature

Note: Use the alias feature to select the additional channels (CH12, CH13) for internal test signals. These channels cannot be selected directly.

The alias register can replace the channel numbers of channels CH0 and CH1 with another channel number. The reset value disables this redirection.

GxALIAS (x = 0 - 3)

0	[7:5]	r	**Reserved, write 0, read as 0**
ALIAS1	[12:8]	rw	**Alias Value for CH1 Conversion Requests** Indicates the channel that is converted instead of channel CH1. The conversion is done with the settings defined for channel CH1.
0	[31:13]	r	**Reserved, write 0, read as 0**

27.7.3 Conversion Modes

A conversion can be executed in several ways. The conversion mode is selected according to the requested resolution of the digital result and according to the acceptable conversion time (**Section 27.8**).
Use bitfield CMS/CME in register **GxICLASS0 (x = 0 - 3)** etc. to select a mode.

Standard Conversions

A standard conversion returns a result value with a predefined resolution. 8-bit, 10-bit, and 12-bit resolution can be selected.

These result values can be accumulated, filtered, or used for digital limit checking and determination of extrema.

Note: The calibrated converters can operate with and without post-calibration.

Fast Compare Mode

In Fast Compare Mode, the selected input voltage is directly compared with a digital value that is stored in the corresponding result register. This compare operation returns a binary result indicating if the compared input voltage is above or below the given reference value. This result is generated quickly and thus supports monitoring of boundary values.

Fast Compare Mode uses a 10-bit compare value stored left-aligned at bit position 11. Separate positive and negative delta values define an arbitrary hysteresis band.

Selecting Compare Values

Values for digital or analog compare operations can be selected from several sources. The separate GxBOUND registers provide software-defined compare values. Compare values can also be taken from a result register where it can be provided by another channel building a reference.

In Fast Compare Mode, the result registers provide the compare value while the bitfields of local GxBOUND registers define positive and negative delta values.

The local boundary register GxBOUND defines group-specific boundary values or delta limits for Fast Compare Mode.
The global boundary register GLOBBOUND defines general compare values for all channels.

Depending on the conversion width, the respective left 12/10/8 bits of a bitfield are used. For 10/8-bit results, the lower 2/4 bits must be zero!

GxBOUND (x = 0 - 3)
Boundary Select Register, Group x

Field	Bits	Type	Description
BOUNDARY0	[11:0]	rw	**Boundary Value 0 for Limit Checking** Standard Mode: This value is compared against the left-aligned conversion result. Fast Compare Mode: This value is added to the reference value (upper delta).
0	[15:12]	r	**Reserved, write 0, read as 0**
BOUNDARY1	[27:16]	rw	**Boundary Value 1 for Limit Checking** Standard Mode: This value is compared against the left-aligned conversion result. Fast Compare Mode: This value is subtracted from the reference value (lower delta).
0	[31:28]	r	**Reserved, write 0, read as 0**

27.7.4 Compare with Standard Conversions (Limit Checking)

The limit checking mechanism can automatically compare each digital conversion result to an upper and a lower boundary value. A channel event can then be generated when the result of a conversion/comparison is inside or outside a user-defined band (see bitfield CHEVMODE and **Figure 27-14**).

This feature supports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain predefined conditions.

Note: Channel events can also be generated for each result value (ignoring the band) or they can be suppressed completely.

The boundary values to which results are compared can be selected from several sources (see register GxCHCTRy).

While bitfield BNDSELX = 0000_B, bitfields BNDSELU and BNDSELL select the valid upper/lower boundary value either from the group-specific boundary register **GxBOUND (x = 0 - 3)** or from the global boundary register **GLOBBOUND**. The group boundary register can be selected for each channel of the respective group, the global boundary register can be selected by each available channel.

Otherwise, the compare values are taken from result registers, where bitfield BNDSELX selects the upper boundary value (GxRES1 … GxRES15), the concatenated bitfields BNDSELU||BNDSELL select the lower boundary value (GxRES0 … GxRES15).

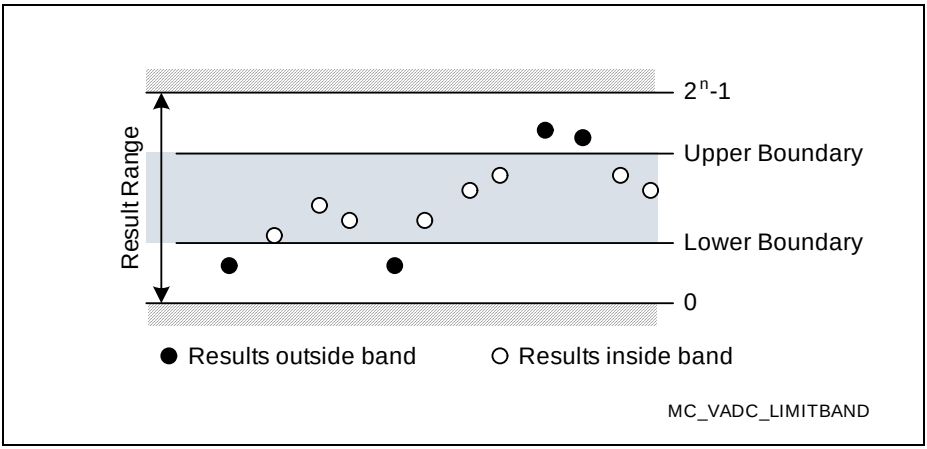

Figure 27-14 Result Monitoring through Limit Checking

A result value is considered inside the defined band when both of the following conditions are true:

- the value is less than or equal to the selected upper boundary
- the value is greater than or equal to the selected lower boundary

The result range can also be divided into two areas:
To select the lower part as valid band, set the lower boundary to the minimum value (000_H) and set the upper boundary to the highest intended value.
To select the upper part as valid band, set the upper boundary to the maximum value (FFF_H) and set the lower boundary to the lowest intended value.

Finding Extrema (Peak Detection)

The limit checking mechanism uses standard conversions and, therefore, always can provide the actual conversion result that was used for comparison. Combining this with a special FIFO mode, that only updates the corresponding FIFO stage if the result was above (or below) the current value of the stage, provides the usual conversion results and at the same time stores the highest (or lowest) result of a conversion sequence. For this operation the FIFO stage below the standard result must be selected as the compare value. Mode selection is done via bitfield FEN in register GxRCRy.

Before starting a peak detection sequence, write a reasonable start value to the result bitfield in the peak result register (e.g. 0000_H to find the maximum and $FFFF_H$ to find the minimum).

27.7.5 Utilizing Fast Compare Mode

In Fast Compare Mode, the input signal is directly compared to a value in bitfield RESULT in the associated result register. This comparison just provides a binary result (above/below), which is available in bit FCR in the same result register. If the exact result value is not required, this saves conversion time. A channel event can then be generated when the input signal becomes higher (or lower) than the compare value (see bitfield CHEVMODE and **Figure 27-15**).

The compare value in Fast Compare Mode is taken from the result register. Bitfields BOUNDARY1 and BOUNDARY0 in register **GxBOUND (x = 0 - 3)** define delta limits in this case. These deltas are added to (or subtracted from) the original compare value and allow defining an arbitrary hysteresis band.

The actual used compare value depends on the Fast Compare Result FCR (see registers **G0RESy (y = 0 - 15)**, etc.):

GxRESy.FCR = 0: reference value + upper delta
(GxRESy.RESULT + GxBOUND.BOUNDARY0)
GxRESy.FCR = 1: reference value - lower delta
(GxRESy.RESULT - GxBOUND.BOUNDARY1)

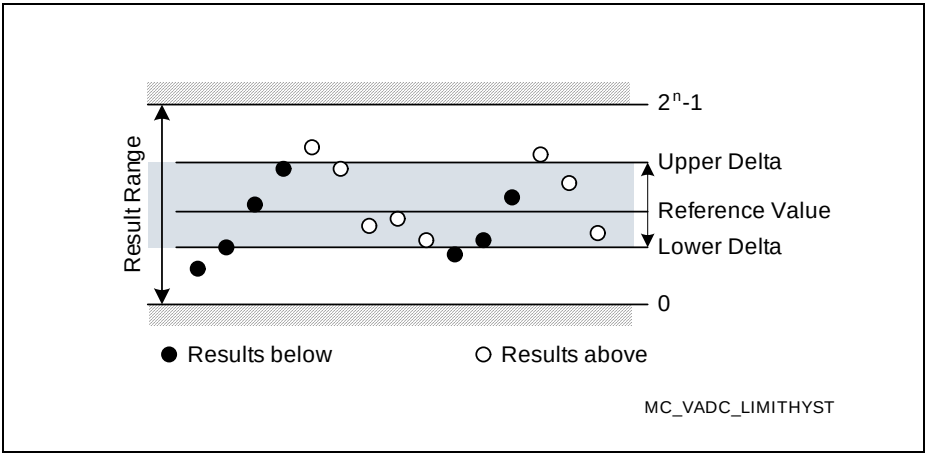

Figure 27-15 Result Monitoring through Compare with Hysteresis

27.7.6 Boundary Flag Control

Both limit checking mechanisms can be configured to automatically control the boundary flags. These boundary flags are also available as control signals for other modules. The flags can be set or cleared when the defined level is exceeded and the polarity of the output signal can be selected. A gate signal can be selected to enable the boundary flag operation while the gate is active.

Each boundary flag is available at group-specific output lines. Node pointers additionally route them to one of four boundary signals or one of the associated common service request lines, see register **GxBFLNP (x = 0 - 3)**.

For standard conversions, a boundary flag will be set/cleared when the conversion result is above the defined band, and will be cleared/set when the conversion result is below the defined band.

The band between the two boundary values defines a hysteresis for setting/clearing the boundary flags.

Using this feature on three channels that monitor linear hall elements can produce signals to feed the three hall position inputs of a unit that generates the corresponding PWM control signals.

In Fast Compare Mode, a boundary flag reflects the result of the comparisons, i.e. it will be set/cleared when the compared signal level is above the compare value, and will be cleared/set when the signal level is below the compare value. The delta values define a hysteresis band around the compare value.

Note: Clear register GxBOUND (i.e. the deltas) if a hysteresis is not wanted.

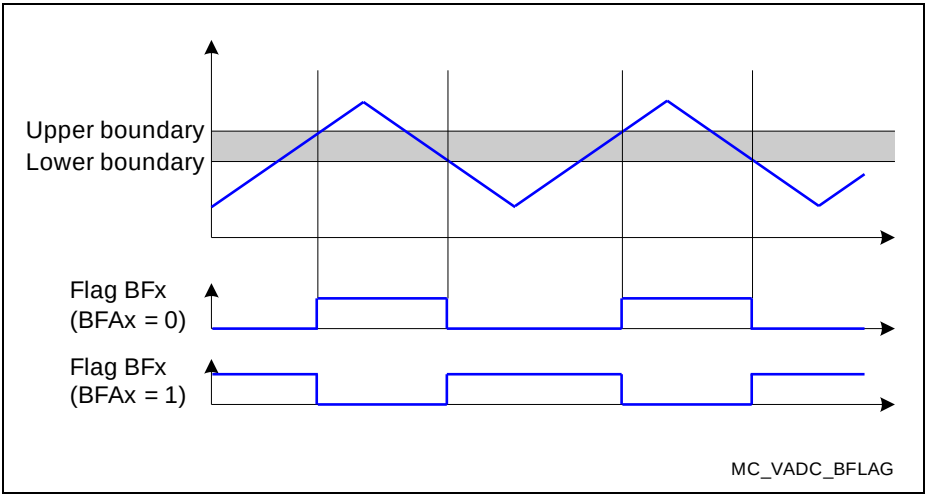

Figure 27-16 Boundary Flag Switching

Boundary flags can be switched by each compare operation, or the influence of compare operations can be restricted to the active phases of the corresponding request source gate signal (see **GxBFLC (x = 0 - 3)**).

Note: If a boundary flag is used together with Fast Compare Mode, it is recommended not to direct results from other channels to the corresponding result register.

The output signal derived from a boundary flag can be controlled by other modules. A select input and a data input are available to temporarily replace the boundary flag signal before sending it to the output pin (see **Figure 27-17**).

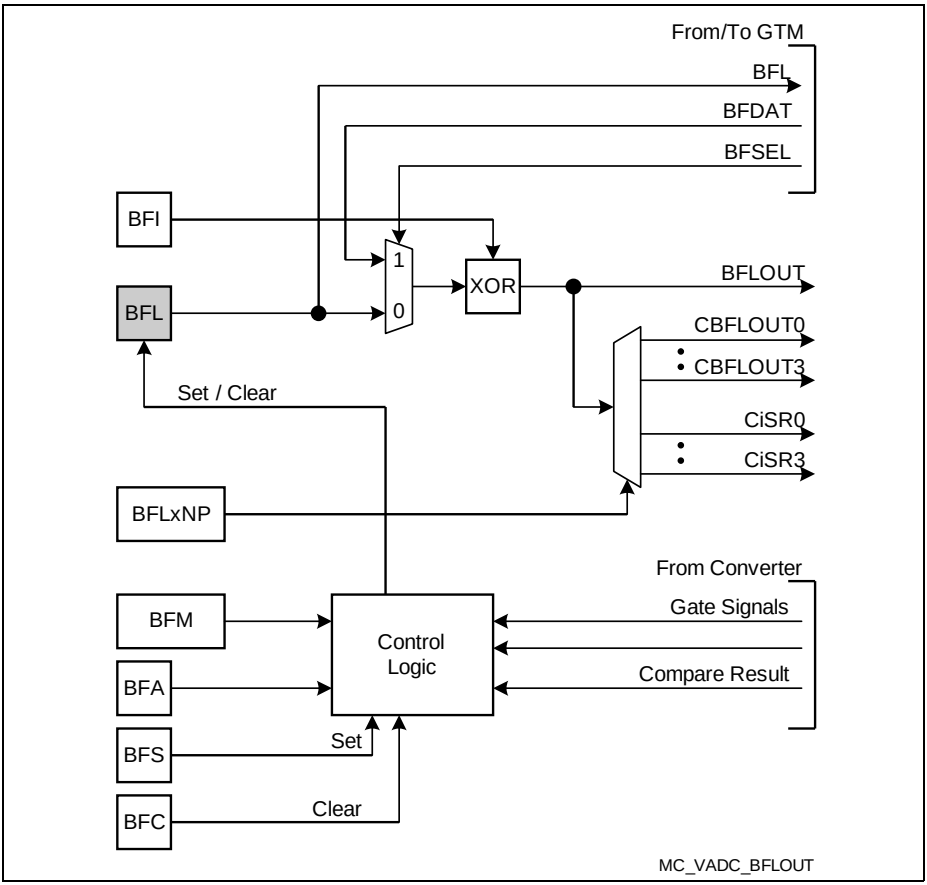

Figure 27-17 Boundary Flag Control

A boundary flag BFLy is assigned to result register GxRESy and thus to an arbitrary channel.

The Boundary Flag Register holds the boundary flags themselves together with bits to select the activation condition and the output signal polarity for each flag.

27.8 Conversion Timing

The total time required for a conversion comprises the time from the start of the sample phase[1] until the availability of the result.

The frequency at which conversions are triggered also depends on several configurable factors:

- The selected conversion time, according to the input class definitions. For conversions using an external multiplexer, also the extended sample times count.
- Delays induced by cancelled conversions that must be repeated.
- Delays due to equidistant sampling of other channels.
- The configured arbitration cycle time.
- The frequency of external trigger signals, if enabled.

The conversion timing depends on the following user-definable factors:

- The ADC conversion clock frequency, where $f_{ADCI} = f_{ADC} / (DIVA+1)$[2]
- The selected sample time, where $t_S = (2 + STC) \times t_{ADCI}$ (STC = additional sample time, see also **Table 27-4**)
- The selected operating mode (normal conversion / fast compare mode)
- The result width N (8/10/12 bits) for normal conversions
- The post-calibration time PC, if selected (PC = 2, otherwise 0)
- The selected duration of the MSB conversion (DM = 0 or 1)
- Synchronization steps done at module clock speed

The conversion time is the sum of sample time, conversion steps, and synchronization. It can be computed with the following formulas:

Standard conversions: $t_{CN} = (2 + STC + N + DM + PC) \times t_{ADCI} + 2 \times t_{ADC}$

Fast compare mode: $t_{CN} = (2 + STC + 2) \times t_{ADCI} + 2 \times t_{ADC}$

Timing Examples

System assumptions:
f_{ADC} = 100 MHz i.e. t_{ADC} = 10 ns, DIVA = 5, f_{ADCI} = 16.67 MHz i.e. t_{ADCI} = 60 ns
According to the given formula the following minimum conversion times can be achieved:

12-bit calibrated conversion:
$t_{CN12C} = (2 + 12 + 2) \times t_{ADCI} + 2 \times t_{ADC} = 16 \times 60\ ns + 2 \times 10\ ns = 980\ ns$

10-bit uncalibrated conversion:
$t_{CN10} = (2 + 10) \times t_{ADCI} + 2 \times t_{ADC} = 12 \times 60\ ns + 2 \times 10\ ns = 740\ ns$

Fast comparison:
$t_{FCM} = (2 + 2) \times t_{ADCI} + 2 \times t_{ADC} = 4 \times 60\ ns + 2 \times 10\ ns = 260\ ns$

1) The time from the trigger event that requests the corresponding conversion until the start of the sample phase depends on the arbitration and can, therefore, only be determined when the system setup is known.

2) The minimum prescaler factor for calibrated converters is 2.

27.9 Conversion Result Handling

The A/D converters can preprocess the conversions result data to a certain extent before storing them for retrieval by the CPU or a DMA channel. This supports the subsequent handling of result data by the application software.

Conversion result handling comprises the following functions:

- **Storage of Conversion Results** to user-configurable registers
- **Data Alignment** according to result width and endianess
- **Wait-for-Read Mode** to avoid loss of data
- **Result Event Generation**
- Data reduction or anti-aliasing filtering (see **Section 27.9.6**)

27.9.1 Storage of Conversion Results

The conversion result values of a certain group can be stored in one of the 16 associated group result registers or in the common global result register (can be used, for example, for the channels of the background source (see **Selecting a Result Register**).

This structure provides different locations for the conversion results of different sets of channels. Depending on the application needs (data reduction, auto-scan, alias feature, etc.), the user can distribute the conversion results to minimize CPU load and/or optimize the performance of DMA transfers.

Each result register has an individual data valid flag (VF) associated with it. This flag indicates when “new” valid data has been stored in the corresponding result register and can be read out.

For standard conversions, result values are available in bitfield RESULT. Conversions in Fast Compare Mode use bitfield RESULT for the reference value, so the result of the operation is stored in bit FCR.

Result registers can be read via two different views. These views use different addresses but access the same register data:

- When a result register is read via the **application view**, the corresponding valid flag is automatically cleared when the result is read. This provides an easy handshake between result generation and retrieval. This also supports wait-for-read mode.
- When a result register is read via the **debug view**, the corresponding valid flag remains unchanged when the result is read. This supports debugging by delivering the result value without disturbing the handshake with the application.

The application can retrieve conversion results through several result registers:

- Group result register:
  Returns the result value and the channel number
- Global result register:
  Returns the result value and the channel number and the group number

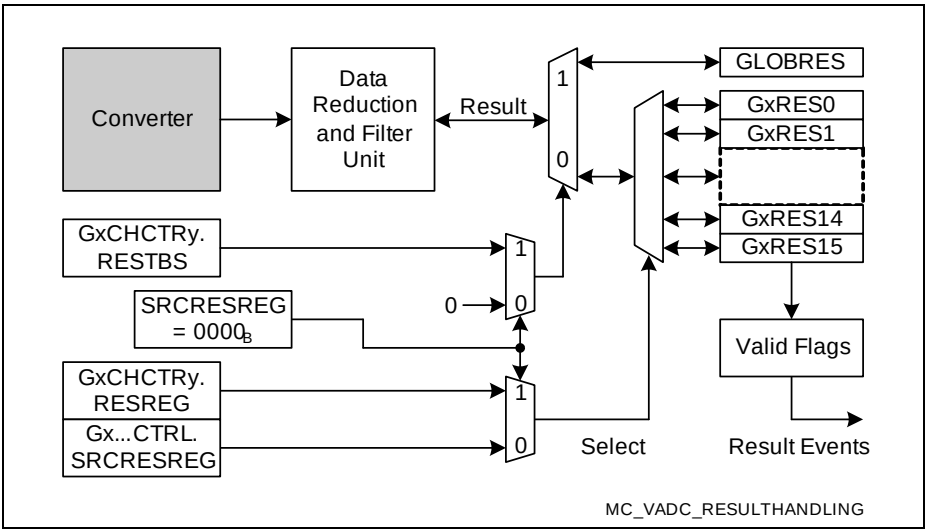

Figure 27-18 Conversion Result Storage

Selecting a Result Register

Conversion results are stored in result registers that can be assigned by the user according to the requirements of the application. The following bitfields direct the results to a register:

- SRCRESREG in register **GxQCTRL0 (x = 0 - 3)**, **GxASCTRL (x = 0 - 3)** or **BRSCTRL**
  Selects the group-specific result register GxRES1 … GxRES15
  when source-specific result registers are used
- RESTBS in register GxCHCTRy
  Selects the global result register for results requested by the background source
- RESREG in register GxCHCTRy
  Selects the group-specific result register GxRES0 … GxRES15
  when channel-specific result registers are used (see below).

Using source-specific result registers allows separating results from the same channel that are requested by different request sources. Usually these request sources are used by different tasks and are triggered at different times.

The group result control registers select the behavior of the result registers of a given group.

27.9.2 Data Alignment

The position of a conversion result value within the selected result register depends on 3 configurations (summary in **Figure 27-19**):

- The selected result width (12/10/8 bits, selected by the conversion mode)
- The selected result position (Left/Right-aligned
- The selected data accumulation mode (data reduction)

These options provide the conversion results in a way that minimizes data handling for the application software.

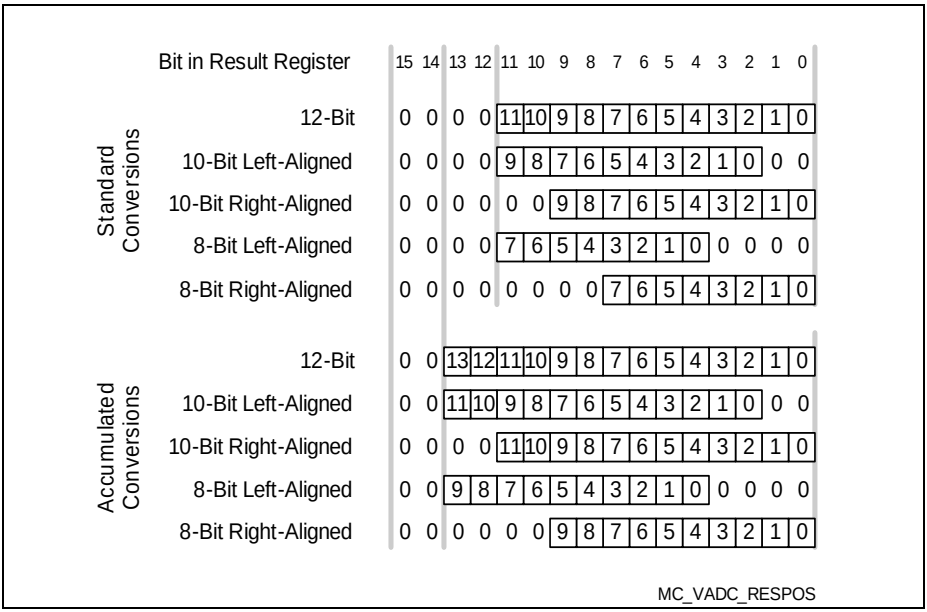

Figure 27-19 Result Storage Options

Bitfield RESULT can be written by software to provide the reference value for Fast Compare Mode. In this mode, bits 11-2 are evaluated, the other bits are ignored.

27.9.3 Wait-for-Read Mode

The wait-for-read mode prevents data loss due to overwriting a result register with a new conversion result before the CPU (or DMA) has read the previous data. For example, auto-scan conversion sequences or other sequences with “relaxed” timing requirements may use a common result register. However, the results come from different input channels, so an overwrite would destroy the result from the previous conversion[1)].

Wait-for-read mode automatically suspends the start of a conversion for this channel from this source until the current result has been read. So a conversion or a conversion sequence can be requested by a hardware or software trigger, while each conversion is only started after the result of the previous one has been read. This automatically aligns the conversion sequence with the CPU/DMA capability to read the formerly converted result (latency).

If wait-for-read mode is enabled for a result register (bit GxRCRy.WFR = 1), a request source does not generate a conversion request while the targeted result register contains valid data (indicated by the valid flag VF = 1) or if a currently running conversion targets the same result register.

If two request sources target the same result register with wait-for-read mode selected, a higher priority source cannot interrupt a lower priority conversion request started before the higher priority source has requested its conversion. Cancel-inject-repeat mode does not work in this case. In particular, this must be regarded if one of the involved sources is the background source (which usually has lowest priority). If the higher priority request targets a different result register, the lower priority conversion can be cancelled and repeated afterwards.

*Note: Wait-for-read mode is ignored for synchronized conversions of synchronization slaves (see **Section 27.10**).*

1) Repeated conversions of a single channel that use a separate result register will not destroy other results, but rather update their own previous result value. This way, always the actual signal data is available in the result register.

27.9.4 Result FIFO Buffer

Result registers can either be used as direct target for conversion results or they can be concatenated with other result registers of the same ADC group to form a result FIFO buffer (first-in-first-out buffer mechanism). A result FIFO stores several measurement results that can be read out later with a “relaxed” CPU response timing. It is possible to set up more than one FIFO buffer structure with the available result registers.

Result FIFO structures of two or more registers are built by concatenating result registers to their following “neighbor” result register (with next higher index, see **Figure 27-20**). This is enabled by setting bitfield GxRCRy.FEN = 01_B.
Conversion results are stored to the register with the highest index of a FIFO structure. Software reads the values from the FIFO register with the lowest index.

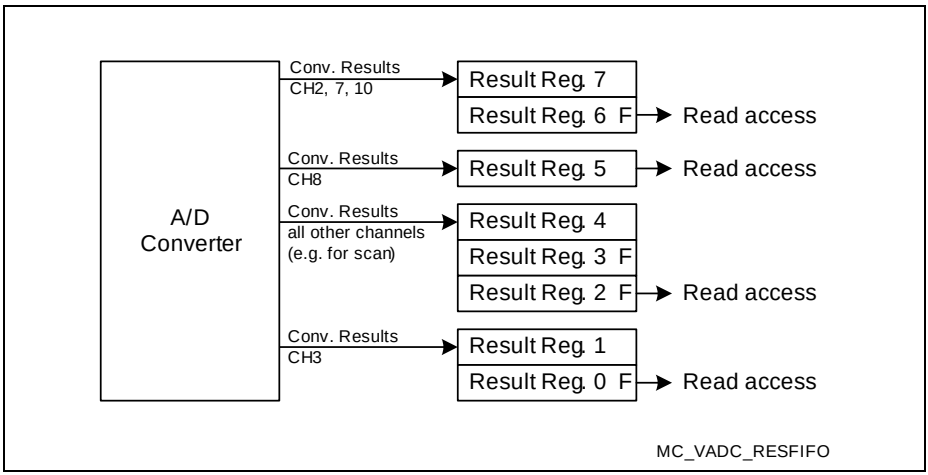

Figure 27-20 Result FIFO Buffers

In the example shown the result registers have been configured in the following way:

- 2-stage buffer consisting of result registers 7-6
- dedicated result register 5
- 3-stage buffer consisting of result registers 4-3-2
- 2-stage buffer consisting of result registers 1-0

Table 27-5 summarizes the required configuration of result registers if they are combined to build result FIFO buffers.

Table 27-5 Properties of Result FIFO Registers

Function	Input Stage	Intermed. Stage	Output Stage
Result target	YES	no	no
Application read	no	no	YES
Data reduction mode	YES	no	no
Wait-for-read mode	YES	no	no
Result event interrupt	no	no	YES
FIFO enable (FEN)	00_B	01_B	01_B
Registers in example	7, 4, 1	3	6, 2, 0

Note: If enabled, a result interrupt is generated for each data word in the FIFO.

27.9.5 Result Event Generation

A result event can be generated when a new value is stored to a result register. Result events can be restricted due to data accumulation and be generated only if the accumulation is complete.

Result events can also be suppressed completely.

27.9.6 Data Modification

The data resulting from conversions can be automatically modified before being used by an application. Several options can be selected (bitfield DMM in register **G0RCRy (y = 0 - 15)** etc.) which reduce the CPU/DMA load required to unload and/or process the conversion data.

- **Standard Data Reduction Mode (for GxRES0 … GxRES15):**
  Accumulates 2, 3, or 4 result values within each result register before generating a result interrupt. This can remove some noise from the input signal.
- **Result Filtering Mode (FIR, for GxRES7, GxRES15):**
  Applies a 3rd order Finite Impulse Response Filter (FIR) with selectable coefficients to the conversion results for the selected result register.
- **Result Filtering Mode (IIR, for GxRES7, GxRES15):**
  Applies a 1st order Infinite Impulse Response Filter (IIR) with selectable coefficients to the conversion results for the selected result register.
- **Difference Mode (for GxRES1 … GxRES15):**
  Subtracts the contents of result register GxRES0 from the conversion results for the selected result register. Bitfield DRCTR is not used in this mode.

Table 27-6 Function of Bitfield DRCTR

DRCTR	Standard Data Reduction Mode (DMM = 00_B)	DRCTR	Result Filtering Mode (DMM = 01_B)[1)]

Table 27-6 Function of Bitfield DRCTR (cont'd)

DRCTR	Standard Data Reduction Mode (DMM = 00_B)	DRCTR	Result Filtering Mode (DMM = 01_B)[1]
1110_B	Reserved	1110_B	IIR filter: a=2, b=2
1111_B	Reserved	1111_B	IIR filter: a=3, b=4

1) The filter registers are cleared while bitfield DMM ≠ 01_B.

Standard Data Reduction Mode

The data reduction mode can be used as digital filter for anti-aliasing or decimation purposes. It accumulates a maximum of 4 conversion values to generate a final result.

Each result register can be individually enabled for data reduction, controlled by bitfield DRCTR in registers **G0RCRy (y = 0 - 15)**ff and **GLOBRCR**. The data reduction counter DRC indicates the actual status of the accumulation.

Note: Conversions for other result registers can be inserted between conversions to be accumulated.

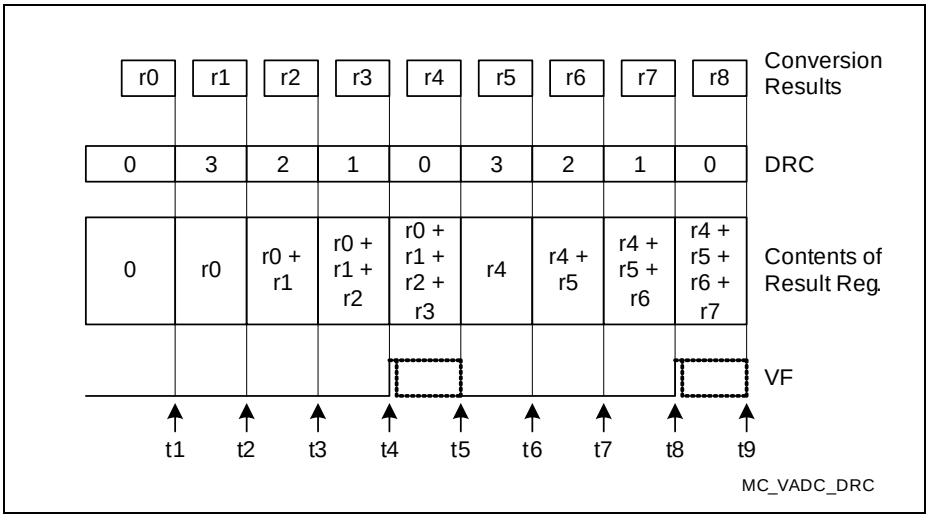

Figure 27-21 Standard Data Reduction Filter

This example shows a data reduction sequence of 4 accumulated conversion results. Eight conversion results (r0 … r7) are accumulated and produce 2 final results.

When a conversion is complete and stores data to a result register that has data reduction mode enabled, the data handling is controlled by the data reduction counter DRC:

- If DRC = 0 (t1, t5, t9 in the example), the conversion result is stored to the register. DRC is loaded with the contents of bitfield DRCTR (i.e. the accumulation begins).
- If DRC > 0 (t2, t3, t4 and t6, t7, t8 in the example), the conversion result is added to the value in the result register.
  DRC is decremented by 1.
- If DRC becomes 0, either decremented from 1 (t4 and t8 in the example) or loaded from DRCTR, the valid bit for the respective result register is set and a result register event occurs.

The final result must be read before the next data reduction sequence starts (before t5 or t9 in the example). This automatically clears the valid flag.

*Note: Software can clear the data reduction counter DRC by clearing the corresponding valid Flag (via **GxVFR (x = 0 - 3)**).*

The response time to read the final data reduction results can be increased by associating the adjacent result register to build a result FIFO (see **Figure 27-22**). In this case, the final result of a data reduction sequence is loaded to the adjacent register. The value can be read from this register until the next data reduction sequence is finished (t8 in the 2nd example).

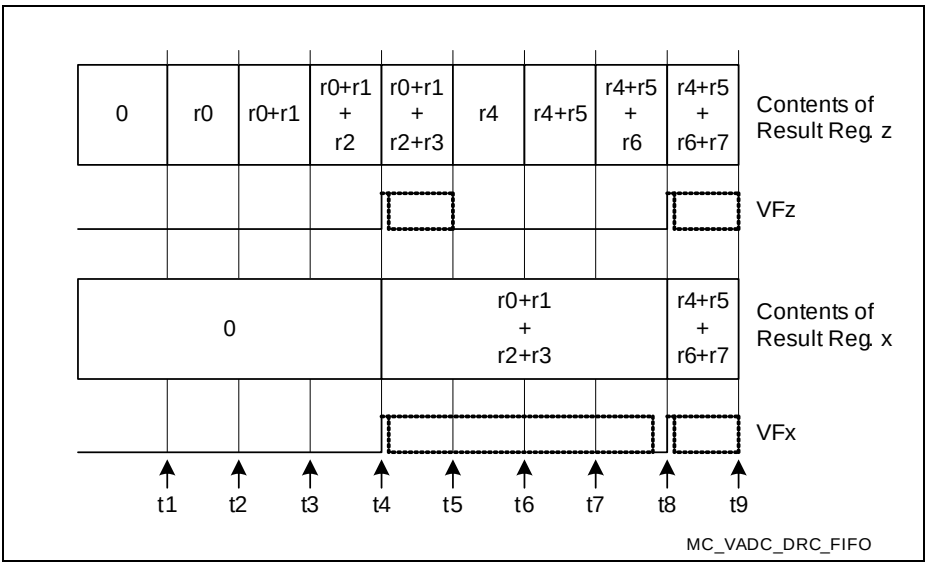

Figure 27-22 Standard Data Reduction Filter with FIFO Enabled

Finite Impulse Response Filter Mode (FIR)

The FIR filter (see **Figure 27-23**) provides 2 result buffers for intermediate results (RB1, RB2) and 3 configurable tap coefficients (a, b, c).

The conversion result and the intermediate result buffer values are added weighted with their respective coefficients to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in **Table 27-6**) in registers **G0RCRy (y = 0 - 15)**ff and **GLOBRCR**. These coefficients lead to a gain of 3 or 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

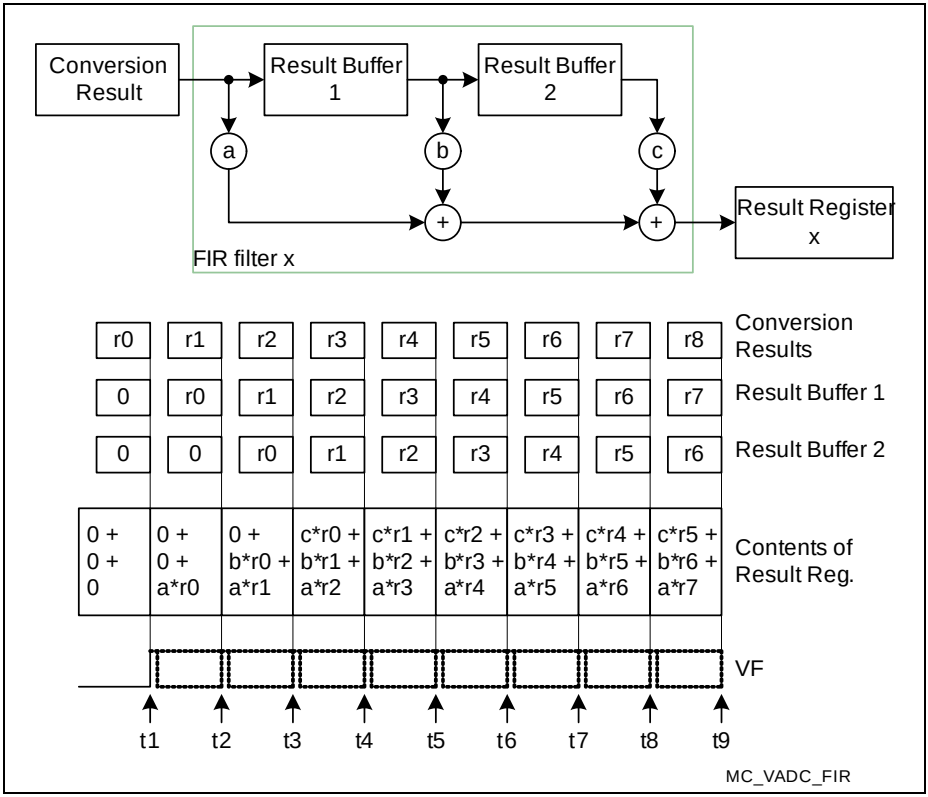

Figure 27-23 FIR Filter Structure

Note: The filter registers are cleared while bitfield DMM ≠ 01_B.

Infinite Impulse Response Filter Mode (IIR)

The IIR filter (see **Figure 27-24**) provides a result buffer (RB) and 2 configurable coefficients (a, b). It represents a first order low-pass filter.

The conversion result, weighted with the respective coefficient, and a fraction of the previous result are added to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in **Table 27-6**) in registers **G0RCRy (y = 0 - 15)**ff and **GLOBRCR**. These coefficients lead to a gain of 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

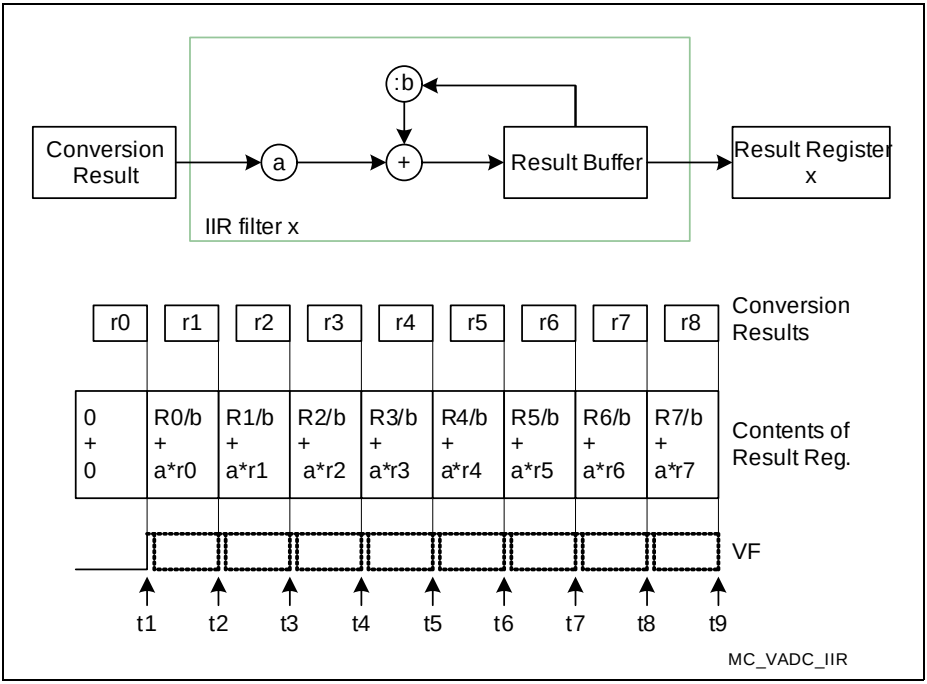

Figure 27-24 IIR Filter Structure

Note: The filter registers are cleared while bitfield DMM ≠ 01_B.

Difference Mode

Subtracting the contents of result register 0 from the actual result puts the results of the respective channel in relation to another signal. No software action is required.

The reference channel must store its result(s) into result register 0. The reference value can be determined once and then be used for a series of conversions, or it can be converted before each related conversion.

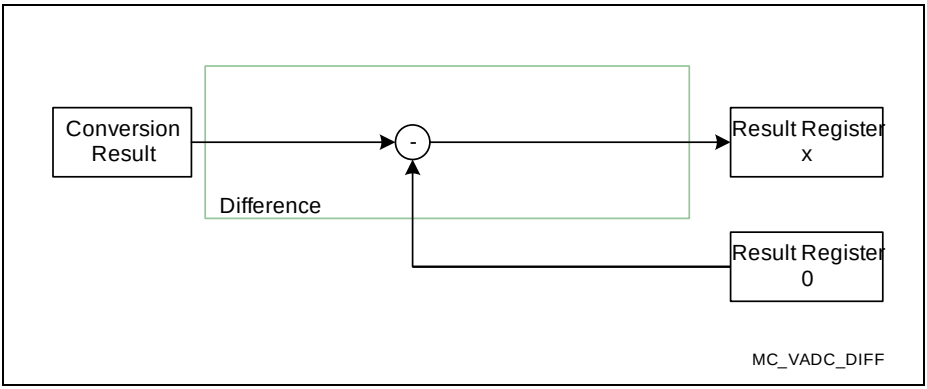

Figure 27-25 Result Difference

27.10 Synchronization of Conversions

The conversions of an ADC kernel can be scheduled either self-timed according to the kernel's configuration or triggered by external (outside the ADC) signals:
Synchronized conversions support parallel conversion of channels within a synchronization group[1]. This optimizes e.g. the control of electrical drives.
Equidistant sampling supports conversions in a fixed raster with minimum jitter. This optimizes e.g. filter algorithms or audio applications.

27.10.1 Synchronized Conversions for Parallel Sampling

Several independent ADC kernels[1] implemented in the TC21x/TC22x/TC23x can be synchronized for simultaneous measurements of analog input channels. While no parallel conversion is requested, the kernels can work independently.

The synchronization mechanism for parallel conversions ensures that the sample phases of the related channels start simultaneously. Synchronized kernels convert the same channel that is requested by the master. Different values for the resolution and the sample phase length of each kernel for a parallel conversion are supported.

A parallel conversion can be requested individually for each input channel (one or more). In the example shown in **Figure 27-26**, input channels CH3 of the ADC kernels 0 and 1 are converted synchronously, whereas other input channels do not lead to parallel conversions.

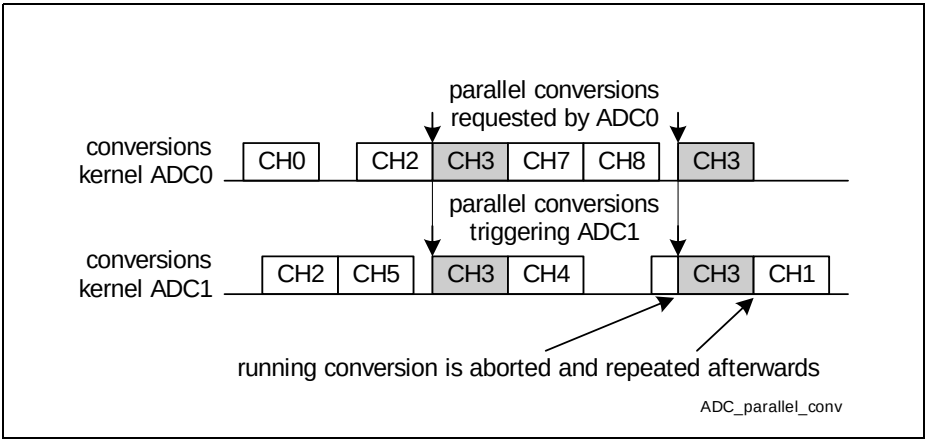

Figure 27-26 Parallel Conversions

1) For a summary, please refer to **"Synchronization Groups in the TC21x/TC22x/TC23x" on Page 27-168**.

One kernel operates as synchronization master, the other kernel(s) operate(s) as synchronization slave. Each kernel can play either role. The arbiters of all involved kernels must run synchronously. This is achieved by switching off all involved kernels before the initialization and switching on the master kernel at the end of the initialization sequence.

Master and slave kernels form a “conversion group” to control parallel sampling:

- The arbiters must run permanently (bits **GxARBCFG (x = 0 - 3)**.ARBM = 0). Initialize the slave before the master to have the arbiters run synchronously. Set the master’s GxARBCFG.ANONC at the end of the initialization.
- **The synchronization master** controls the slave(s) by providing the control information **GxARBCFG (x = 0 - 3)**.ANONS (see **Figure 27-27**) and the requested channel number.
  - Bitfield **GxSYNCTR (x = 0 - 3)**.STSEL = 00_B selects the master’s ANON information as the source of the ANON information for all kernels of the synchronization group.[1)]
  - The ready signals indicate when a slave kernel is ready to start the sample phase of a parallel conversion. Bit **GxSYNCTR (x = 0 - 3)**.EVALRy = 1 enables the control by the ready signal (in the example kernel 1 is the slave, so EVALR1 = 1).
  - The master requests a synchronized conversion of a certain channel (SYNC = 1 in the corresponding channel control register GxCHCTRy), which is also requested in the connected slave ADC kernel(s).
  - Wait-for-read mode is supported for the master.
- **The synchronization slave** reacts to incoming synchronized conversion requests from the master. While no synchronized conversions are requested, the slave kernel can execute “local” conversions.
  - Bitfield **GxSYNCTR (x = 0 - 3)**.STSEL = 01_B/10_B/11_B selects the master’s ANON information as the source of the ANON information for all kernels of the synchronization group[1)] (in the example kernel 0 is the master, so STSEL = 01_B).
  - The ready signals indicate when the master kernel and the other slave kernels are ready to start the sample phase of a parallel conversion. Bit **GxSYNCTR (x = 0 - 3)**.EVALRy = 1 enables the control by the ready signal (in the example kernel 0 is the master, so EVALR1 = 1).
  - The slave timing must be configured according to the master timing (ARBRND in register **GxARBCFG (x = 0 - 3)**) to enable parallel conversions.
  - A parallel conversion request is always handled with highest priority and cancel-inject-repeat mode.
  - Wait-for-read mode is ignored in the slave. Previous results may be overwritten, in particular, if the same result register is used by other conversions.

1) STSEL = 00_B selects the own ANON information. The other control inputs (STSEL = 01_B/10_B/11_B) are connected to the other kernels of a synchronization group in ascending order (see also **Table 27-9 “Synchronization Groups in the TC21x/TC22x/TC23x” on Page 27-168**).

- Once started, a parallel conversion cannot be aborted.

*Note: Synchronized conversions request the same channel number, defined by the master. Using the alias feature (see **Section 27.7.2**), analog signals from different input channels can be converted. This is advantageous if e.g. CH0 is used as alternate reference.*

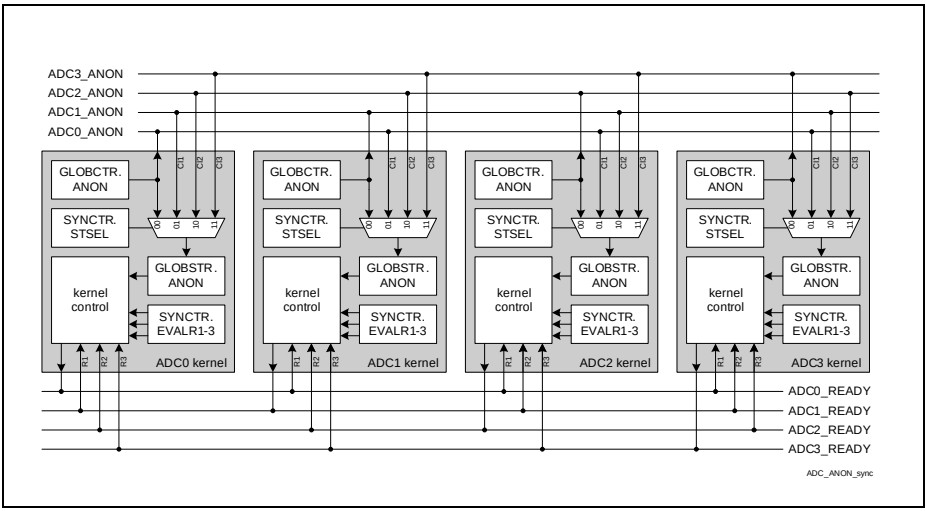

Figure 27-27 Synchronization via ANON and Ready Signals

The Synchronization Control Register controls the synchronization of kernels for parallel conversions.

Note: Program register GxSYNCTR only while bitfield GxARBCFG.ANONS = 00_B in all ADC kernels of the conversion group. Set the master's bitfield ANONC to 11_B afterwards.

27.10.2 Equidistant Sampling

To optimize the input data e.g. for filter or audio applications, conversions can be executed in a fixed timing raster. Conversions for equidistant sampling are triggered by an external signal (e.g. a timer). To generate the trigger signal synchronous to the arbiter, the ADC provides an output signal (ARBCNT) that is activated once per arbitration round and serves as timing base for the trigger timer. In this case, the arbiter must run permanently (**GxARBCFG (x = 0 - 3)**.ARBM = 0). If the timer has an independent time base, the arbiter can be stopped while no requests are pending. The preface time (see **Figure 27-28**) must be longer than one arbitration round and the highest possible conversion time.

Select timer mode (TMEN = 1 in register **GxQCTRL0 (x = 0 - 3)** or **GxASCTRL (x = 0 - 3)**) for the intended source of equidistant conversions. In timer mode, a request of this source is triggered and arbitrated, but only started when the trigger signal is removed (see **Figure 27-28**) and the converter is idle.

To ensure that the converter is idle and the start of conversion can be controlled by the trigger signal, the equidistant conversion requests must receive highest priority. The preface time between request trigger and conversion start must be long enough for a currently active conversion to finish.

The frequency of signal REQTRx defines the sampling rate and its high time defines the preface time interval where the corresponding request source takes part in the arbitration.

Depending on the used request source, equidistant sampling is also supported for a sequence of channels. It is also possible to do equidistant sampling for more than one request source in parallel if the preface times and the equidistant conversions do not overlap.

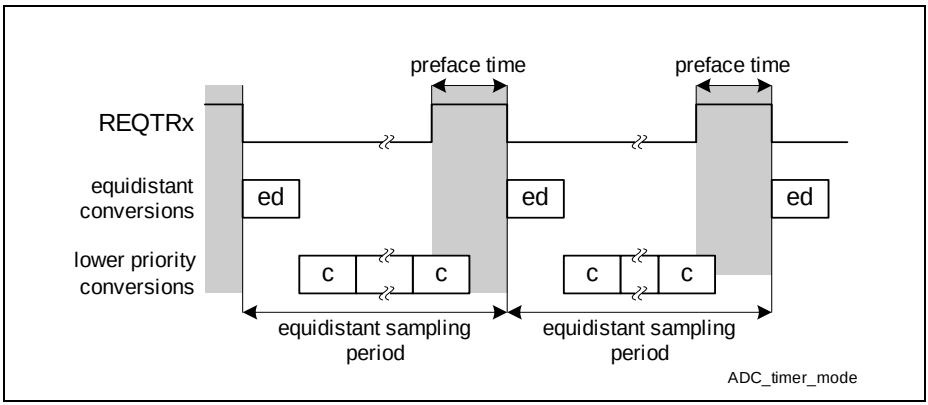

Figure 27-28 Timer Mode for Equidistant Sampling

27.11 Safety Features

Several test features can be enabled to verify the validity of the analog input signals of an application. These test features aim at different sections of the signal flow:

- **Broken Wire Detection** validates the connection from the sensor to the input pin
- **Signal Path Test Modes** validate the operation of the internal analog input multiplexer and the Analog/Digital converter itself
- **Automatic Execution of Test Sequences** supports the safety software by generating predefined sets of data to validate the signal path

27.11.1 Broken Wire Detection

To test the proper connection of an external analog sensor to its input pin, the converter's capacitor can be precharged to a selectable value before the regular sample phase. If the connection to the sensor is interrupted the subsequent conversion value will rather represent the precharged value than the expected sensor result. By using a precharge voltage outside the expected result range (broken wire detection preferably uses V_{AGND} and/or V_{AREF}) a valid measurement (sensor connected) can be distinguished from a failure (sensor detached).

While broken wire detection is disabled, the converter's capacitor is precharged to $V_{AREF}/2$.

Note: The duration of the complete conversion is increased by the preparation phase (same as the sample phase) if the broken wire detection is enabled. This influences the timing of conversion sequences.

Broken wire detection can be enabled for each channel separately by bitfield BWDEN in the corresponding channel control register (GxCHCTRy). Bitfield BWDCH selects the level for the preparation phase.

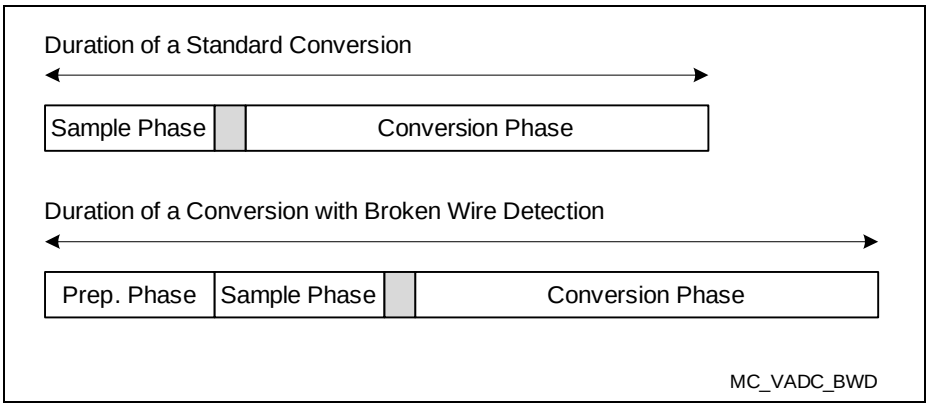

Figure 27-29 Broken Wire Detection

27.11.2 Signal Path Test Modes

Additional test structures can be activated to test the signal path from the sensor to the input pin and the internal signal path from the input pin through the multiplexer to the converter. These test structures apply additional loads to the signal path (see summary in **Figure 27-30**).

Multiplexer Diagnostics

To test the proper operation of the internal analog input multiplexer, additional pull-up and/or pull-down devices can be connected to channels CH1 and CH2. In combination with a known external input signal this test function shows if the multiplexer connects any pin to the converter input and if this is the correct pin.

Pull-Down Diagnostics

One single input channel provides a further strong pull-down (R_{PDD}) that can be activated to verify the external connection to a sensor.

Converter Diagnostics

To test the proper operation of the converter itself, several signals can be connected to the converter input. The test signals can be connected to the converter input either instead of the standard input signal or in parallel to the standard input signal.

The test signal can be selected from four different signals as shown in **Figure 27-30**.

Attention: If the Multiplexer Diagnostics are used on channels that are overlaid on IO ports, enable these functions by setting the corresponding control bits in registers Pxx_PCSR.

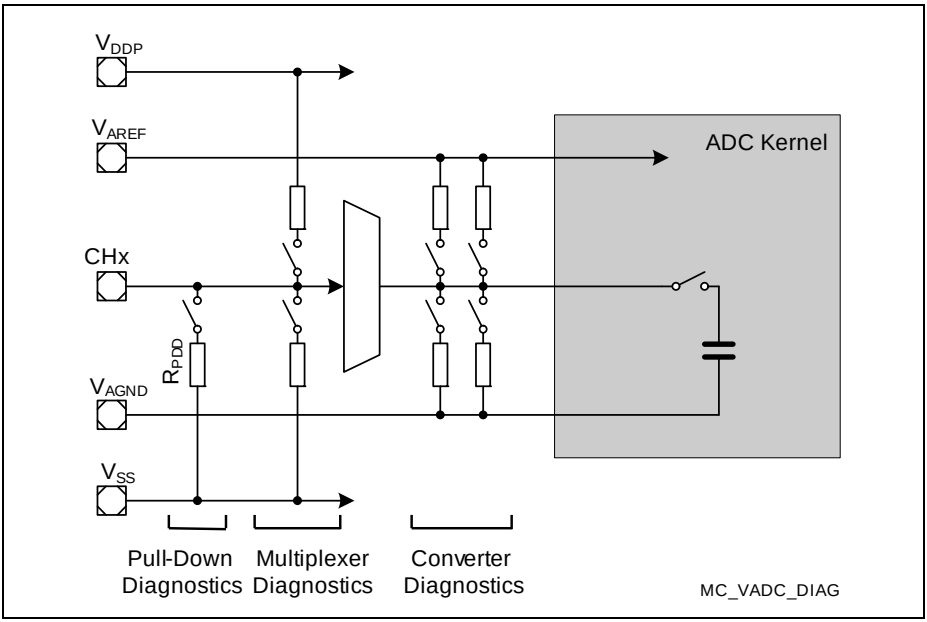

Figure 27-30 Signal Path Test

Note: When internal pull devices are activated, they may need some time to pull the input signal to the intended level, depending on the connected external circuitry. This can be accomplished by increasing the sample time for those conversions.

27.11.3 Configuration of Test Functions

The pull-up and pull-down devices for the test functions can be enabled individually under software control. Various test levels can be applied controlling the devices in an adequate way. Because these test functions interfere with the normal operation of the A/D Converters, they are controlled by a separate register set.

Not all test options are available for each channel. Selecting an unavailable function has no effect.

*Note: The pull device control bits in register **GLOBTF** can only activate the test pull devices of a group, when the corresponding control bit in register **GLOBTE** is zero.*

When automatic test sequences (see **Section 27.11.4**) are enabled, the scheduled conversions will activate the configured test pull devices. To make sure that this does not happen inadvertently, the activation of the test functions must be particularly enabled.

The release is done by setting the corresponding bit in the Global Test Enable register (GLOBTE). This prevents spurious control signals from spoiling a configured test sequence. GLOBTE can be write-protected via bit APTF in register ACCPROT1 (ACCPROT1 itself is safe-endinit protected).

*Note: The pull device control bits in register **GLOBTF** can only activate the test pull devices of a group, when the corresponding control bit in register **GLOBTE** is zero.*

The Global Test Enable register enables the control of the available test pull devices for each group separately.

27.11.4 Automatic Execution of Test Sequences

Validating the correct connection of an input signal (sensor) to the converter in a system requires some action, depending on the properties of the signal to be converted. For example, sensors with a limited signal range can be validated by checking the conversion result for values outside of the defined signal range.

In other cases pull devices (up / down) can be connected to the signal input, which alter the signal level and, as a consequence, the conversion result in a known way. The alteration can be anticipated when the signal source impedance is known.

Timing Considerations

Test sequences that are executed during the initialization of a system usually are not time-critical. They increase the startup time but otherwise have no impact on the application. Safety-critical systems, however, monitor the operability of the system during the operation time. In this case, the test sequences must be interleaved with the normal application sequences. A test sequence shall be executed immediately after an application sequence, so the relaxation time until the next application sequence becomes maximal.

Test sequences can be triggered by each available request source.

In either case the overall timing must be selected so overlaps are avoided.

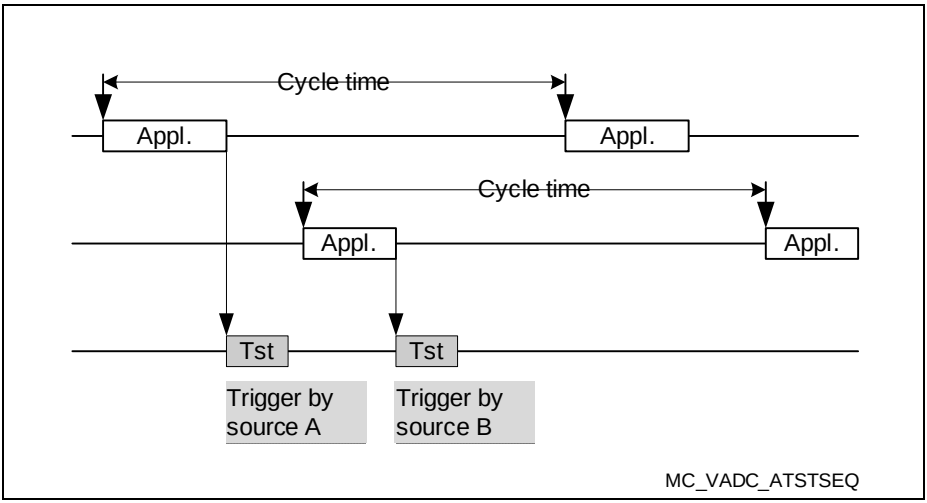

Figure 27-31 Positions of Test Sequences

Note that the test conversions can target arbitrary channels.

Using the Test Queue

The test queue request source (queue 3) is similar to the standard queued request source (queue 0) with some additional control bits to select test functions of the pins.

Leaving these control bits as zero allows using queue 3 as an additional request source for the application.

Note: When queue 3 is to be used, the arbiter must be programmed to an 8-step arbitration cycle, so the queue can take part in the arbitration process.

Queue 3 can be activated by external triggers (same as other sources) or by internal triggers from the other group request sources. These additional internal trigger signals are selected by an additional multiplexer whose output is connected to the uppermost input of the gate multiplexer. To use the internal triggers, select the uppermost trigger input (XTSEL = 1111_B) and the uppermost gate input (GTSEL = 1111_B).

A trigger counter activates queue 3 after a defined number of triggers. Test sequences can, therefore, be inserted into the application-specific conversion sequences at a certain rate without additional software intervention.

Control the internal triggers and the trigger counter via register **GxTRCTR (x = 0 - 3)**.

Queue 3 contains entries building a sequence of test conversions which enable arbitrary diagnostic functions. A trigger for a test sequence is generated automatically when the sequence of a standard request source is completed.

The trigger sequence counter starts a (test) sequence after a programmable number of triggers. The (test) sequence is started if the trigger sequence counter equals 0 when the trigger occurs. For other values of the trigger sequence counter, each trigger decrements the counter. No software intervention is required to interleave test sequences into the normal operation.

Activation/Deactivation of Pull-Devices

When specific test functions are enabled for an entry in queue 3, the correponding enabled pull-devices are controlled automatically.
They are activated when the sample phase for this conversion begins.
They are deactivated automatically after the sample phase is completed.

Depending on the properties of the connected sensor, a test sequence may require an additional settling time. This can be covered by selecting an increased sample time for these test conversions.

Detecting Irregular Test Sequences

An overflow bit (OV) is set when an internal trigger for queue 3 occurs while the queue is active. This indicates that a test sequence has been triggered when it cannot be executed as expected.

Queue 3 is assumed to be active between the occurrence of an internal trigger and the generation of a source event of queue 3. This phase is indicated by bit Q3ACT = 1.

Software can clear bits OV and Q3ACT by writing 1 to bit COV (see register **GxTRCTR (x = 0 - 3)**).

Securing the Test Functions

When test sequences are enabled, the scheduled conversions will activate the configured test pull devices. To make sure that this does not happen inadvertently, the activation of the test functions must be explicitly enabled.

The release is done by setting the corresponding bit in the Global Test Enable register (**GLOBTE**). This prevents spurious control signals from spoiling a configured test sequence. GLOBTE can be write-protected via bit APTF in register ACCPROT1 (ACCPROT1 itself is safe-endinit protected).

*Note: The pull device control bits in register **GLOBTF** can only activate the test pull devices of a group, when the corresponding control bit in register **GLOBTE** is zero.*

Evaluation of Test Results

The effect of the selected test pull devices depends on the properties of the connected signal source. These properties are system-specific and are not known to the controller. Therefore, the system software must evaluate the test results by comparing them to the expected results. This is influenced by several parameters:

- Selected pull device
- Properties of signal source, e.g. impedance
- Properties of input signal (e.g. current level of dynamic signals)
- Acceptable failure detection time

These aspects must be evaluated to assess the validity of the input signal on the channel being checked.

27.12 External Multiplexer Control

The number of analog input channels can be increased by connecting external analog multiplexers to an input MUX channel. The ADC can be configured to control these external multiplexers automatically.

For each available EMUX interface (see register **EMUXSEL**) one MUX channel or a set of MUX channels from one group can be selected for this operating mode. The ADC supports 1-out-of-8 multiplexers with several control options:

- **Sequence mode** automatically converts all configured external channels when the selected MUX channel is encountered. In the example in **Figure 27-32** the following conversions are done: --4-32-31-30-2-1-0--4-32-31-30-2-1-0--…
- **Single-step mode** converts one external channel of the configured sequence when the selected MUX channel is encountered. In the example in **Figure 27-32** the following conversions are done: --4-32-2-1-0--4-31-2-1-0--4-30-2-1-0--4-32-… (Single-step mode works best with one channel)
- **Steady mode** converts the configured external channel when the selected MUX channel is encountered. In the example in **Figure 27-32** the following conversions are done: --4-32-2-1-0--4-32-2-1-0--4-32-2-1-0--…

*Note: The example in **Figure 27-32** has an external multiplexer connected to MUX channel CH3. The start selection value EMUXSET is assumed as 2.*

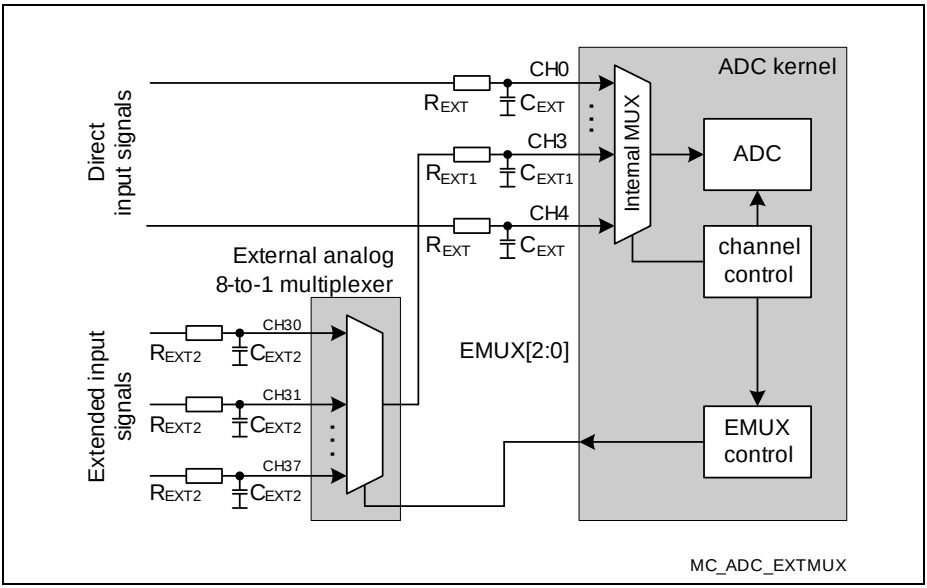

Figure 27-32 External Analog Multiplexer Example

Bitfield EMUXACT determines the control information sent to the external multiplexer. In single-step mode, EMUXACT is updated after each conversion of an enabled MUX channel. If EMUXACT = 000_B it is reloaded from bitfield EMUXSET, otherwise it is decremented by 1.

Additional external channels may have different properties due to the modified signal path. Local filters may be used at the additional inputs (R_{EXT2}-C_{EXT2} on CH3x in **Figure 27-32**). For applications where the external multiplexer is located far from the ADC analog input, it is recommended to add an RC filter directly at the analog input of the ADC (R_{EXT1}-C_{EXT1} on CH3 in **Figure 27-32**).

Note: Each RC filter limits the bandwidth of the analog input signal.

Conversions for external channels, therefore, use the alternate conversion mode setting CME. This automatically selects a different conversion mode if required.

Switching the external multiplexer usually requires an additional settling time for the input signal. Therefore, the alternate sample time setting STCE is applied each time the external channel is changed. This automatically fulfills the different sampling time requirements in this case.

Control Signals

The external channel number that controls the external multiplexer can be output in standard binary format or Gray-coded. Gray code avoids intermediate multiplexer switching when selecting a sequence of channels, because only one bit changes at a time. **Table 27-7** indicates the resulting codes.

Table 27-7 EMUX Control Signal Coding

Channel	0	1	2	3	4	5	6	7
Binary	000_B	001_B	010_B	011_B	100_B	101_B	110_B	111_B
Gray	000	001	011	010	110	111	101	100

Operation Without External Multiplexer

If no external multiplexers are used in an application, the reset values of the control registers provide the appropriate setup.

EMUXMODE = 00_B disables the automatic EMUX control.

Since the control output signals are alternate port output signals, they are only visible at the respective pins if explicitly selected.

In each group an arbitrary MUX channel or set of MUX channels can be assigned to external multiplexer control (register **GxEMUXCTR (x = 0 - 3)**). Each available port interface selects the group whose control lines are output (register **EMUXSEL**).

27.13 Service Request Generation

Each A/D Converter can activate up to 4 group-specific service request output signals and up to 4 shared service request output signals to issue an interrupt or to trigger a DMA channel. Two common service request groups are available, see **Table 27-8 "General Converter Configuration in the TC21x/TC22x/TC23x" on Page 27-167**.

Several events can be assigned to each service request output. Service requests can be generated by three types of events:

- **Request source events:** indicate that a request source completed the requested conversion sequence and the application software can initiate further actions.
  For a scan source (group or background), the event is generated when the complete defined set of channels (pending bits) has been converted.
  For a group queue source, the event is generated according to the programming, i.e. when a channel with enabled source interrupt has been converted or when an invalid entry is encountered.
- **Channel events:** indicate that a conversion is finished. Optionally, channel events can be restricted to result values within a programmable value range. This offloads the CPU/DMA from background tasks, i.e. a service request is only activated if the specified conversion result range is met or exceeded.
- **Result events:** indicate a new valid result in a result register. Usually, this triggers a read action by the CPU (or DMA). Optionally, result events can be generated only at a reduced rate if data reduction is active.
  For example, a single DMA channel can read the results for a complete auto-scan sequence, if all channels of the sequence target the same result register and the transfers are triggered by result events.

Each ADC event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding event indication flag. This ensures efficient DMA handling of ADC events (the ADC event can generate a service request without the need to clear the indication flag).

Event flag registers indicate all types of events that occur during the ADC's operation. Software can set each flag by writing a 1 to the respective position in register GxCEFLAG/GxRFLAG to trigger an event. Software can clear each flag by writing a 1 to the respective position in register GxCEFCLR/GxREFCLR. If enabled, service requests are generated for each occurrance of an event, even if the associated flag remains set.

r	r	r	r	r	r	r	rwh	r	r	r	r	r	r	r	rwh

Field	Bits	Type	Description
SEVGLB	0	rwh	**Source Event (Background)** 0_B No source event 1_B A source event has occurred
0	[7:1]	r	**Reserved, write 0, read as 0**
REVGLB	8	rwh	**Global Result Event** 0_B No result event 1_B New result was stored in register GLOBRES
0	[15:9]	r	**Reserved, write 0, read as 0**
SEVGLBCLR	16	w	**Clear Source Event (Background)** 0_B No action 1_B Clear the source event flag SEVGLB
0	[23:17]	r	**Reserved, write 0, read as 0**
REVGLBCLR	24	w	**Clear Global Result Event** 0_B No action 1_B Clear the result event flag REVGLB
0	[31:25]	r	**Reserved, write 0, read as 0**

Note: Software can set flags REVGLB and SEVGLB and trigger the corresponding event by writing 1 to the respective bit. Writing 0 has no effect.
Software can clear these flags by writing 1 to bit REVGLBCLR and SEVGLBCLR, respectively.
Setting both bits (e.g. SEVGLB and SEVGLBCLR) simultaneously clears the corresponding flag (e.g. SEVGLB).

Node Pointer Registers

Requests from each event source can be directed to a set of service request nodes via associated node pointers. Requests from several sources can be directed to the same node; in this case, they are ORed to the service request output signal.

27.14 Implementation into the TC21x/TC22x/TC23x

This section describes the actual implementation of the ADC module into the TC21x/TC22x/TC23x, i.e. the incorporation into the microcontroller system.

The following information is listed:

- **"Product-Specific Configuration" on Page 27-167**
- **"Summary of Registers and Locations" on Page 27-169**
- **"Analog Module Connections in the TC21x/TC22x/TC23x" on Page 27-174**
- **"Digital Module Connections in the TC21x/TC22x/TC23x" on Page 27-176**

27.14.1 Product-Specific Configuration

The functional description describes the features and operating modes of the A/D Converters in a general way. This section summarizes the configuration that is available in this product (TC21x/TC22x/TC23x).

The standard product device features 2 converter groups (G0, G1) which provide 14 analog input channels each. 12 channels can be selected directly, 2 additional channels (for internal test signals) can be selected via the alias feature.

The special ADAS device features 2 additional converter groups (G0, G1, G2, G3) which provide one analog input channel each. These additional channels are overlaid on existing channels of the standard device.

Note: The additional ADAS groups do not provide the test request source queue 3.

Each converter group is equipped with a separate analog converter module and a dedicated analog input multiplexer.

Table 27-8 General Converter Configuration in the TC21x/TC22x/TC23x

Converter Group	Input Channels	Channels w. Altern. Reference	12-bit Performance	Common Service Req. Group	Associated Standard Reference
G0	0 … 11[1)]	8	Calibrated	C0	V_{AREF}, V_{AGND}
G1	0 … 11[1)]	12	Calibrated	C1	V_{AREF}, V_{AGND}
G2	0	0	Calibrated	C0	V_{AREF}, V_{AGND}
G3	0	0	Calibrated	C1	V_{AREF}, V_{AGND}

1) Two additional channels for internal test signals via the alias feature.

Note: The standard device provides groups G0 … G1,
the ADAS device provides groups G0 … G3.

Synchronization Groups in the TC21x/TC22x/TC23x

The converter kernels in the TC21x/TC22x/TC23x can be connected to synchronization groups to achieve parallel conversion of several input channels.

Table 27-9 summarizes which kernels can be synchronized for parallel conversions.

Table 27-9 Synchronization Groups in the TC21x/TC22x/TC23x

ADC Kernel	Synchr. Group	Master selected by control input CIx[1]			
		CI0[2]	CI1	CI2	CI3
ADC00	A	ADC00	ADC01	ADC02	ADC03
ADC01	A	ADC01	ADC00	ADC02	ADC03
ADC02	A	ADC02	ADC00	ADC01	ADC03
ADC03	A	ADC03	ADC00	ADC01	ADC02

1) The control input is selected by bitfield STSEL in register **GxSYNCTR (x = 0 - 3)**. Select the corresponding ready inputs accordingly by bits EVALRx.

2) Control input CI0 always selects the own control signals of the corresponding ADC kernel. This selection is meant for the synchronization master or for stand-alone operation.

Note: The shaded part of the above table applies to the ADAS device only.

27.14.2 Summary of Registers and Locations

The Versatile ADC is built from a series of converter blocks that are controlled in an identical way. This makes programming versatile and scalable. The corresponding registers, therefore, have an individual offset assigned (see **Table 27-11**). The exact register location is obtained by adding the respective register offset to the base address (see **Table 27-10**) of the corresponding group.

Due to the regular group structure, several registers appear within each group. Other registers are provided for each channel. This is indicated in the register overview table by placeholders:

- X###$_H$ means: x × 0400$_H$ + 0###$_H$, for x = 0 - 3
- ###Y$_H$ means: ###0$_H$ + y × 0004$_H$, for y = 0 - N (depends on register type)

Table 27-10 Registers Address Space

Module	Base Address	End Address	Note
VADC	F002 0000$_H$	F002 3FFF$_H$

27.14.3 Analog Module Connections in the TC21x/TC22x/TC23x

The VADC module accepts a number of analog input signals. The analog input multiplexers select the input channels to be converted from the signals available in this product.

Note: If an analog input channel is connected to an I/O port pin, make sure the output driver and/or the digital input path are disabled.

The exact number of analog input channels and the available connection to port pins depend on the employed product type (see also **Table 27-8**). A summary of channels enclosing all versions of the TC21x/TC22x/TC23x can be found below.

Input channels marked “PDD” provide a pull-down device for pull-down diagnostics.

Input channels marked “MD” can activate the pullup and pulldown devices for multiplexer diagnostics.

Input channels marked “AltRef” can be selected as an alternate reference voltage for conversions on channels of the same group or for conversions on channels of the same cluster.

Input channels marked “noAltref” cannot select an alternate reference voltage, but only the corresponding standard reference voltage.

Input channels marked “(A)” can be selected via the alias feature (**Section 27.7.2**), not directly.

Table 27-12 Analog Connections in the TC21x/TC22x/TC23x

Signal	Dir.	Source/Destin.	Description
V_{AREF}	I	VAREF	positive analog reference
V_{AGND}	I	VAGND	negative analog reference

27.14.4 Digital Module Connections in the TC21x/TC22x/TC23x

The VADC module accepts a number of digital input signals and generates a number of output signals. This section summarizes the connection of these signals to other on-chip modules or to external resources via port pins.

Note: The control bitfields for triggers and gates select the corresponding multiplexer input. Values 0000_B … 1111_B select inputs with suffix -A … -P.

27.15 Use Case Example for VADC

This section provides a code example for the VADC module to give an overview about the core functionality. The code example realizes an event triggered analog to digital conversion. The result is stored as a 12-bit digital value and triggers a result service request.

The VADC contains several ADC groups (G0 … G3). Each group is connected to up to 8 analog input channels via a multiplexer. The following code example initializes one of the groups and uses one static allocated analog channel as input.

The code example realizes an analog-to-digital conversion by using the background source. The conversion can either run continuously in autoscan mode or can be triggered by an event, like in the following example. This is useful if the conversion needs to be executed at certain times. The result from the most recent conversion is acceccible in the global result register **GLOBRES**. A result service request is activated after each conversion. The initialization is done in the following order:

1. Load the global VADC module registers
2. Enable the analog/digital converter 0 (G0)
3. Select channel 0 of G0 as analog input
4. Initialize the conversion result service request
5. Start first conversion

Step Description to Initialize the VADC Module:

(Line 1) reset ENDINIT to get access to ENDINIT protected registers. (see also ENDINIT protection in chapter SCU).

(Line 2) enable control of the module, in clock control register **CLC**.

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

(Line 4) set ENDINIT to lock the protected register again.

(Line 5) set group 0 to normal operation mode. This activates the converter of group 0. (see also **Section 27.4.1** and **GxARBCFG (x = 0 - 3)**).

(Line 6) load the global configuration register GLOBCFG with the divider factor for the analog internal clock (see also **Figure 27-7**). Set DIVWC[15] to enable write access and initiate the start-up calibration by setting SUCAL[31]. The calibration is necessary to get a precise conversion.

(Line 7) This line enables the arbitration slot 2, that's the background scan source slot which the examples uses. (see also Arbitration Priority Register **GxARBPR (x = 0 - 3)**)

(Line 8) This line sets RESTBS[20], so each conversion result from group 0 input channel 0 is now stored in the global result register GLOBRES. (see also GxCHCTRy)

(Line 9) This line selects input channel 0 of group 0 as part of the background scan sequence. (see also **BRSSELx (x = 0 - 3)**).

(Line 10) By setting ENGT[0..1]=01 a conversion request can be issued for every channel which was enabled in line 10. here only channel 0. (see also **BRSMR**)

(Line 11) This line enables the group 0 service request in the service request control register SRC_VADCG0SR0 and sets the interrupt priority to VADC0INT (1...255)

(Line 12) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example in chapter IR for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority VADC0INT.

(Line 13) This command enables the result interrupt. It occurs after a result event.

(Line 14) wait until start-up calibration (start in line 6) is done.

(Line 15) setting LDEV=1 generates a load event which starts a conversion.

Note: The conversion result ISR function prototype would be: void VADC_SCAN_irq (void); here could be your ISR code;

Basic Initialization of the VADC:

```
//=========================> Load global module registers
(1)  SCU_vResetENDINIT (0);     // Access to ENDINIT-prot. reg.
(2)  VADC_CLC = 0x0000;         // Enable module clock and ctrl.
(3)  dummy = VADC_CLC;          // Read back ensures write oper.
(4)  SCU_vSetENDINIT (0);       // Lock ENDINIT-protected reg.
//=========================> Enable converter for group 0
(5)  VADC_G0ARBCFG = 0x3;       // ANONC = 11, analog converter ON
(6)  VADC_GLOBCFG = (1<<31)     /* SUCAL = 1, start-up calib. */ \
                    |(1<<15)    /* DIVWC = 1, enable write */ \
                    | 0x9;      // DIVA = 9 (clock prescaler)
(7)  VADC_G0ARBPR = (1<<26);    // AREN2 = 1, enable arb. slot 2
                                //          (= background source)
(8)  VADC_G0CHCTR0 = (1<<20);   // RESTBS = 1, global result reg.
(9)  VADC_BRSSEL0 = 0x1;        // Select CH0 of group 0 for scan
(10) VADC_BRSMR = 0x1;          // ENGT = 10B, enable conv. req.
//=========================> Init and install service request
(11) SRC_VADCCG0SR0 = (1<<10)   /* Enable SR node 0, group 0 */ \
                     |VADC0INT; // Set prio to <VADC0INT>(1..255)
(12) interruptHandlerInstall (VADC0INT, & VADC_SCAN_irq);
(13) VADC_GLOBRCR = (1<<31);    // SRGEN = 1, result service requ.
//=========================> Wait for completion of startup cal.
(14) while((VADC_G0ARBCFG.U & 0x30000000) != 0x20000000);
                                // CALS = 1, CAL = 0: calibr. done
//=========================> Start a conversion
(15) VADC_BRSMR |= (1<<9);      // LDEV = 1, generate a load event
```

Note: Before a service request can occur, the service request system must be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compilers support the attribute (or similar) to set this bit (see Architecture Manual for more details): ***__enable();***

28 Input Output Monitor (IOM)

28.1 Overview

The Input Output Monitor (IOM) module serves as a smart I/O comparison unit, observing and checking for the correct operation of system peripheral outputs that may serve and/or control externally-attached hardware, as well as the correct operation of the hardware itself, including any sensors whose signals may serve as an input to the monitoring function.

The monitoring function may be achieved in a number of configurable ways depending upon the application and the type of safety measure to be deployed. (Examples of such measures are included later-on within this chapter). Triggering via software is also permissible in this manner.

Monitor and reference signals (where needed) are taken from applicable system peripherals (i.e. Capture/Compare Units and General Purpose Timer Units) where they connect to internal padlogic (that feeds/controls I/O Ports), which may or may not be driven to the pads (configuration dependent). In this manner connectivity can be made to a signal that is to be driven externally, and to another signal that may serve as a reference, although may not be driven off-chip. A driven signal may also serve as a reference in order to compare against another that may be provided via a GPIO input, e.g. from a sensor external to the device.

Up to 16 monitoring points can be configured, with the capability to generate a system event that may be driven from one individual, several individual or multiple occurrences of a monitored condition, or a combination of several depending upon configuration.

28.2 Features

- 16 Filter & Prescaler Channels, each connected to a specific pad (Pn_IN), the output of which to serve as a monitor or reference signal.
- 16 Logic Analyzer Modules (LAMs), with each channel comprising a mux to independently select monitor and reference signal inputs, with which to undertake the compare. A local event (i.e. internal to IOM) is generated when parity or disparity occurs between the selected monitor and reference signals. Configurable via register settings.
- 1 EXOR combiner, configurable (via register) to select a range of upto 8 GTM inputs in order to generate a combined signal to serve as a reference.
- Event Combiner Module (ECM), that takes the 16 local event signals (1 from each of the LAM modules) and generates a system event signal (connecting to system Safety Management Unit) from a single, combination or multiple local event(s). Configurable via register settings.

- System Peripheral Bus (SPB) interface for configuration and status register interaction.

28.3 Interfaces

The IOM features the following interfaces:

- System Peripheral Bus (SPB) - for the configuration of constituent parts of the IOM and the interrogation of associated status registers/bitfields.
- Multiple port logic/module connectivity, serving as reference or monitor signals. See SoC Integration section within this chapter for device-specific connections to GTM, GPT12, QSPI, CCU, GPIO (for GTM, etc.).
- Safety Management Unit (SMU) - a single global event signal used inform the SMU of a generated event within the IOM.
- System Signals - FPI Clock, GTM Clock, System Reset.

Note: The functionality of the IOM is independent from system debug, and no connectivity or mode of operation exists for this purpose.

28.4 Kernel Description

In addition to the Logic Analyzer Modules, Filter & Prescaler Blocks and Event Combiner Module, the IOM also features a System Peripheral Bus (SPB) interface for configuration and status register access. Note: All the configuration registers are protected by the register access protection mechanism (global definition).

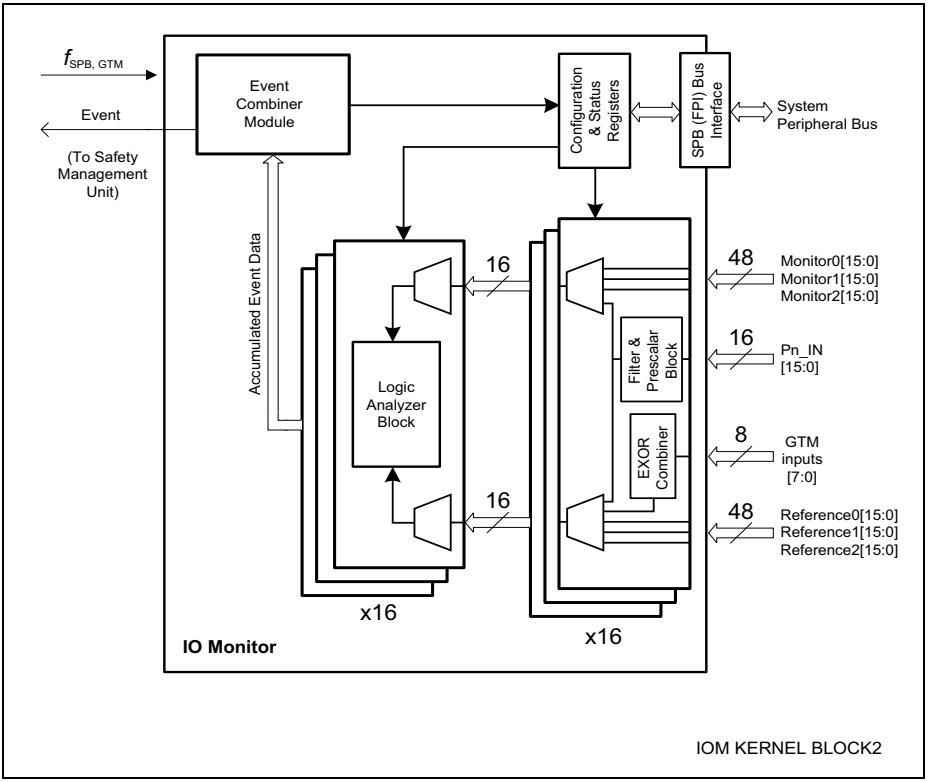

Figure 28-1 IO Monitor Block Diagram

The operational clock for the IOM is derived by combining the SPB and GTM clocks as a logical OR, the resultant frequency of which is therefore determined to be the higher of the two frequencies (assuming a synchronous relationship between the two, both being derived from the same system-level clock). This provides the capability for the IOM to sample GTM-related signals when the SPB (FPI) clock is lower than that of the GTM within the system.

28.5 Filter & Prescaler Channel Description

The IOM instances 16 Filter & Prescaler Channels(FPC's) for the purposes of preconditioning and filtering the signals received from the pads (Pn_IN inputs) that may be used as a reference or monitor.

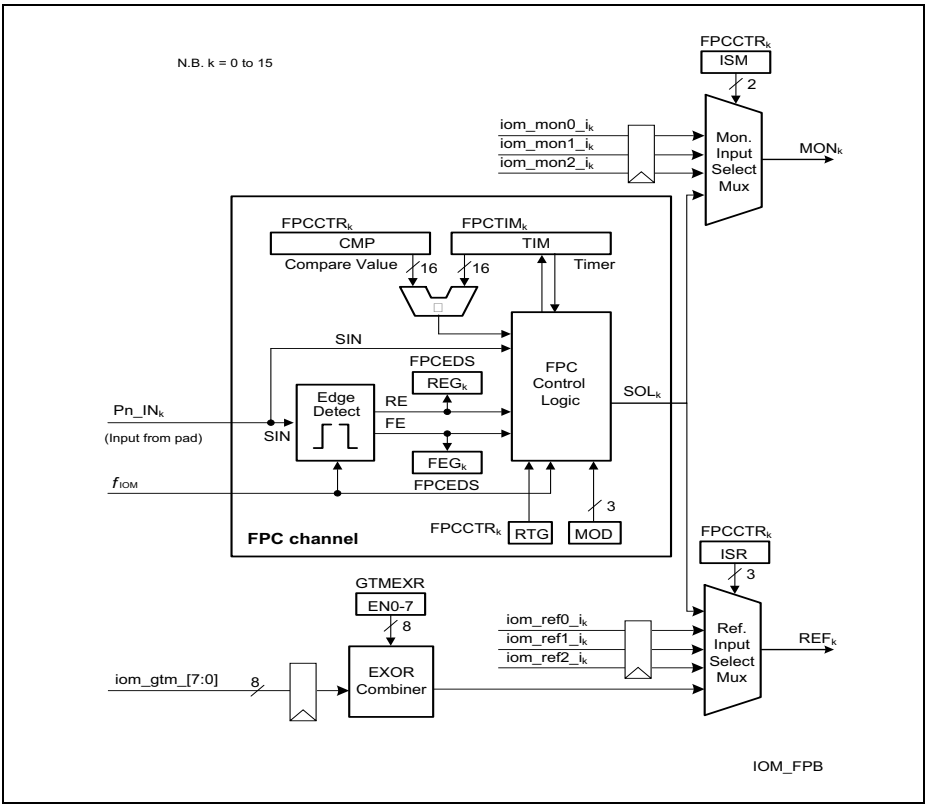

Figure 28-2 Monitor & Reference Selection logic incorporating Filter and Prescaler channel

As shown in **Figure 28-2**, each FPC channel (cell) is equipped with an signal input multiplexer, a clock multiplexer, an edge detection circuitry, a 16-bit timer, a 16-bit compare register, a 16-bit comparator, and a FPC control circuitry. The edge detection circuitry detects respective edges for the prescaler modes and detects glitches in all other modes.

FPC Registers

The following registers are assigned to the Filter and Prescaler Cells FPC_k (k = 0-15):

- FPCESR = Filter and Prescaler Cells Rising and Falling Edge Status Register.
- $FPCCTR_k$ = Filter and Prescaler Cell Control Register k
- $FPCTIM_k$ = Filter and Prescaler Cell Timer Register k

FPC Operating Modes

Each filter and prescaler cell can be individually configured to operate in one of the following operating modes:

- Delayed Debounce Filter Mode on both edges
- Immediate Debounce Filter Mode on both edges
- Rising edge: Immediate Debounce Filter Mode, falling edge: No filtering
- Rising edge: No filtering, falling edge: Immediate Debounce Filter Mode
- Rising edge: Delayed Debounce Filter Mode, falling edge: Immediate Debounce Filter Mode
- Rising edge: Immediate Debounce Filter Mode, falling edge: Delayed Debounce Filter Mode
- Prescaler Mode (triggered by edge detection circuitry on rising edge)
- Prescaler Mode (triggered by edge detection circuitry on falling edge)

The operation mode is selected by bit field $FPCCTR_k$.MOD.

FPC Input Signal notes

The maximum FPC input signal frequency must be less than or equal to the sampling rate ($f_{FPI}/2$).

FPC Output Signal notes

A level output, representative signal SOL_k, indicating the direction of the detected signal transition, that can be configured to connect to the Logic Analyzer $Module_m$.

Delayed Debounce Filter Mode

In Delayed Debounce Filter Mode, the signal input SIN is filtered from all signal transitions and glitches with a width smaller than the selected clock period length multiplied by the compare register value.

The input signal SIN is analyzed at the selected filter clock rate of f_{IOM}. If the state of the input sample differs from the current output signal value, the 16-bit timer is increased by one. When the timer register $FPCTIM_k$ is not in its idle state (0000_H) **and** the state of the input sample matches the current output signal value, the 16-bit timer is decremented by one (see **Figure 28-3**); if bit $FPCCTR_k$.RTG is set, the timer will be set to idle state again (see **Figure 28-4**). A rising or falling edge, occurring on the signal input line SIN when the timer is greater than zero but less than the compare value, sets the corresponding glitch flag FPCRES.REG (on rising edge glitch) or FPCFES.FEG (on falling edge glitch). When the timer matches the 16-bit compare value stored in $FPCCTR_k$.CMP (timer threshold), the level output signal line SOL_k is inverted, and the timer is reset to 0000_H. The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value $FPCCTR_k$.CMP is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal.

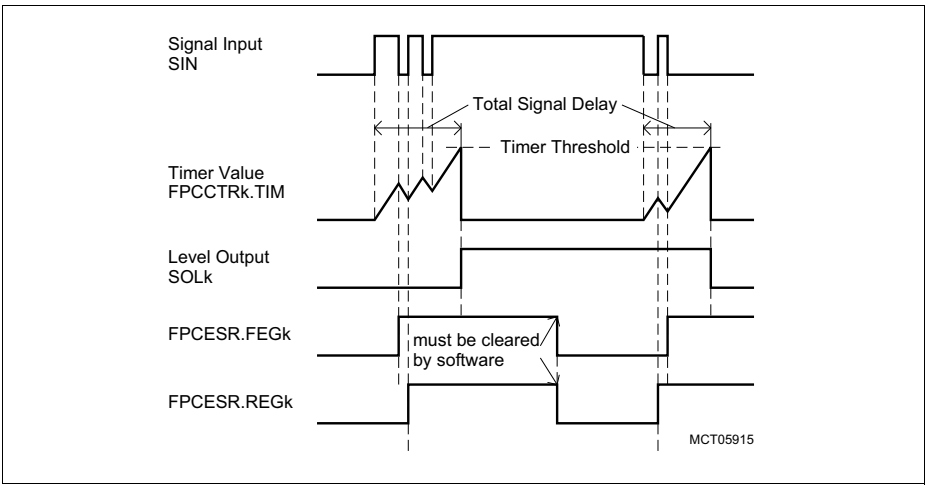

Figure 28-3 FPC Delayed Debounce Filter Algorithm with Timer Decrement

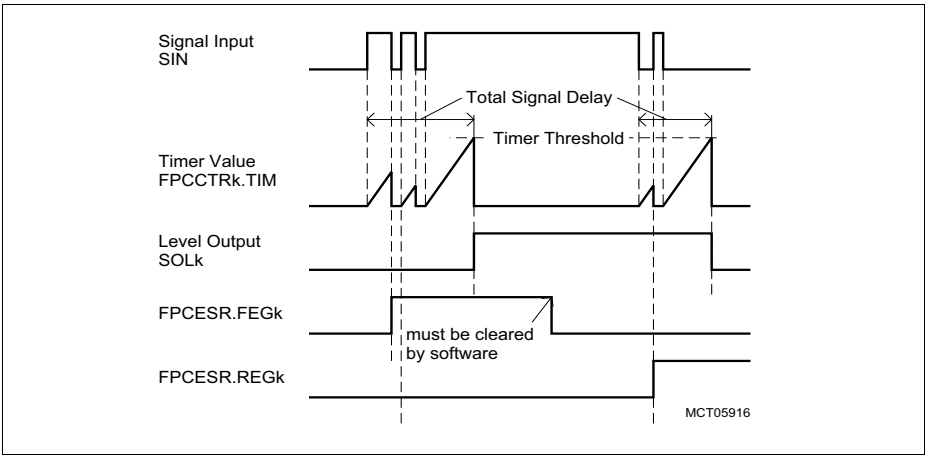

Figure 28-4 FPC Delayed Debounce Filter Algorithm with Timer Reset

The total signal delay from input to output depends on the programmed compare register value, the number of high-frequency pulses (glitches) during the filter operating time, and the timer behaviour in case of a glitch (decrement or reset).

The FPC Delayed Debounce Filter Mode is selected by:

- $FPCCTR_k.MOD = 000_B$

Immediate Debounce Filter Mode

In Immediate Debounce Filter Mode, the input signal is filtered from signal transitions and glitches arriving a programmable time after an input signal edge detection (see **Figure 28-5**).

The input signal SIN is sampled with f_{FPI} and the input signal SIN edge detection is also performed with f_{FPI}. The further analysis (e.g. filter timer increment, glitch detection) is also achieved with f_{FPI}.

As long as the timer is reset, the FPC control circuitry copies the sampled input value directly to the level output signal line SOLk. When a rising or falling edge occurs on the signal input line SIN and the 16-bit compare value FPCCTR$_k$.CMP is not zero, the timer is enabled to be increased by the selected clock and the copy mechanism is disabled. When the timer value FPCTIM$_k$.TIM matches the compare value FPCCTR$_k$.CMP, the timer is reset and the copy mechanism is enabled again. A rising or falling edge, occurring on SIN while the timer is greater than zero but less than the compare value, sets the corresponding glitch flag FPCRES.REG (on rising edge glitch) or FPCFES.FEG (on falling edge glitch). The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value FPCCTR$_k$.CMP is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal without any disable periods.

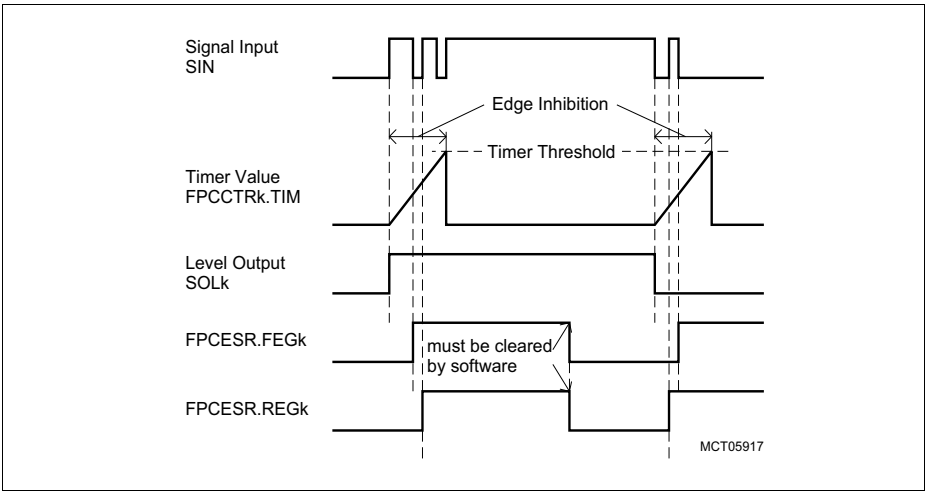

Figure 28-5 FPC Immediate Debounce Filter Algorithm on Both Edges

Note: During the last clock cycle of edge inhibition time (where timer value is equal to the compare value) an input signal glitch will be filtered but the corresponding glitch status flag in register FPCRES/FPCFES is not set.

The Immediate Debounce Filter can be enabled only for one edge, either rising or falling. In this case, the signal output follows the signal input value immediately after the timer threshold of the filtered edge is reached, without re-starting the timer (see **Figure 28-6**).

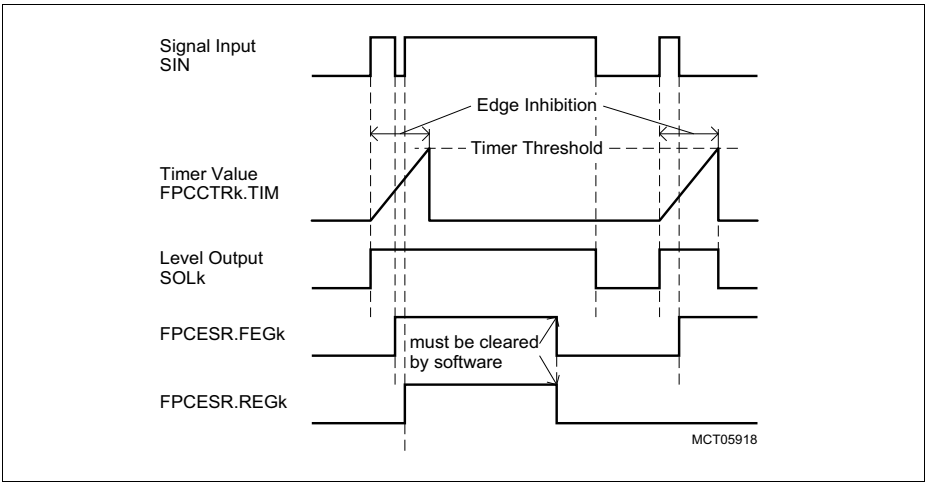

Figure 28-6 FPC Immediate Debounce Filter Algorithm on Rising Edge only

The FPC Immediate Debounce Filter Modes are selected by:

- $FPCCTR_k.MOD = 001_B$: Immediate Debounce Filter Mode on both edges
- $FPCCTR_k.MOD = 010_B$: Immediate Debounce Filter Mode on rising edge only, no filtering on falling edge.
- $FPCCTR_k.MOD = 011_B$: Immediate Debounce Filter Mode on falling edge only, no filtering on rising edge.

Mixed Filter Modes

In the Mixed Filter Modes, one edge of a signal is filtered in the Delayed Debounce Mode, and the other edge is filtered in the Immediate Debounce Mode. The Debounce Mode is switched when the timer threshold is reached. Note that both filter modes use the same timer threshold in this case (see **Figure 28-7**, demonstrating Delayed Debounce Mode with Timer Decrement on Rising Edge and Immediate Debounce of on Falling Edge).

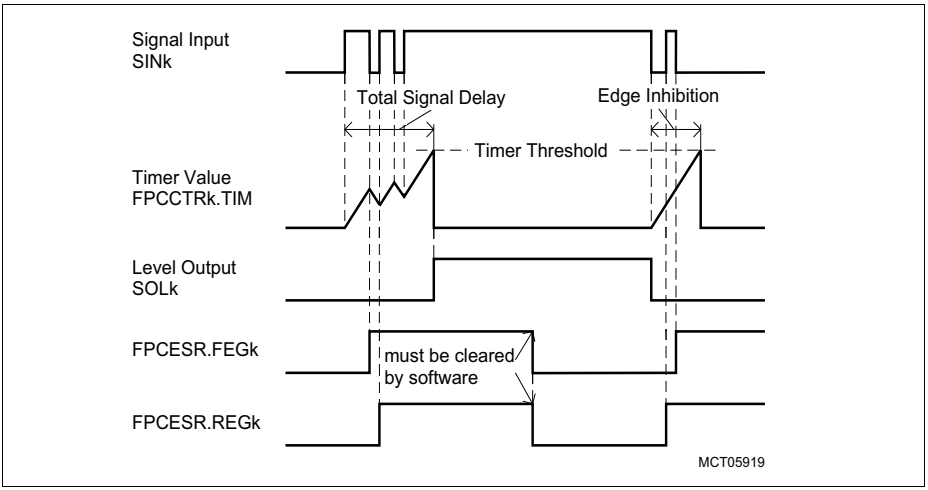

Figure 28-7 FPC Mixed Filter Algorithm

The FPC Mixed Filter Modes are selected by:

- $FPCCTR_k.MOD = 100_B$: Delayed Debounce Filter Mode on rising edge
  Immediate Debounce Filter Mode on falling edge
- $FPCCTR_k.MOD = 101_B$: Immediate Debounce Filter Mode on rising edge
  Delayed Debounce Filter Mode on falling edge

Prescaler Mode

In Prescaler Mode, the input signal is sampled and analyzed with f_{FPI}. The FPC control circuitry counts each rising (or falling) edge of the input signal. When the timer value matches the compare value:

- one IOM module clock pulse is generated at the level output signal SOL_k
- the timer $FPCTIM_k$.TIM is reset to 0000_H

Figure 28-8 shows a divide-by-6 operation using the FPC in Prescaler Mode with trigger on rising edge selected.

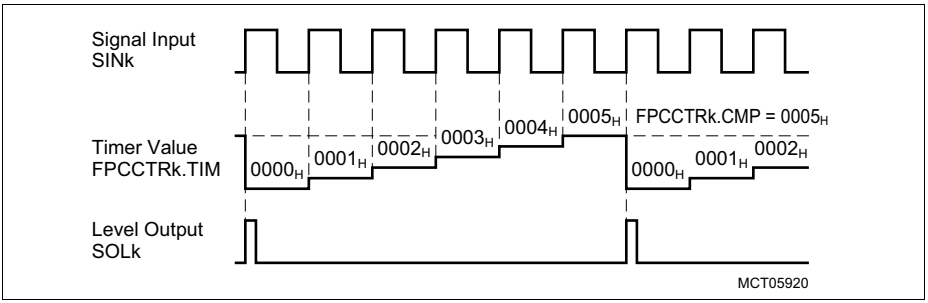

Figure 28-8 FPC Prescaler Mode

For a divide-by-n operation, the compare value $FPCCTR_k$.CMP must be set to n - 1.

The FPC Prescaler Modes are selected by:

- $FPCCTR_k$.MOD = 110_B: Prescaler Mode triggered by edge detection circuitry on rising edge
- $FPCCTR_k$.MOD = 111_B: Prescaler Mode triggered by edge detection circuitry on falling edge

28.6 EXOR Combiner Description

The EXOR Combiner can be configured to accepts upto 8 external inputs from GTMmodule outputs, used for replicate a typical *combined* signal from an automotive multi-phase motor. The output from which can then be used as a reference to monitor such a motor.

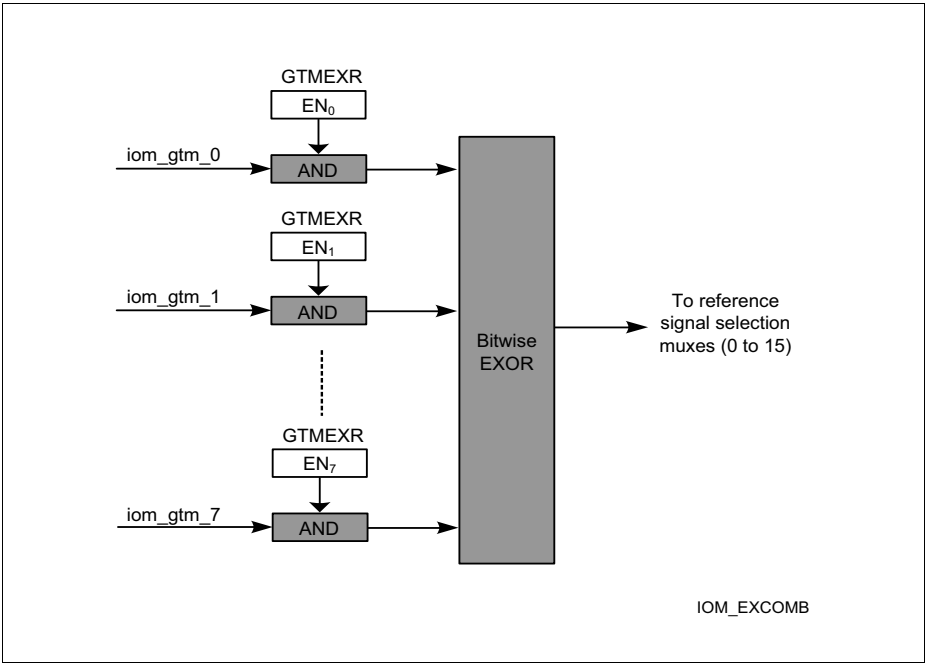

Figure 28-9 EXOR Combiner block diagram

EXOR Combiner Registers

The following registers are assigned to the block:

- GTMEXR = GTM Input EXOR Combiner Selection Configuration Register.

EXOR Combiner Input Signals

- 8 inputs from the GTM module(s).

EXOR Combiner Output Signals

- 1 output signal reflecting the combined logical EXOR function on the associated (and enabled input(s)).

28.7 Logic Analyzer Module (LAM) Description

The IOM instances 16 Logic analyzer Modules (LAM's) for the purposes of monitor and reference signal comparison. Each block accepts one monitor and one reference level signal from the 16 monitor & 16 reference signals available, from the FPC/Input selection block. The behaviour of each LAM is set by configuring the associated register settings.

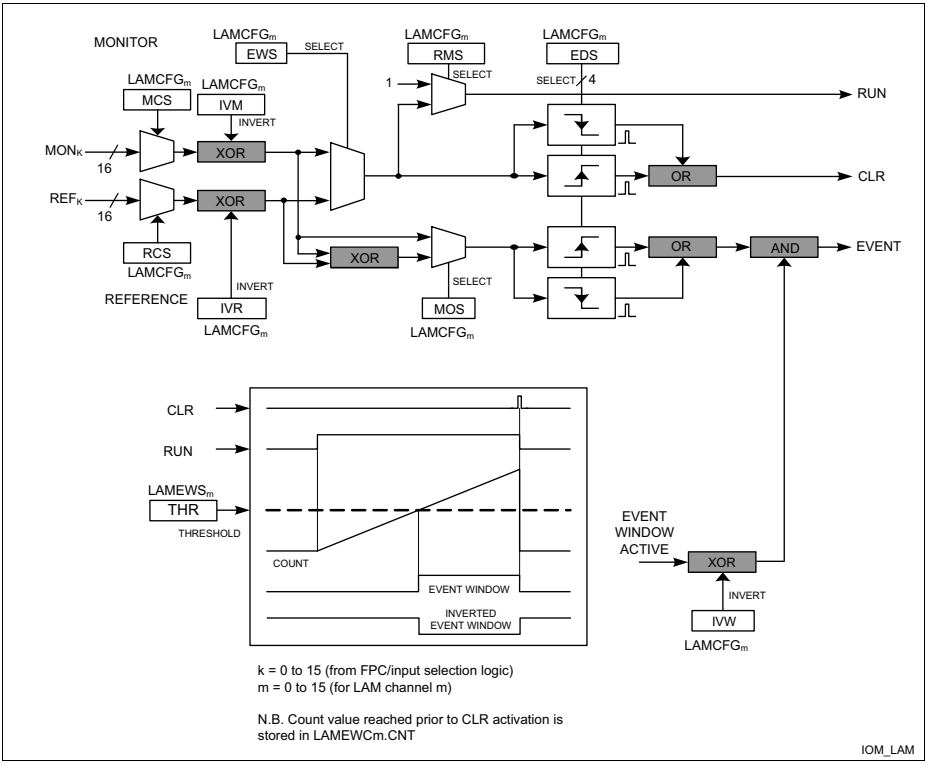

Figure 28-10 Logic Analyzer Module (LAM) block diagram

As shown in **Figure 28-9**, each Logic Analyzer Module features inputs for the Reference & Monitor points, fed from the requisite Filter & Prescaler block. Depending upon the Logic Analyzer Module configuration register (LAMCFG), and the event window settings register (LAMEWS), the block may be configured to monitor a particular type of signal behaviour, input from sensors external to the device in order to monitor, govern and/or control external application behaviour with particular regard to any given safety requirements.

LAM Registers

The following registers are assigned to the Logic Analyzer Module LAM_m (m = 0-15):

- $LAMCFG_m$ = Logic Analyzer Module Configuration Register m
- $LAMEWS_m$ = Logic Analyzer Module Event Window Settings Register m
- $LAMEWC_m$ = Logic Analyzer Module Event Window Count Status Register m

LAM Input Signals

Two inputs exist for each LAM_m:

- Reference signal input, fed from the requisite Filter & Prescaler block.
- Monitor signal input, fed from the requisite Filter & Prescaler block.

Depending upon the required function, both inputs or just the Monitor input may be utilised.

LAM Output Signals

One output is provided by each LAM:

- Event trigger output, configured to be active when a monitored signal falls outside the intended timed and/or periodic behaviour.

28.8 Event Combiner Module (ECM) Description

The IOM instances one Event Combiner Module, which takes the event outputs from each of the 16 Logic Analyzer Modules (LAM's). Some or all of these events can then be combined in a variety of configurable ways in order to generate a single system event.

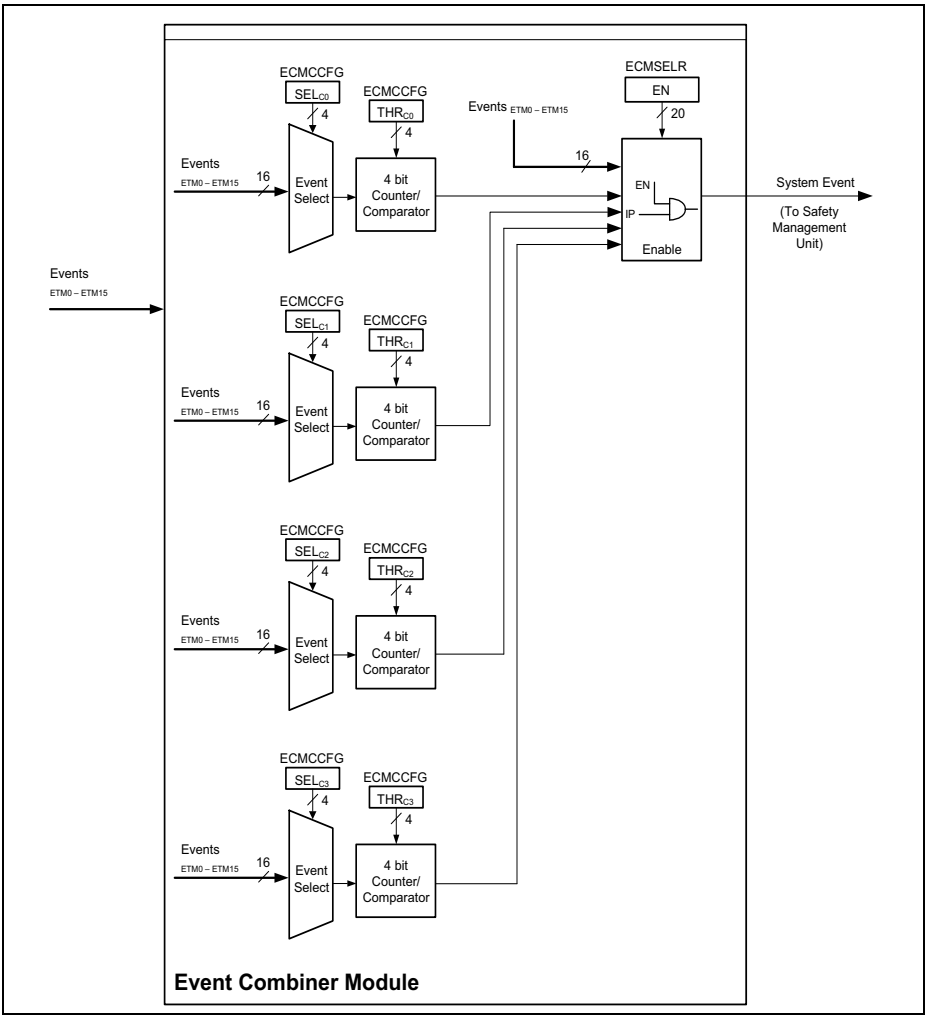

Figure 28-11 Event Combiner Module (ECM) block diagram

Four separate 4bit counters with configurable thresholds are also available to be assigned to count multiple occurring events from any of the 16 available LAM's. The output of these counter units (active once a count threshold has been met/surpassed) can also be included (via configuration) within the generation of the system event. (Note: the alarm output will be connected to the Safety Management Unit, SMU.EMM).

The ECM also includes two Event Trigger History (ETMETH0/1) registers, updated with each system event, used to record the status of the 16 LAM event outputs, thereby identifying which triggers were responsible.

In addition, the ECM incorporates a System Peripheral Bus (SPB) interface for writing configuration and reading status registers appertaining to all subblock within the IOM.

ECM Registers

The following registers are assigned to the ECM:

- ECMCCFG = ECM counter configuration register (for the four 4bit local event counters).
- ECMSELR = ECM global event selection register (for the selection of local events, or multiples thereof, required to generate the global event signal).

ECM Input Signals

- From Logic Analyzer Modules (LAM's)
  - Local event triggers from LAM blocks (0 to 15).
- System Peripheral Bus.

ECM Output Signals

One output is generated by each LAM:

- Global event trigger output, intended to be connected to the Safety Management Unit.
- System Peripheral Bus.

28.9 IOM Registers

This section describes the kernel registers of the IOM unit.

All read and write accesses to an undefined address location within the IOM address space will result in a bus error on the System Peripheral Bus (SPB).

IOM Kernel Register Overview

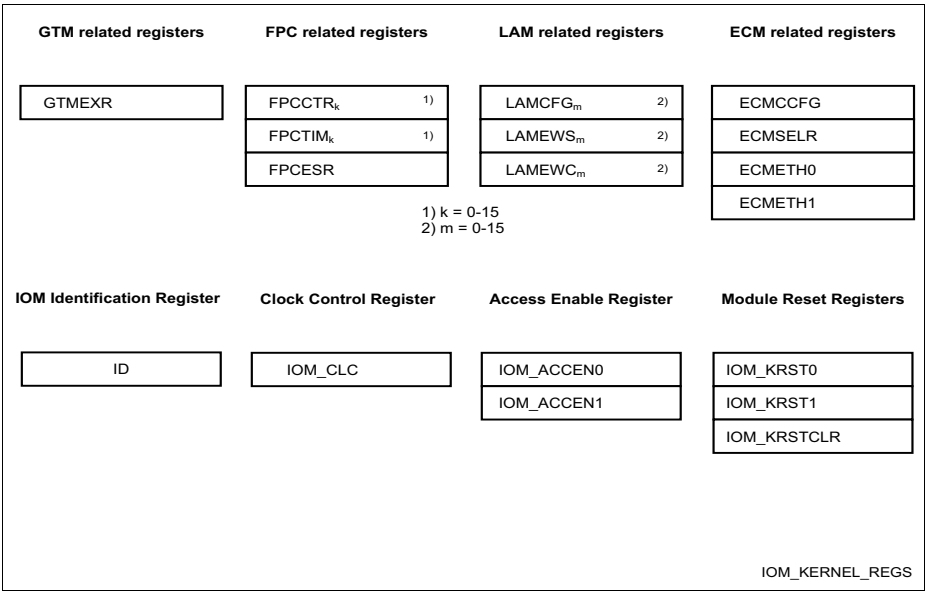

Figure 28-12 IOM Kernel Registers

In the TC21x/TC22x/TC23x, the registers of the IOM units are located in the following address ranges.

Table 28-1 Registers Address Space

Module	Base Address	End Address	Note
IOM	$F003\ 5000_H$	$F003\ 51FF_H$	-

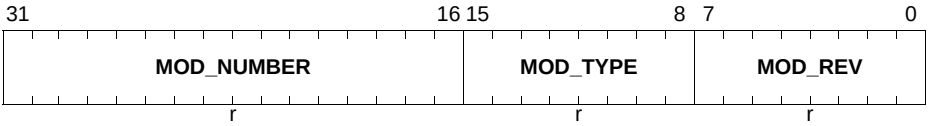
28.9.1 IOM Identification Register (IOM_ID)

The IOM Identification Register ID contains read-only information about the module version.

IOM_ID
IOM Identification Register **(008_H)** **Reset Value: $00CC\ C001_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the Module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Number Value** This bit field defines the module as a 32 bit module: $C0_H$
MOD_NUM	[31:16]	r	**Module Number Value** This bit field defines the identification number for the IOM.

28.9.2 Filter & Prescaler Cell (FPC) Registers

IOM Filter and Prescaler Cells Rising & Falling Edge Status Register (IOM_FPCESR)

The Filter and Prescaler Edge Status Register stores the state of detected rising and falling edges from each of the FPC cells.

The register can be written to selectively clear individual bits.

Individual bits are also cleared with a write to the control register (FPCCTRk) or timer register (FPCTIMk).

IOM_FPCESR

0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

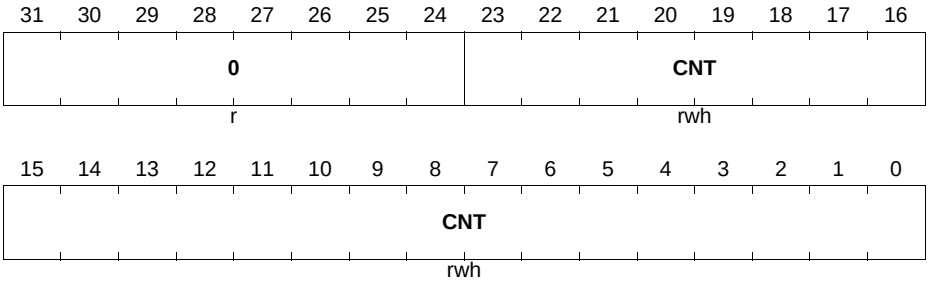
28.9.4 Logic Analyzer Module (LAM) Registers

IOM Logic Analyzer Module Event Window Count Status register (IOM_LAMEWCm)

Used to store the window count value reached prior to being cleared in the LAM block once an event has been generated.

Note: A write to this register will result in a bus error, i.e.existing contents unaffected.

IOM_LAMEWCm (m = 0-15)
IOM Logic Analyzer Module Event Window Count Status Register$_m$
(100_H+m*4_H) **Reset Value: 0000 0000_H**

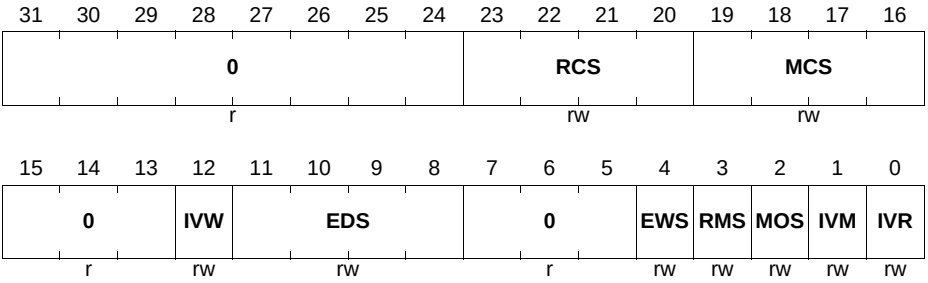


Field	Bits	Type	Description
CNT	[23:0]	r	**Event Window Count Value LAM block m** The count value of the event window attained coincident with an event occuring.
0	[31:24]	r	**Reserved** Read as 0.

IOM Logic Analyzer Module Configuration Register (IOM_LAMCFGm)

Use to configure the application-specific settings for each LAM block, including signal selection muxes at the block inputs.

IOM_LAMCFGm (m = 0-15)
IOM Logic Analyzer Module Configuration Register$_m$
(180_H+m*4_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
IVR	0	rw	**Invert Reference LAM block m** This bit field determines whether the reference signal from the FPCrch is inverted or not. 0_B Don't invert reference signal from FPC. 1_B Invert reference signal from FPC.
IVM	1	rw	**Invert Monitor LAM block m** This bit field determines whether the monitor signal from the FPCmch is inverted or not. 0_B Don't invert monitor signal from FPC. 1_B Invert monitor signal from FPC.
MOS	2	rw	**Monitor Source Select LAM block m** This bit field determines whether the monitor signal from the FPCmch is sourced directly or compared (EXOR'd) with the reference signal from the FPCrch for the event compare. 0_B Monitor signal is sourced directly from FPCmch. 1_B Monitor signal is EXOR'd with FPCrch.

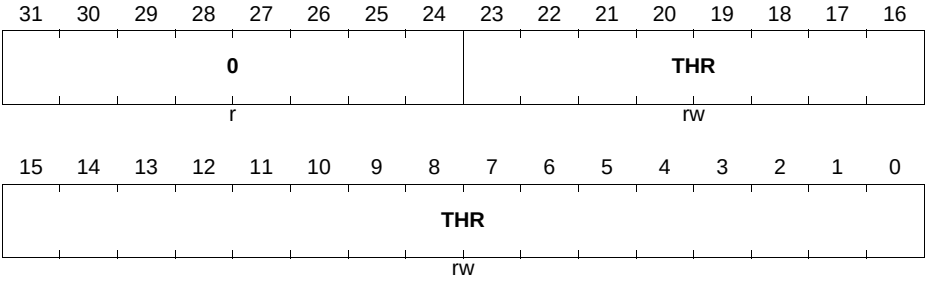
Field	Bits	Type	Description
RMS	3	rw	**Runmode Select LAM block m** This bit field determines whether the event window generation is free-running or gated with the monitor or reference. 0_B Event window generation is free-running. 1_B Event window generation is gated with the monitor or reference signal.
EWS	4	rw	**Event Window Select LAM block m** This bit field determines whether the event window generation is from the monitor or reference signal. 0_B Event window generation is determined from the reference signal. 1_B Event window generation is determined from the monitor signal.
0	[7:5]	r	**Reserved** Read as 0; should be written with 0.
EDS	[11:8]	rw	**Event Window Active Edge Selection LAM block m** This bit field determines which active edges of the monitor and reference signals are used for the event window generation. $xx00_B$ Neither edge used to clear event windowcounter. $xx01_B$ Positive edge used to clear event windowcounter. $xx10_B$ Negative edge used to clear event windowcounter. $xx11_B$ Either edge used to clear event windowcounter. $00xx_B$ Neither edge used to gate event generation. $01xx_B$ Positive edge used to gate event generation. $10xx_B$ Negative edge used to gate event generation. $11xx_B$ Either edge used to gate event generation.
IVW	12	rw	**Invert Event Window LAM block m** This bit field determines whether the event window polarity is inverted or not. 0_B Event window non-inverted. 1_B Event window inverted.
0	[15:13]	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
MCS	[19:16]	rw	**Monitor Input Signal Selection LAM block m** This bit field determines which FPC/mux block k monitor output signal is to be used for LAM block m. 0000_B Monitor signal provided by FPC/mux block 0. 0001_B Monitor signal provided by FPC/mux block 1. 0010_B Monitor signal provided by FPC/mux block 2. 0011_B Monitor signal provided by FPC/mux block 3. 0100_B Monitor signal provided by FPC/mux block 4. 0101_B Monitor signal provided by FPC/mux block 5. 0110_B Monitor signal provided by FPC/mux block 6. 0111_B Monitor signal provided by FPC/mux block 7. 1000_B Monitor signal provided by FPC/mux block 8. 1001_B Monitor signal provided by FPC/mux block 9. 1010_B Monitor signal provided by FPC/mux block 10. 1011_B Monitor signal provided by FPC/mux block 11. 1100_B Monitor signal provided by FPC/mux block 12. 1101_B Monitor signal provided by FPC/mux block 13. 1110_B Monitor signal provided by FPC/mux block 14. 1111_B Monitor signal provided by FPC/mux block 15.
RCS	[23:20]	rw	**Reference Input Signal Selection LAM block m** This bit field determines which FPC/mux block k reference output signal is to be used for LAM block m. 0000_B Reference signal provided by FPC/mux block 0. 0001_B Reference signal provided by FPC/mux block 1. 0010_B Reference signal provided by FPC/mux block 2. 0011_B Reference signal provided by FPC/mux block 3. 0100_B Reference signal provided by FPC/mux block 4. 0101_B Reference signal provided by FPC/mux block 5. 0110_B Reference signal provided by FPC/mux block 6. 0111_B Reference signal provided by FPC/mux block 7. 1000_B Reference signal provided by FPC/mux block 8. 1001_B Reference signal provided by FPC/mux block 9. 1010_B Reference signal provided by FPC/mux block 10. 1011_B Reference signal provided by FPC/mux block 11. 1100_B Reference signal provided by FPC/mux block 12. 1101_B Reference signal provided by FPC/mux block 13. 1110_B Reference signal provided by FPC/mux block 14. 1111_B Reference signal provided by FPC/mux block 15.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

IOM Logic Analyzer Module Event Window Configuration Register (IOM_LAMEWSm)

Used to set the threshold value for the event window counter.

IOM_LAMEWSm (m = 0-15)
IOM Logic Analyzer Module Event Window Configuration Register$_m$
($1C0_H$+m*4_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
THR	[23:0]	rw	**Event Window Count Threshold** This bit field determines the threshold value for the event window counter from which an event is generated. Note: if THR has a value of 0 then no event will be generated.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

28.9.5 Event Combiner Module (ECM) Registers

Event Combiner Module Counter Configuration register (IOM_ECMCCFG)

The Event Combiner Configuration register is used to configure each of the four event counter submodules, enabling multiple events from one selected LAM block (for each event counter submodule) to be counted in the generation of a system event.

IOM_ECMCCFG
IOM Event Combiner Module Counter Configuration Register
(030_H) Reset Value: $0000\ 0000_H$

CTSn (n=0-3)	n+16	rw	**Accumulated (Counted) Event Combiner Selection** The setting of individual bitfields determines the inclusion of the respective channel event counter output (1 of 4) in the generation of the global event (AND function). 0_B Don't include channel event/event counter output within the global event generation. 1_B Include channel event/event counter output within the global event generation.
0	[31:20]	r	**Reserved** Read as 0; should be written with 0.

Event Combiner Module Event Trigger History Register (IOM_ECMETH0)

One of two registers (IOM_ECMETH0 and IOM_ECMETH1) that record the status of LAM's 0 to 15 event outputs for the last 4 generated system events.

The generation of a system event will cause the status of the event outputs from LAM blocks 0 to 15 to be recorded in ETA0-15, respectively. Just prior to this happening, the previous status held in ETA0-15 is moved to ETB0-15. Similarly, the previous contents of ETB0-15 and ETC0-15 are moved to ETC0-15 and ETD15-0, respectively. The old contents of ETD15-0, being lost.

At reset (or a register write to either IOM_ECMETH0 or IOM_ECMETH1), all Event Trigger Active flags (ETA, ETB, ETC, ETD) will be cleared.

28.9.6 System Registers

IOM Clock Control Register (IOM_CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the $f_{<>}$ module clock signal, sleep mode and disable mode for the module.

IOM_CLC
IOM Clock Control Register (000_H) Reset Value: 0000 0003$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RMC								0				EDIS	0	DISS	DISR
rw								r				rw	rw	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
0	2	rw	**Reserved** Read as 0; should be written with 0.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
RMC	[15:8]	rw	**8-bit Clock Divider Value in RUN Mode**
0	[31:16], [7:4]	r	**Reserved** Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing

CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

IOM Access Enable Register (IOM_ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

IOM_ACCEN0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

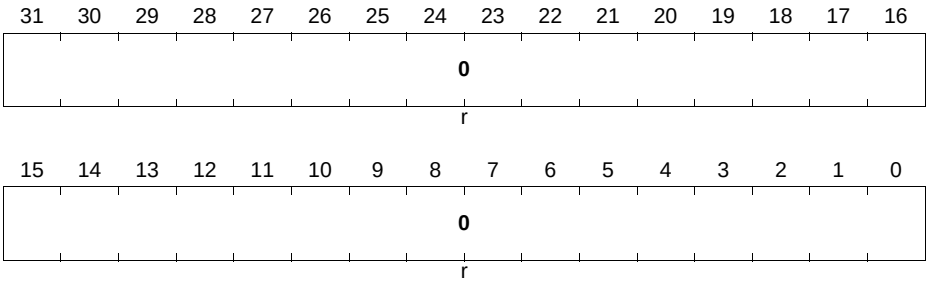
1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

IOM Access Enable Register (IOM_ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

IOM_ACCEN1
IOM Access Enable Register 1 (028_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

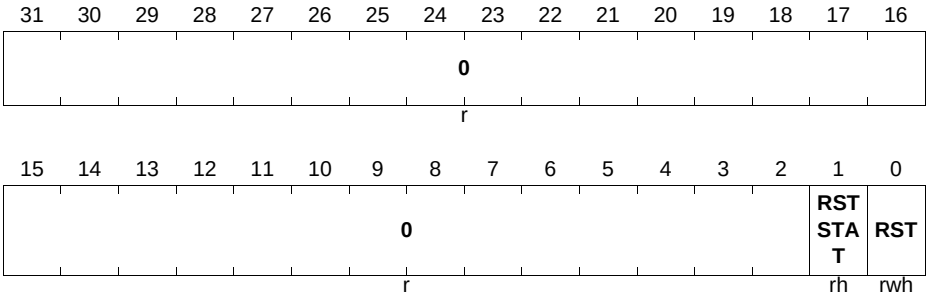
IOM Kernel Reset Register 0 (IOM_KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

IOM_KRST0
IOM Kernel Reset Register 0 (024_H) Reset Value: 0000 0000$_H$



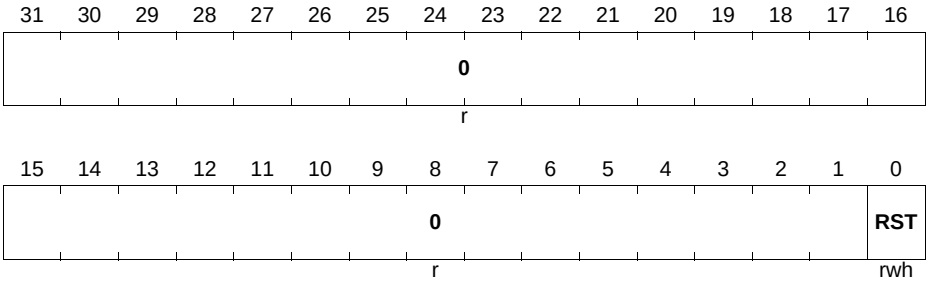
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.

Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

IOM Kernel Reset Register 1 (IOM_KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

IOM_KRST1
IOM Kernel Reset Register 1 (020_H) Reset Value: 0000 0000_H

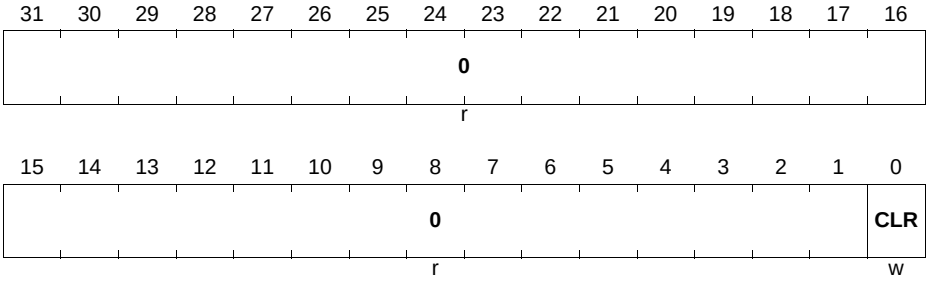


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

IOM Kernel Reset Status Clear Register (IOM_KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

IOM_KRSTCLR
IOM Kernel Reset Status Clear Register($01C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

28.11 Example Monitor/Safety Measures

For each channel the following measurements shall be possible:

- Duty cycle measurement
- Set-up and/or hold time measurement
- Delay window (min,max) with respect to rising or falling edge

The following waveforms provide more examples of typical signal monitoring functionality that could be deployed using the IOM. Some typical configuration settings are also provided on some of the examples.

28.11.1 Example 1 - Pulse or duty cycle too short

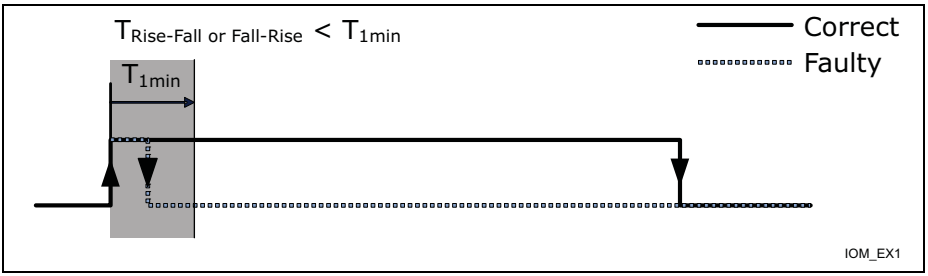

Figure 28-16 example 1 - pulse or duty cycle too short

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal (or invert for non-duty part of period)

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x9 ; CLR on positive edge, EVT on negative edge

LAMCFG.IVW : 0x1 ; invert window, capture events under the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (minimum duty cycle length required. If duty cycle is shorter than this value then EVT will trigger)

28.11.2 Example 2 - Pulse or duty cycle too long

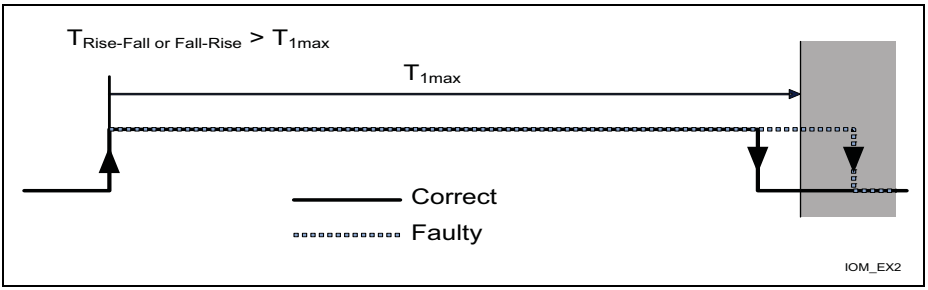

Figure 28-17 example 2 - pulse or duty cycle too long

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal (or invert for non-duty part of period)

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x9 ; CLR on positive edge, EVT on negative edge

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum duty cycle length required. If duty cycle is longer than this value then EVT will trigger)

28.11.3 Example 3 - Period too short

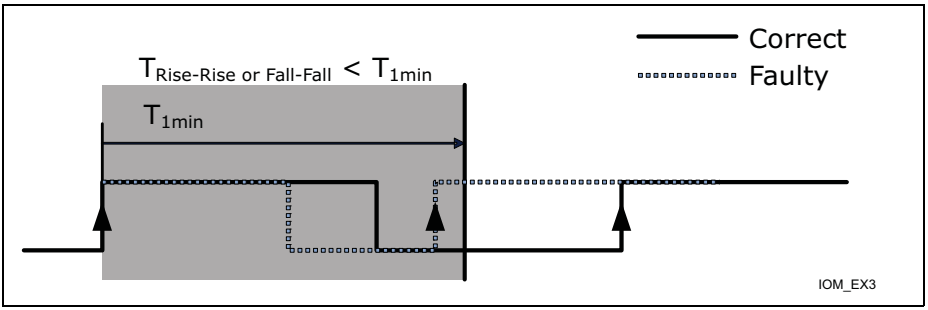

Figure 28-18 example 3 - period too short

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x5 ; CLR on positive edge, EVT on positive edge

LAMCFG.IVW : 0x1 ; invert window, capture events under the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (minimum period length required. If duty cycle is shorter than this value then EVT will trigger)

28.11.4 Example 4 - Period too long

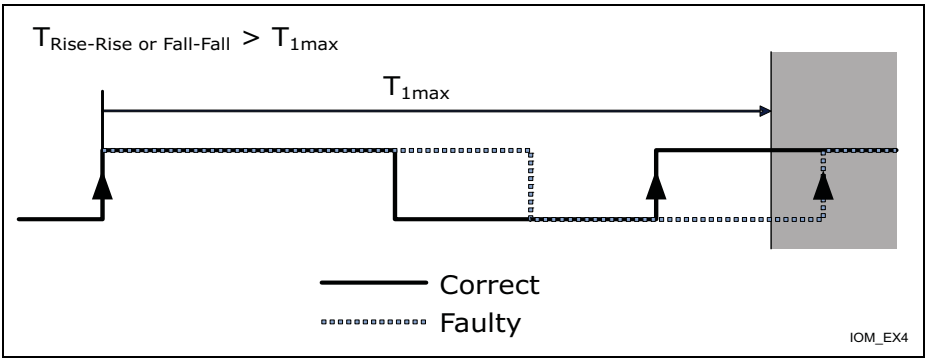

Figure 28-19 example 4 - period too long

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x5 ; CLR on positive edge, EVT on positive edge

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum period length required. If duty cycle is longer than this value then EVT will trigger)

28.11.5 Example 5 - Diagnosis of Command and Feedback - acceptable propagation window and/or signal consistency check

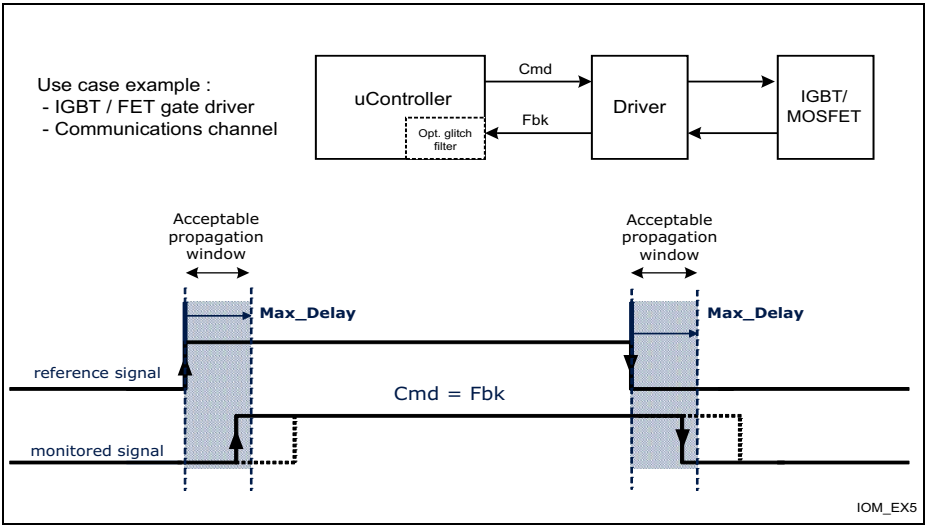

Figure 28-20 example 5 - Diagnosis of Command & Feedback

Using the driven signal (off-chip) as a reference, using a feedback signal (input to device) as the monitor. Checking that the monitored signal shows activity within an acceptable propagation window, and/or that the feedback signal shows the same behaviour as the reference (Command = Feedback).

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't invert reference signal

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x1 ; (MON xor REF) signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xB ; CLR on both edges of REF, EVT on falling edge (of xor'd signal)

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; set to max delay allowed

28.11.6 Example 6 - Diagnosis of Set-up and Hold times

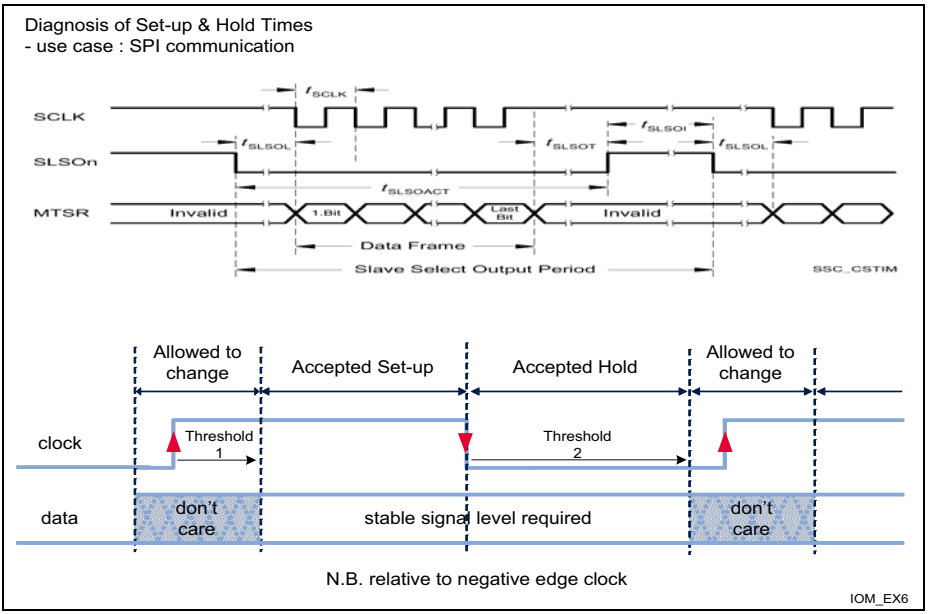

Figure 28-21 example 6 - Diagnosis of Set-up & Hold times

Ensuring that data remains stable within the Set-up and Hold windows, generating an event otherwise, and/or ensuring that data only changes within the specified windows.

Note that 2 LAM channels will be required for this purpose, one for set-up, one for hold.

Example settings for LAM block registers for Set-up :

LAMCFG.IVR: 0x0 ; don't invert reference signal

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x1 ; run is gated

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xF ; CLR on both edges, EVT on both edges

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; Acceptable Set-up (ref Threshold 1 on waveforms shown)

Example settings for LAM block registers for Hold:

LAMCFG.IVR: 0x0 ; invert reference signal (use for gating)

LAMCFG.IVM: 0x0 ; don’t invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x1 ; event window is gated

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xD ; CLR on positive edge (inverted neg. edge), EVT on both edges

LAMCFG.IVW : 0x1 ; invert window, capture events below the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; Acceptable Hold (ref Threshold 2 on waveforms shown)

29 Advanced Driver Assistance Subsystem (ADAS)

Some product derivatives include hardware support for Advanced Driver Assistance Systems (See Introduction chapter).

In ADAS derivative products the following additional hardware is present:

- Camera and RADAR Interface (CIF) (TC26x and TC29x only)
  - Parallel interface
  - On-the-fly JPEG encoding of camera signals
  - De-interleaving of external ADC radar signals
- Fast Fourier Transform Accelerator (FFT)
  Integrated windowing support and up to 2048 point FFTs
- Extended Memory
- A high speed Backbone Bus
- Additional ADC channels (TC23x only)
  - Supports 4 channel concurrent sampling throughout all ADAS products
- A high speed input capture unit
  - For high precision frequency measurements of low speed signals
  - See QSPI module, section “High Speed Input Capture”

This chapter describes these peripherals in the context of radar and video based applications for Advanced Driver Assistance Systems

Figure 29-1 shows an overview of the ADAS subsytem.

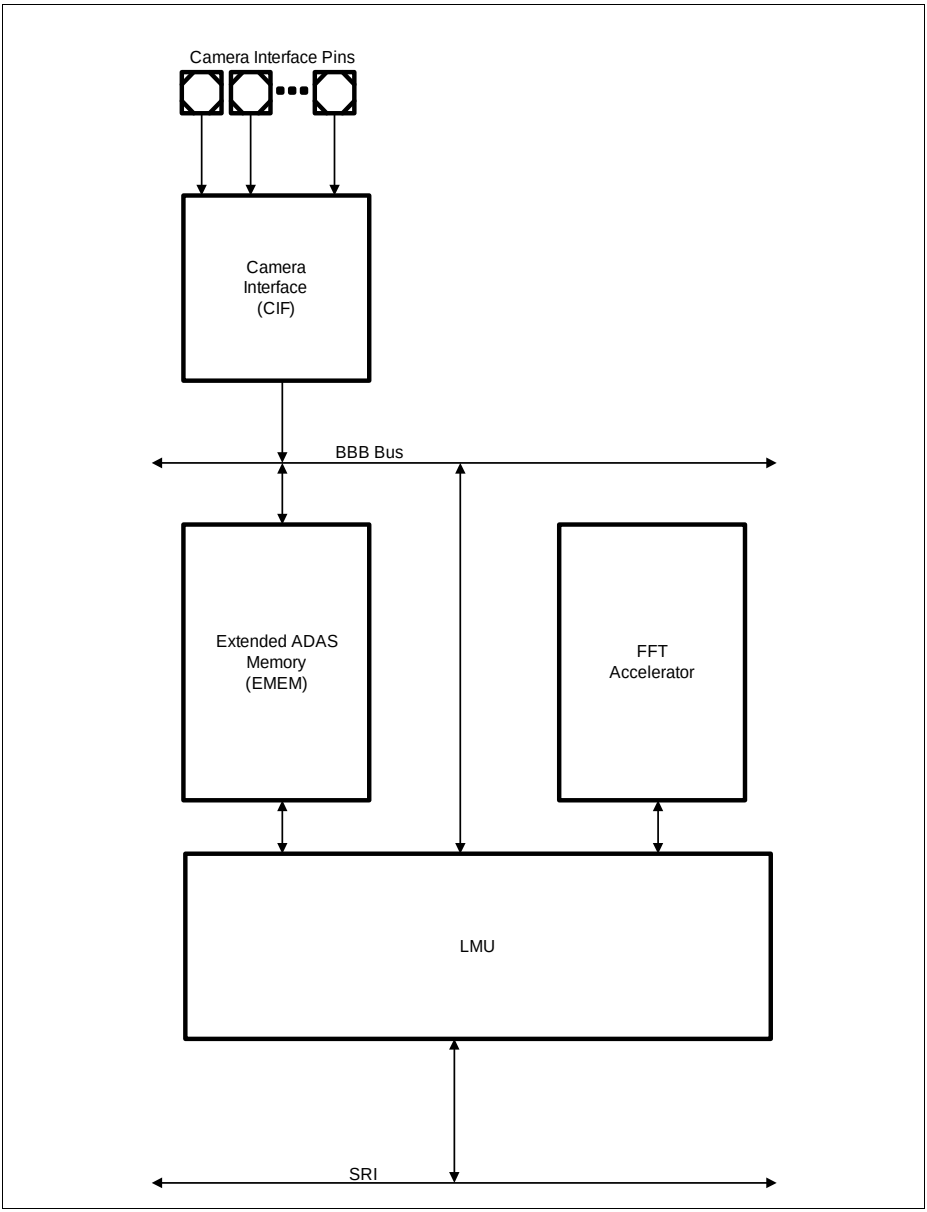

Figure 29-1 Block Diagram of the ADAS Subsystem

29.1 FFT Engine (FFT)

This chapter describes the FFT Engine, an algorithm specific accelerator. The FFT Engine is not available in all devices and only those with the ADAS feature set.

The FFT Engine utilises the SRI connectivity of the LMU. The FFT Engine is clocked at the same frequency as the SRI and all cycle counts are in terms of SRI clocks.

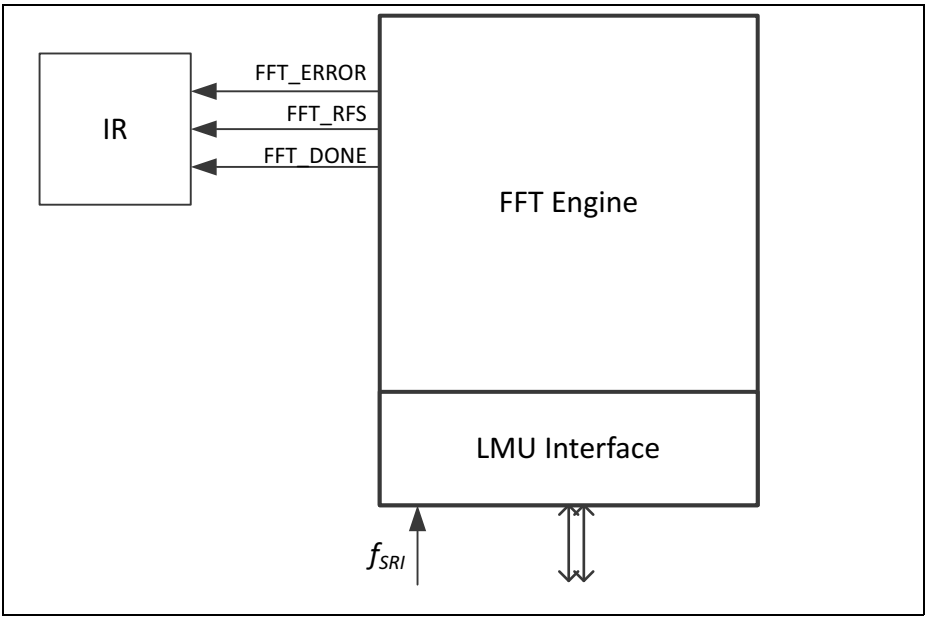

Figure 29-2 FFT Engine Integration into the LMU

29.1.1 Overview

The FFT Engine calculates forward and inverse FFTs of lengths 8 to 2048 (powers of 2 only). It operates on real and complex data which can have co-efficients of 16 or 32-bits in length.

The actual forward and inverse transforms calculated by this core are given by

$$X[k] = \frac{1}{N}\sum_{n=0}^{N-1} x[n]\exp(-j2\pi kn/N) \qquad \text{Forward}$$

$$x[n] = \frac{1}{N}\sum_{k=0}^{N-1} X[k]\exp(j2\pi kn/N) \qquad \text{Inverse}$$

In usual DSP literature the forward transform is not divided by N, but this is performed in hardware for consistency between transforms and to implement a transform that cannot overflow.

29.1.2 Feature List

General features:

- Per transform selection of FFT or inverse FFT (IFFT).
- Per transform selection of FFT/IFFT size from 8, 16, 32, 64, 128, 256, 512, 1024 or 2048 points.
- Per transform selection of real or complex input operands.
- Per transform selection of input operands with 16-bit or 32-bit precision.
- Per transform selection of output results with 16-bit or 32-bit precision.
- Internal calculation to 32-bits of precision.

In addition to standard FFT calculations, the FFT Engine also supports a window function to be applied to input operands. The window function utilises a window RAM to hold coefficients which allows any real symmetrical function to be used. Use of this features is described in **Section 29.1.7**. Another important performance enhancement is the use of double buffering to support the overlap of loading and unloading the FFT Engine while computation continues

Input operands for FFT or inverse FFT calculations which are loaded with 16-bits of precision are converted to 32-bits prior to storage inside the FFT engine. Calculations are carried out to 32-bits of precision using block floating point and adaptive scaling to ensure there is no loss of dynamic range during the intermediate calculations. Results are adjusted to natural scaling for software convenience before being read out. Output results which are unloaded with 16-bits of precision are converted from the 32-bit internal result by rounding (to nearest even) with saturation as they are transferred out.

29.1.3 FFT Engine Performance

After operands are loaded into the FFT Engine, the number of cycles the engine takes to complete a computation is a function of the length of the transform it has been programmed to execute. If N is the length of the transform, then the number of clock cycles to complete is:

```
(N+16)*ceil(log4(N))
```

The cycle count till availability of results for the supported FFT/IFFT lengths is show in **Table 29-1**.

Table 29-1 FFT Engine Execution Times

Transform Length	Cycles	Transform Length	Cycles
-	-	128	576
8	48	256	1088
16	64	512	2640
32	144	1024	5200
64	240	2048	12384

29.1.4 System Performance

The complete steps required for the execution of an FFT/IFFT are:

- writing to the FFT_CSR to configure the required operation (input format, length, window operation, output format, start) with a single write
- transferring the required number of operands into the FFT Engine
- waiting for the engine to complete (or being interrupted)
- unloading the results from the FFT Engine

Total execution time for an FFT/IFFT calculation must take into consideration the time for storing of operands into the FFT Engine, and reading of the results out as well as the calculation time shown in the table FFT Engine Execution Times.

29.1.4.1 Data Movement Optimisation

The loading and unloading cycles will be a significant part of the total execution time required and is one of the major optimisation opportunities. Using the minimum operand size for input or output (16-bit versus 32-bit) can halve the amount of time in loading and unloading.

FFT transforms based on real operands only, could be calculated by loading complex values with imaginary components of zero along with real component values. However the FFT Engine supports optimising out this unnecessary transfer, and setting FFT_CSR.IN_FMT appropriatly for real operands will halve the loading time. Both these transform options will significantly reduce the end to end cycle count for an operation, despite the fact that they have no effect on the transform calculation time.

Programmed loading and unloading by TriCore CPUs can transfer 64-bits at a time. For smaller transform lengths this may be most efficient. For longer transforms, the optimum bandwidth to load and unload the FFT Engine is obtained using the DMA to transfer bursts of four 64-bit words at a time.

29.1.4.2 Double Buffering Optimisation

As well as the opportunity to optimise the data movement time, the FFT Engine also provide the mechanisms to overlap FFT/IFFT execution with loading and unloading results. The FFT Engine is provided with two buffers each capable of supporting a maximum length FFT/IFFT transform. These two buffers are operated in a ping-pong arrangement and allow the overlap of transfer in and out of the FFT Engine, with the calculation of a transform with an earlier loaded set of operands. Thus, the throughput of FFT/IFFT operations is higher than determined by the total latency (loading, execution, unloading) of an individual transform.

29.1.5 Address Spaces and Access Protection

The FFT Engine responds to three address spaces in the system address map:

- a register space located from F870_0C00h to F870_0CFFh,
- a data space located at BE00_0000h to BE07_FFFFh,
- a window coefficient space located at BE10_0000h to BE17_FFFFh.

All three addresses spaces within the FFT Engine are protected by the access enable registers of the LMU which protects the resources against writes from unauthorised SoC masters.

29.1.5.1 Register Address Space

The FFT register space consists of 32-bit registers that only respond correctly to 32-bit read and write operations.

- any read from register space which is an 8-,16- or 64-bit operation will result in an undefined value,
- any read from register space which is a burst transfer will result in a transaction error,
- any write to register space which is a burst transfer or an 8-,16- or 64-bit operation will result in a transaction error,
- any atomic operation to register space will result in a transaction error.

29.1.5.2 Data Space

The data space only supports 64-bit and burst-4 transfers. Accesses that are 8-,16- or 32-bit or burst-2 transfers to the data space will have undefined results.

The data space does not have standard memory characteristics. Instead this region operates as access to two separate FIFOs. Write accesses (regardless of addresses used) will place operands in order into one of the ping-pong buffers; for example for a 512 length FFT, the first data transferred will be ‘sample 0’, and the 512th sample transferred will be ‘sample 511’ regardless of the addresses used (provided they are all

within the FFT Engine data space). There is no ability to direct accesses to either of the ping-pong buffers, this is purely controlled by the FFT Engine.

Read accesses to the data space will return results out of one of the FIFOs in the same manner. The first read of a completed transform will receive ‘result 0’, and the Nth read will receive ‘result N-1’, again the addresses used will not influence the result element returned.

Bit FFTPFDIS should be cleared (0) in register LMU_MEMCON (see Local Memory Unit chapter) before accessing the data space.

Intermixing single transfers of 64-bits or burst-4 transfers during the same loading phase, or same unloading phase will have undefined results.

29.1.5.3 Window Coefficient Space

The widow coefficient space only supports 64-bit and burst-4 transfers. Accesses that are 8-,16- or 32-bit or burst-2 transfers to the window space will have undefined results. Within the window coeffcient address space is a RAM holding the window coefficients - the window RAM.

The window RAM occupies 2-KByte (with corresponding aliases) of the window address space. Read and writes to this 2-KByte RAM will have standard memory characteristics only when validly accessed.

Accesses to the window RAM are only well behaved (reads to an address will return the same data last written) when

- the FFT Engine is idle,
- the FFT Engine does not have any results to be unloaded and
- bit FFTPFDIS should be set (1) in register LMU_MEMCON (see Local Memory Unit chapter).

For this reason writing to the window RAM should only be performed when the three conditions above have been met.

Note: The entire window RAM must be initialised before the FFT Engine can run a transform. This requirement is regardless of whether the window function is enabled or not for the transform.

29.1.6 Data Value Formats

The data formats supported by the FFT Engine for operands are identical to the corresponding TriCore architecture fractional formats for ease of manipulation. While, the window coefficient format which is manipulated less frequently uses a different format to slightly enhance precision.

29.1.6.1 Time and Frequency Sample Format

Data with 16-bit precision corresponds to TriCore signed fractional data with 16-bits (also known as 1.15 or Q15 format). Data with 32-bit precision corresponds to TriCore signed fractional data with 32-bits (also known as 1.31 or Q31 format).

Data values in this format have a single high-order sign bit, where 0 represents positive (+) and 1 represents negative (-), followed by an implied binary point and fraction. Their values are therefore in the range [-1,1).

Complex data corresponds to an array of two elements in little-endian order, where the first element (index 0 in ‘C’ notation) is the real coefficient, and the second element (index 1 in ‘C’ notation) is the imaginary coefficient.

29.1.6.2 Window Coefficient Format

A valid window function will have coefficients in the range [0,1]. However, strictly only the central window coefficient requires to be 1.0 and the remainder are in the range [0,1). If the 1.15 or Q15 format was used for window coefficients, then as all the coefficients are positive, the MSBs of co-efficients stored in the window RAM (the central coefficient is not loaded), would be redundant.

To take advantage of this fact, the FFT Engine calculate with unsigned window coefficients and the stored values to the window RAM are the 16 fractional bits of a nominal 1.16 format.

29.1.7 Window Usage

The window RAM allows the user to load a window function of their choice and apply it (or not) to subsequent transforms. The parameters in the window RAM are only changed when the window function is required to be changed, they otherwise persist between transform operations (i.e. have standard memory characteristics).

The window RAM only contains half the maximum length transform entries (see **Section 29.1.6.2** for the format) and exploits symmetry to generate a complete window for that length of transform. If a window function is to be used for any length transform, it must be fully loaded and the FFT Engine will select the appropriate coefficients.

The expected usage is that a window function will be selected for a good match to the system and application properties, loaded at system initialisation, and then either applied or not (using FFT_CSR.WIN_BYP clear or set respectively) to subsequent FFT operations. While the window function can be changed during system operation, any change must respect the requirements listed in **Section 29.1.5.3**. Thus, any change will incur some latency till the next transform operation is possible; either with or without the new window function applied.

*Note: As specified in **Section 29.1.5.3** the window RAM must be initialised before any FFT Engine transform operation.*

29.1.7.1 Window Parameters

If the window function is to be used, the coefficients for a maximum length transform must be computed. First generate a window of odd length and with a central maximum value of 1.0. For example if using MATLAB then this command

```
w = hamming(2048,'periodic');
```

or

```
w = hamming(2049,'symmetric');
```

will return the first 2048 points of a 2049 point periodic window. Next select the first 1024 values of w and scale them up and round to an unsigned 16-bit integer

```
wi = round(65536*w(1:1024));
```

These are the values to load into the window RAM. Note that this procedure is generic for any window, always start with a length 2049 symmetric or 2048 period variant. A common window in radar is Blackman-Harris, which would be generated in MATLAB with

```
w = blackmanharris(2049);
wi = round(65536*w(1:1024));
```

Note that the 1.0 central coefficient is internally generated by the hardware so it is essential that the window is correctly scaled to 1.0.

For FFT transform sizes less than the maximum the hardware will index the full window table to generate the correct coefficients for a smaller FFT size.

Although the hardware will not stop you applying a window in the frequency domain it may not be desirable.

29.1.8 Interrupt and DMA Operation

As well as inspecting the CSR register to determine when FFT/IFFT operations may be commenced, the FFT Engine allows interrupt driven data movement. There are two SRC registers in the IR connected to triggers from the FFT Engine. These are SRC_FFTRFS and SRC_FFTDONE. As is standard, each of these SRCs can select either a CPU or DMA channel to service the event.

A trigger will be sent to SRC_FFTRFS whenever FFT_CSR.RFS transitions from 0 to 1, this alerts the system to the fact the FFT_ENGINE can be loaded with another transform. Since there are two (ping-pong) buffers, this event means the FFT Engine may still be busy computing a previously loaded transform.

A trigger will be sent to SRC_FFTDONE whenever a transform calculation has completed and the unload operation can be performed.

A possible operational sequence utilising both of these trigger conditions is described below

1. A CPU reads the FFT_CSR register and looks for RFS bit to be set. Software then writes to the FFT_CSR register with START set to 1, and the desired values for IFFT, LENGTH, WIN_BYP, IN_FMT, OUT_FMT.
2. The same CPU programs DMA channel(s) to send data to the FFT Engine, and configures the service request control (SRC) registers in the interrupt router SRC_FFTRFS and SRC_FFTDONE as required.
   At this stage the CPU could return to some other task (perhaps preparing operands or examining results).
3. A CPU receiving the interrupt corresponding to SRC_FFTRFS, can write the next START command and initiate the DMA to transfer the next transforms operands to the FFT Engine.
   Again at this stage the CPU is then free to return to some other task.
4. An interrupt corresponding to SRC_FFTDONE can trigger an already configured DMA channel to read back data from the FFT Engine, which when it has unloaded the results can then trigger a CPU to inform it of the unload completion.
5. Loop back to 3

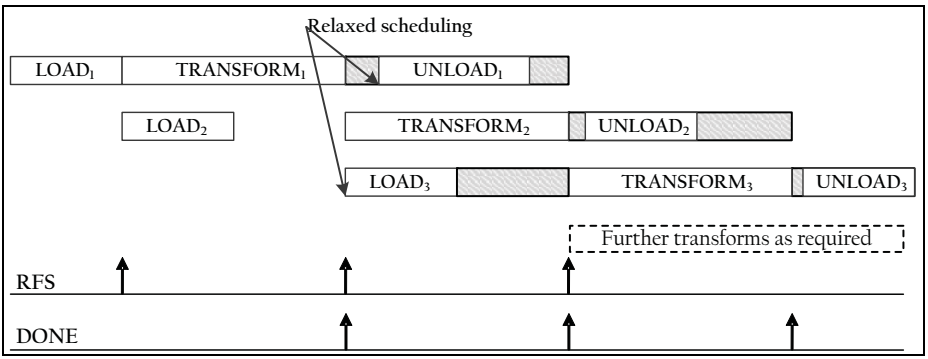

Figure 29-3 Three Consecutive Transforms

The double buffer architecture allows overlapping FFT execution with the DMA load/unload operation. This is illustrated in **Figure 29-3** where this example shows three transforms. The use of two memory buffers allows more relaxed scheduling of the DMA load/unload during overlapped transforms as shown by the unload operation being delayed until after the load operation for the third transform has commenced.

29.1.9 FFT Engine Registers

This section described the register interface to the FFT Engine. This address region should not be unintentionally read or written because this might cause side effects on FFT Engine state.

All registers are reset by the application reset apart from **FFT_ODA** and **FFT_OCS**. These registers are cleared by Debug Reset and by each System Reset when OCDS is disabled. They are not changed by System Reset when OCDS is enabled.

Where a register is defined as "ACCEN Enable Protected" (designated with "P" for writes), then the LMU ACCEN settings will be used.

Table 29-2 Registers Address Space

Module	Base Address	End Address	Note
FFT	F870 0C00$_H$	F870 0CFF$_H$	-

Table 29-3 Registers Overview

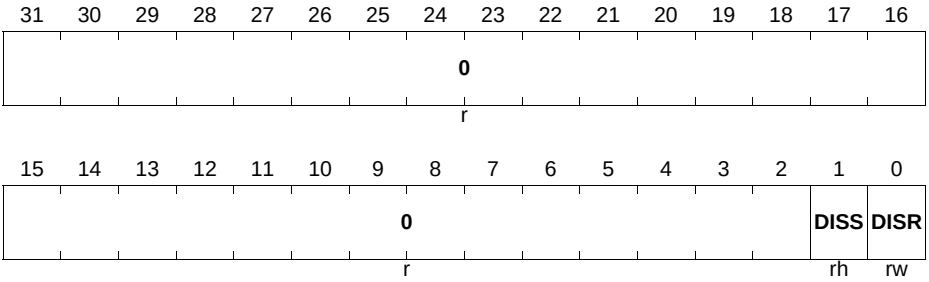
Register Short Name	Register Long Name	Offset Address	Read Access	Write Access	Reset Value
FFT_CLC	FFT Clock Control Register	00$_H$	U/SV	SV,E,P	0000 0002$_H$
FFT_ID	FFT Identification Register	08$_H$	U/SV	R	00E2 C002$_H$
FFT_CSR	FFT Control and Status Register	40$_H$	U/SV	U/SV,P	0010 0000$_H$
FFT_HISTORY0	FFT History Register 0	60$_H$	U/SV	R	0000 0000$_H$
FFT_HISTORY1	FFT History Register 1	70$_H$	U/SV	R	0000 0000$_H$
FFT_ODA	FFT OCDS Debug Access Register	E4$_H$	U/SV	SV,P	0000 0000$_H$
FFT_OCS	FFT OCDS Control and Status Register	E8$_H$	U/SV	SV,P	0000 0000$_H$
FFT_KRSTCLR	FFT Kernel Reset Status Clear Register	EC$_H$	U/SV	SV,P	0000 0000$_H$
FFT_KRST1	FFT Kernel Reset Register 1	F0$_H$	U/SV	SV, P	0000 0000$_H$
FFT_KRST0	FFT Kernel Reset Register 0	F4$_H$	U/SV	SV, P	0000 0000$_H$

29.1.9.1 FFT Clock Control Register

FFT Clock Control Register (FFT_CLC)

The FFT Clock Control Register, FFT_CLC, acts globally and allows the complete FFT Engine to be disabled to reduce power consumption when the FFT is not required. When the FFT Engine is disabled (DISS=1_B), only register accesses to the FFT Engine are permitted. All other accesses to the FFT address space will receive a transaction error.

FFT_CLC
FFT Clock Control Register (0000_H) Reset Value: $0000\ 0002_H$



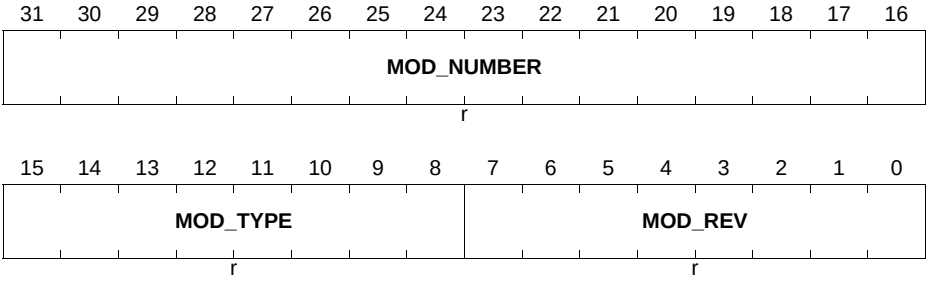
Field	Bits	Type	Description
DISR	0	rw	**FFT Disable Request Bit** Used for enable/disable control of the FFT Engine.
DISS	1	rh	**FFT Disable Status Bit** Bit indicates the current status of the FFT Engine. DISABLED after reset.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

29.1.9.2 FFT Module Identification Register

FFT Identification Register (FFT_ID)

The FFT identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the FFT Engine.

FFT_ID
FFT Identification Register **(0008_H)** **Reset Value: $00E2\ C002_H$**



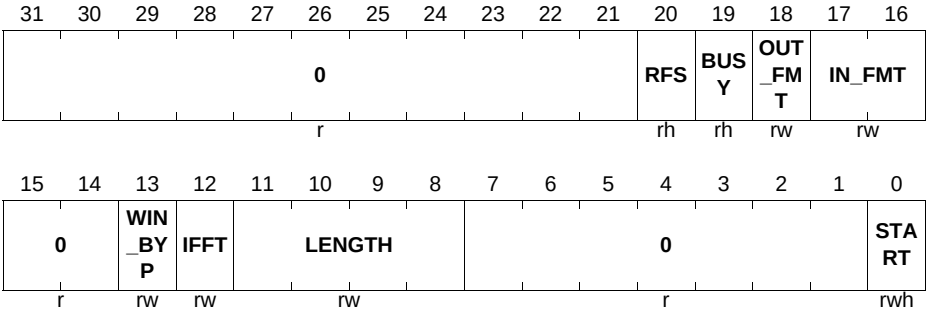
Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision Number** This bit field defines the module revision number. 01_H : the value for max. 1K point engine 02_H : the value for max. 2K point engine.
MOD_TYPE	15:8	r	**Module Type** The bit field is set to $C0_H$ which defines the module as a 32-bit module.
MOD_NUMBER	31:16	r	**Module Number Value** This bit field defines a module identification number. The value for the FFT Engine is $00E2_H$.

29.1.9.3 FFT Control and Status Register

FFT Control and Status Register (FFT_CSR)

This is the main register to control FFT/IFFT operation and provide feedback on the current state of the FFT Engine.

FFT_CSR
FFT Control and Status Register (0040$_H$) **Reset Value: 0010 0000$_H$**



Field	Bits	Type	Description
START	0	rwh	**Start Transform** Start a new transform - cleared by hardware.
LENGTH	11:8	rw	**Length of Transform** Log base 2 of the required transform size. Length must be between 3 (transform of 8) and 11 (transform of 2048).
IFFT	12	rw	**Inverse FFT** 0_B perform FFT. 1_B perform IFFT.
WIN_ BYP	13	rw	**Window Bypass** 0_B use window function 1_B bypass window function
IN_FMT	17:16	rw	**Input Format** 0_D 1 complex 32-bit datum per 64-bit word 1_D 2 real 32-bit data per 64-bit word 2_D 2 complex 16-bit data per 64-bit word 3_D 4 real 16-bit data per 64-bit word
OUT_FMT	18	rw	**Output Format** 0_D 1 complex 32-bit datum per 64-bit word 1_D 2 complex 16-bit data per 64-bit word
BUSY	19	rh	**FFT Engine Busy** 0_D : FFT Engine Idle - no pending transforms 1_D : FFT Engine has at least one transform in operation.

Field	Bits	Type	Description
RFS	20	rh	**Ready For Start** 0_D : cannot accept a START operation 1_D : can accept a START operation.
0	31:21, 15:14, 7:1	r	**Reserved** Read as 0; should be written with 0

This register may be written at any time without setting the START bit, but this will have no effect on the FFT Engine. Only updates with the START bit set will change the FFT Engine state, and must be done before data can be loaded into the FFT Engine, to inform it of the input data formats and operational mode for that transform.

However the FFT Engine must be ready to accept a new START request. This register can be read and the RFS - ready for start - bit examined. If the RFS is true then a new transform can be started. A trigger will be sent to SRC_FFTERR if START is set when the FFT Engine is not ready. The commencement of new transforms in an interrupt driven manner is described in **Section 29.1.8**.

The IN_FMT field determines how data on the little-endian 64-bit data bus is loaded into the FFT Engine.

Table 29-4 Input Data Formats

IN_FMT	Halfword[3]	Halfword[2]	Halfword[1]	Halfword[0]
0	imag[0]		real[0]	
1	real[1]		real[0]	
2	imag[1]	real[1]	imag[0]	real[0]
3	real[3]	real[2]	real[1]	real[0]

The OUT_FMT field determines how data on the little-endian 64-bit data bus is unloaded from the FFT Engine.

Table 29-5 Output Data Formats

OUT_FMT	Halfword[3]	Halfword[2]	Halfword[1]	Halfword[0]
0	imag[0]		real[0]	
1	imag[1]	real[1]	imag[0]	real[0]

The BUSY bit reports the status of the FFT engine. If BUSY is set then at least one transform has either been requested with a START or is executing or is waiting for unloading

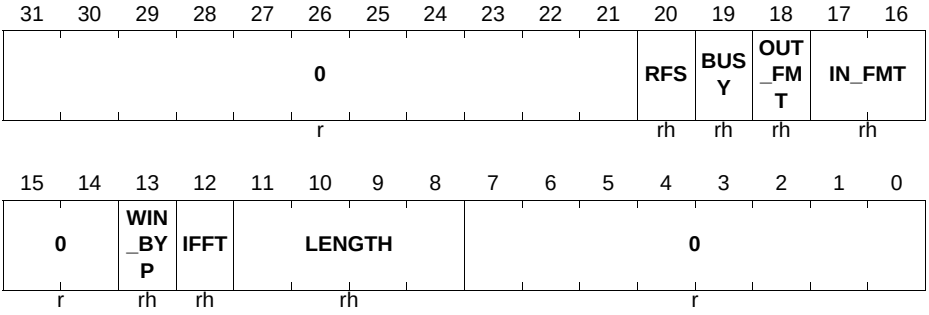
29.1.9.4 FFT History Registers

History registers allow the last few commands issued to the CSR to be retained for debug, the registers have no other effect upon the FFT Engine. They are reset to 0, and contain a non-zero value whenever they have been loaded by performing a write to the CSR register with START set. This write may or may not have setup a transform operation correclty depending upon the state of CSR.RFS at the time the START was issued.

FFT History Register 0 (FFT_HISTORY0)

The value of FFT CSR control fields when START was last issued.

FFT_HISTORY0
FFT History0 Register **(0060_H)** **Reset Value: $0000\ 0000_H$**



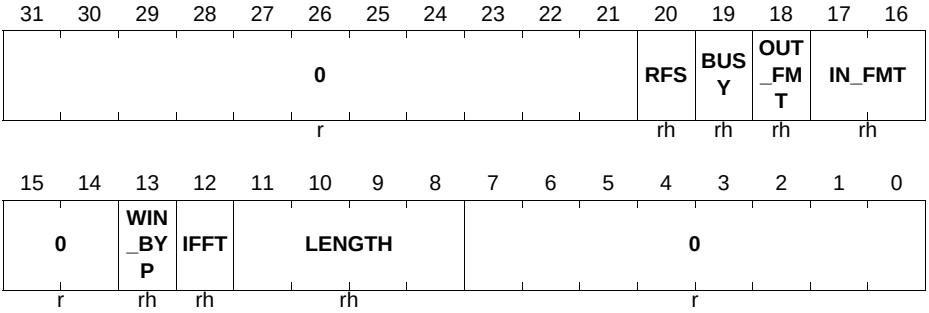
Field	Bits	Type	Description
LENGTH	11:8	rh	**Length of Transform** value of FFT_CSR.LENGTH when START command was last issued.
IFFT	12	rh	**Inverse FFT** value of FFT_CSR.IFFT when START command was last issued.
WIN_BYP	13	rh	**Window Bypass** value of FFT_CSR.WIN_BYP when START command was last issued.
IN_FMT	17:16	rh	**Input Format** value of FFT_CSR.IN_FMT when START command was last issued.

Field	Bits	Type	Description
OUT_FMT	18	rh	**Output Format** value of FFT_CSR.OUT_FMT when START command was last issued.
BUSY	19	rh	**FFT Engine Busy** value of FFT_CSR.BUSY when START command was last issued.
RFS	20	rh	**Ready For Start** value of FFT_CSR.RFS when START was last issued.
0	31:21, 15:14, 7:0	r	**Reserved** Always read as 0.

FFT History Register 1 (FFT_HISTORY1)

The value of FFT History Register 0 when START was last issued.

FFT_HISTORY1
FFT History1 Register **(0070_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
LENGTH	11:8	rh	**Length of Transform** value of FFT_HISTORY0.LENGTH when START command was last issued.
IFFT	12	rh	**Inverse FFT** value of FFT_HISTORY0.IFFT when START command was last issued.

Field	Bits	Type	Description
WIN_BYP	13	rh	**Window Bypass** value of FFT_HISTORY0.WIN_BYP when START command was last issued.
IN_FMT	17:16	rh	**Input Format** value of FFT_HISTORY0.IN_FMT when START command was last issued.
OUT_FMT	18	rh	**Output Format** value of FFT_HISTORY0.OUT_FMT when START command was last issued.
BUSY	19	rh	**FFT Engine Busy** value of FFT_HISTORY0.BUSY when START command was last issued.
RFS	20	rh	**Ready For Start** value of FFT_HISTORY0.RFS when START was last issued.
0	31:21, 15:14, 7:0	r	**Reserved** Always read as 0.

29.1.9.5 FFT Debug Control Registers

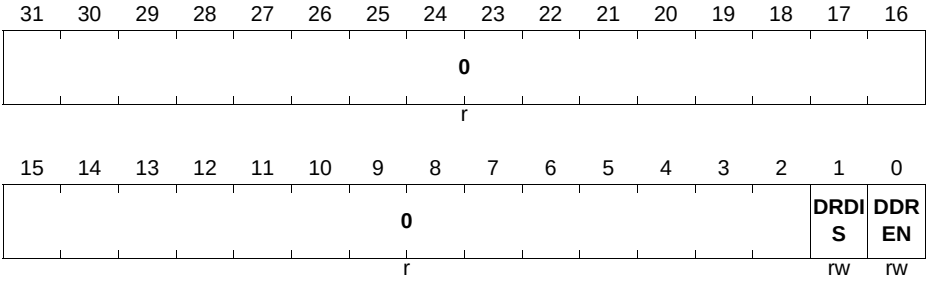
FFT OCDS Debug Access Register (FFT_ODA)

The FFT OCDS Debug Access (FFT_ODA) register is cleared by Debug Reset and by each System Reset when OCDS is disabled. It is not affected by System Reset when OCDS is enabled.

This register is used to control whether or not register bits which change state on read do so when read by the on-chip debug system.

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_ODA
FFT OCDS Debug Access Register (00E4$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
DDREN	0	rw	**Destructive Debug Read Enable** *Note: For details see **Table 29-6*** 0_B Destructive read for debug read accesses are disabled 1_B Destructive read for debug read accesses are enabled
DRDIS	1	rw	**Destructive Read Disable** *Note: For details see **Table 29-6*** 0_B Destructive reads for read accesses are allowed. 1_B Destructive reads for read accesses are disabled
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Table 29-6 Destructive Read Control encoding

DRDIS	DDREN	Description
0	0	Destructive read access are enabled for all masters except the OCDS master.
0	1	Destructive read access are enabled for all masters
1	-	Destructive read access are disabled for all masters

FFT OCDS Control and Status Register (FFT_OCS)

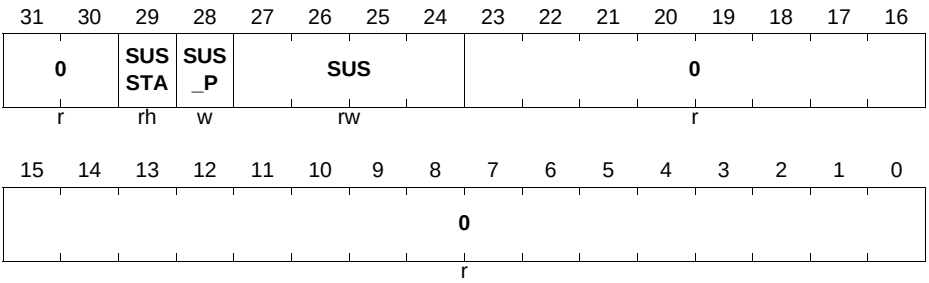
The FFT OCDS Control and Status (FFT_OCS) register is cleared by Debug Reset and by each System Reset when OCDS is disabled. It is not affected by System Reset when OCDS is enabled (signal eec_reset_n_i).

The FFT_OCS control register bits are only effective while the system is in debug mode. While not in debug mode, OCS reset values/modes are effective.

When a triggered by a high level on the suspend signal, the FFT/IFFT calculation will be halted as soon as practicable. Operation should resume when the suspend input is cleared.

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_OCS
FFT OCDS Control and Status (00E8$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS). 0_H Will not suspend 1_H Reserved for Hard suspend which is not implemented. 2_H Soft suspend (Halt Mode) **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended

Field	Bits	Type	Description
0	23:0, 31:30	r	**Reserved** Read as 0; must be written with 0.

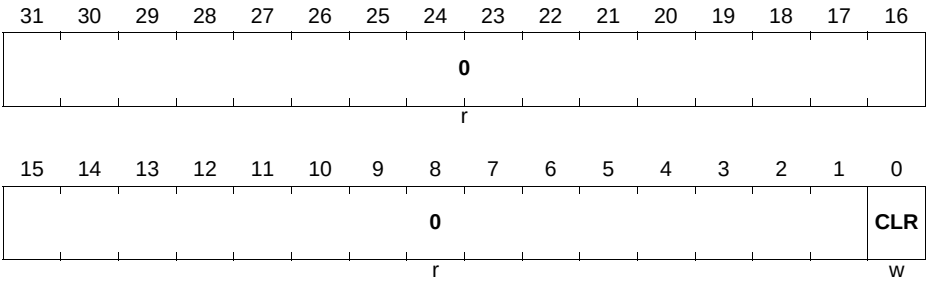
29.1.9.6 FFT Kernel Reset Registers

FFT Kernel Reset Status Clear Register (FFT_KRSTCLR)

The FFT Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_KRSTCLR
FFT Kernel Reset Status Clear Register(00EC$_H$) **Reset Value: 0000 0000$_H$**



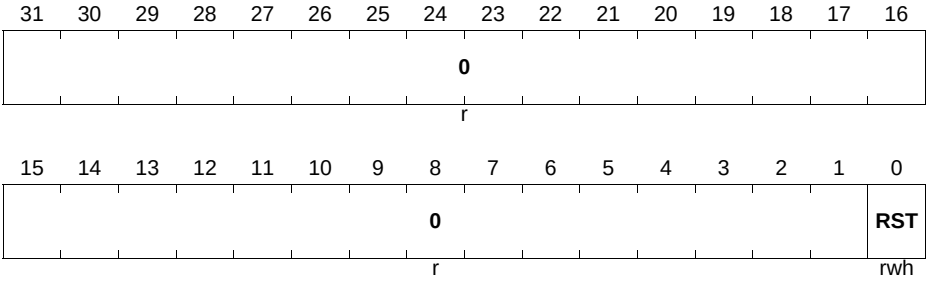
Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** *Note: Read always as 0_B.* 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT
0	31:1	r	**Reserved** Read as 0_B; should be written with 0_B.

FFT Kernel Reset Register 1 (FFT_KRST1)

The FFT Kernel Reset function is used to synchronously reset all the FFT Engine registers (except those connected to Debug reset) and the FFT Engine operation. To activate the kernel reset, it is necessary to set the RST bits by writing the value 1_B in both Kernel Reset Registers. The RST bit will be reset by hardware at the end of the kernel reset sequence.

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_KRST1
FFT Kernel Reset Register 1 **($00F0_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers are set. The RST bit will be cleared (re-set to 0_B) after the kernel reset is executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0_B; should be written with 0_B.

FFT Kernel Reset Register 0 (FFT KRST0)

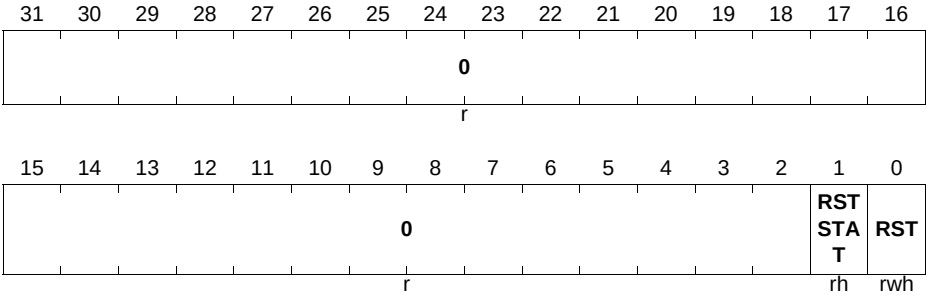
The FFT Kernel Reset function is used to synchronously reset all the FFT Engine registers (except those connected to Debug Reset) and the FFT Engine operation. To activate the kernel reset, it is necessary to set the RST bits by writing the value 1_B in both Kernel Reset Registers. The RST bit will be reset by hardware at the end of the kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to 1_B in the same clock cycle the RST bit is reset. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

During the execution of the kernel reset; until RSTSTAT is set, all write accesses to the kernel registers will result in an error acknowledge.

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_KRST0
FFT Kernel Reset Register 0 (00F4$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (reset to 0_B) b after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates whether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle both reset bits are cleared (FFT_KRST0.RST and FFT_KRST1.RST). This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

29.2 Extended Memory (EMEM)

The Extended Memory (EMEM) contains RAM blocks (Tiles) which can be used as global memory. It has interfaces to the LMU and the BBB. The EMEM architecture is similar to the EMEM of the Emulation Devices (ED).

Applications:

- Data and program code storage
- FFT data buffering
- Image buffering

Features:

- 512 Kbyte RAM in total
- Concurrent access from LMU and BBB to different tiles possible
- BBB burst transfers supported
- ECC with SECDED (Single Error Correction, Double Error Detection)

29.2.1 Block Diagram

The Extended Memory consists of a regular memory array (ADM - Application Data Memory) build out of 64 Kbyte RAM Tiles. Additionally on certain products of the family the optional extension memories XAM is offered.

The Extended Memory provides two internal interfaces:

- LMU Interface
- BBB Interface with master and slave interface

The two interfaces allow a concurrent access to two different Tiles.

29.2.1.1 Extended Application Memory (XAM)

The XAM feature is a family concept for products, which require more than 1 MB Application RAM. The first EMEM RAM block (ADM) is partitioned into 16 Tiles. The following XAM EMEM block is without partitioning. A wrapper routes the accesses to ADM or XAM as a single continuous address range. The availability of XAM for different members of the product family is listed in **Table 29-7**.

29.2.1.2 Family Overview

Figure 29-4 shows an EMEM configuration example and **Table 29-7** the Extension Memory configurations for the different products of the family.

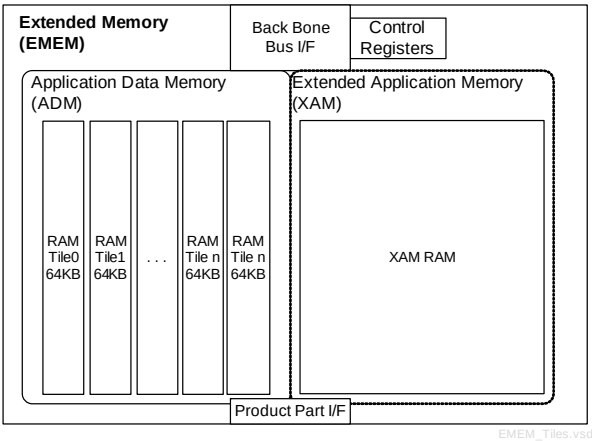


Figure 29-4 EMEM Configuration Example with ADM, XAM Tiles

Table 29-7 Extension Memory availability for the Product Family

Product	Total RAM Size	ADM Size	XAM Size	XAM Addr. LMU/BBB
TC29x	2048 KB	1 MB	1 MB	xx10 0000[1)]
TC27x	1024 KB	1 MB	-	-
TC26x	512 KB	512 KB	-	-
TC24x	256 KB	256 KB	-	-
TC23x	512 KB	512 KB	-	-

1) More information can be found in **Table 29-9**.

29.2.2 Operational Overview

The Extended Memory as a whole can be in Standby Locked Mode or in Enabled Mode.

Immediately after Power On Reset, the entire Extended Memory is in Unused Mode, thus the Tiles are not yet reserved for application mode. At any time, each Tile can be individually assigned to Application or again Unused Memory by setting its mode.

If a Tile has to be configured to Application Mode to activate the Extended Memory for the application.

This two step approach with selecting the global assignment for the Extended Memory of a Tile first and then operating it supports a safe operation.

Note: Before using the EMEM the boundary to this memory must be enabled by de-asserting the OSCU control bit OSTATE.EECDIS. Failing to do so will result in a hang-up of the CPU/DMA on the first read access to the EMEM.

Tile in Unused Mode

After Power On Reset, the Tiles are still in Unused Mode and are not yet reserved. They cannot be accessed before being assigned to Extended Memory by software. Later on, each Tile can be individually returned to Unused Memory space.

Tile in Application Mode

A RAM Tile in Application Mode can be accessed from the LMU or the BBB. The arbitration for concurrent accesses is done within the Extended Memory by delaying the BBB access.

Simultaneous Accesses

Up to two different Tiles can be accessed in parallel via the two interfaces, if these Tiles are configured in Application mode.

29.2.3 Extended Memory

By writing to Register **TILECONFIG**, unused Tiles can be assigned to Extended Memory. In Application Mode, write and read accesses can be performed by the LMU or BBB interfaces in arbitrary sequence. The arbitration is done internally with higher priority for the LMU interface.

29.2.4 Access Error Generation

If a Tile is accessed over an interface which is not supported in the current mode of the Tile, an error is signalled to the access initiator.

Any access attempt to RAM or a register during Standby Locked Mode is answered with an access error.

Table 29-8 Error Signaling for RAM Accesses

	LMU I/F	BBB I/F
Application Mode	Ok[1)]	Ok[1)]

1) If an ECC error is detected, an access error is signalled to the corresponding interface. If the width of a write access is smaller than the addressed memory word, an internal read-modify-write access is performed which potentially results in an ECC error for the read part. An ECC error is also generated, if a RAM location was not initialized before!

In Locked Mode, the registers **CLC**, **ID**, and **SBRCTR** are accessible via the LMU through the BBB master interface, access to other registers raises an error.

29.2.5 Tiles and RAM Address Ranges

The Extended Memory (ADM RAM area) can be accessed from two interfaces:

- LMU Interface
- BBB Interface

Accesses to the Extended Memory via the LMU are done by one of the CPUs or other SRI bus masters. To cater for cached/non-cached access the Extended Memory is mapped to two segments by the LMU.

The addressing of ADM and XAM depends on the interface. LMU and BBB have the same addressing view, just with a different base address.

The LMU/BBB addressing is based on the 1 MB ADM address area, followed by XAM always starting at the 1 MB address.

Assignment of Tiles to Trace Memory usually starts with Index 0 (**Table 29-9**).

Table 29-9 EMEM Tiles and Address Ranges

Tile	LMU[1)] TC24x	BBB	SBDAP Address
t; (ADM) t=0…7	$sF0t0000_H$ $sF0tFFFF_H$	$AF0t0000_H$ $AF0tFFFF_H$	$000t0000_H$ $000tFFFF_H$

1) $s = B_H$: non-cached access by CPU, $s = 9_H$: cached access by CPU

For register accesses see **Table 29-10**.

Figure 29-5 shows TC29x and TC26x as an example.

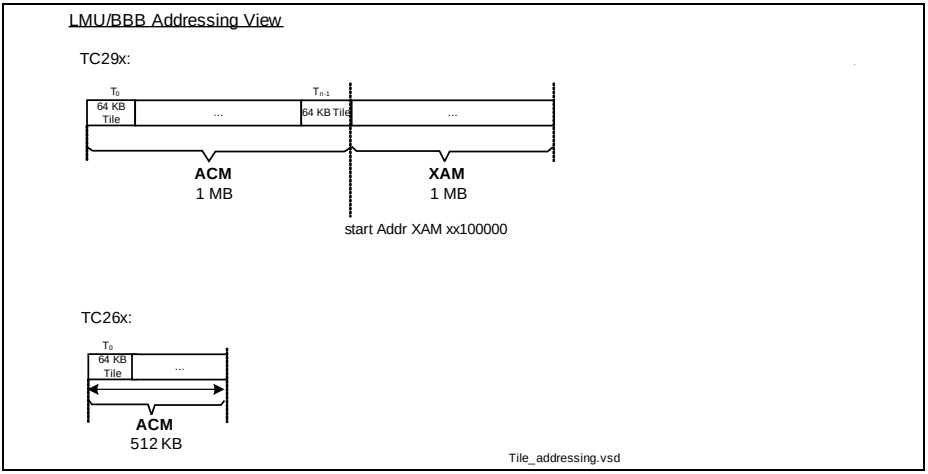

Figure 29-5 TCM and AXM interface addressing view.

More details about ADM and XAM addressing can be found in **Table 29-9**.

29.2.6 EMEM Initialization

After Power-on Reset the EMEM is locked and requires an unlock sequence similar to the EMEM of Emulation Device to get the memory initialized.

Unlocking the EMEM

To unlock EMEM, the following sequence is written to the **SBRCTR** register.

1. $0000\ 0002_H$,
2. $0000\ 0006_H$,
3. $0000\ 000E_H$

Writing any other value to **SBRCTR** before the complete sequence was written will reset the state machine, i.e. the sequence must be started again from the beginning. Writing to other registers however does not influence the sequence checker state machine.

The current state is signalled with bit **SBRCTR**.**STBLOCK**.

29.2.7 Usage Constraints

In this section assumptions are listed for using the EMEM module.

29.2.7.1 Clock Constraints

The clock for the BBB must not be faster than the EMEM clock. For the TC21x/TC22x/TC23x the LMU clock is equal to SRI clock.

29.2.7.2 BBB Interface

The BBB slave interface supports burst transfers, e.g. for image buffering.

29.2.8 Power Saving

In order to minimise power consumption, the clocks of inactive Tiles can be gated.

If clock gating is enabled (**SBRCTR**.ACGEN), all Tiles in Unused Mode are no longer clocked.

Tiles in Application are not gated directly. For this purpose they can first be set to Unused Mode.

The current clock gating status is individually indicated for each Tile (**SBRCTR**.ACGSTi).

29.2.9 EMEM Configuration

For power saving reasons, each tile is initially in unused mode. The register bits **TILECONFIG** allow to allocate the specific tiles as appliation memory.
The configuration state of each Tile is indicated in register **TILESTATE**.

29.2.10 EMEM Interfaces

As each Tile is arbitrated individually, transactions from the different interfaces into different Tiles are handled concurrently, i.e. up to two.

According to the word-lengths of the addressed RAM blocks, measures are taken for optimizing RAM accesses. Internal read-modify-write transactions are only required (due to ECC) if the word-length of data for the physical write access is smaller than the word-length of the memory.

29.2.10.1 LMU Interface

Read and write transactions are initiated by the LMU. Burst and read-modify-write transactions are not supported, but are split into basic and concatenated transactions.

Wide Read Transactions

Read accesses wider than the read-data word-length at the LMU are transformed into multi-beat transactions in subsequent cycles, taking into account wrapping around for unaligned addresses.

Concatenated read accesses of small words are not expected due to the wide-read access feature. If concatenated read accesses should occur anyhow, the EMEM processes them just like sequences of single read accesses without waiting for the master request to become inactive in between.

Concatenated Write Transactions

For write-widths smaller than the word-width of the memory, generally a complete memory word has to be synthesized before physically writing to memory, due to the required ECC which refers to complete memory words only. Whenever a write access is received from the LMU, a speculative read is immediately started and a ready signal returned to the LMU. In the next cycle, the read data is updated with the previous write data and written back, if the first write access is single. If instead another concatenated write transaction is received, the just obtained read data is not used, but the two subsequent write data portions are combined and written to memory. Thus, for a concatenated write, only the first of two consecutive write accesses causes a speculative internal read, because the protocol does not yet allow to decide for a first write, whether a second concatenated one is about to follow.

29.2.10.2 BBB Slave Interface

Transactions from the BBB to EMEM memory are initiated by any BBB master. In order to avoid internal read-modify-write accesses to EMEM-RAM, BBB write data received by the EMEM slave interface in burst operations is accumulated before being written into the memory. The EMEM control decides from the FPI opcode and the given memory word size whether a combination is possible or an internal read is required. These optimizations include unaligned burst transfers.

29.2.11 Feed-Through Transactions

The EEC must also be accessed from the product chip part. For this purpose, the EMEM feeds through transactions received from the LMU to the BBB Master Interface, if none of the EMEM's RAMs is addressed. Thus LMU and EMEM jointly act as bus-bridge between the SRI bus and the Backbone bus.

When acting as BBB Bus Master the EMEM tag and Supervisor Mode (SVM) is used.

29.2.11.1 EMEM Register Accesses

The SFRs of the EMEM are accessed via the BPI part of the BBB Slave Interface by any component connected to the BBB through a master interface, such as IOC32, and also the EMEM itself.

A register access from the product side is performed via LMU, the BBB Master Interface to the BBB, and from there via the BBB Slave Interface.

29.2.12 Address Map

All EMEM registers are prefixed "EMEM_" in the register map of the device.

EMEMoccupies an address window of 256 bytes. The relative register addresses in the register descriptions below are given as offset addresses to the base address of the window.

The base addresses for register accesses are identical for LMU and BBB. Internally in the EMEM, a window of 2 MB, addr[21:0] is available for addressing registers via BBB.

Note: This window is mapped to another segment when accessed via the SRI. Please, check production device address mapping to find the correct offset.

Access rights within the address range of EMEM:

- Read access to defined register addresses: U, SV
- Write access to defined register addresses: U, SV (no BE even if read-only register)
- Read access to empty addresses: No error (returns 0)
- Write access to empty addresses: BE
- Read or write when the kernel clock is turned off: BE (unless **CLC**)

Table 29-10 Registers Address Space

Module	Base Address	End Address	Note
EMEM	F90E 6000$_H$	F90E 60FF$_H$	CPU address

Table 29-11 Registers Overview

29.2.13 EMEM Register Description

As detailed in the OCDS chapter, several reset domains exist on TC21x/TC22x/TC23x. All registers of the EMEM module belong to the Power On Reset domain and are reset by PORST. The **CLC** register additionally belongs to the EEC Reset domain.

TILECONFIG
Tile Configuration Register **(20_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

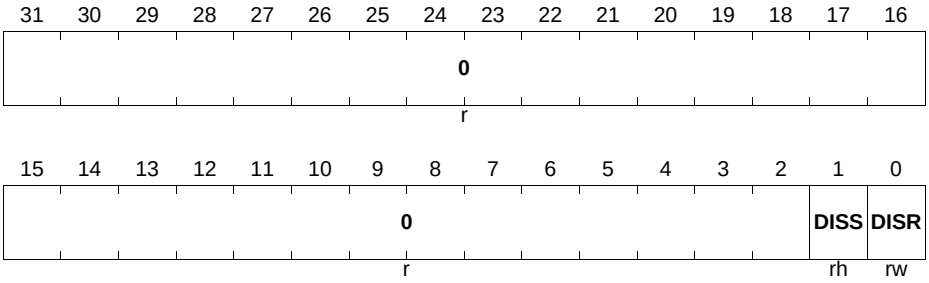
0			ACGEN		0		0		STBSLK				STBULK		STBLOCK
r			rw		r		r		w				w		rh

Field	Bits	Type	Description
STBLOCK	0	rh	**Lock Flag** Shows the current lock state of the Extended Memory. 0_B Extended memory is locked 1_B Extended memory is unlocked
STBULK	[3:1]	w	**Unlock Lock Flag** In order to unlock the Extended Memory in Locked Mode in three consecutive[1] cycles the following pattern have to be written into this bit field: • 001_B • 011_B • 111_B At the same time 0 has to be written always into bit field STBSLK. If any of STBSLK is set when writing a non-zero pattern to STBULK, this is treated as invalid pattern and the Extended Memory in Locked Mode will not be unlocked. Reading this bit field always will return 0s
STBSLK	[7:4]	w	**Set Lock Flag** In order to lock the Extended Memory in operating mode 1001_B has to be written into this bit field. At the same time 0 has to be written into the bit field STBULK. If any of bits STBULK is set when writing 1001_B to STBSLK, this is treated as invalid pattern and the Lock Flag is not set. Reading this bit field always will return 0s
ACGEN	12	rw	**Automatic Clock Gating Enabling** 0_B Disabled 1_B Enabled
ACGSTx (x = 0 - 7)	x +16	rh	**Automatic Clock Gating Status of Tile x** 0_B Clock off 1_B Clock on *Note: These bits are cleared automatically when entering Locked Mode.*
0	[11:9], 8, 15, [14:13], [31:24]	r	**Reserved** returns 0 if read; should be written with 0.

1) Intermediate read or write cycles not accessing **SBRCTR** are allowed.

CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Disable Request Bit** 0_B Module disable is not requested 1_B Module disable is requested
DISS	1	rh	**Disable Status Bit** 0_B Module enabled 1_B Module disabled
0	[31:2]	r	**Reserved** returns 0 if read; should be written with 0

The clock control register allows to switch the memory subsystem on or off. After Power On Reset the memory subsystem is disabled. The memory subsystem can be enabled by clearing bit DISR. It is ensured that the **CLC** is still writable when the clock is switched off.

30 Ethernet MAC (ETH)

This chapter describes the Ethernet MAC [1) 2)] of the TC21x/TC22x/TC23x.

30.1 Overview

Figure 30-1 shows the basic structure of the module:

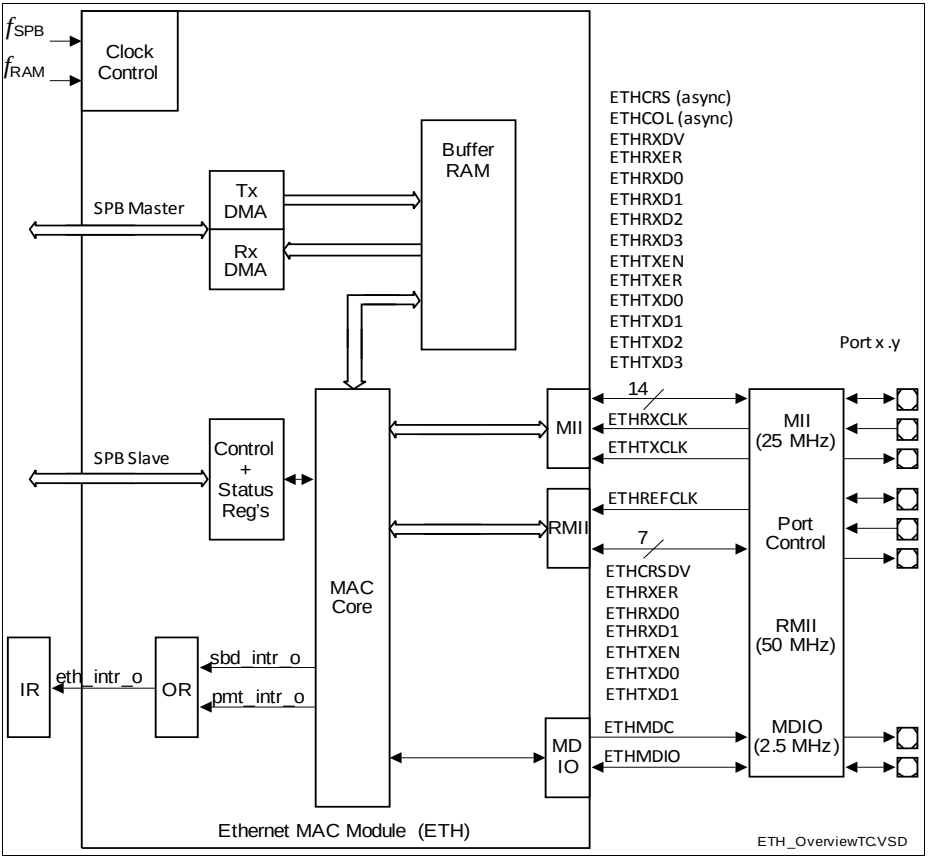

Figure 30-1 Ethernet MAC Module Overview

1) Excerpted portions are Synopsys Proprietary. Used with permission.

2) Module is not available in some variants. In these variants registers are still accessible but functionality cannot be guaranteed.

30.1.1 General Module Description

The DWC Ether MAC 10/100/1000 Universal, V3.7a, commonly referred to as GMAC-UNIV in this document, enables a host to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2002 standard. In TC21x/TC22x/TC23x it is configured to support 10 and 100 Mbit modes. Note that Gigabit mode is not configured, nevertheless the core is referred to as GMAC to avoid confusion with other cores.

The GMAC-UNIV provides an optimized (with respect to gate count and latency), configurable, flexible product to meet the needs of various applications and customers, and supports a multitude of industry standard interfaces to the PHY: Media Independent Interface (MII) defined in the IEEE 802.3 specifications and Reduced Media Independent Interface (RMII).The GMAC-AHB is designed to interface to the industry standard AMBA High-Performance Bus (AHB) on the application side. In TC21x/TC22x/TC23x an adaptation logic interfaces to the SPB bus.

The GMAC-UNIV is compliant to the following standards:

- IEEE 802.3-2002 for Ethernet MAC
- IEEE 1588-2008 standard for precision networked clock synchronization
- RMII specification from RMII consortium
- MII specification IEEE 802.3

Note: Although the naming convention used in this databook and the source code indicate “GMAC,” the databook is also applicable to the 10/100 Universal product.

30.1.2 System Overview

30.1.2.1 System-Level Block Diagram

A system-level block diagram is shown in **Figure 30-2**.

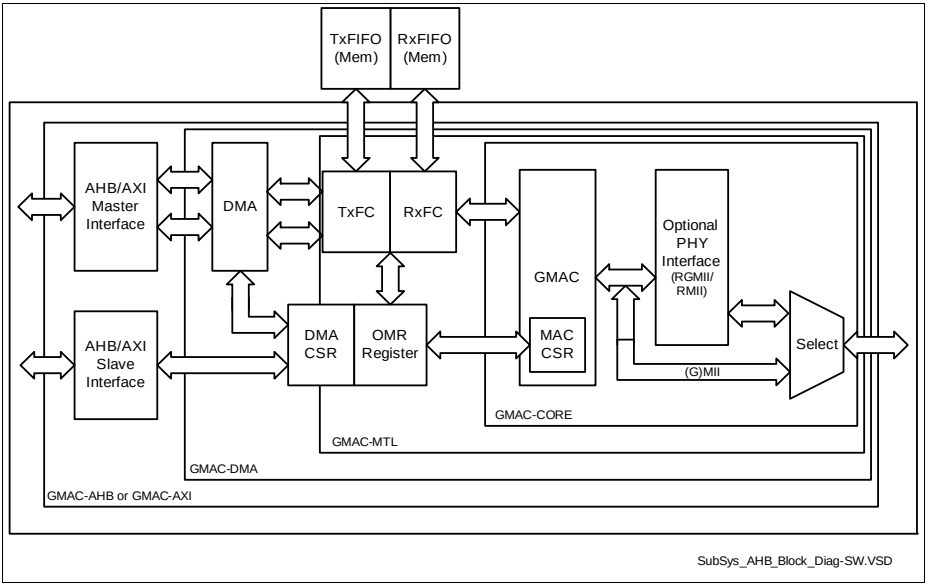

Figure 30-2 GMAC-UNIV Block Diagram

30.1.2.2 Interfaces

The GMAC-AHB transfers data to system memory through the AHB master interface. The host CPU uses the default 32-bit AHB Slave interface to access the GMAC subsystem's Control and Status registers (CSRs).

The GMAC-UNIV supports the following PHY interfaces:

- Media Independent Interface (MII)
- Reduced MII (RMII)

30.1.2.3 Transmit and Receive FIFOs

The Transmit FIFO (Tx FIFO) buffers data read from system memory by the DMA before transmission by the GMAC Core. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they are transferred to system memory by

the DMA. These are asynchronous FIFOs, as they also transfer the data between the application clock and the GMAC line clocks.

Tx/Rx FIFOs are 32 bits wide and 4/4 kByte deep.

30.1.3 Features List

The GMAC-UNIV includes the following features, listed by category.

30.1.3.1 GMAC Core Features

- Supports 10/100-Mbit/s data transfer rates with the following PHY interfaces
  - IEEE 802.3-compliantRMII/MII (default) interface to communicate with an external Fast Ethernet PHY
- Supports both full-duplex and half-duplex operation
  - Supports CSMA/CD Protocol for half-duplex operation
  - Supports IEEE 802.3x flow control for full-duplex operation
  - Optional forwarding of received pause control frames to the user application in full-duplex operation
  - Back-pressure support for half-duplex operation
  - Automatic transmission of zero-quanta pause frame on deassertion of flow control input in full-duplex operation
- Preamble and start-of-frame data (SFD) insertion in Transmit, and deletion in Receive paths
- Automatic CRC and pad generation controllable on a per-frame basis
- Options for Automatic Pad/CRC Stripping on receive frames
- Programmable frame length to support Standard or Jumbo Ethernet frames with sizes up to 16 KB
- Programmable InterFrameGap (40-96 bit times in steps of 8)
- Supports a variety of flexible address filtering modes:
  - Up to 31 additional 48-bit perfect (DA) address filters with masks for each byte
  - Up to 31 48-bit SA address comparison check with masks for each byte
  - 64-bit Hash filter (optional) for multicast and uni-cast (DA) addresses
  - Option to pass all multicast addressed frames
  - Promiscuous mode support to pass all frames without any filtering for network monitoring
  - Passes all incoming packets (as per filter) with a status report
- Separate 32-bit status returned for transmission and reception packets
- Supports IEEE 802.1Q VLAN tag detection for reception frames
- Separate transmission, reception, and control interfaces to the Application
- Supports 32-bit data transfer interface on the system-side
- Complete network statistics (optional) with RMON/MIB Counters (RFC1757/RFC2819/RFC2665). It is completely under control of higher protocol level (SW) to make use of these counters.
- MDIO Master interface for PHY device configuration and management, e.g. for switching the PHY in external loopback mode.

- Optional module for detection of LAN wake-up frames and AMD Magic Packet frames
- Optional Receive module for checksum off-load for received IPv4 and TCP packets encapsulated by the Ethernet frame
- Optional Enhanced Receive module for checking IPv4 header checksum and TCP, UDP, or ICMP checksum encapsulated in IPv4 or IPv6 datagrams.
- Optional module to support Ethernet frame time stamping as described in IEEE 1588-2008. Sixty-four-bit time stamps are given in each frame's transmit or receive status.

30.1.3.2 DMA Block Features

The DMA block exchanges data between the MTL block and host memory. A set of registers (DMA CSR) to control DMA operation is accessible by the host.

DMA features include:

- 32-bit data transfers
- Single-channel Transmit and Receive engines
- Fully synchronous design operating on a single system clock (except for CSR module, when a separate CSR clock is configured)
- Optimization for packet-oriented DMA transfers with frame delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptor architecture, allowing large blocks of data transfer with minimum CPU intervention; each descriptor can transfer up to 8 KB of data
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst size (SINGLE, INCR4/8, not supported by the System: INCR of undefined length) for Transmit and Receive DMA Engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-frame Transmit/Receive complete interrupt control
- Round-robin or fixed-priority arbitration between Receive and Transmit engines
- Start/Stop modes
- Separate ports for host CSR access and host data interface

30.1.3.3 Transaction Layer (MTL) Features

The MTL block consists of two sets of FIFOs: a Transmit FIFO with programmable threshold capability, and a Receive FIFO with a configurable threshold (default of 64 bytes).

MTL features include:

- 32--bit Transaction Layer block providing a bridge between the application and the GMAC-CORE

- Single-channel Transmit and Receive engines
- Data transfers executed using simple FIFO-protocol
- Synchronization for all clocks in the design (Transmit, Receive and system clocks)
- Optimization for packet-oriented transfers with frame delimiters
- Four Separate ports for system-side and GMAC-CORE-side transmission and reception
- Two RAM-based asynchronous FIFOs with synchronous/asynchronous Read and Write operation with respect to the Read and Write clocks (one for transmission and one for reception)
- Receive Status vectors inserted into the Receive FIFO after the EOF transfer enables multiple-frame storage in the Receive FIFO without requiring another FIFO to store those frames' Receive Status.
- Configurable Receive FIFO threshold (default fixed at 64 bytes) in Cut-Through mode
- Option to filter all error frames on reception and not forward them to the application in Store-and-Forward mode
- Option to forward under-sized good frames
- Supports statistics by generating pulses for frames dropped or corrupted (due to overflow) in the Receive FIFO
- Supports Store and Forward mechanism for transmission to the GMAC core
- Supports threshold control for transmit buffer management
- Supports configurable number of frames to be stored in FIFO at any time. The default is up to 8 frames in GMAC-MTL configuration.
- Automatic generation of PAUSE frame control or backpressure signal to the GMAC core based on Receive FIFO-fill (threshold configurable) level.
- Handles automatic retransmission of Collision frames for transmission
- Discards frames on late collision, excessive collisions, excessive deferral and underrun conditions
- Software control to flush Tx FIFO
- Data FIFO RAM chip-select disabled when inactive, to reduce power consumption
- Optional module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum in frames transmitted in Store-and-Forward mode.

30.1.3.4 Monitoring, Test, and Debugging Support Features

- Supports internal loopback on the MII for debugging
- external loopback is supported via the integrated MDIO controlling the PHY
- DMA states (Tx and Rx) given as status bits
- Debug status register that gives status of FSMs in Transmit and Receive data-paths and FIFO fill-levels.
- Application Abort status bits
- MMC (RMON) module in the GMAC core
- Current Tx/Rx Buffer pointer as status registers
- Current Tx/Rx Descriptor pointer as status registers

30.2 Architecture

30.2.1 Introduction

The GMAC-UNIV is a highly configurable product with multiple interfaces to the system side or the PHY side. Major modules and functions are only selected when required. A block diagram of the GMAC-UNIV's system configuration is provided in **Figure 30-3**.

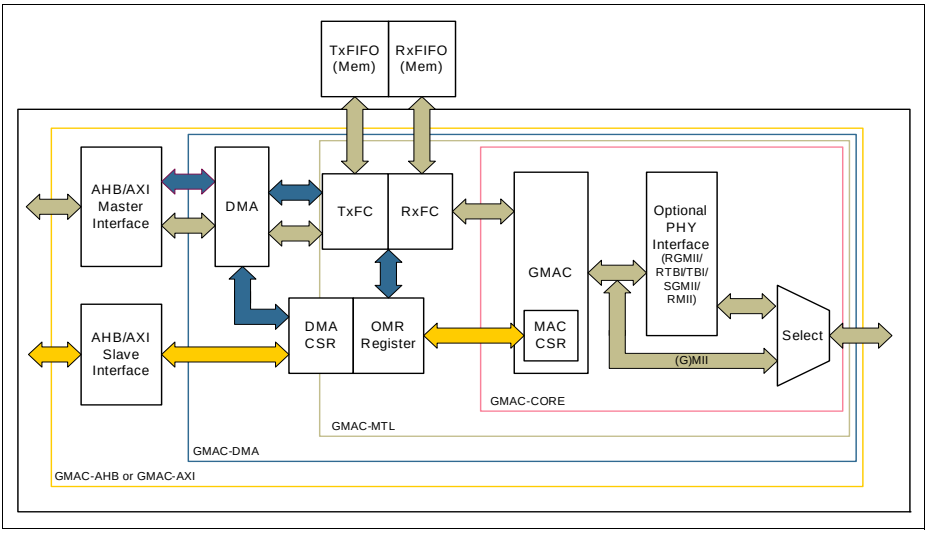

Figure 30-3 GMAC-UNIV Block Diagram

The following sections describe the functionality of the major blocks and timing behavior of the interfaces.

- **Section 30.2.2** provides an overview of precision network time synchronization using the Precision Time Protocol established under the IEEE 1588 standard.
- **Section 30.2.3** describes the functionality of the AHB interfaces in GMAC-AHB configuration
- **Section 30.2.4** describes the functioning of the DMA.
- **Section 30.2.5** explains the functioning of the MAC Transaction Layer (MTL) module which controls the Receive and Transmit FIFO memories.
- **Section 30.2.6** describes the functionality of the (G)MAC core transmitter and receiver.
- **Section 30.2.7**, **Section 30.2.8**, and **Section 30.2.8** describe the optional RMON, Power Management, and SMA interface modules.
- **Section 30.2.11** describes the Interrupt signal structure in the (G)MAC core.

30.2.2 IEEE 1588-2002 Overview

The IEEE 1588 standard defines a protocol enabling precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The protocol applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The messaged-based protocol, named Precision Time Protocol (PTP), is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing/clock information. The protocol's technique for synchronizing a slave node to a master node by exchanging PTP messages is depicted in **Figure 30-4**.

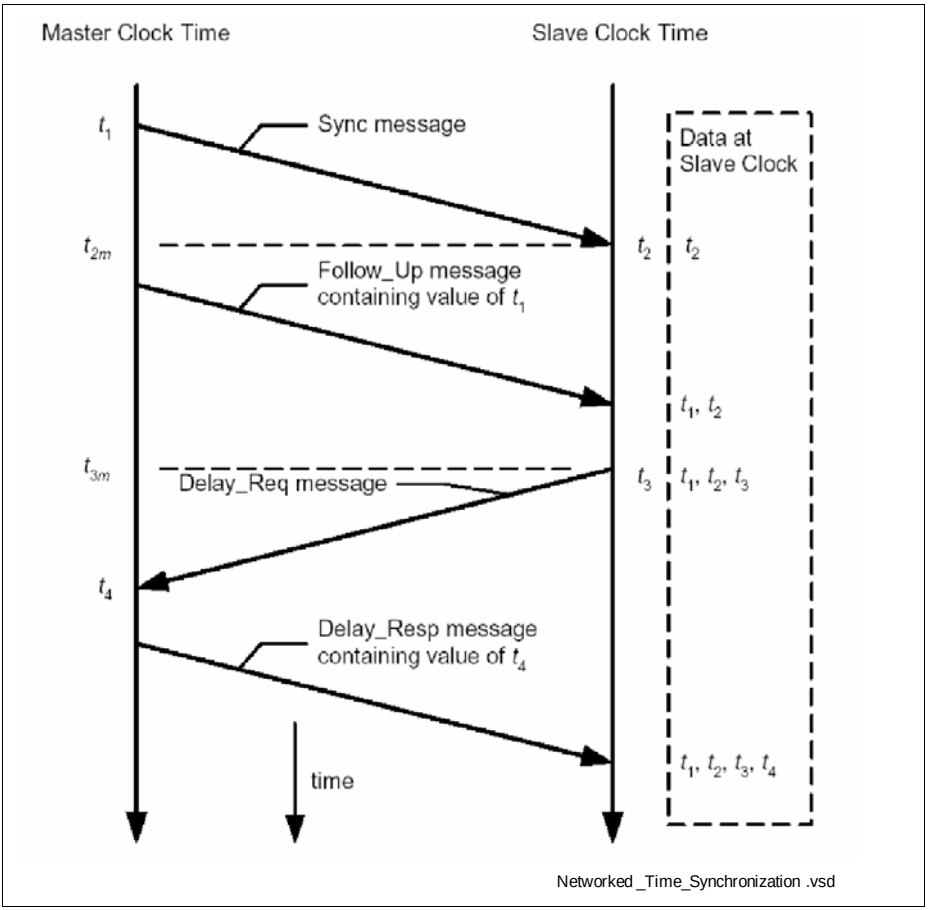

Figure 30-4 Networked Time Synchronization

1. The master broadcasts PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t1 and must, for Ethernet ports, be captured at the MII.
2. A slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master then sends the slave a Follow_up message, which contains t1 information for later use.
4. The slave sends the master a Delay_Req message, noting the exact time, t3, at which this frame leaves the MII.

5. The master receives this message, capturing the exact time, t4, at which it enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the protocol implementation occurs in the software, above the UDP layer. As described above, however, hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.

30.2.2.1 Reference Timing Source

To get a snapshot of the time, the core requires a reference time in 64-bit format (split into two 32-bit channels, with the upper 32-bits providing time in seconds, and the lower 32-bits indicating time in nanoseconds) as defined in the IEEE 1588 specification.

Internal Reference Time

This takes only the reference clock input and uses it to generate the Reference time (also called the System Time) internally and use it to capture time stamps. The generation, update, and modification of the System Time are described in **System Time Register Module**.

30.2.2.2 Transmit Path Functions

When a frame's SFD is output on the MII, a time stamp is captured. Frames for which capturing a time stamp is required are controllable on a per-frame basis. In other words, each transmit frame can be marked to indicate whether or not a time stamp must be captured for that frame.

No snooping or processing of the transmitted frames is performed to identify PTP frames. Framewise control is exercised through control bits in the transmit descriptor (as described in **Descriptor Format With IEEE 1588 Time Stamping Enabled**).

Captured time stamps are returned to the application in a manner similar to that in which status is provided for frames. The time stamp is returned to software inside the corresponding transmit descriptor, thus connecting the time stamp automatically to the specific PTP frame. The 64-bit time stamp information is written back to the TDES2 and TDES3 fields, with TDES2 holding the time stamp's 32 least significant bits, except as described in **Transmit Time Stamp Field**.

Note: When the alternate (enhanced) descriptor is selected, the 64-bit time-stamp is written in TDES6 and TDES7, respectively

30.2.2.3 Receive Path Functions

When the IEEE 1588 time-stamping feature is selected and enabled, the Ethernet MAC captures the time stamp of all frames received on the MII. No snooping or processing of the received frames is performed to identify PTP frames in the default mode (Advanced Time Stamp feature is not selected).

The core returns the time-stamp to the software in the corresponding receive descriptor. The 64-bit time stamp information is written back to the RDES2 and RDES3 fields, with RDES2 holding the time stamp's 32 least significant bits, except as mentioned in **Receive Time Stamp** The time stamp is only written to the receive descriptor for which the Last Descriptor status field has been set to 1 (the EOF marker). When the time stamp is not available (for example, due to an RxFIFO overflow) an all-ones pattern is written to the descriptors (RDES2 and RDES3), indicating that time stamp is not correct. If the software uses a control register bit to disable time stamping, the DMA does not alter RDES2 or RDES3.

Note: When the alternate (enhanced) descriptor is selected, the 64-bit time-stamp is written in RDES6 and RDES7, respectively. RDES0[7] will indicate whether the time-stamp is updated in RDES6/7 or not.

30.2.2.4 Time Stamp Error Margin

According to the IEEE 1588 specifications, the time stamp must be captured at the SFD of transmitted and received frames at the MII interface. Since the reference timing source (the PTP clock, clk_ptp_ref_i) is different from the MII clocks, a small error margin is introduced, due to the transfer of information across asynchronous clock domains.

In the transmit path, the captured and reported time stamp has a maximum error margin of 2 PTP clocks. In other words, the captured time stamp has the value of the reference time source given within 2 clocks after the SFD has been transmitted on the MII.

Similarly, on the receive path, the error margin is 3 MII clocks, plus up to 2 PTP clocks. You can ignore the error margin due to the 3 MII clocks by assuming that this constant delay is present in the system (or link) before the SFD data reaches the GMAC's MII interface.

30.2.2.5 Frequency Range of Reference Timing Clock

Because asynchronous logic is in place for time stamp information transfers across clock domain, a minimum delay is required between two consecutive time stamp captures. This delay is 3 clock cycles of both the MII and PTP clocks. If the gap is shorter, the GMAC does not take a time stamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time and the timing constraints achievable for logic operating on the PTP clock. Another factor to consider is that the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Hence, a higher PTP clock

frequency gives better system performance. The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the MII clock frequency is fixed by IEEE specification, the minimum PTP clock frequency required for proper operation depends on the core's operating mode and operating speed.

For example, in 100 Mbit/s full-duplex operation, the minimum gap between two SFDs is 160 MII clocks (128 clocks for a 64-byte frame + 24 clocks of min IFG + 8 clocks of preamble).

In the example, (3 x PTP) + (3 x MII) ≤ 160 x MII; thus, the minimum PTP clock frequency is about 0.5 MHz ((160 - 3) x 40 ns / 3 = 2.093 ns period)

30.2.2.6 Advanced Time Stamp Feature Support

In addition to the basic features for time stamp mentioned in **IEEE 1588-2002 Overview**, the advanced time stamp option has the following features.

- Support for the IEEE 1588-2008 (Version 2) timestamp format.
- Option to take snapshot for all frames or for PTP type frames.
- Option for taking snapshot for event messages only.
- Option to take the snapshot based on the clock type (ordinary, boundary, end-to-end and peer-to-peer)
- Option to select the node to be a Master or Slave for ordinary and boundary clock.
- Identification of PTP message type, version, and PTP payload sent directly over Ethernet given as status.
- Option to measure time in digital or binary format.

Peer-to-Peer PTP (Pdelay) Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports Pdelay message in addition to SYNC, Delay Request, Follow-up and Delay Response messages. **Figure 30-5** shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

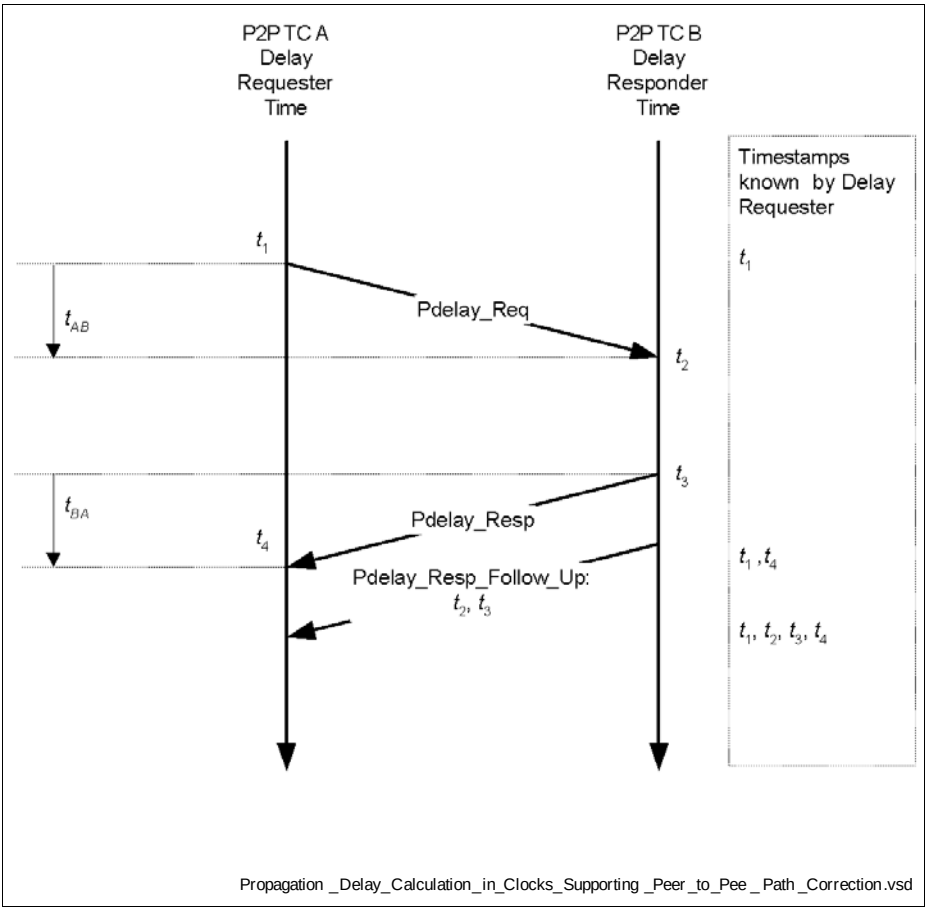

Figure 30-5 Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

The link delay measurement starts with port-1 issuing a “Pdelay_Req” message and generating a timestamp, for the Pdelay_Req message. Port-2 receives the “Pdelay_Req” message and generates a timestamp, t2, for this message. Port-2 returns a Pdelay_Resp message and generates a timestamp, t3, for this message. To minimize errors due to any frequency offset between the two ports, Port-2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message.

Port-2 either:

- Returns the difference between the timestamps t2 and t3 in the Pdelay_Resp message,
- Returns the difference between the timestamps t2 and t3 in a Pdelay_Resp_Follow_Up message, or
- Returns the timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.

Port-1 generates a timestamp, t4, upon receiving the Pdelay_Resp message. Port-1 then uses these four timestamps to compute the mean link delay.

Clock Types

The type of clock nodes supported in IEEE 1588-2008 is described in this section. The corresponding support provided by the advanced time stamp feature for each of the clock type is also mentioned.

1. Ordinary clock support: In this type the clock can be a grandmaster or a slave clock. This clock has a single PTP state.
   Table 30-1 shows the messages for which time-stamp snapshot is taken on the receive side for Master and Slave nodes.
   The ordinary clock in the domain supports a single copy of the protocol and has a single PTP state and will typically be a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as sensors and actuators. In telecom applications, the ordinary clock may be associated with a timing demarcation device.
   Typically for ordinary clock, you will need to take snapshot for only one type of PTP messages. For e.g. you will require supporting either version 1 or 2 PTP messages, not both.
   The following features are supported.
   a) Sends and receives PTP messages. The time stamp snapshot can be controlled as described in **32-bit Register - Timestamp_Control**.
   b) Maintains the data sets (e.g., time stamp values).
2. Boundary clock support: This type of clock is similar to the ordinary clock except for the following.
   Hence the features of ordinary clock holds good for the boundary clock also.
   The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy and signaling terminate in the protocol engine of the boundary clock and are not forwarded. The PTP message type status given by the core (refer to **Receive Path Functions**) will help you to quickly identify the type of message and take appropriate action.
   a) The clock data sets are common to all ports of the boundary clock
   b) The local clock is common to all ports of the boundary clock.
3. End to end transparent clock support: The end-to-end transparent clock forwards all messages like normal bridge, router or repeater. The resident time needs to be

computed to update the correctionField. Hence snapshot needs to be taken for the messages mentioned in **Table 30-2**.

In the end-to-end transparent clock, the residence times are accumulated in a special field (correctionField) of the PTP event (SYNC) message or the associated Follow-up (FOLLOW_UP) Message. Hence it is important to take a snapshot for these messages alone. This can be quickly done by setting the control bit (TSEVNTENA), which enables snapshot to be taken for event messages and also selecting the type of clock in the “Time Stamp Control Register”.

The residence time is also corrected for Delay_Req messages (but snapshot of the timestamp is not required). The message type statuses provided helps you to quickly identity the message and update the correctionField.

The message type status provided will also help in taking appropriate action depending on the type of PTP message received.

4. Peer to peer transparent clock support: In this type of clock the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp and Pdelay_Resp_Follow_Up messages with the link peer. Hence support for taking snapshot for the event messages related to Pdelay is added. **Table 30-3**.

   The transparent clock corrects only the SYNC and Follow-up message. As discussed earlier this can be achieved using the message status provided.

   The type of clock to be implemented will be configurable through control register, as mentioned in **32-bit Register - Timestamp_Control**. To ensure that the snapshot is taken only for the messages indicated in the table for the corresponding clock type, the “TSEVNTENA: Enable Time Stamp Snapshot for Event Messages” bit has to be set.

Table 30-1 PTP Messages for which Snapshot is Taken on Receive Side for Ordinary Clock

PTP Processing and Control

The common message header for PTP messages is shown below. This format is taken from IEEE standard 1588-2008 (Revision of IEEE Std. 1588-2002).

Table 30-4 Message Format Defined in IEEE 1588-2008

BITS		OCTETS	OFFSET
transportSpecific	messageType	1	0
Reserved	versionPTP	1	1
messageLength		2	2
domainNumber		1	4
Reserved		1	5
flagField		2	6
correctionField		8	8
Reserved		4	16
sourcePortIdentity		10	20
sequenceId		2	30
controlField[1)]		1	32
logMessageInterva		1	33

1) controlField is used in version 1. For version 2, messageType field will be used for detecting different message types.

There are some fields in the PTP frame that are used to detect the type and control the snapshot to be taken. This is different for PTP frames sent directly over Ethernet, PTP frames sent over UDP / IPv4 and PTP frames that are sent over UDP / IPv6. The following sections provide information on the fields that are used to control taking the snapshot.

PTP Frame Over IPv4

Table 30-5 gives the details of the fields that will be matched to control snapshot for PTP packets over UDP over IPv4 for IEEE 1588 version 1 and 2. Note that the octet positions

for tagged frames will be offset by 4. This is based on Appendix-D of the IEEE 1588-2008 standard and the message format defined in **Table 30-4**.

Table 30-5 IPv4-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x0800	IPv4 datagram
IP Version and Header Length	14	0x45	IP version is IPv4
Layer-4 protocol	23	0x11	UDP
IP Multicast address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0,0x00, 0x01,0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed. 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP-primary multicast address: 224.0.1.129 PTP-Pdelay multicast address: 224.0.0.107
UDP destination port	36, 37	0x013F, 0x0140	0x013F – PTP event message[1)] 0x0140 – PTP general messages
PTP control field (IEEE version 1)	74	0x00/0x01/0x02 /0x03/0x04	0x00 – SYNC, 0x01 – Delay_Req, 0x02 – Follow_Up 0x03 – Delay_Resp 0x04 – Management

Table 30-5 IPv4-UDP PTP Frame Fields Required for Control and Status (cont'd)

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE version 2)	42 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xB/0xC/0xD	0x0 – SYNC 0x1 – Delay_Req 0x2 – Pdelay_Req 0x3 – Pdelay_Resp 0x8 – Follow_Up 0x9 – Delay_Resp 0xA – Pdelay_Resp_Follow_Up 0xB – Announce 0xC – Signaling 0xD - Management
PTP version field	43 (nibble)	0x1 or 0x2	0x1 – Supports PTP version 1 0x2 – Supports PTP version 2

1) PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only).

PTP Frame Over IPv6

Table 30-6 gives the details of the fields that will be matched to control snapshot for PTP packets over UDP over IPv6 for IEEE 1588 version 1 and 2. Note that the octet positions for tagged frames will be offset by 4. This is based on Appendix-E of the IEEE 1588-2008 standard and the message format defined in **Table 30-4**.

Table 30-6 IPv6-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x86DD	IP datagram
IP version	14 (bits [7:4])	0x6	IP version is IPv6
Layer-4 protocol	20[1)]	0x11	UDP
PTP Multicast address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	PTP – primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex) PTP – Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)

Table 30-6 IPv6-UDP PTP Frame Fields Required for Control and Status (cont'd)

Field Matched	Octet Position	Matched Value	Description
UDP destination port	56, 57 (*)	0x013F, 0x140	0x013F – PTP event message 0x0140 – PTP general messages
PTP control field (IEEE 1588 Version 1)	93 (*)	0x00/0x01/0x02/ 0x03/0x04	0x00 – SYNC, 0x01 – Delay_Req, 0x02 – Follow_Up 0x03 – Delay_Resp 0x04 – Management (version1)
PTP Message Type Field (IEEE version 2)	74 (*) (nibble)	0x0/0x1/0x2/0x3/ 0x8/0x9/0xB/0xC /0xD	0x0 – SYNC 0x1 – Delay_Req 0x2 – Pdelay_Req 0x3 – Pdelay_Resp 0x8 – Follow_Up 0x9 – Delay_Resp 0xA – Pdelay_Resp_Follow_Up 0xB – Announce 0xC – Signaling 0xD - Management
PTP version field	75 (nibble)	0x1 or 0x2	0x1 – Supports PTP version 1 0x2 – Supports PTP version 2

1) The Extension Header is not defined for PTP packets.

PTP Frame Over Ethernet

Table 30-7 gives the details of the fields that will be matched to control snapshot for PTP packets over Ethernet for IEEE 1588 version 1 and 2. Note that the octet positions for tagged frames will be offset by 4. This is based on Appendix-E of the IEEE 1588-2008 standard and the message format defined in **Table 30-4**.

Table 30-7 Ethernet PTP Frame Fields Required for Control And Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x88F7	PTP Ethernet frame.
PTP control field (IEEE Version 1)	45	0x00/0x01/0x02/ 0x03/0x04	0x00 – SYNC 0x01 – Delay_Req 0x02 – Follow_Up 0x03 – Delay_Resp 0x04 – Management
PTP Message Type Field (IEEE version 2)	14 (nibble)	0x0/0x1/0x2/0x3/0x 8/0x9/0xB/ 0xC/0xD	0x0 – SYNC 0x1 – Delay_Req 0x2 – Pdelay_Req 0x3 – Pdelay_Resp 0x8 – Follow_Up 0x9 – Delay_Resp 0xA – Pdelay_Resp_Follow_Up 0xB – Announce 0xC – Signaling 0xD – Management
MAC Destination multicast address[1)]	0-5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All except peer delay messages - 01-1B-19-00-00-00 Pdelay messages - 01-80-C2-00-00-0E
PTP version field	15 (nibble)	0x1 or 0x2	0x1 – Supports PTP version 1 0x2 – Supports PTP version 2

1) In addition, the address match of destination addresses (DA) programmed in MAC address 1 to 31 will be used, if the control bit 18 (TSENMACADDR: Enable MAC address for PTP frame filtering) of the Time Stamp Control register is set.

Reference Timing Source (for Advance Timestamp Feature)

The updated functionality for advanced timestamp support is mentioned in the following points.

1. The IEEE 1588-2008 standard defines the seconds field of the time to be 48 bits wide. The fields to time-stamp will be the following.
   a) UInteger48- seconds field
   b) UInteger32-nanoseconds field
   The “seconds” field is the integer portion of the timestamp in units of seconds. The

"nanoseconds" field is the fractional portion of the timestamp in units of nanoseconds. E.g. 2.000000001 seconds is represented as secondsField = 0x0000_0000_0002 and nanoSeconds = 0x0000_0001. Thus the maximum value in nanoseconds field in this format will be 0x3B9A_C9FF value (i.e (10e9-1) nano-seconds). This is defined as digital rollover mode of operation. It will also support the older mode in which the nano-seconds field will roll-over and increment the seconds field after the value of 0x7FFF_FFFF. (Accuracy is ~0.466 ns per bit). This is defined as the binary rollover mode. The modes can be controlled using the "TSCTRLSSR: Time Stamp Digital or Binary rollover control" bit of the time stamp control register.

2. When the Advanced IEEE 1588 time-stamp feature is selected time maintained in the core will still be 64-bit wide, as the overflow to the upper 16-bits of seconds register happens once in 130 years. The value of the upper 16-bits of the seconds field can only be obtained from the CSR register. This is optional and can be controlled by the coreKit parameter "IEEE1588 Higher Word Register Enable" described in Chapter 6. A CSR status bit which indicates if the 32-bit "seconds" field has overflowed is also provided.
3. There is also a pulse-per-second output given to indicate 1 second interval (default). Option is provided to change the interval. Refer **32-bit Register - Timestamp_Control**. for more information.
4. Option to take auxiliary time-stamp snapshot with an external event is supported. Refer to section **Auxiliary Snapshot** for details.

Transmit Path Functions

There are no changes in the transmit path functions for GMAC-CORE and GMAC-MTL configuration for the Advanced time stamp option.

The structure of the descriptor changes when Advanced IEEE 1588 version support is enabled. The IEEE 1588 timestamp feature is supported using Alternate (Enhanced) descriptors format only. The descriptor is 32-bytes long (8 DWORDS) and the snapshot of the timestamp is written in descriptor 6 and 7.

Receive Path Functions

When the advanced time stamp feature is selected, processing of the received frames to identify valid PTP frames is done. The snapshot of the time to be sent to the application can be controlled.

The following options are provided in the time stamp control register to control the snapshot.

1. Option to enable snapshot for all frames.
2. Enable snapshot for IEEE 1588 version 2 or version 1 time stamp.
3. Enable snapshot for PTP frames transmitted directly over Ethernet or UDP-IP-Ethernet.

4. Enable time stamp snapshot for the received frame for IPv4 or IPv6.
5. Enable time stamp snapshot for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ or PDELAY_RESP) only.
6. Enable the node to be a Master or Slave. This will control the type of messages for which snap-shot will be taken (this depends on the type of clock that is selected and is valid for ordinary or boundary clock only).

Note that PTP messages over VLAN frames are also supported.

The time stamp is returned to the software inside the corresponding Transmit and Receive Descriptor. The Advanced time stamp feature is supported using Alternate (Enhanced) descriptors only which is 32-bytes long. Extended status containing the time stamp message status and the IPC offload status is written back in descriptor 4 and the snapshot of the time stamp is written back in descriptor 6 and 7. The complete details on the descriptors when the advanced time stamping is enabled are provided in **Alternate or Enhanced Descriptors**.

Auxiliary Snapshot

The auxiliary snap shot feature allows you to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the sideband signal ptp_aux_ts_trig_i. This feature is independent of whether the system time is generated internally or given as input (on ptp_timestamp_i bus). Such snap-shots are stored in a 4-deep FIFO. Only 64-bit of the time will be stored in the FIFO. The upper 16-bits of the seconds register can be read from “Time Stamp Higher Word Register” when it is present.

The storing of the snapshot can be indicated to the host with an interrupt. The value of the snapshot is read out through a FIFO register access (see **32-bit Register - Timestamp_Control**). When the FIFO becomes full and an external trigger to take the snapshot is asserted, then a snapshot trigger-missed status is set in the Time Stamp Status Register. This indicates that the latest auxiliary snapshot of the timestamp was not stored in the FIFO. The latest snapshot will not be written to the FIFO when it is full. When the host reads the 64-bit timestamp from the FIFO, space is available to store the next snapshot. This FIFO can be cleared using the control bit “ATSFC: Auxiliary Snapshot FIFO clear” defined in the Time Stamp Control Register. When multiple snapshots are present in the FIFO, the count is indicated in the “ATSNS: Auxiliary Time Stamp Number of Snapshots” bits of the Time Stamp Status Register.

30.2.3 AHB Application Host Interface

In the GMAC-AHB core, the DMA Controller interfaces with the Host through the AMBA AHB Interface. The AHB Master Interface controls data transfers while the AHB Slave interface accesses CSR space. The DMA can be used in embedded applications where DMA is required to optimize data transfer between the GMAC and system memory.

The AHB Master interface converts the internal DMA request cycles into AHB cycles.

Characteristics of this interface include the following:

- Fully AMBA 2.0-compliant AHB Master: with restrictions
- You can choose fixed burst length only (SINGLE, INCR4, INCR8) by programming the FB in the DMA Bus Mode register (see **Register Description**).
  – When fixed burst length is chosen, the AHB master always initiates a burst with SINGLE or INCR4/8type. But when such a burst is responded with SPLIT/RETRY/early burst termination, the AHB master will re-initiate the pending transfers of the burst with INCR or SINGLE burst-length type. It will terminate such INCR bursts when the original requested fixed-burst is transferred. In Fixed Burst-Length mode, if the DMA requests a burst transfer that is not equal to INCR4/8, the AHB Host interface splits the transfer into multiple burst transactions. For example, if the DMA requests a 15-beat burst transfer, the AHB interface splits it into multiple transfers of INCR8 and INCR4 and 3 SINGLE transactions.
- The AHB slaves interfaced to the GMAC-AHB must support SINGLE and INCR transfers, at a minimum.
- Takes care of AHB SPLIT, RETRY, and ERROR conditions. Any ERROR response will halt all further transactions for that DMA, and indicate the error as fatal through the CSR and interrupt. The application must give a hard or soft reset to the module to restart the operation.
- Takes care of AHB 1K boundary breaking
- Handles all data transfers (according to the data bus width configuration), except for Descriptor Status Write accesses (which are always 32-bit). In any burst data transfer, the address bus value is always aligned to the data bus width and need not be aligned to the beat size.
  All AHB burst transfers can be aligned to an address value by enabling the DMA Bus Mode register's AAL bit. If both the FB and AAL bits are set to 1, the AHB interface and the DMA together ensure that all initiated beats are aligned to the address, completing the frame transfer in the minimum number of required beats.
  For example, in 32-bit data bus mode, if a data buffer transfer's start address is 0xF000_0008 and the DMA is configured for a maximum beat size of 8, the AHB transfers occur in the following sequence:
  – 2 SINGLE transfers at addresses 0xF000_0008 and 0xF000_000C
  – 1 INCR4 transfer at address 0xF000_0010
  – All subsequent beats are INCR8 transfers starting from address 0xF000_0020. For an address-aligned INCR8 transfer, the 5 least-significant bits of the address must be 0.
- The DMA Controller requests an AHB Burst Read transfer only when it can accept the received burst data completely. Data read from the AHB is always pushed into the DMA without any delay or BUSY cycles.
- The DMA requests an AHB Burst Write transfer only when it has the sufficient data to transfer the burst completely. The AHB interface always assumes that it has data available to push into the AHB bus. However, the DMA can prematurely indicate end-

of-valid data (due to the transfer of end-of-frame of an Ethernet frame) during the burst. In Fixed Burst Length mode, the AHB Master interface continues the burst with dummy data until the specified length is completed.

The AHB 32-bit Slave interface provides access to the DMA and GMAC CSR space. Characteristics of this interface include the following:

- Fully AMBA 2.0 Compliant AHB Slave—no restrictions
- Supports single and INCR4/8 transfers
- Supports busy and early terminations
- Supports 32-bit, 16-bit, and 8-bit write/read transfers to the CSR; 32-bit access to the CSR are recommended to avoid any SW synchronization problems.
- Generates OKAY only response; does not generate SPLIT, RETRY, or ERROR responses.

30.2.4 DMA Controller

The DMA has independent Transmit and Receive engines, and a CSR space. The Transmit Engine transfers data from system memory to the device port (MTL), while the Receive Engine transfers data from the device port to system memory. The controller utilizes descriptors to efficiently move data from source to destination with minimal Host CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the Host CPU for situations such as Frame Transmit and Receive transfer completion, and other normal/error conditions.

The DMA and the Host driver communicate through two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

Control and Status registers are described in detail in **Chapter 30.3.1.1**. Descriptors are described in detail in **Chapter 30.4**.

The DMA transfers data frames received by the core to the Receive Buffer in the Host memory, and Transmit data frames from the Transmit Buffer in the Host memory. Descriptors that reside in the Host memory act as pointers to these buffers.

There are two descriptor lists; one for reception, and one for transmission. The base address of each list is written into DMA Registers 3 and 4, respectively. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by setting the second address chained in both Receive and Transmit descriptors (RDES1[24] and TDES1[24]). The descriptor lists resides in the Host physical memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the Host physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data, buffer

status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA will skip to the next frame buffer when end-of-frame is detected. Data chaining can be enabled or disabled.

The descriptor ring and chain structure is shown in **Figure 30-6**.

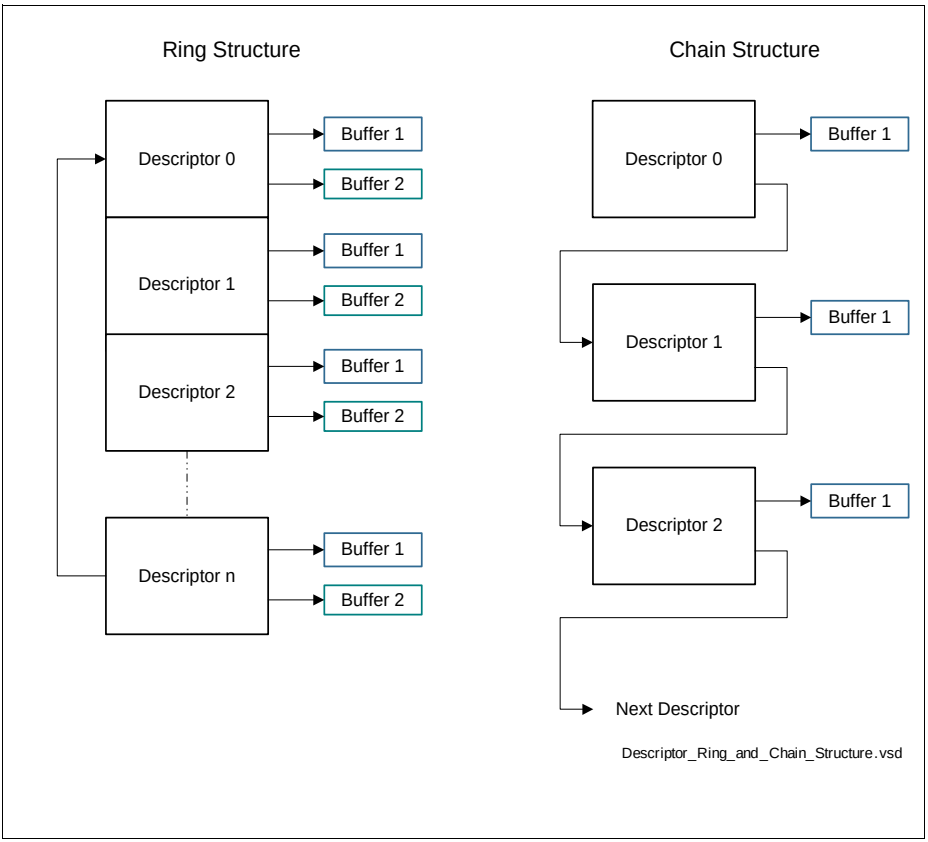

Figure 30-6 Descriptor Ring and Chain Structure

30.2.4.1 Initialization

Initialization for the GMAC is as follows.

1. Write to DMA Register 0 to set Host bus access parameters.
2. Write to DMA Register 7 to mask unnecessary interrupt causes.

3. The software driver creates the Transmit and Receive descriptor lists. Then it writes to both DMA Register 3 and DMA Register 4, providing the DMA with the starting address of each list.
4. Write to GMAC Registers 1, 2, and 3 for desired filtering options.
5. Write to GMAC Register 0 to configure and enable the Transmit and Receive operating modes. The PS and DM bits are set based on the auto-negotiation result (read from the PHY).
6. Write to DMA Register 6 to set bits 13 and 1 to start transmission and reception.
7. The Transmit and Receive engines enter the Running state and attempt to acquire descriptors from the respective descriptor lists. The Receive and Transmit engines then begin processing Receive and Transmit operations. The Transmit and Receive processes are independent of each other and can be started or stopped separately.

Host Bus Burst Access

The DMA will attempt to execute fixed-length Burst transfers on the AHBMaster interface if configured to do so (FB bit of DMA Register 0). The maximum Burst length is indicated and limited by the PBL field (DMA Register 0[13:8]). The Receive and Transmit descriptors are always accessed in the maximum possible (limited by PBL or 16 * 8/bus width) burst-size for the 16-bytes to be read.

The Transmit DMA will initiate a data transfer only when sufficient space to accommodate the configured burst is available in MTL Transmit FIFO or the number of bytes till the end of frame (when it is less than the configured burst-length). The DMA will indicate the start address and the number of transfers required to the AHB Master Interface. When the AHB Interface is configured for fixed-length burst, then it will transfer data using the best combination of INCR4/8 and SINGLE transactions.

The Receive DMA will initiate a data transfer only when sufficient data to accommodate the configured burst is available in MTL Receive FIFO or when the end of frame (when it is less than the configured burst-length) is detected in the Receive FIFO. The DMA will indicate the start address and the number of transfers required to the AHB Master Interface. When the AHB Interface is configured for fixed-length burst, then it will transfer data using the best combination of INCR4/8 and SINGLE transactions. If the end-of frame is reached before the fixed-burst ends on the AHB interface, then dummy transfers are performed in-order to complete the fixed-burst.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer the AHB initiates is less than or equal to the size of the configured PBL. Thus, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 8 (for PBL > 8), because the AHB interface does not support more than INCR8.

Host Data Buffer Alignment

The Transmit and Receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame.

Example - Buffer Read

If the Transmit buffer address is 32'h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, then the DMA will read five full words from address 32'h00000FF0, but when transferring data to the MTL Transmit FIFO, the extra bytes (the first two bytes) will be dropped or ignored. Similarly, the last 3 bytes of the last transfer will also be ignored. The DMA always ensures it transfers a full 32-bit data to the MTL Transmit FIFO, unless it is the end-of-frame.

Buffer Size Calculations

The DMA does not update the size fields in the Transmit and Receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by buffer size field of TDES1) towards the GMAC core. If a descriptor is marked as first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of frame to the MTL.

The Receive DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the MTL. If a descriptor is not marked as last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The Receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to the system bus's data width, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1.024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the Receive descriptor to have a 0x1002 offset. The Receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual

useful space in this buffer is 1.022 bytes, even though the buffer size is programmed as 1.024 bytes, due to the start address offset.

DMA Arbiter

The arbiter inside the DMA module performs the arbitration between the Transmit and Receive channel accesses to the AHB Master interface. Two types of arbitrations are possible: round-robin, and fixed-priority.

When round-robin arbitration is selected (DA bit of DMA Register 0 is reset), the arbiter allocates the data bus in the ratio set by the PR bits of DMA Register 0, when both Transmit and Receive DMAs are requesting for access simultaneously. When the DA bit is set, the Receive DMA always gets priority over the Transmit DMA for data access.

30.2.4.2 Transmission

TxDMA Operation: Default (Non-OSF) Mode

The Transmit DMA engine in default mode proceeds as follows:

1. The Host sets up the transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet Frame data.
2. Once the ST bit (DMA Register 6[13]) is set, the DMA enters the Run state.
3. While in the Run state, the DMA polls the Transmit Descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the Host, or if an error condition occurs, transmission is suspended and both the Transmit Buffer Unavailable (DMA Register 5[2]) and Normal Interrupt Summary (DMA Register 5[16]) bits are set. The Transmit Engine proceeds to Step 8.
4. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1’b1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
5. The DMA fetches the Transmit data from the Host memory and transfers the data to the MTL for transmission.
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps Step 2, Step 3, and Step 4 are repeated until the end-of-Ethernet-frame data is transferred to the MTL.
7. When frame transmission is complete, if IEEE 1588 time stamping was enabled for the frame (as indicated in the transmit status) the time-stamp value obtained from MTL is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the Own bit is cleared during this step, the Host now owns this

descriptor. If time stamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3.

8. Transmit Interrupt (DMA Register 5[0]) is set after completing transmission of a frame that has Interrupt on Completion (TDES1[31]) set in its Last Descriptor. The DMA engine then returns to Step 2.
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby return to Step 2) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared.

The TxDMA transmission flow in default mode is shown in **Figure 30-7**.

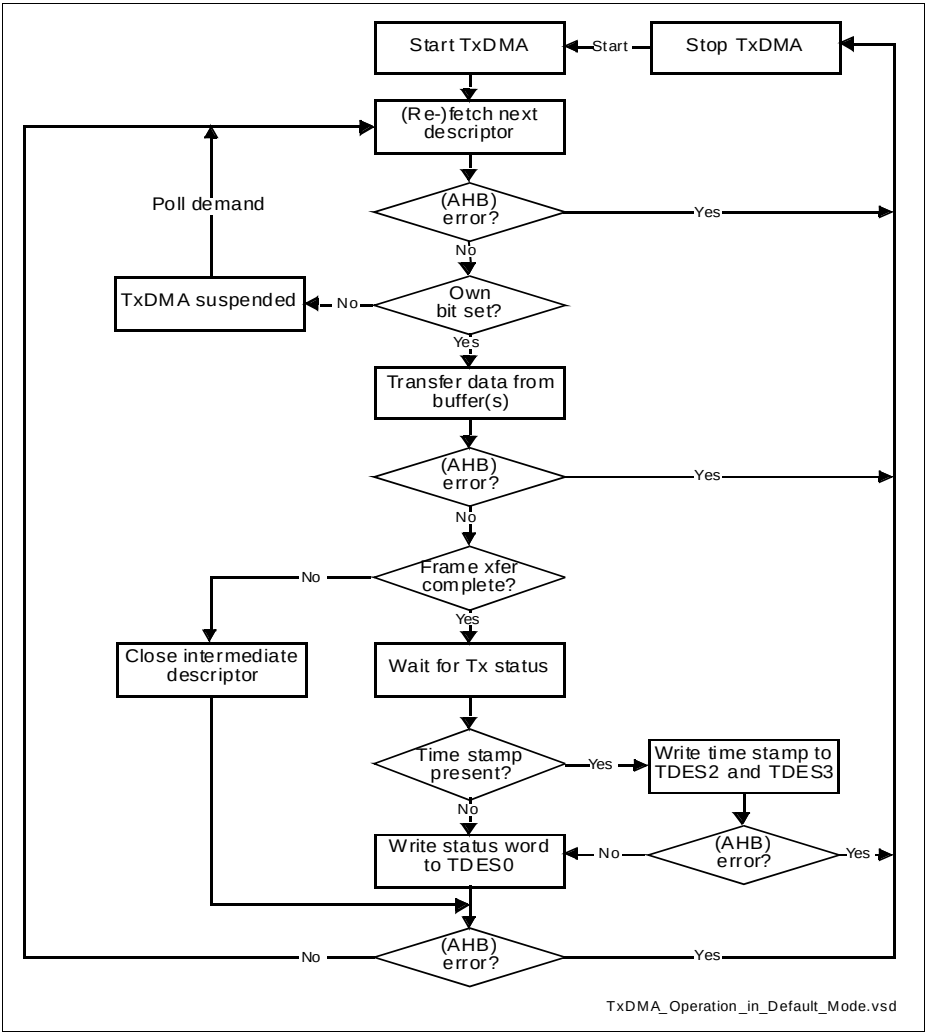

Figure 30-7 TxDMA Operation in Default Mode

TxDMA Operation: OSF Mode

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first (if the OSF bit is set in DMA Register 6[2]). As the transmit process finishes transferring the first frame, it immediately polls the

Transmit Descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information.

In OSF mode, the Run state Transmit DMA operates in the following sequence:

1. The DMA operates as described in Step 1–Step 5 of the TxDMA (default mode).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step 6.
4. The DMA fetches the Transmit frame from the Host memory and transfers the frame to the MTL until the End-of-Frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the previous frame's frame transmission status and time stamp. Once the status is available, the DMA writes the time stamp to TDES2 and TDES3, if such time stamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared Own bit, to the corresponding TDES0, thus closing the descriptor. If time stamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3.
6. If enabled, the Transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to Step 2 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step 6).
7. In Suspend mode, if a pending status and time stamp are received from the MTL, the DMA writes the time stamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to Suspend mode.
8. The DMA can exit Suspend mode and enter the Run state (go to Step 1 or Step 2 depending on pending status) only after receiving a Transmit Poll demand (DMA Register 1).

Note: As the DMA fetches the next descriptor in advance before closing the current descriptor, the descriptor chain should have more than 2 different descriptors for correct and proper operation.

The basic flow is charted in **Figure 30-8**.

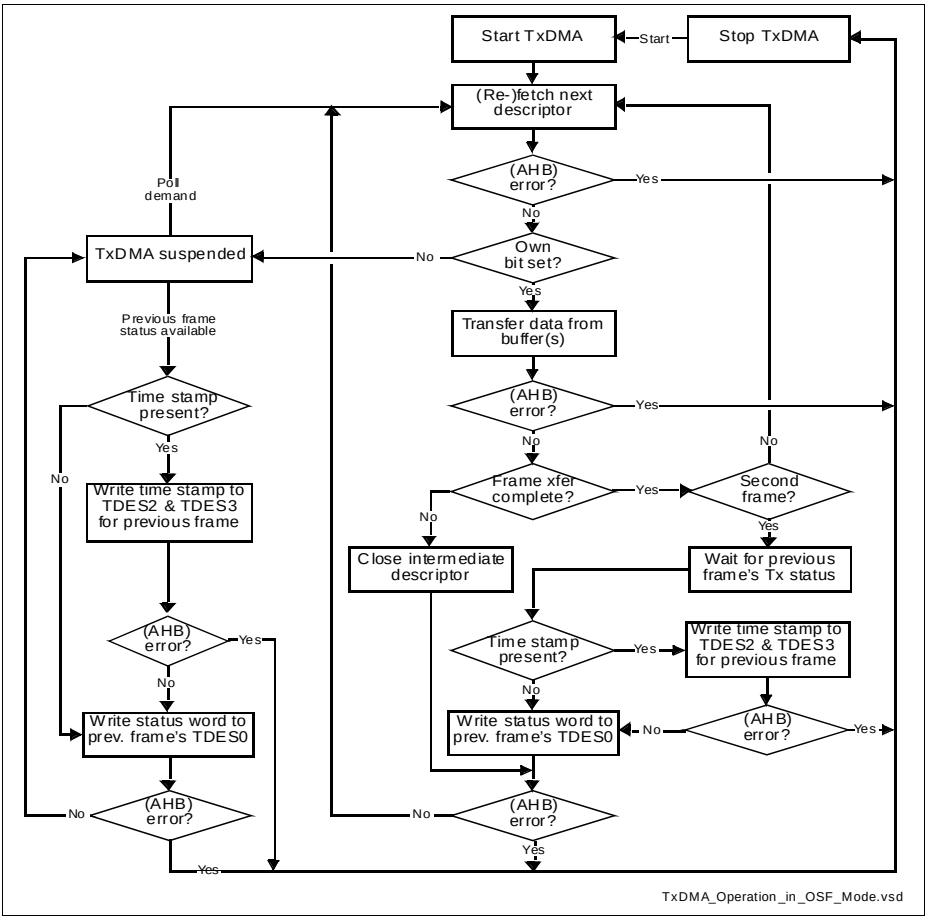

Figure 30-8 TxDMA Operation in OSF Mode

Transmit Frame Processing

The Transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Len fields contain valid data. If the Transmit Descriptor indicates that the MAC core must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes.

Frames can be data-chained and can span several buffers. Frames must be delimited by the First Descriptor (TDES1[29]) and the Last Descriptor (TDES1[30]), respectively.

As transmission starts, the First Descriptor must have (TDES1[29]) set. When this occurs, frame data transfers from the Host buffer to the MTL Transmit FIFO. Concurrently, if the current frame has the Last Descriptor (TDES1[30]) clear, the Transmit Process attempts to acquire the Next Descriptor. The Transmit Process expects this descriptor to have TDES1[29] clear. If TDES1[30] is clear, it indicates an intermediary buffer. If TDES1[30] is set, it indicates the last buffer of the frame.

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 0 (TDES0) word of the descriptor that has the last segment set in Transmit Descriptor 1 (TDES1[30]). At this time, if Interrupt on Completion (TDES1[31]) was set, Transmit Interrupt (DMA Register 5[0]) is set, the Next Descriptor is fetched, and the process repeats.

Actual frame transmission begins after the MTL Transmit FIFO has reached either a programmable transmit threshold (DMA Register 6[16:14]), or a full frame is contained in the FIFO. There is also an option for Store and Forward Mode (DMA Register 6[21]). Descriptors are released (Own bit TDES0[31] clears) when the DMA finishes transferring the frame.

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the Host (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command.
- A frame transmission is aborted when a transmit error due to underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set.

If the second condition occur, both Abnormal Interrupt Summary (DMA Register 5[15]) and Transmit Underflow bits (DMA Register 5 [5]) are set, and the information is written to Transmit Descriptor 0, causing the suspension. If the DMA goes into SUSPEND state due to the first condition, then both Normal Interrupt Summary (DMA Register 5 [16]) and Transmit Buffer Unavailable (DMA Register 5 [2]) are set.

In both cases, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA.

The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

30.2.4.3 Reception

The Receive DMA engine's reception sequence is depicted in **Figure 30-9** and proceeds as follows:

1. The host sets up Receive descriptors (RDES0-RDES3) and sets the Own bit (RDES0[31]).

2. Once the SR (DMA Register 6[1]) bit is set, the DMA enters the Run state. While in the Run state, the DMA polls the Receive Descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the host), the DMA enters the Suspend state and jumps to Step 8.
3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the Receive engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 6. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error bit in the RDES0 (unless flushing is disabled). The DMA closes the current descriptor (clears the Own bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value (marks it as Last Descriptor if flushing is not disabled), then proceeds to Step 7. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 3.
7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the receive frame's status from the MTL and writes the status word to the current descriptor's RDES0, with the Own bit cleared and the Last Segment bit set.
8. The Receive engine checks the latest descriptor's Own bit. If the host owns the descriptor (Own bit is 1'b0) the Receive Buffer Unavailable bit (Register 5[7]) is set and the DMA Receive engine enters the Suspended state (Step 8). If the DMA owns the descriptor, the engine returns to Step 3 and awaits the next frame.
9. Before the Receive engine enters the Suspend state, partial frames are flushed from the Receive FIFO (You can control flushing using Bit 24 of DMA Register 6).
10. The Receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the MTL's Receive FIFO. The engine proceeds to Step 1 and refetches the next descriptor.

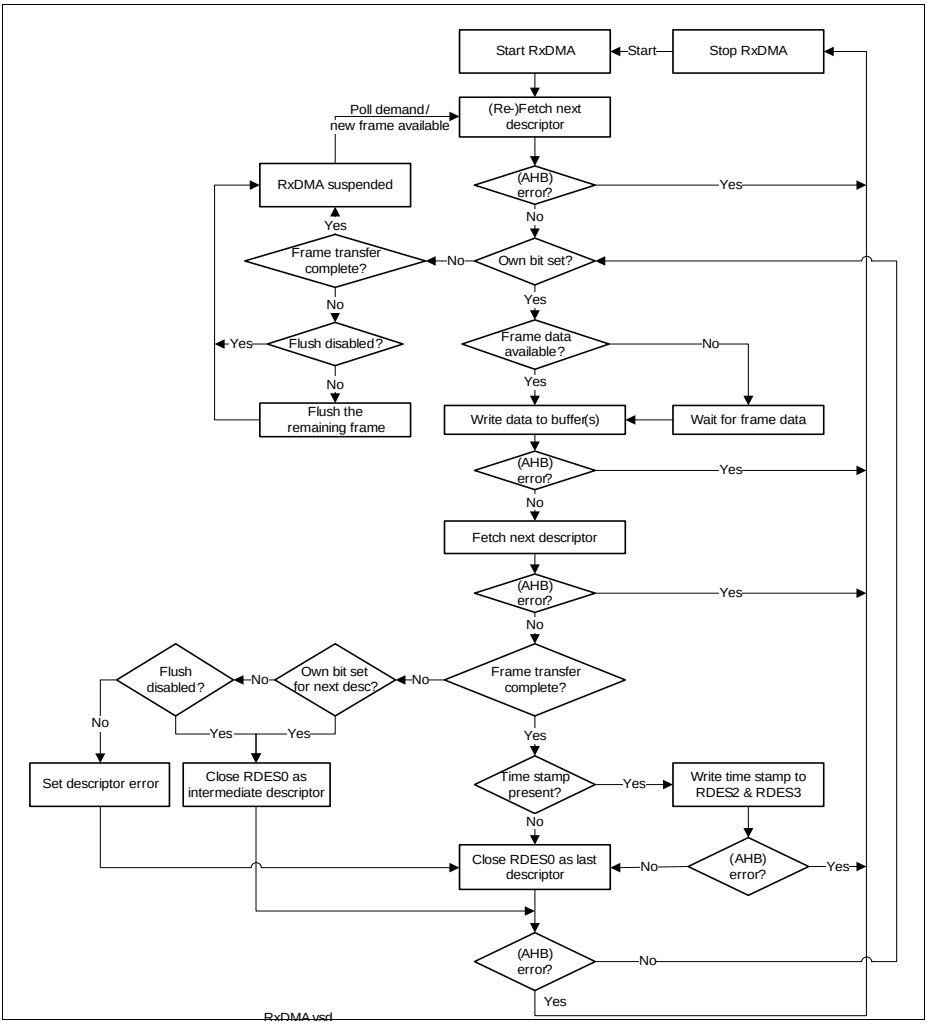

Figure 30-9 Receive DMA Operation

The DMA does not acknowledge accepting the status from the MTL until it has completed the time stamp write-back and is ready to perform status write-back to the descriptor.

If software has enabled time stamping through CSR, when a valid time stamp value is not available for the frame (for example, because the receive FIFO was full before the time stamp could be written to it), the DMA writes all-ones to RDES2 and RDES3.

Otherwise (that is, if time stamping is not enabled), the RDES2 and RDES3 remain unchanged.

Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- The receive Start/Stop bit (Register 6[1]) has been set immediately after being placed in the Run state.
- The data buffer of current descriptor is full before the frame ends for the current transfer.
- The controller has completed frame reception, but the current Receive Descriptor is not yet closed.
- The receive process has been suspended because of a host-owned buffer (RDES0[31] = 0) and a new frame is received.
- A Receive poll demand has been issued.

Receive Frame Processing

The GMAC transfers the received frames to the Host memory only when the frame passes the address filter and frame size is greater than or equal to configurable threshold bytes set for the Receive FIFO of MTL, or when the complete frame is written to the FIFO in Store-and-Forward mode.

If the frame fails the address filtering, it is dropped in the GMAC block itself (unless Receive All GMAC Register 1[31] bit is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be purged from the MTL Receive FIFO.

After 64 (configurable threshold) bytes have been received, the MTL block requests the DMA block to begin transferring the frame data to the Receive Buffer pointed to by the current descriptor. The DMA sets First Descriptor (RDES0[9]) after the DMA Host Interface (AHB/AXI or MDC) becomes ready to receive a data transfer (if DMA is not fetching transmit data from the host), to delimit the frame. The descriptors are released when the Own (RDES[31]) bit is reset to 1’b0, either as the Data buffer fills up or as the last segment of the frame is transferred to the Receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (RDES[8]) and First Descriptor (RDES[9]) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (RDES[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets Receive Interrupt (Register 5[6]). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs, the Receive Process sets Receive Buffer Unavailable (Register 5[7]) and then enters the Suspend state. The position in the receive list is retained.

Receive Process Suspended

If a new Receive frame arrives while the Receive Process is in Suspend state, the DMA refetches the current descriptor in the Host memory. If the descriptor is now owned by the DMA, the Receive Process re-enters the Run state and starts frame reception. If the descriptor is still owned by the host, by default, the DMA discards the current frame at the top of the MTL Rx FIFO and increments the missed frame counter. If more than one frame is stored in the MTL Rx FIFO, the process repeats.

The discarding or flushing of the frame at the top of the MTL Rx FIFO can be avoided by setting Operation Mode register bit 24 (DFF). In such conditions, the receive process sets the Receive Buffer Unavailable status and returns to the Suspend state.

30.2.4.4 Interrupts

Interrupts can be generated as a result of various events. DMA Register 5 contains all the bits that might cause an interrupt. DMA Register 7 contains an enable bit for each of the events that can cause an interrupt.

There are two groups of interrupts, Normal and Abnormal, as described in DMA Register 5. Interrupts are cleared by writing a 1’b1 to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the interrupt signal sbd_intr_o is deasserted. If the GMAC core is the cause for assertion of the interrupt, then any of the GLI, GMI, or GPI bits of DMA Register 5 will be set high.

Note: DMA Register 5 is the (interrupt) status register. The interrupt pin (sbd_intr_o) will be asserted due to any event in this status register only if the corresponding interrupt enable bit is set in DMA Register 7.

Interrupts are not queued and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, Receive Interrupt (DMA Register 5[6]) indicates that one or more frames was transferred to the Host buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for simultaneous, multiple events. The driver must scan DMA Register 5 for the cause of the interrupt. The interrupt is not generated again unless a new interrupting event occurs, after the driver has cleared the appropriate bit in DMA Register 5. For example, the controller generates a Receive interrupt (DMA Register 5[6]) and the driver begins reading DMA Register 5. Next, Receive Buffer Unavailable (DMA Register 5[7]) occurs. The driver clears the Receive interrupt. Even then, the sbd_intr_o signal is not deasserted, due to the active or pending Receive Buffer Unavailable interrupt.

An interrupt timer is given for flexible control of Receive Interrupt (DMA register 5[6]). When this Interrupt timer is programmed with a non-zero value, it will get activated as soon as the RxDMA completes a transfer of a received frame to system memory without

asserting the Receive Interrupt because it is not enabled in the corresponding Receive Descriptor (RDES1[31] in Table 7-3). When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RI is enabled in DMA Register 7. This timer gets disabled before it runs out, when a frame is transferred to memory and the RI is set because it is enabled for that descriptor.

30.2.5 MAC Transaction Layer (MTL)

The MAC Transaction Layer provides FIFO memory to buffer and regulate the frames between the application system memory and the GMAC core. It also enables the data to be transferred between the application clock domain and the GMAC clock domains. The MTL layer has 2 data paths, namely the Transmit path and the Receive Path. The data path for both directions is 32-bit wide and operates with a simple FIFO protocol.

The GMAC-MTL communicates with the application side with the Application Transmit Interface (ATI), Application Receive Interface (ARI), and the MAC Control Interface (MCI).

30.2.5.1 Transmit Path

The DMA controls all transactions for the transmit path through the ATI. Ethernet frames read from the system memory is pushed into the FIFO by the DMA. The frame is then popped out and transferred to the GMAC core when triggered. When the end-of-frame is transferred, the status of the transmission is taken from the GMAC core and transferred back to the DMA.

The Transmit FIFO has a depth of 4K bytes. 4FIFO-fill level is indicated to the DMA so that it can initiate a data fetch in required bursts from the system memory, using the AHB interface. The data from the AHB Master interface is pushed into the FIFO with the appropriate byte lanes qualified by the DMA. The DMA also indicates the start-of-frame (SOF) and end-of-frame (EOF) transfers along with a few sideband signals controlling the pad-insertion/CRC generation for that frame in the GMAC core.

Per-frame control bits, such as Automatic Pad/CRC Stripping disable, time stamp capture, and so forth are taken as sideband control inputs on the ATI, stored in a separate register FIFO, and passed on to the core transmitter when the corresponding frame data is read from the Transmit FIFO.

There are two modes of operation for popping data towards the GMAC core. In Threshold mode, as soon as the number of bytes in the FIFO crosses the configured threshold level (or when the end-of-frame is written before the threshold is crossed), the data is ready to be popped out and forwarded to the GMAC core. The threshold level is configured using the TTC bits of DMA Register 0. In store-and-forward mode, the MTL pops the frame towards the GMAC core only when one or more of the following conditions are true:

- When a complete frame is stored in the FIFO

- When the TX FIFO becomes almost full
- When the ATI watermark becomes low. The watermark becomes low when the requested FIFO does not have space to accommodate the requested burst-length on the ATI.

Therefore, the MTL never stops in the store-and-forward mode even if the Ethernet frame length is bigger than the Tx FIFO depth.

The application can flush the Transmit FIFO of all contents by setting the FTF (DMA Register 6[20]) bit. This bit is self-clearing and initializes the FIFO pointers to the default state. If the FTF bit is set during a frame transfer from the MTL to the GMAC core, then the MTL stops further transfer as the FIFO is considered to be empty. Hence an underflow event occurs at the GMAC transmitter and the corresponding Status word is forwarded to the DMA.

Initialization through **Transmit Status Word** detail initialization and transmit operations for the MTL Layer.

Initialization

Upon reset, the MTL is ready to manage the flow of data to and from the DMA and the GMAC.

There are no requirements for enabling the MTL. However, the GMAC block and the DMA controller must be enabled individually through their respective CSRs.

Single-Packet Transmit Operation

During a transmit operation, the MTL block is slaved to the DMA controller. The general sequence of events for a transmit operation is as follows.

1. If the system has data to be transferred, the DMA controller, if enabled, fetches data from the Host through the AHB/AXI Master interface and starts forwarding it to the MTL. The MTL pushes the data received from the DMA into the FIFO. It continues to receive the data until the end-of frame of the frame is transferred.
2. The data is taken out of the FIFO and sent to the MAC by the FIFO controller engine. When the threshold level is crossed or a full packet of data is received into the FIFO, the MTL pops out the frame data and drives them to the GMAC core. The engine continues to transfer data from the FIFO until a complete packet has been transferred to the MAC. Upon completion of the frame, the MTL receives the Status from the GMAC and then notifies the DMA controller

Transmit Operation—Two Packets in the Buffer

1. Because the DMA must update the descriptor status before releasing it to the Host, there can be at the most two frames inside a transmit FIFO. The second frame will be fetched by the DMA and put into the FIFO only if the OSF (Operate on Second

Frame bit is set). If this bit is not set, the next frame will be fetched from the memory only after the MAC has completely processed the frame and the DMA has released the descriptors.

2. If the OSF bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. The MTL, in the meantime, receives the second frame into the FIFO while transmitting the first frame. As soon as the first frame has been transferred and the status is received from the MAC, the MTL pushes it to the DMA. If the DMA has already completed sending the second packet to the MTL, it must wait for the status of the first packet before proceeding to the next frame.

Transmit Operation—Multiple Packets in Buffer

In GMAC-MTL configuration, the transmit FIFO can be configured to accept more than 2 packets at a time. This option limits the number of status words that can be stored in the MTL before it is transferred to the DMA/host. By default, this number is limited to 2 but can be configured for 4 or 8 as well. Once the MTL FIFO accepts the number of frames equal to the status FIFO depth, it will stop accepting further frames unless the transmit Status that is given out and accepted by the host/DMA thus freeing up the space in this small FIFO.

Retransmission During Collision

While a frame is being transferred from the MTL to the GMAC, a collision event occurs on the GMAC line interface in Half-Duplex mode. The GMAC then indicates a retry attempt to the MTL by giving the status even before the end-of-frame is transferred from MTL. Then the MTL will enable the retransmission by popping out the frame again from the FIFO.

After more than 96 bytes are popped towards the GMAC core, the FIFO controller frees up that space and makes it available to the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the GMAC core indicates a late-collision event.

Transmit FIFO Flush Operation

The GMAC provides a control to the software to flush the Transmit FIFO in the MTL layer through the use of Bit 20 of the Operation Mode register. The Flush operation is immediate and the MTL clears the Tx FIFO and the corresponding pointers to the initial state even if it is in the middle of transferring a frame to the GMAC Core. The data which is already accepted by the MAC transmitter will not be flushed. It will be scheduled for transmission and will result in underflow as TxFIFO does not complete the transfer of rest of the frame. As in all underflow conditions, a runt frame will be transmitted and observed on the line. The status of such a frame will be marked with both Underflow and Frame Flush events (TDES0 bits 13 and 1).

The MTL layer also stops accepting any data from the application (DMA) during the Flush operation. It will generate and transfer Transmit Status Words to the application for the number of frames that is flushed inside the MTL (including partial frames). Frames that are completely flushed in the MTL will have the Frame Flush Status bit (TDES0 13) set. The MTL completes the Flush operation when the application (DMA) accepts all of the Status Words for the frames that were flushed, and then clears the Transmit FIFO Flush control register bit. At this point, the MTL starts accepting new frames from the application (DMA).

Transmit Status Word

At the end of transfer of the Ethernet frame to the GMAC core and after the core completes the transmission of the frame, the MTL outputs the transmit status to the application.The detailed description of the Transmit Status is the same as for bits [23:0] of TDES0, given in **Table 30-28**.

If IEEE 1588 time stamping is enabled, the MTL returns specific frame's 64-bit time stamp, along with the ATI's transmit status.

Transmit Checksum Offload Engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the GMAC-UNIV has an Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path. This section explains the operation of the Checksum Offload Engine for transmitted frames.

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete frame, then inserted into its corresponding header field. Due to this requirement, this function is enabled only when the Transmit FIFO is configured for Store-and-Forward mode (that is, when the TSF bit is set in DMA Register 6). If the core is configured for Threshold (cut-through) mode, the Transmit COE is bypassed.

Note: You must make sure that the Transmit FIFO is deep enough to store a complete frame before that frame is transferred to the GMAC Core transmitter. The reason being that when space is not available to accept the programmed burst length of the data, then the MTL TxFIFO starts reading to avoid dead-lock. Once reading starts, then checksum insertion engine fails and consequently all succeeding frames may get corrupted due to improper recovery. Therefore, you must enable the checksum insertion only in the frames that are less than the following number of bytes in size (even in the store-and-forward mode):
FIFO Depth – PBL – 3 FIFO Locations
The PBL is the programmed burst-length.

This module supports two types of checksum calculation and insertion. This checksum engine can be controlled for each frame by setting the CIC bits (Bits 28:27 of TDES1, described in **Transmit Descriptor 1 (TDES1)**) in GMAC-AHB or GMAC-DMA configurations.

Note: See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Ethernet frame's Type field has the value 0x0800 and the IP datagram's Version field has the value 0x4. The input frame's checksum field is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field; thus, the COE does not modify IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 16 in **Table 30-28**). This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the IP header Length field.

In other words, this bit is set when an IP header error is asserted under the following circumstances:

For IPv4 datagrams

- The received Ethernet type is 0x0800, but the IP header's Version field does not equal 0x4
- The IPv4 Header Length field indicates a value less than 0x5 (20 bytes)
- The total frame length is less than the value given in the IPv4 Header Length field

For IPv6 datagrams

- The Ethernet type is 0x86dd but the IP header Version field does not equal 0x6
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

Even when the COE detects such an IP header error, it inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP.

Note: For non-TCP, -UDP, or -ICMP/ICMPv6 payloads, this checksum engine is bypassed and nothing further is modified in the frame.

Note: Fragmented IP frames (IPv4 or IPv6), IP frames with security features (such as an authentication header or encapsulated security payload), and IPv6 frames with routing headers are not processed by this engine, and therefore must be bypassed. In other words, payload checksum insertion must not be enabled for such frames.

The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. This engine can work in the following two modes:

- In the first mode, the TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the input frame's Checksum field. This engine includes the Checksum field in the checksum calculation, then replaces the Checksum field with the final calculated checksum.
- In the second mode, the engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12 in **Table 30-28**). This engine sets the Payload Checksum Error status bit when it detects that the frame has been forwarded to the MAC Transmitter engine in Store-and-Forward mode without the end-of-frame being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

30.2.5.2 Receive Path

This module receives the frames given out by the GMAC core and pushes them into the Rx FIFO. The status (fill level) of this FIFO is indicated to the DMA once it crosses the configured Receive threshold (RTC of DMA Register 6). The MTL also indicates the FIFO fill level so that the DMA can initiate pre-configured burst transfers towards the AHB interface.

Receive Operation through **Receive Status Word** detail receive operations for the MTL Layer.

Receive Operation

During an Rx operation, the MTL is slaved to the GMAC. The general sequence of Receive operation events is as follows:

1. When the GMAC receives a frame, it pushes in data along with byte enables. The GMAC also indicates the SOF and EOF. The MTL accepts the data and pushes it into the Rx FIFO. After the EOF is transferred, the GMAC drives the status word, which is also pushed into the same Rx FIFO by the MTL.
2. When IEEE 1588 time stamping is enabled and the 64-bit time stamp is available along with the receive status, it is appended to the frame received from the GMAC and is pushed into the RxFIFO before the corresponding receive status word is written. Thus, two additional locations per frame are taken for storing the time stamp in the RxFIFO.
3. The MTL_RX engine takes the data out of the FIFO and sends it to the DMA. In the default Cut-Through mode, when 64 bytes (configured with RTC bits of DMA Register 6) or a full packet of data are received into the FIFO, the MTL_RX engine pops out the data and indicates its availability to the DMA. Once the DMA initiates the transfer to the AHBinterface, the MTL_RX engine continues to transfer data from the FIFO until a complete packet has been transferred. Upon completion of the EOF frame transfer, the MTL pops out the status word and sends it to the DMA controller.
4. In Rx FIFO Store-and-Forward mode (configured by the RSF bit of DMA Register 6), a frame is read out only after being written completely into the Receive FIFO. In this mode, all error frames are dropped (if the core is configured to do so) such that only valid frames are read out and forwarded to the application. In Cut-Through mode, some error frames are not dropped, because the error status is received at the end-of-frame, by which time the start of that frame has already been read out of the FIFO.

Note: In 32-bit data bus mode, the time-stamp transfer takes two clock cycles and the lower 32-bit of the time-stamp is given out first. The status also may be extended to two cycles when Advanced Time-stamp feature is enabled.

Receive Operation Multiframe Handling

Since the status is available immediately following the data, the MTL is capable of storing any number of frames into the FIFO, as long as it is not full.

GMAC Flow Control

The flow control operation of the GMAC can also be enabled (EFC bit of DMA Register 6) by the Rx FIFO control logic. The flow control signal to the GMAC is asserted whenever the Rx FIFO fill level crosses the configured threshold (RFA bits of DMA Register 6). This flow control signal is deasserted once the FIFO fill-level falls below the

configured threshold (RFD bits). This operation is independent of whether the GMAC is configured for full-duplex or half-duplex.

The above hardware flow control operation is applicable only when the Rx FIFO is 4.096 or more bytes deep. A separate sideband flow control signal (sbd_flowctrl_i) is optionally provided at the top-level I/O for all GMAC-AHB, GMAC-AXI, GMAC-DMA and GMAC-MTL configurations. For 4.096-byte or larger Rx FIFOs, this sideband signal is logically ORed with the hardware flow control signal. Thus, flow control is enabled when either of these signals is asserted and disabled when both these signals are deasserted.

Error Handling

If the MTL Rx FIFO is full before it receives the EOF data from the GMAC, an overflow is declared, the whole frame (including the status word) is dropped, and the overflow counter in the DMA (Register 8) is incremented. This is true even if the Forward Error Frame (FEF bit of DMA Register 6) is set. If the start address of such a frame has already been transferred to the Read Controller, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with the status word. The status will indicate a partial frame due to overflow. In such frames, the Frame Length field is invalid.

The MTL Rx Control logic can filter error and undersized frames, if enabled (using the DMA Register 6 FEF and FUF bits). If the start address of such a frame has already been transferred to the Rx FIFO Read Controller, that frame is not filtered. The start address of the frame is transferred to the Read Controller after the frame crosses the receive threshold (set by the DMA Register 6 RTC bits).

If the MTL Receive FIFO is configured to operate in Store-and-Forward mode, all error frames can be filtered and dropped.

Receive Status Word

At the end of the transfer of the Ethernet frame to the host, the MTL outputs the receive status to the Application. The detailed description of the receive status is the same as for Bits[31:0] of RDES0, given in **Table 30-23**, except that Bits 31, 14, 9, and 8 are reserved and have a reset of 1'b0 by default. When the status of a partial frame due to overflow is given out, the Frame Length field in the status word is not valid.

*Note: When Advanced Time Stamp feature is enabled, the status is composed of two parts - normal (default [31:0]), and extended. The extended status[63:32] gives the information about the received ethernet payload when it is carrying PTP packets or TCP/UDP/ICMP over IP packets. In 32-bit data-bus, these are transferred over two clock cycles. The detailed description of the receive status is the same as described in RDES0 and RDES4 in **Receive Descriptor** , except that bits 31, 14, 9, and 8 of normal status is reserved and have a reset value of 1'b0. When the status of a partial frame due to overflow is given out, the Frame Length field in the status word is not valid.*

30.2.6 GMAC Core

The GMAC core supports many interfaces towards the PHY chip. In TC21x/TC22x/TC23x MII and RMII are implemented. The PHY interface can be selected only once after reset. The GMAC core communicates with the application side with the MAC Transmit Interface (MTI), MAC Receive Interface (MRI) and the MAC Control Interface (MCI).

30.2.6.1 Transmission

Transmission is initiated when the MTL Application pushes in data with the SOF . When the SOF signal is detected, the GMAC accepts the data and begins transmitting to the MII. The time required to transmit the frame data to the RMII/MII after the Application initiates transmission is variable, depending on delay factors like IFG delay, time to transmit preamble/SFD, and any back-off delays for Half-Duplex mode. Until then, the GMAC does not accept the data received from MTL.

After the EOF is transferred to the GMAC Core, the core complete normal transmission and then gives the Status of Transmission back to the MTL. If a normal collision (in Half-duplex mode) occurs during transmission, the GMAC core makes valid the Transmit Status to the MTL. It then accepts and drops all further data until the next SOF is received. The MTL block should retransmit the same frame from SOF on observing a Retry request (in the Status) from the GMAC.

The GMAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. During the normal transfer of a frame from MTL, if the GMAC receives a SOF without getting an EOF for the previous frame, then it (the SOF) is ignored and the new frame is considered as continuation of the previous frame.

The following six modules constitute the transmission function of the GMAC:

- Transmit Bus Interface Module (TBU)
- Transmit Frame Controller Module (TFC)
- Transmit Protocol Engine Module (TPE)
- Transmit Scheduler Module (STX)
- Transmit CRC Generator Module (CTX)
- Transmit Flow Control Module (FTX)

Transmit Bus Interface Module

This module interfaces the transmit path of the GMAC core with the external frame with a FIFO interface.

This module also outputs the (32-bit) Transmit Status to the application at the end of normal transmission or collision.

Additionally, this module outputs the Transmit Snapshot register value.

Transmit Frame Controller Module

The Transmit Frame Controller (TFC) consists of two registers to hold data, byte enables, and the last data control received from the TBU. The register provides a buffer between the Application and the TPE to regulate data flow as well as converts the input data into an 8-bit bus towards the TPE.

When the number of bytes received from the Application falls below 60 (DA+SA+LT+DATA), the state machine that interfaces with the TBU automatically appends zeros to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE 802.3. The GMAC can be programmed not to append any padding.

The cyclic redundancy check (CRC) for the Frame Check Sequence (FCS) field is calculated before transmission to the TPE module. This value is computed by CTX module. The TFC module receives the computed CRC and appends it to the data being transmitted to the TPE module. When the GMAC is programmed to not append the CRC value to the end of Ethernet frames, the TFC module ignores the computed CRC and transmits only the data received from the TBU module to the TPE module. An exception to this rule is that when the GMAC is programmed to append pads for frames (DA+SA+LT+DATA) less than 60 bytes sent by the TBU module, the TFC module will append the CRC at the end of padded frame.

The TFC converts the data received on the 32/64/128-bit interface from the TBU into 8-bit data for the TPE module.

Transmit Protocol Engine Module

The Transmit Protocol Engine (TPE) module consists of a transmit state machine that controls the operation of Ethernet frame transmission. The module's transmit state machine performs the following functions to meet the IEEE 802.3 specifications.

- Generates preamble and SFD
- Generates jam pattern in Half-Duplex mode
- Jabber timeout
- Flow control for Half-Duplex mode (back pressure)
- Generates transmit frame status
- Contains time stamp snapshot logic for IEEE 1588 support

When a new frame transmission from the TFC is requested, the transmit state machine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 8'b10101010 pattern, and the SFD is defined as 1 byte of 8b'10101011 pattern.

The collision window is defined as 1 slot time (512 bit times for 10/100 Mbit/s Ethernet). The jam pattern generation is applicable only to Half-Duplex mode, not to Full-Duplex mode. In Full-Duplex mode, the transmit state machine ignores the phy_col_i signal from the PHY.

In MII mode, if a collision occurs any time from the beginning of the frame to the end of the CRC field, the transmit state machine sends a 32-bit jam pattern of 32'h55555555 on the MII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the transmit state machine completes the transmission of preamble and SFD and then sends the jam pattern.

If the collision occurs after the collision window and before the end of the FCS field (or the end of Burst if the Frame Burst mode is enabled), the transmit state machine sends a 32-bit jam pattern and sets the late collision bit in the transmit frame status.

The TPE module maintains a jabber timer (only in 10/100-Mbit/sMbit/s mode) to cut off the transmission of Ethernet frames if the TFC module transfers more than 2.048 (default) bytes. The time-out is changed to 10.240 bytes when the Jumbo frame is enabled.

The Transmit state machine uses the deferral mechanism for the flow control (Back Pressure) in Half-Duplex mode. When the Application requests to stop receiving frames, the Transmit state machine sends a JAM pattern of 32 bytes whenever it senses a reception of a frame, provided the transmit flow control is enabled. This will result in a collision and the remote station will back off. The Application requests the flow control by setting BPA bit of Regsiter6. If the application requests a frame to be transmitted, then it will be scheduled and transmitted even when the backpressure is activated. Note that if the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur) then the remote stations will abort their transmissions due to excessive collisions.

If IEEE 1588 time stamping is enabled for the transmit frame, this block takes a snapshot of the system time when the SFD is put onto the transmit MII bus. The system time source is either an external input or internally generated, according to the configuration selected.

Transmit Scheduler Module

The Transmit Scheduler (STX) module is responsible for scheduling the frame transmission on the MII. The two major functions of this module are to maintain the inter-frame gap between two transmitted frames and to follow the Truncated Binary Exponential Back-off algorithm for Half-Duplex mode. This module provides an enable signal to the TPE module after satisfying the IFG and Back-off delays.

The STX module maintains an idle period of the configured inter-frame gap (IFG bits of Register 0 between any two transmitted frames. If frames from the TFC arrive at the TPE module sooner than the configured IFG time, the TPE module waits for the enable signal from the STX module before starting the transmission on the MII. The STX module starts its IFG counter as soon as the carrier signal of the MII goes inactive. At the end of programmed IFG value, the module issues an enable signal to the TPE module in Full-Duplex mode. In Half-Duplex mode and when IFG is configured for 96 bit times, the STX module follows the rule of deference specified in Section 4.2.3.2.1 of the IEEE 802.3

specification. The module resets its IFG counter if a carrier is detected during the first two-thirds (64-bit times for all IFG values) of the IFG interval. If the carrier is detected during the final one third of the IFG interval, the STX module continues the IFG count and enables the transmitter after the IFG interval.

The STX module implements the Truncated Binary Exponential Back-off algorithm when it operates in Half-Duplex mode.

Transmit CRC Generator Module

The Transmit CRC Generator (CTX) module interfaces with the TFC module to generate CRC for the FCS field of the Ethernet frame. The TFC module sends the frame data and any necessary padding to the CTX module through an 8-bit interface.

This module calculates the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial.

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

The module gets the Ethernet frame's byte data from the TFC module (DA + SA + LT + DATA + PAD) qualified with a Data Valid signal. The TFC also indicates to the CTX when to reset the previously calculated CRC and to start the new CRC calculation for the coming frame. The TFC module issues the start command before sending the new frame data for calculation. The calculated CRC is valid on the next clock after the data is received.

Transmit Flow Control Module

The Transmit Flow Control (FTX) module generates Pause frames and transmit them to the TFC module as necessary, in Full-Duplex mode. The TFC module receives the Pause frame from the FTX module, appends the calculated CRC, and sends the frame to the TPE module. Pause frame generation can be initiated in two ways. The Application can request the FTX module to send a Pause frame either by setting the FCB bit in the Flow Control register Register 6 or by asserting the mti_flowctrl_i signal in response to the receive FIFO full conditions (packet buffer).

If the Application has requested the flow control by setting the FCB bit of Register 6, the FTX module will generate and transmit a single Pause frame to the TFC module. The value of the Pause Time in the generated frame contains the programmed Pause Time value in Register 6. To extend the pause or end the pause prior to the time specified in the previously transmitted Pause frame, the application must request another Pause frame transmission after programming the Pause Time register with appropriate value.

If the Application has requested the flow control by asserting the mti_flowctrl_i signal, the FTX module will generate and transmit a Pause frame to the TFC module. The value of the Pause Time in the generated frame contains the programmed Pause Time value in the Register 6. The FTX module monitors the mti_flowctrl_i signal. If it remains asserted at a configurable number of slot-times (PLT bits of GMAC Register 6) before this Pause-

time runs-out, a second Pause frame will be transmitted to the TFC module. The process will be repeated as long as the mti_flowctrl signal remains asserted.

If the mti_flowctrl_i signal goes inactive prior to the sampling time, the FTX module will transmit a Pause frame with zero Pause Time to indicate to the remote end that the receive buffer is ready to receive new data frames.

30.2.6.2 MAC Transmit Interface Protocol

The MAC Transmit Interface (MTI) connects the application (MTL module in the GMAC) with the GMAC to provide the Ethernet data for transmission.

The application initiates the Ethernet frame transmission by writing the first data of the frame to the GMAC, provided the GMAC is ready to accept data . The Application can push-in data as long as the GMAC core is ready to accept it.

If the frame transmission is not successful (due to underflow, collision, jabber timeout, excessive deferral events), the GMAC core will assert the transmit status even before the EOF is received. The Application will have to take the appropriate action as per the status. The GMAC will drop all further data input to it until the next SOF.

30.2.6.3 Reception

A receive operation is initiated when the GMAC detects an SFD on the MII. The core strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The received frame is stored in a shallow buffer until the address filtering is performed. The frame is dropped in the core if it fails the address filter.

The following are the functional blocks in the Receive path of the GMAC core.

- Receive Protocol Engine Module (RPE)
- Receive CRC Module (CRX)
- Receive Frame Controller Module (RFC)
- Receive Flow Control Module (FRX)
- Receive IP Checksum checker (IPC)
- Receive Bus Interface Unit Module (RBU)
- Address Filtering Module (AFM)

Receive Protocol Engine Module

The RPE consists of the receive state machine which strips the preamble and SFD. Once the phy_rxdv_i signal of the MII becomes active, the RPE's receive state machine begins hunting for the SFD field from the receive modifier logic. Until then, the state machine drops the receiving preambles. Once the SFD is detected, the state machine begins sending the data of the Ethernet frame to the RFC module, beginning with the first byte following the SFD (destination address).

If IEEE 1588 time stamping is enabled, the RPE takes a snapshot of the system time when any frame's SFD is detected on the MII. Unless the MAC filters out and drops the frame, this time stamp is passed on to the application.

In MII mode, the RPE converts the received nibble data into bytes, then forwards the valid frame data to the RFC module

The receive state machine of the RPE module decodes the Length/Type field of the receiving Ethernet frame. If the Length/Type field is less than 600 (hex) and if the MAC is programmed for the auto crc/pad stripping option, the state machine sends the data of the frame up to the count specified in the Length/Type field, then starts dropping bytes (including the FCS field). The state machine of the RPE module decodes the Length/Type field and checks for the Length interpretation.

If the Length/Type field is greater than or equal to 600 (hex), the RPE module will send all received Ethernet frame data to the RFC module, irrespective of the value on the programmed auto-CRC strip option.

As a default, the GMAC is programmed for watchdog timer to be enabled, that is, frames above 2.048 (10.240 if Jumbo Frame is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. This feature can be disabled by programming the GMAC Configuration register, Watchdog Disable. However even if the watchdog timer is disabled, frames greater than 16 KB in size are cut off and a watchdog time-out status is given.

The GMAC supports loopback of transmitted frames onto its receiver. As a default, the GMAC loopback function is disabled, but this feature can be enabled by programming the GMAC Configuration register, Loopback bit. The transmit and receive clocks can have an asynchronous timing relationship, so an asynchronous FIFO is used to make the loopback path of the phy_txd_o data onto the receive path. The asynchronous FIFO is 10 bits (6 bits in 10/100 Mbit/s mode) wide to accommodate phy_txd_o, phy_txen_o, and phy_txer_o. The FIFO nine deep in 10/100 Mbit/s mode and free-running to write on the write clock (clk_tx_i) and read on every read clock (clk_rx_i).

The write and read pointers gets re-initialized to have an offset of 2 (4 in 10/100 Mbit/s mode) at the start of each frame read out of the FIFO. This helps to avoid overflow/underflow during the transfer of a frame, and ensures that the overflow/underflow occurs only during the IFG period between the frames. Please note that the FIFO depth of nine is sufficient to prevent data corruption for frame sizes up to 9.022 bytes with a difference of 200 ppm between the MII Transmit and Receive clock frequencies. Hence, bigger frames should not be looped back, as they may get corrupted in this loopback FIFO.

At the end of every received frame, the RPE module generates received frame status and sends it to the RFC module. Control, missed frame, and filter fail status are added to the receive status in the RFC module.

Receive CRC Module

The Receive CRC (CRX) interfaces to the RPE module to check for any CRC error in the receiving frame.

This module calculates the 32-bit CRC for the received frame that includes the Destination address field through the FCS field. The encoding is defined by the following generating polynomial.

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

The module gets the data from the RPE module (DA+SA+LT+DATA+PAD+FCS). The RPE module also sends a control signal that indicates the validity of the data. Irrespective of the auto pad/CRC strip, the CRX module receives the entire frame to compute the CRC check for received frame. As a note on the auto pad/CRC strip settings, the entire frame is not transferred between the RPE and RFC 8-bit interface.

Receive Checksum Offload Engine

The Checksum Offload engine is optional (not available in the default configuration) and selectable during configuration. Two types of Receive Checksum Offload engine are available for configuration. Full Checksum Offload, the Type 2 engine is instantiated.

Type 2

In this mode, both IPv4 and IPv6 frames in the received Ethernet frames are detected and processed for data integrity. You can enable this module by setting the IPC bit in the GMAC Configuration register. The GMAC receiver identifies IPv4 or IPv6 frames by checking for value 0x0800 or 0x86DD, respectively, in the received Ethernet frames' Type field. This identification applies to VLAN-tagged frames as well.

The Receive Checksum Offload engine calculates IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received frame does not have enough bytes, as indicated by the IPv4 header's Length field (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP/UDP/ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not tally to the expected payload length given in the IP header.

As mentioned in **TCP/UDP/ICMP Checksum Engine**, this engine bypasses the payload of fragmented IP datagrams, IP datagrams with security features, IPv6 routing headers, and payloads other than TCP, UDP or ICMP.

In this configuration, the core does not append any payload checksum bytes to the received Ethernet frames.

Receive Frame Controller Module

The Receive Frame Controller (RFC) receives the Ethernet frame data and status from the RPE module. The RFC module consists of a FIFO of parameterized depth (default set to 4 deep and 37 bits wide) and two state machines for writing and reading the FIFO. The FIFO holds the received Ethernet frame data and byte enables, along with a control bit to indicate the last data. The state machines manage the FIFO and provide a frame buffering for the receiving Ethernet frame from the RPE module. The main functions of the RFC module are:

- Data path conversion, which converts the 8-bit data to 32-bit data to the RBU module.
- Frame filtering
- Attaching the calculated IP Checksum input from IPC.
- Update the Receive Status and forward to RBU.

If the RA bit of the GMAC CSR Frame Filter register is set, the RFC module initiates the data transfer to the RBU module as soon as 4 bytes of Ethernet data are received from the RPE module. At the end of the data transfer, the RFC module sends out the received frame status that includes the frame filter bits (SA Filterfail and DAFilterfail) and status from the RFC module. These bits are generated based on the filter-fail signals from the AFM module. This status bit indicates to the Application whether the received frame has passed the filter controls (both address filter and Frame Filter controls from CSR). The RFC module will not drop any frame on its own in this mode.

If the RA bit is reset, the RFC module performs frame filtering based on the destination/source address (the Application still needs to perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, etc. The RFC module waits to receive the first 14 bytes of received data (type field) from the RPE module. Until then, the module will not initiate any transfers to the RBU module. After receiving the destination/source address bytes, the RFC checks the filter-fail signal from the AFM module for an address match. On detecting a filter-fail from AFB, the frame is dropped at the RFC module and not transferred to the Application.

On a delayed filter response from the AFM (this can only occur if you change the AFM logic), the RFC module waits until the FIFO is full, and then proceeds with the frame transfer to the RBU module. However, it will still take the delayed response from the AFM module and if it is a (DA/SA) filter failure, then it will drop the rest of the frame and send the Rx Status Word (with zero frame-length, CRC Error and Runt Error bits set) immediately indicating the filter-fail. If there is no response from the AFM until the end of frame is transmitted, the filter fail status in the Rx Status Word is updated accordingly.

When the PMT module is configured for power-down mode, all received frames are dropped by this block, and are not forwarded to the application.

Receive Flow Control Module

The Receive Flow Controller (FRX) detects the receiving Pause frame and pauses the frame transmission for the delay specified within the received Pause frame. The FRX module is enabled only in Full-Duplex mode. The Pause frame detection function can be enabled or disabled with the RFE bit of GMAC CSR Register 6.

Once the receive flow control is enabled, the FRX module begins monitoring the received frame destination address for any match with the multicast address of the control frame (48'h0180C2000001). If a match is detected, the FRX module indicates to the RFC module, that the destination address of the received frame matches the reserved control frame destination address. The RFC module then decides whether or not to transfer the received control frame to the Application, based on the (PCF) bit setting of GMAC CSR Register 1 (Filter register).

The FRX module also decodes the Type, Op-code, and Pause Timer field of the receiving control frame. At the end of received frame, the FRX module gets the received frame status from RPE. If the byte count of the status indicates 64 bytes, and if there is no CRC error, the FRX module requests the MAC transmitter to pause the transmission of any data frame for the duration of the decoded Pause Time value, multiplied by the slot time (64 byte times). Meanwhile, if another Pause frame is detected with a zero Pause Time value, the FRX module resets the Pause Time and gives another pause request to the Transmitter. If the received control frame matches neither the Type field (16'h8808), Opcode (16'h00001), nor byte length (64 bytes), or if there is a CRC error, the FRX module does not generate a Pause request to Transmitter.

In the case of a pause frame with a multicast destination address, the RFC filters the frame based on the address match from the FRX module. For a pause frame with a unicast destination address, the filtering in the FRX module depends on whether the DA matched the contents of the MAC Address Register 0 and the UP Bit of GMAC Core Register 6 is set (detecting a pause frame even with a unicast destination address). The PCF register bits (Bit [7:6] of GMAC Register 1) controls the filtering for control frames in addition to the Address filter module.

Receive Bus Interface Unit Module

The Receive Bus Interface Unit (RBU) converts the 32-bit data received from the RFC module into a 32-bit FIFO protocol on the Application side. The RBU module interfaces with the Application through the MAC receive interface (MRI).

If IEEE 1588 time stamping is enabled, the RBU also outputs the time stamp captured from the received frame.

Address Filtering Module

The Address Filtering (AFM) module performs the destination and source address checking function on all received frames and reports the address filtering status to the RFC module. The address checking is based on different parameters (Frame Filter register) chosen by the Application. These parameters are inputs to the AFM module as control signals, and the AFM module reports the status of the address filtering based on the combination of these inputs. The AFM module does not filter the receive frames by itself, but reports the status of the address filtering (whether to drop the frame or not) to the RFC module. The AFM module also reports whether the receiving frame is a multicast frame or a broadcast frame, as well as the address filter status.

The AFM module probes the 8-bit receive data path between the RPE module and the RFC module and checks the destination and source address field of each incoming packet. In MII mode the module takes 14/26 clocks (from the start of frame) to compare the destination/ source address of the receiving frame. The AFM module gets the station's physical (MAC) address and the Multicast Hash table from CSR module for address checking. The CSR module provides the Frame Filter register parameters to AFM.

Unicast Destination Address Filter

The AFM supports up to 32 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of Frame Filter register is reset), the AFM compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr31 are selected with an individual enable bit. Each byte of these other addresses (MacAddr1–MacAddr31) can be masked during comparison with the corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This helps group address filtering for the DA.

In Hash filtering mode (When HUC bit is set), the AFM performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 000000 selects Bit 0 of the selected register, and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

Multicast Destination Address Filter

The GMAC can be programmed to pass all multicast frames by setting the PM bit in the Frame Filter register. If the PM bit is reset, the AFM performs the filtering for multicast addresses based on the HMC bit of Frame Filter register. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the AFM performs imperfect filtering using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received multicast address to index the content of the Hash table. A value of 000000 selects Bit 0 of the selected register and a value of 111111 selects Bit 63 of the Hash Table register.

If the corresponding bit is set to 1, then the multicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

Hash or Perfect Address Filter

The DA filter can be configured to pass a frame when its DA matches either the Hash filter or the Perfect filter by setting the HPF bit of the Frame Filter register and setting the corresponding HUC or HMC bits. This configuration applies to both unicast and multicast frames. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to the received frame.

Broadcast Address Filter

The AFM doesn't filter any broadcast frames in the default mode. However, if the GMAC is programmed to reject all broadcast frames by setting the DBF bit in the Frame Filter register, the DAF module asserts the Filter fail signal to RFC, whenever a broadcast frame is received. This will tell the RFC module to drop the frame.

Unicast Source Address Filter

The GMAC can also perform a perfect filtering based on the source address field of the received frames. By default, the AFM compares the SA field with the values programmed in the SA registers. The MAC Address registers [1:31] can be configured to contain SA instead of DA for comparison, by setting Bit 30 of the corresponding Register. Group filtering with SA is also supported. The frames that fail the SA Filter are dropped by the GMAC if the SAF bit of Frame Filter register is set.

When SAF bit is set, the result of SA Filter and DA filter is AND'ed to decide whether the frame needs to be forwarded. This means that either of the filter fail result will drop the frame and both filters have to pass in-order to forward the frame to the application.

Inverse Filtering Operation

For both Destination and Source address filtering, there is an option to invert the filter-match result at the final output. These are controlled by the DAIF and SAIF bits of the Frame Filter register respectively. The DAIF bit is applicable for both Unicast and Multicast DA frames. The result of the unicast/multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 30-8 and **Table 30-9** summarize the Destination and Source Address filtering based on the type of frames received.

Table 30-8 Destination Address Filtering Table

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DB	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames.
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match.
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match.
	0	0	1	0	X	X	X	Pass on Hash filter match.
	0	0	1	1	X	X	X	Fail on Hash filter match.
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match.
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match.
Multicast	1	X	X	X	X	X	X	Pass all frames.
	X	X	X	X	X	1	X	Pass all frames.
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.
	0	0	X	0	1	0	X	Pass on Hash filter match and drop PAUSE control frames if PCF = 0x.
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.

Table 30-8 Destination Address Filtering Table (cont'd)

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DB	DA Filter Operation
	0	0	X	1	1	0	X	Fail on Hash filter match and drop PAUSE control frames if PCF = 0x.
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.

Table 30-9 Source Address Filtering Table

Frame Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all frames.
	0	0	0	Pass status on Perfect/Group filter match but do not drop frames that fail.
	0	1	0	Fail status on Perfect/Group filter match but do not drop frame.
	0	0	1	Pass on Perfect/Group filter match and drop frames that fail.
	0	1	1	Fail on Perfect/Group filter match and drop frames that fail.

30.2.6.4 System Time Register Module

64-bit time is maintained in this module and updated using the input reference clock. This time is the source for taking snapshots (time stamps) of Ethernet frames being transmitted or received at the MII.

The System Time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Time Stamp Update register. For initialization, the System Time counter is written with the value in the Time Stamp Update registers, while for system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, a slave clock's frequency drift with respect to the master clock (as defined in IEEE 1588) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in

Figure 30-10. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider. This algorithm is depicted in **Figure 30-10**:

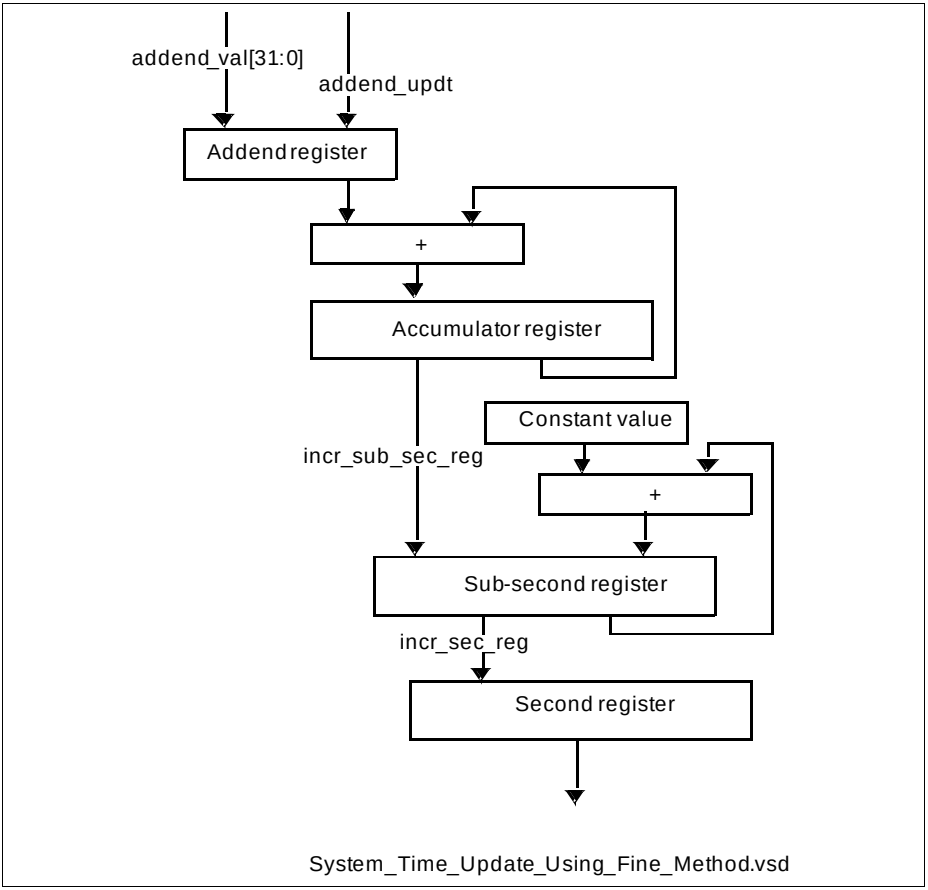

Figure 30-10 System Time Update Using Fine Method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (clk_ptp_ref_i) is, for example, 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Hence, the default addend value to be set in the register is 2^{32} / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, to 65 MHz for example, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 2^{32} / 1.30, or 0xC4EC4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (2^{32} / 1.32) must be programmed.

In **Figure 30-10**, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20-ns steps). Two different methods are used to update the System Time register, depending on which configuration you choose (See **Architecture**).

The software must calculate the drift in frequency based on the Sync messages and update the Addend register accordingly.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$FreqCompensationValue_0 = 2^{32} / FreqDivisionRatio$

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm described below must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time $MasterSyncTime_n$ the master sends the slave clock a Sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as:
  $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$
- The master clock count for current Sync cycle, $MasterClockCount_n$ is given by:
  $MasterClockCount_n = MasterClockTime_n – MasterClockTime_{n-1}$ (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, $SlaveClockCount_n$ is given by:
  $SlaveClockCount_n = SlaveClockTime_n – SlaveClockTime_{n-1}$
- The difference between master and slave clock counts for current Sync cycle, $ClockDiffCount_n$ is given by:
  $ClockDiffCount_n = MasterClockCount_n – SlaveClockCount_n$
- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$ is given by:
  $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n$
- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is given by:
  $FreqCompensationValue_n = FreqScaleFactor_n * FreqCompensationValue_{n-1}$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, due to changing network propagation delays and operating conditions.

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm will correct it at the cost of more Sync cycles.

30.2.7 MAC Management Counters

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted frames. These include a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the MAC Control Interface (MCI). Each register is 32 bits wide. The write data is qualified with the corresponding mci_be_i signals. Thus, non-32-bit accesses are allowed as long as the address is word-aligned.

The organization of these registers is shown in **Table 1-17**. The MMCs are accessed using transactions, in the same way the CSR address space is accessed. The following sections in the chapter describe the various counters and list the address for each of the statistics counters. This address will be used for Read/Write accesses to the desired transmit/receive counter.

The Receive MMC counters are updated for frames that are passed by the Address Filter (AFM) block. Statistics of frames that are dropped by the AFM module are not updated unless they are runt frames of less than 6 bytes (DA bytes are not received fully).

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet frames. This gathering is only enabled when Full Checksum Offload Engine is selected during RTL configuration. The address map of the corresponding registers, 0x0200–0x02FC, is given in **Table 1-17**.

30.2.7.1 Address Assignments

The MMC register naming convention is as follows.

- “tx” as a prefix or suffix indicates counters associated with transmission
- “rx” as a prefix or suffix indicates counters associated with reception
- “_g” as a suffix indicates registers that count good frames only
- “_gb” as a suffix indicates registers that count frames regardless of whether they are good or bad

The following explanations pertain to terminology used in **Table 1-17** through **Table 1-24**.

Transmitted frames are considered “good” if transmitted successfully. In other words, a transmitted frame is good if the frame transmission is not aborted due to any of the following errors:

- Jabber Timeout

- No Carrier/Loss of Carrier
- Late Collision
- Frame Underflow
- Excessive Deferral
- Excessive Collision

Received frames are considered “good” if none of the following errors exists:

- CRC error
- Runt Frame (shorter than 64 bytes)
- Alignment error (in 10/100 Mbit/s only)
- Length error (non-Type frames only)
- Out of Range (non-Type frames only, longer than maximum size)

The maximum frame size depends on the frame type, as follows:

- Untagged frame maxsize = 1518
- VLAN Frame maxsize = 1522
- Jumbo Frame maxsize = 9018
- JumboVLAN Frame maxsize = 9022

Table 30-10 MMC Register Map

GMAC CSR Register No.	Address Offset	Register Name	Register Description
64	0x0100	mmc_cntrl	MMC Control establishes the operating mode of MMC. For more details, refer to **Table 1-18**.
65	0x0104	mmc_intr_rx	MMC Receive Interrupt maintains the interrupt generated from all of the receive statistic counters. For more details, refer to **Table 1-19**.
66	0x0108	mmc_intr_tx	MMC Transmit Interrupt maintains the interrupt generated from all of the transmit statistic counters. For more details, refer to **Table 1-20**.
67	0x010C	mmc_intr_mask_rx	MMC Receive Interrupt mask maintains the mask for the interrupt generated from all of the receive statistic counters. For more details, refer to **Table 1-21**.

Table 30-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
68	0x0110	mmc_intr_mask_tx	MMC Transmit Interrupt Mask maintains the mask for the interrupt generated from all of the transmit statistic counters. For more details, refer to **Table 1-22**.
69	0x0114	txoctetcount_gb	Number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad frames.
70	0x0118	txframecount_gb	Number of good and bad frames transmitted, exclusive of retried frames.
71	0x011C	txbroadcastframes_g	Number of good broadcast frames transmitted.
72	0x0120	txmulticastframes_g	Number of good multicast frames transmitted.
73	0x0124	tx64octets_gb	Number of good and bad frames transmitted with length 64 bytes, exclusive of preamble and retried frames.
74	0x0128	tx65to127octets_gb	Number of good and bad frames transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.
75	0x012C	tx128to255octets_gb	Number of good and bad frames transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.
76	0x0130	tx256to511octets_gb	Number of good and bad frames transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.
77	0x0134	tx512to1023octets_gb	Number of good and bad frames transmitted with length between 512 and 1.023 (inclusive) bytes, exclusive of preamble and retried frames.

Table 30-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
78	0x0138	tx1024tomaxoctets_gb	Number of good and bad frames transmitted with length between 1.024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.
79	0x013C	txunicastframes_gb	Number of good and bad unicast frames transmitted.
80	0x0140	txmulticastframes_gb	Number of good and bad multicast frames transmitted.
81	0x0144	txbroadcastframes_gb	Number of good and bad broadcast frames transmitted.
82	0x0148	txunderflowerror	Number of frames aborted due to frame underflow error.
83	0x014C	txsinglecol_g	Number of successfully transmitted frames after a single collision in Half-duplex mode.
84	0x0150	txmulticol_g	Number of successfully transmitted frames after more than a single collision in Half-duplex mode.
85	0x0154	txdeferred	Number of successfully transmitted frames after a deferral in Half-duplex mode.
86	0x0158	txlatecol	Number of frames aborted due to late collision error.
87	0x015C	txexesscol	Number of frames aborted due to excessive (16) collision errors.
88	0x0160	txcarriererror	Number of frames aborted due to carrier sense error (no carrier or loss of carrier).
89	0x0164	txoctetcount_g	Number of bytes transmitted, exclusive of preamble, in good frames only.
90	0x0168	txframecount_g	Number of good frames transmitted.
91	0x016C	txexcessdef	Number of frames aborted due to excessive deferral error (deferred for more than two max-sized frame times).

Table 30-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
92	0x0170	txpauseframes	Number of good PAUSE frames transmitted.
93	0x0174	txvlanframes_g	Number of good VLAN frames transmitted, exclusive of retried frames.
94	0x0178	Reserved	
95	0x017C	Reserved	
96	0x0180	rxframecount_gb	Number of good and bad frames received.
97	0x0184	rxoctetcount_gb	Number of bytes received, exclusive of preamble, in good and bad frames.
98	0x0188	rxoctetcount_g	Number of bytes received, exclusive of preamble, only in good frames.
99	0x018C	rxbroadcastframes_g	Number of good broadcast frames received.
100	0x0190	rxmulticastframes_g	Number of good multicast frames received.
101	0x0194	rxcrcerror	Number of frames received with CRC error.
102	0x0198	rxalignmenterror	Number of frames received with alignment (dribble) error.
103	0x019C	rxrunterror	Number of frames received with runt (<64 bytes and CRC error) error.
104	0x01A0	rxjabbererror	Number of giant frames received with length (including CRC) greater than 1.518 bytes (1.522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.
105	0x01A4	rxundersize_g	Number of frames received with length less than 64 bytes, without any errors.
106	0x01A8	rxoversize_g	Number of frames received with length greater than the maxsize (1.518 or 1.522 for VLAN tagged frames), without errors.

Table 30-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
107	0x01AC	rx64octets_gb	Number of good and bad frames received with length 64 bytes, exclusive of preamble.
108	0x01B0	rx65to127octets_gb	Number of good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.
109	0x01B4	rx128to255octets_gb	Number of good and bad frames received with length between 128 and 255 (inclusive) bytes, exclusive of preamble.
110	0x01B8	rx256to511octets_gb	Number of good and bad frames received with length between 256 and 511 (inclusive) bytes, exclusive of preamble.
111	0x01BC	rx512to1023octets_gb	Number of good and bad frames received with length between 512 and 1.023 (inclusive) bytes, exclusive of preamble.
112	0x01C0	rx1024tomaxoctets_gb	Number of good and bad frames received with length between 1.024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.
113	0x01C4	rxunicastframes_g	Number of good unicast frames received.
114	0x01C8	rxlengtherror	Number of frames received with length error (Length type field ¼ frame size), for all frames with valid length field.
115	0x01CC	rxoutofrangetype	Number of frames received with length field not equal to the valid frame size (greater than 1.500 but less than 1.536).
116	0x01D0	rxpauseframes	Number of good and valid PAUSE frames received.
117	0x01D4	rxfifooverflow	Number of missed received frames due to FIFO overflow.
118	0x01D8	rxvlanframes_gb	Number of good and bad VLAN frames received.

Table 30-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
119	0x01DC	rxwatchdogerror	Number of frames received with error due to watchdog timeout error (frames with a data load larger than 2.048 bytes).
120:127	0x01E0–0x01FC	Reserved	
128	0x0200	mmc_ipc_intr_mask_rx	MMC IPC Receive Checksum Offload Interrupt Mask maintains the mask for the interrupt generated from the receive IPC statistic counters. See **Table 1-23** for further detail.
129	0x0204	Reserved	
130	0x0208	mmc_ipc_intr_rx	MMC Receive Checksum Offload Interrupt maintains the interrupt that the receive IPC statistic counters generate. See **Table 1-24** for further detail.
131	0x020C	Reserved	
132	0x0210	rxipv4_gd_frms	Number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload
133	0x0214	rxipv4_hdrerr_frms	Number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors
134	0x0218	rxipv4_nopay_frms	Number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine
135	0x021C	rxipv4_frag_frms	Number of good IPv4 datagrams with fragmentation
136	0x0220	rxipv4_udsbl_frms	Number of good IPv4 datagrams received that had a UDP payload with checksum disabled
137	0x0224	rxipv6_gd_frms	Number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads

Table 30-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
138	0x0228	rxipv6_hdrerr_frms	Number of IPv6 datagrams received with header errors (length or version mismatch)
139	0x022C	rxipv6_nopay_frms	Number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers
140	0x0230	rxudp_gd_frms	Number of good IP datagrams with a good UDP payload. This counter is not updated when the rxipv4_udsbl_frms counter is incremented.
141	0x0234	rxudp_err_frms	Number of good IP datagrams whose UDP payload has a checksum error
142	0x0238	rxtcp_gd_frms	Number of good IP datagrams with a good TCP payload
143	0x023C	rxtcp_err_frms	Number of good IP datagrams whose TCP payload has a checksum error
144	0x0240	rxicmp_gd_frms	Number of good IP datagrams with a good ICMP payload
145	0x0244	rxicmp_err_frms	Number of good IP datagrams whose ICMP payload has a checksum error
146:147	0x0248–0x024C	Reserved	
148	0x0250	rxipv4_gd_octets	Number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter or in the octet counters listed below).
149	0x0254	rxipv4_hdrerr_octets	Number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter.

Table 30-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
150	0x0258	rxipv4_nopay_octets	Number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 header's Length field is used to update this counter.
151	0x025C	rxipv4_frag_octets	Number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 header's Length field is used to update this counter.
152	0x0260	rxipv4_udsbl_octets	Number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes.
153	0x0264	rxipv6_gd_octets	Number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data
154	0x0268	rxipv6_hdrerr_octets	Number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the IPv6 header's Length field is used to update this counter.
155	0x026C	rxipv6_nopay_octets	Number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 header's Length field is used to update this counter.
156	0x0270	rxudp_gd_octets	Number of bytes received in a good UDP segment. This counter (and the counters below) does not count IP header bytes.
157	0x0274	rxudp_err_octets	Number of bytes received in a UDP segment that had checksum errors
158	0x0278	rxtcp_gd_octets	Number of bytes received in a good TCP segment

Table 30-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
159	0x027C	rxtcp_err_octets	Number of bytes received in a TCP segment with checksum errors
160	0x0280	rxicmp_gd_octets	Number of bytes received in a good ICMP segment
161	0x0284	rxicmp_err_octets	Number of bytes received in an ICMP segment with checksum errors
162:191	0x0288–0x02FC	Reserved	

30.2.7.2 MMC Register Description

MMC Control Register

The MMC Control register establishes the operating mode of the management counters.

Table 30-11 MMC Control Register

Bit	Access Type	Reset Value	Description
31:6	R	0000_000H	Reserved
5	rw	0	Full-Half preset When low and bit4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16) When high and bit4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16)

Table 30-11 MMC Control Register (cont'd)

Bit	Access Type	Reset Value	Description
4	rwh	0	Counters Preset When set, all counters will be initialized or preset to almost full or almost half as per Bit5 above. This bit will be cleared automatically after 1 clock cycle. This bit along with bit5 is useful for debugging and testing the assertion of interrupts due to MMC counter becoming half-full or full.
3	rw	0	MMC Counter Freeze When set, this bit freezes all the MMC counters to their current value. (None of the MMC counters are updated due to any transmitted or received frame until this bit is reset to 0. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.)
2	rw	0	Reset on Read When set, the MMC counters will be reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.
1	rw	0	Counter Stop Rollover When set, counter after reaching maximum value will not roll over to zero.
0	rwh	0	Counters Reset When set, all counters will be reset. This bit will be cleared automatically after 1 clock cycle

Note: When Bit 0 and Bit 4 are set in the same cycle, Counters get preset immediately after getting cleared.

MMC Receive Interrupt Register

The MMC Receive Interrupt register maintains the interrupts generated when the receive statistic counters reach half their maximum values (0x8000_0000), and when they cross their maximum values (0xFFFF_FFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Note: Access restriction applies: Any read access to the register clears this register!

Table 30-12 MMC Receive Interrupt Register

Bit	Access Type	Reset Value	Description
31:24	r	00H	Reserved
23	rh	0	The bit is set when the rxwatchdog error counter reaches half the maximum value, and also when it reaches the maximum value.
22	rh	0	The bit is set when the rxvlanframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
21	rh	0	The bit is set when the rxfifooverflow counter reaches half the maximum value, and also when it reaches the maximum value.
20	rh	0	The bit is set when the rxpauseframes counter reaches half the maximum value, and also when it reaches the maximum value.
19	rh	0	The bit is set when the rxoutofrangetype counter reaches half the maximum value, and also when it reaches the maximum value.
18	rh	0	The bit is set when the rxlengtherror counter reaches half the maximum value, and also when it reaches the maximum value.
17	rh	0	The bit is set when the rxunicastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
16	rh	0	The bit is set when the rx1024tomaxoctets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
15	rh	0	The bit is set when the rx512to1023octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
14	rh	0	The bit is set when the rx256to511octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
13	rh	0	The bit is set when the rx128to255octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.

Table 30-12 MMC Receive Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
12	rh	0	The bit is set when the rx65to127octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
11	rh	0	The bit is set when the rx64octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
10	rh	0	The bit is set when the rxoversize_g counter reaches half the maximum value, and also when it reaches the maximum value.
9	rh	0	The bit is set when the rxundersize_g counter reaches half the maximum value, and also when it reaches the maximum value.
8	rh	0	The bit is set when the rxjabbererror counter reaches half the maximum value, and also when it reaches the maximum value.
7	rh	0	The bit is set when the rxrunterror counter reaches half the maximum value, and also when it reaches the maximum value.
6	rh	0	The bit is set when the rxalignmenterror counter reaches half the maximum value, and also when it reaches the maximum value.
5	rh	0	The bit is set when the rxcrcerror counter reaches half the maximum value, and also when it reaches the maximum value.
4	rh	0	The bit is set when the rxmulticastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
3	rh	0	The bit is set when the rxbroadcastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
2	rh	0	The bit is set when the rxoctetcount_g counter reaches half the maximum value, and also when it reaches the maximum value.

Table 30-12 MMC Receive Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
1	rh	0	The bit is set when the rxoctetcount_gb counter reaches half the maximum value, and also when it reaches the maximum value.
0	rh	0	The bit is set when the rxframecount_gb counter reaches half the maximum value, and also when it reaches the maximum value.

Note: rh means that this register bit is set internally and is cleared when the Counter register is read.

MMC Transmit Interrupt Register

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000), and when they cross their maximum values (0xFFFF_FFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Note: Access restriction applies: Any read access to the register clears this register!

Table 30-13 MMC Transmit Interrupt Register

Bit	Access Type	Reset Value	Description
31:25	r	00_H	Reserved
24	rh	0	The bit is set when the txvlanframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
23	rh	0	The bit is set when the txpauseframes error counter reaches half the maximum value, and also when it reaches the maximum value.
22	rh	0	The bit is set when the txoexcessdef counter reaches half the maximum value, and also when it reaches the maximum value.
21	rh	0	The bit is set when the txframecount_g counter reaches half the maximum value, and also when it reaches the maximum value.

Table 30-13 MMC Transmit Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
20	rh	0	The bit is set when the txoctetcount_g counter reaches half the maximum value, and also when it reaches the maximum value.
19	rh	0	The bit is set when the txcarriererror counter reaches half the maximum value, and also when it reaches the maximum value.
18	rh	0	The bit is set when the txexesscol counter reaches half the maximum value, and also when it reaches the maximum value.
17	rh	0	The bit is set when the txlatecol counter reaches half the maximum value, and also when it reaches the maximum value.
16	rh	0	The bit is set when the txdeferred counter reaches half the maximum value, and also when it reaches the maximum value.
15	rh	0	The bit is set when the txmulticol_g counter reaches half the maximum value, and also when it reaches the maximum value.
14	rh	0	The bit is set when the txsinglecol_g counter reaches half the maximum value, and also when it reaches the maximum value.
13	rh	0	The bit is set when the txunderflowerror counter reaches half the maximum value, and also when it reaches the maximum value.
12	rh	0	The bit is set when the txbroadcastframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
11	rh	0	The bit is set when the txmulticastframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
10	rh	0	The bit is set when the txunicastframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.

Table 30-13 MMC Transmit Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
9	rh	0	The bit is set when the tx1024tomaxoctets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
8	rh	0	The bit is set when the tx512to1023octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
7	rh	0	The bit is set when the tx256to511octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
6	rh	0	The bit is set when the tx128to255octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
5	rh	0	The bit is set when the tx65to127octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
4	rh	0	The bit is set when the tx64octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
3	rh	0	The bit is set when the txmulticastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
2	rh	0	The bit is set when the txbroadcastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
1	rh	0	The bit is set when the txframecount_gb counter reaches half the maximum value, and also when it reaches the maximum value.
0	rh	0	The bit is set when the txoctetcount_gb counter reaches half the maximum value, and also when it reaches the maximum value.

MMC Receive Interrupt Mask Register

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

Table 30-14 MMC Receive Interrupt Mask Interrupt Register

Bit	Access Type	Reset Value	Description
31:24	r	00_H	Reserved
23	rw	0	Setting this bit masks the interrupt when the rxwatchdog counter reaches half the maximum value, and also when it reaches the maximum value.
22	rw	0	Setting this bit masks the interrupt when the rxvlanframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
21	rw	0	Setting this bit masks the interrupt when the rxfifooverflow counter reaches half the maximum value, and also when it reaches the maximum value.

1	rh	0	The bit is set when the rxipv4_hdrerr_frms counter reaches half the maximum value, and also when it reaches the maximum value.
0	rh	0	The bit is set when the rxipv4_gd_frms counter reaches half the maximum value, and also when it reaches the maximum value.

30.2.8 Power Management Block

This section describes the power management (PMT) mechanisms supported by the GMAC. PMT supports the reception of network (remote) wake-up frames and Magic Packet frames. PMT does not perform the clock gate function, but generates interrupts for wake-up frames and Magic Packets received by the GMAC. The PMT block sits on the receiver path of the GMAC and is enabled with remote wake-up frame enable and Magic Packet enable. These enables are in the PMT Control and Status register and are programmed by the Application. You can include the optional PMT module by selecting it in the coreKit during configuration. You have the option to select either or both types of power-management frames (remote wake-up and Magic Packet)

PMT registers are accessed in the same manner as with GMAC-CSR registers. Refer to registers 10 and 11, for mapping information.

When the power down mode is enabled in the PMT, then all received frames are dropped by the core and they are not forwarded to the application. The core comes out of the power down mode only when either a Magic Packet or a Remote Wake-up frame is received and the corresponding detection is enabled.

30.2.8.1 PMT Block Description

PMT Control and Status Register

The PMT CSR program the request wake-up events and monitor the wake-up events.

Note: Access restriction applies: Any read access to the register clears this register!

Table 30-18 PMT Control and Status Register

Bit	Access Type	Reset Value	Description
31	rwh	0	Wake-Up Frame Filter Register Pointer Reset When set, resets the Remote Wake-up Frame Filter register pointer to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies: setting sets + clearing has no effect.
30:10	R	0000_00_H	Reserved
9	rw	00	Global Unicast When set, enables any unicast packet filtered by the GMAC (DAF) address recognition to be a wake-up frame.
8:7	R	0	Reserved
6	rh	0	Wake-Up Frame Received When set, this bit indicates the power management event was generated due to reception of a wake-up frame. This bit is cleared by a Read into this register.
5	rh	0	Magic Packet Received When set, this bit indicates the power management event was generated by the reception of a Magic Packet. This bit is cleared by a Read into this register.
4:3	R	00	Reserved
2	rw	0	Wake-Up Frame Enable When set, enables generation of a power management event due to wake-up frame reception.

Table 30-18 PMT Control and Status Register (cont'd)

Bit	Access Type	Reset Value	Description
1	rw	0	Magic Packet Enable When set, enables generation of a power management event due to Magic Packet reception.
0	rwh	0	Power Down When set, all received frames will be dropped. This bit is cleared automatically when a magic packet or Wake-Up frame is received, and Power-Down mode is disabled. Frames received after this bit is cleared are forwarded to the application.This bit must only be set when either the Magic Packet Enable, Global Unicast, or Wake-Up Frame Enable bit is set high. Access restriction applies: setting sets + clearing has no effect.

Remote Wake-Up Frame Filter Register

The register wkupfmfilter_reg, address (028_H), loads the Wake-up Frame Filter register. To load values in a Wake-up Frame Filter register, the entire register (wkupfmfilter_reg) must be written. The wkupfmfilter_reg register is loaded by sequentially loading the eight register values in address (028) for wkupfmfilter_reg0, wkupfmfilter_reg1,... wkupfmfilter_reg7, respectively. wkupfmfilter_reg is read in the same way.

Note: The internal counter to access the appropriate wkupfmfilter_reg is incremented when lane3 is accessed by the CPU. This should be kept in mind if you are accessing these registers in byte or half-word mode.

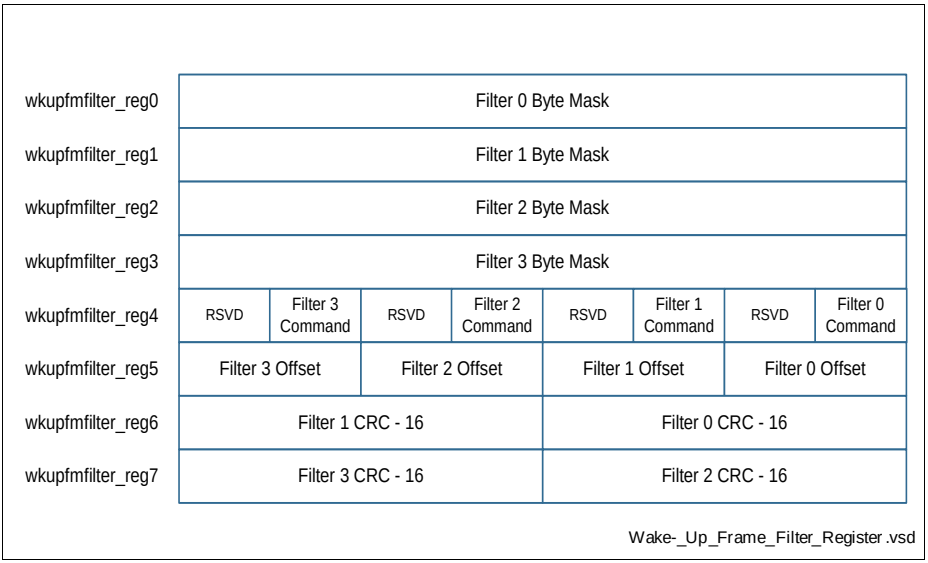

Figure 30-11 Wake-Up Frame Filter Register

Filter i Byte Mask

This register defines which bytes of the frame are examined by filter i (0, 1, 2, and 3) in order to determine whether or not the frame is a wake-up frame. The MSB (thirty-first bit) must be zero. Bit j [30:0] is the Byte Mask. If bit j (byte number) of the Byte Mask is set, then Filter i Offset + j of the incoming frame is processed by the CRC block; otherwise Filter i Offset + j is ignored.

Filter i Command

This 4-bit command controls the filter i operation. Bit 3 specifies the address type, defining the pattern's destination address type. When the bit is set, the pattern applies to only multicast frames; when the bit is reset, the pattern applies only to unicast frame. Bit 2 and Bit 1 are reserved. Bit 0 is the enable for filter i; if Bit 0 is not set, filter i is disabled.

Filter i Offset

This register defines the offset (within the frame) from which the frames are examined by filter i. This 8-bit pattern-offset is the offset for the filter i first byte to examined. The minimum allowed is 12, which refers to the 13th byte of the frame (offset value 0 refers to the first byte of the frame).

Filter i CRC-16

This register contains the CRC_16 value calculated from the pattern, as well as the byte mask programmed to the wake-up filter register block.

30.2.8.2 Remote Wake-Up Frame Detection

When the GMAC is in sleep mode and the remote wake-up bit is enabled in PMT Control and Status register (002C), normal operation is resumed after receiving a remote wake-up frame. The Application writes all eight wake-up filter registers, by performing a sequential Write to address (0028). The Application enables remote wake-up by writing a 1 to Bit 2 of the PMT Control and Status register.

PMT supports four programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of Filter Command, and if Filter CRC-16 matches the incoming examined pattern, then the wake-up frame is received.

Filter_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter Byte Mask determines which bytes of the frame must be examined. The thirty-first bit of Byte Mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The wake-up frame is checked only for length error, FCS error, dribble bit error, GMII error, collision, and to ensure that it is not a runt frame. Even if the wake-up frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wake-up frame detection is updated in the PMT Control and Status register for every remote Wake-up frame received. A PMT interrupt to the Application triggers a Read to the PMT Control and Status register to determine reception of a wake-up frame.

30.2.8.3 Magic Packet Detection

The Magic Packet frame is based on a method that uses Advanced Micro Device's Magic Packet technology to power up the sleeping device on the network. The GMAC receives a specific packet of information, called a Magic Packet, addressed to the node on the network.

Only Magic Packets that are addressed to the device or a broadcast address will be checked to determine whether they meet the wake-up requirements. Magic Packets that pass the address filtering (unicast or broadcast) will be checked to determine whether they meet the remote Wake-on-LAN data format of 6 bytes of all ones followed by a GMAC Address appearing 16 times.

The application enables Magic Packet wake-up by writing a 1 to Bit 1 of the PMT Control and Status register. The PMT block constantly monitors each frame addressed to the node for a specific Magic Packet pattern. Each frame received is checked for a 48'hFF_FF_FF_FF_FF_FF pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the GMAC address without

any breaks or interruptions. In case of a break in the 16 repetitions of the address, the 48'hFF_FF_FF_FF_FF_FF pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (48'hFF_FF_FF_FF_FF_FF). The device will also accept a multicast frame, as long as the 16 duplications of the GMAC address are detected.

If the MAC address of a node is 48'h00_11_22_33_44_55, then the GMAC scans for the data sequence:

```
Destination Address Source Address …….. FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
…CRC
```

Magic Packet detection is updated in the PMT Control and Status register for Magic Packet received. A PMT interrupt to the Application triggers a read to the PMT CSR to determine whether a Magic Packet frame has been received.

30.2.8.4 System Considerations During Power-Down

GMAC-UNIV neither gates nor stops clocks when Power-Down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with clk_rx_i during Power-Down mode, because it is involved in magic packet/wake-on-LAN frame detection. However, the transmit path and the application path clocks can be gated off during Power-Down mode.

The pmt_intr_o signal is asserted when a valid wake-up frame is received. This signal is generated in the clk_rx_i domain.

The recommended power-down and wake-up sequence is as follows.

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. These transmissions can be detected when Transmit Interrupt (TI–DMA Register 5[0]) is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC Configuration register.
3. Wait until the Receive DMA empties all the frames from the Rx FIFO (a software timer may be required).
4. Enable Power-Down mode by appropriately configuring the PMT registers.
5. Enable the MAC Receiver and enter Power-Down mode.

6. Gate the application and transmit clock inputs to the core (and other relevant clocks in the system) to reduce power and enter Sleep mode.
7. On receiving a valid wake-up frame, the GMAC-UNIV asserts the pmt_intr_o signal and exits Power-Down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the PMT Status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

30.2.9 Station Management Agent

The Station Management Agent (SMA) module allows the Application to access any PHY registers through a 2-wire Station Management interface (MIM). The interface supports accessing up to 32 PHYs.

The application can select one of the 32 PHYs and one of the 32 registers within any PHY and send control data or receive status information. Only one register in one PHY can be addressed at any given time. For more details on the communication from the Application to the PHYs, refer to the Reconciliation Sublayer and Media Independent Interface Specifications section of the IEEE 802.3z specification, 1000BASE Ethernet. The application sends the control data to the PHY and receives status information from the PHY through the SMA module, as shown in **Figure 30-12**.

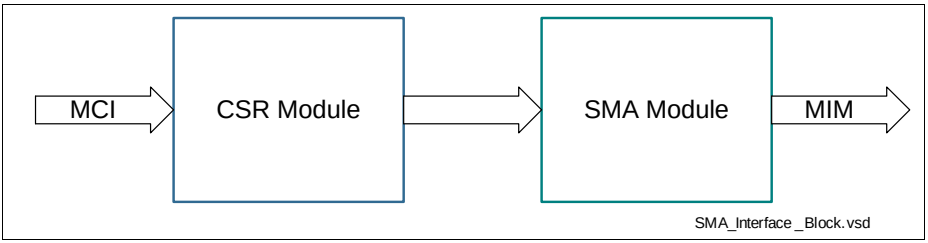

Figure 30-12 SMA Interface Block

30.2.9.1 Functions

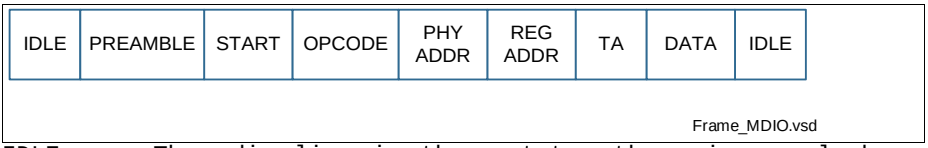
The GMAC initiates the Management Write/Read operation. The clock gmii_mdc_o is a divided clock from the Application clock clk_csr_i. The divide factor depends on the clock range setting in the GMII Address register. Clock range is set as follows:

Selection	clk_csr_i	MDC Clock
0000	60-100 MHz	clk_csr_i/42
0001	100-150 MHz	clk_csr_i/62
0010	20-35 MHz	clk_csr_i/16

Selection	clk_csr_i	MDC Clock
0011	35-60 MHz	clk_csr_i/26
0100	150-250 MHz	clk_csr_i/102
0101	250-300 MHz	clk_csr_i/124
0110, 0111	Reserved	

The gmii_mdc_o is the derivative of the Application clock clk_csr_i. The Management operation is performed through the gmii_mdi_i, gmii_mdo_o and gmii_mdo_o_e signals. A three-state buffer is implemented outside the GMAC to interface with an external PHY.

The frame structure on the MDIO line is shown below.



```
IDLE       The mdio line is three-state; there is no clock on
gmii_mdc_o
PREAMBLE   32 continuous bits of value 1
START      Start-of-frame is 2'01
OPCODE     2'b10 for Read and 2'b01 for Write
PHY ADDR   5-bit address select for one of 32 PHYs
REG ADDR   Register address in the selected PHY
TA         Turnaround is 2'bZ0 for Read and 2'b10 for Write
DATA       Any 16-bit value. In a Write operation, the GMAC drives
mdio; in a Read
           operation, PHY drives it.
```

30.2.9.2 MII Management Write Operation

When the user sets the GMII Write and Busy bits (see GMII Address Register, **"32-bit Register - GMII_Address" on Page 1-309**), the GMAC CSR module transfers the PHY address, the register address in PHY, and the write data (GMII Data Register) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the GMII Management Interface using the Management Frame Format specified in the GMII specifications (Section 22.2.4.5 of IEEE Standard). The application should not change the GMII Address register contents or the GMII Data register while the transaction is ongoing. Write operations to the GMII Address register or the GMII Data Register during this period are ignored (the Busy bit is high), and the transaction is completed without any error on the MCI interface.

After the Write operation has completed, the SMA indicates this to the CSR which then resets the Busy bit. The SMA module divides the CSR (Application) clock with the clock divider programmed (CR bits of GMII Address Register) to generate the MDC clock for this interface. The GMAC drives the MDIO line for the complete duration of the frame. The frame format for the Write operation is as follows:

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	01	AAAAA	RRRRR	10	DDD . . . .DDD	Z

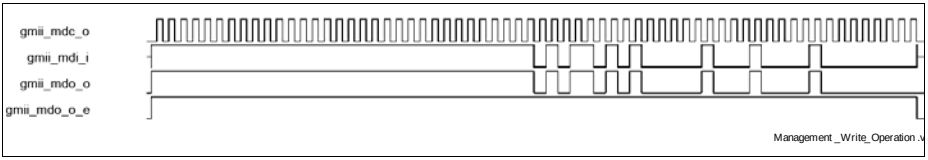


Figure 30-13 Management Write Operation

Figure 30-13 is a reference for the Write operation.

30.2.9.3 MII Management Read Operation

When the user sets the GMII Busy bit (see GMII Address Register, **“32-bit Register - GMII_Address” on Page 1-309**) with the GMII Write bit as 0, the GMAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers. At this point, the SMA module starts a Read operation on the GMII Management Interface using the Management Frame Format specified in the GMII specifications (Section 22.2.4.5 of IEEE Standard). The application should not change the GMII Address register contents or the GMII Data register while the transaction is ongoing. Write operations to the GMII Address register or GMII Data Register during this period are ignored (the Busy bit is high) and the transaction completed without any error on the MCI interface.

After the Read operation has completed, the SMA indicates this to the CSR, which then resets the Busy bit and updates the GMII Data register with the data read from the PHY. The SMA module divides the CSR (Application) clock with the clock divider programmed (CR bits of GMII Address Register) to generate the MDC clock for this interface. The GMAC drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line. The frame format for the Read operation is as follows:

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	10	AAAAA	RRRRR	Z0	DDD . . . .DDD	Z

Figure 30-14 is a reference for the read operation.

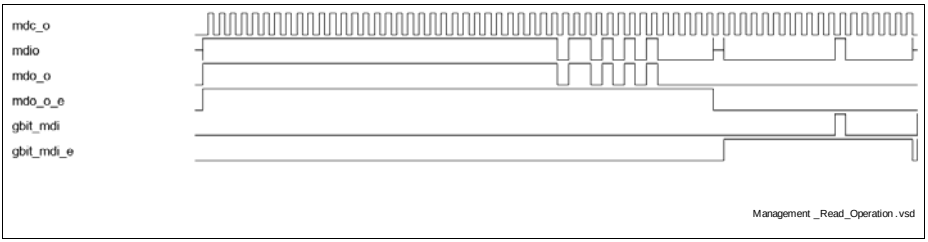

Figure 30-14 Management Read Operation

30.2.10 Reduced Media Independent Interface

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Switch ASICs (only in 10/100 mode). According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces (such as switches), the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port — a 62.5% decrease in pin count.

- The RMII module is instantiated between the GMAC and the PHY. This helps translation of the MAC's MII into the RMII. The RMII block has the following characteristics:
- Supports 10 Mbit/s and 100 Mbit/s operating rates.
- Two clock references are sourced externally, providing independent, 2-bit wide transmit and receive paths.

30.2.10.1 Block Diagram

Figure 30-15 shows the position of the RMII block relative to the Ethernet MAC and RMII PHY. The RMII block is placed in front of the Ethernet MAC to translate the MII signals to RMII signals.

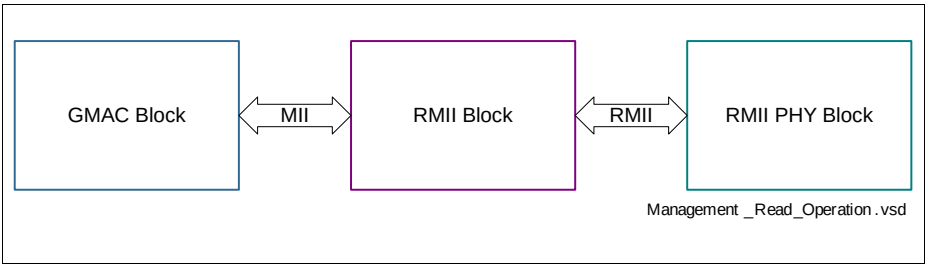

Figure 30-15 RMII Block Diagram

30.2.10.2 Block Overview

The following list describes the RMII's hardware components, which are shown in **Figure 30-16**. Each of these blocks is briefly described in the following sections.

MII-RMII Transmit (MRT) Block: This block translates all MII transmit signals to RMII transmit signals. All RMII signals are synchronous to clk_rmii_i.

MII-RMII Receive (MRR) Block: This block translates all RMII receive signals to MII receive signals. All MII signals are synchronous to clk_rx_i. You must ensure that the same clock is connected to both clk_tx_i and clk_rx_i clock input ports in RMII mode. This is required because clock-MUXing logic is avoided inside the GMAC core.

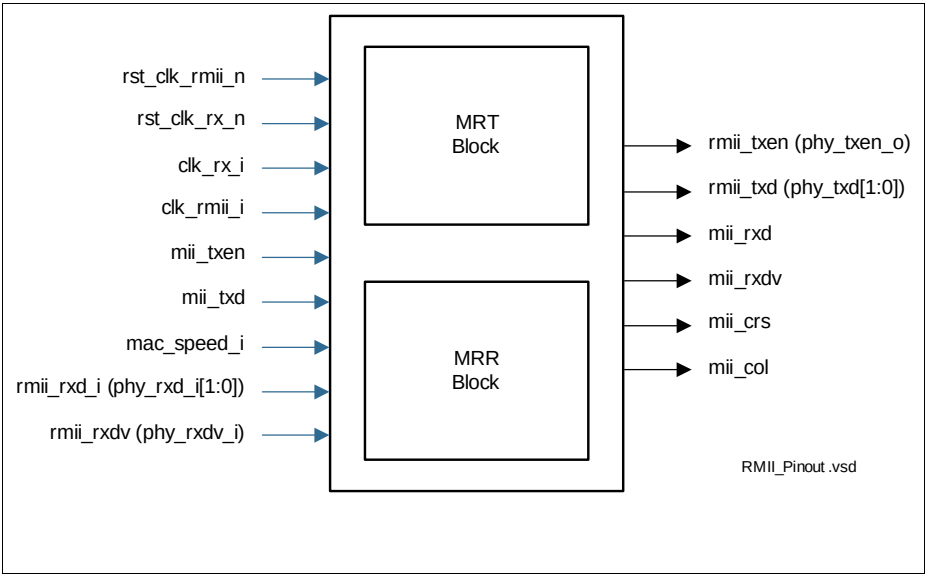

Figure 30-16 RMII Pinout

Note: The mac_speed_i signal configures the RMII to operate at 10 Mbit/s or 100 Mbit/s. This signal is driven from the MAC Configuration register's FES bit.

30.2.10.3 Transmit Bit Ordering

Each nibble from the MII must be transmitted on the RMII a di-bit at a time with the order of di-bit transmission shown in **Figure 30-17**. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

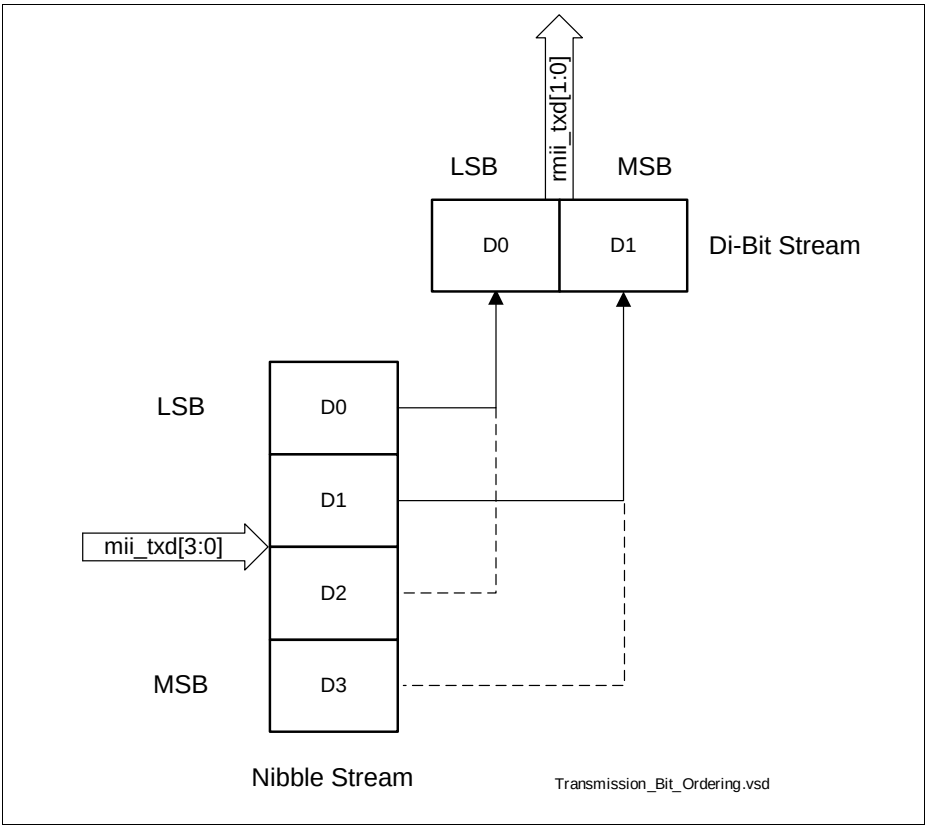

Figure 30-17 Transmission Bit Ordering

30.2.10.4 RMII Transmit Timing Diagrams

Figure 30-18 through **Figure 30-21** show MII-to-RMII transaction timing.

Figure 30-18 shows the start of MII transmission and the following RMII transmission in 100 Mbit/s mode.

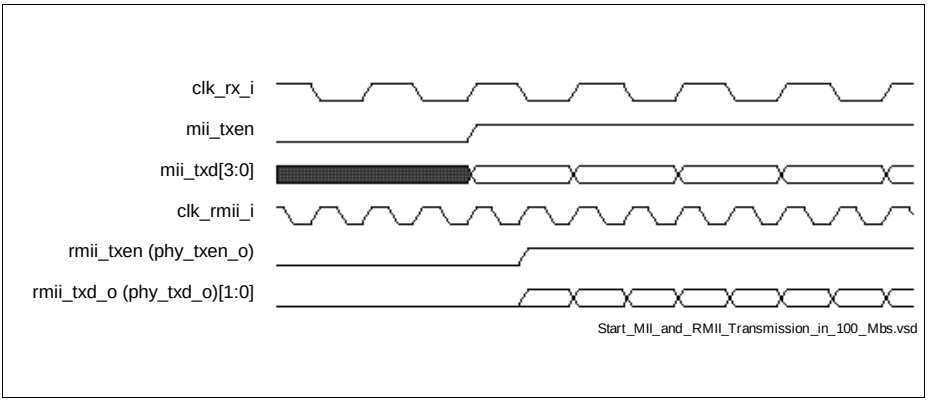

Figure 30-18 Start of MII and RMII Transmission in 100 Mbit/s Mode

Figure 30-19 shows the end of frame transmission for MII and RMII in 100 Mbit/s mode.

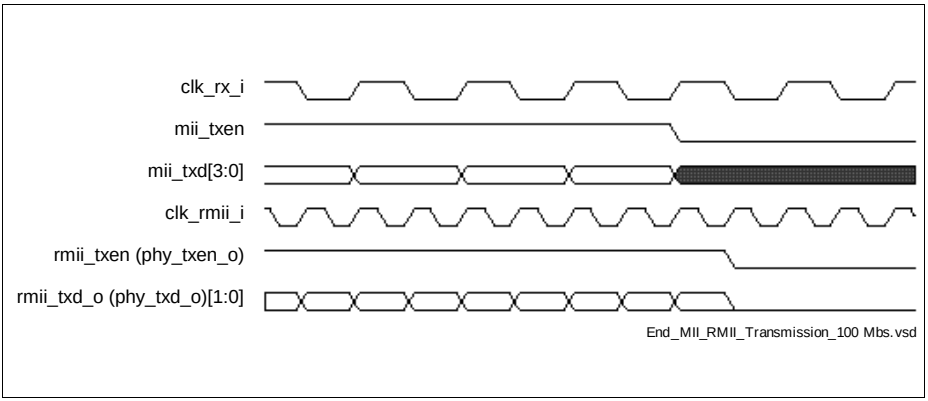

Figure 30-19 End of MII and RMII Transmission in 100 Mbit/s Mode

Figure 30-20 shows the start of MII transmission and the following RMII transmission in 10 Mbit/s mode.

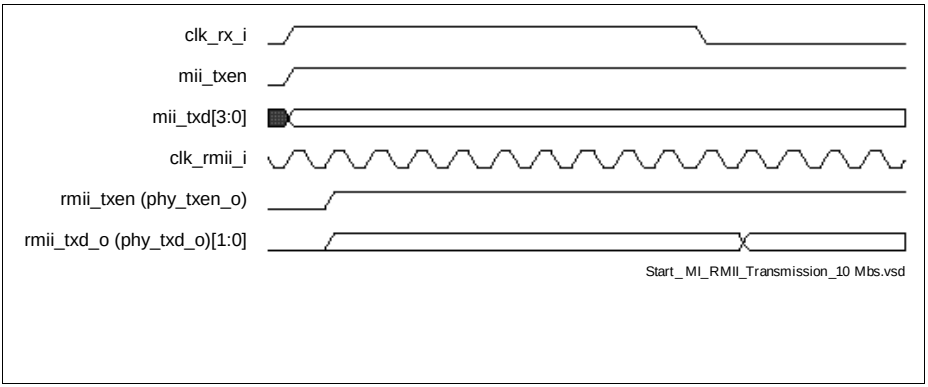

Figure 30-20 Start of MII and RMII Transmission in 10 Mbit/s Mode

Figure 30-21 shows the end of MII transmission and RMII transmission in 10 Mbit/s mode.

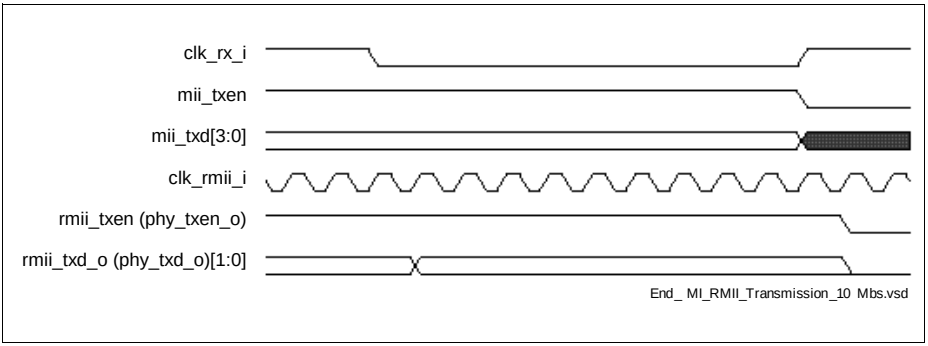

Figure 30-21 End of MII and RMII Transmission in 10 Mbit/s Mode

Receive Bit Ordering

Each nibble is transmitted to the MII from the di-bit received from the RMII in the nibble transmission order shown in **Figure 30-22**. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

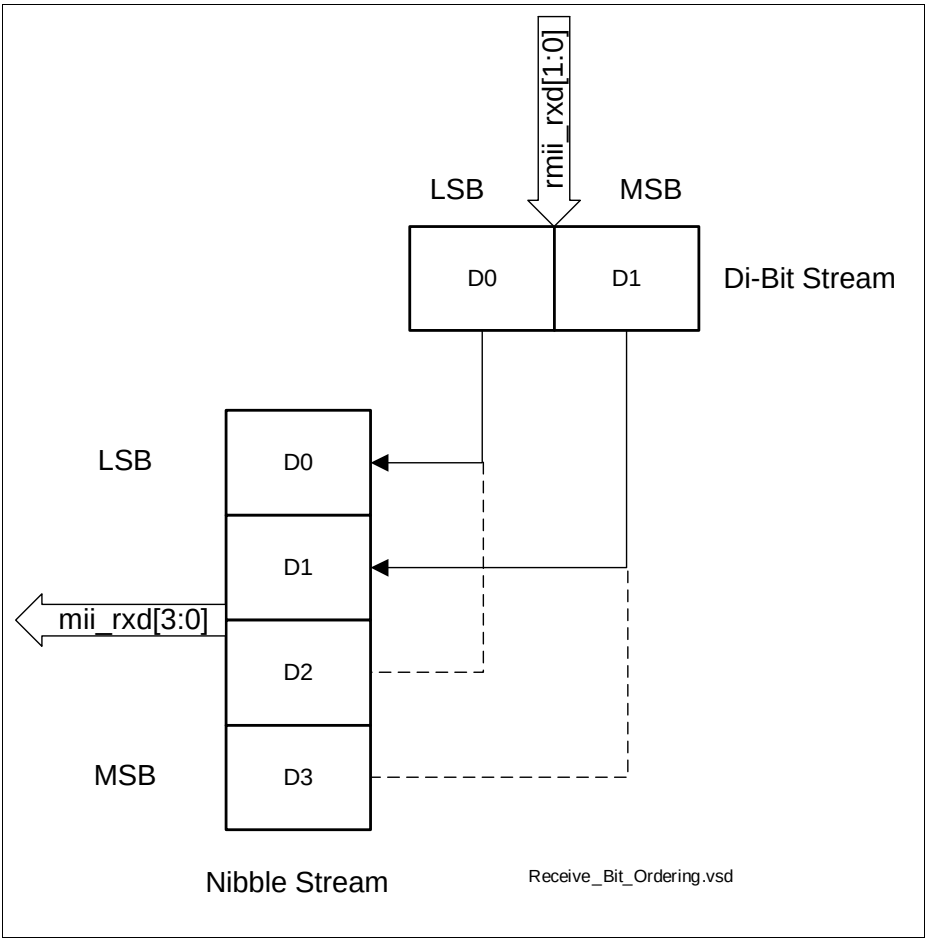

Figure 30-22 Receive Bit Ordering

30.2.11 Interrupts From the GMAC Core

Interrupts can be generated from the GMAC core as a result of various events in the optional modules in it.

The Interrupt Status register in the GMAC Register Map (**"GMAC Register Map" on Page 1-281**) describes the events that can cause an interrupt from the GMAC core. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the Interrupt Mask register.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt. For example, Bit 0 of the Interrupt register, set high, indicates that the link status on the RGMII interface has changed. You must read Register 54 (the RGMII Status register) to clear this interrupt event.

The interrupts from the RGMII and PCS blocks are combined (OR'ed) and given as the GLI bit in the DMA Status register. The TTI, GPI, and GMI signals in **Figure 30-23** refer to the bits that can be read in the DMA Status register.

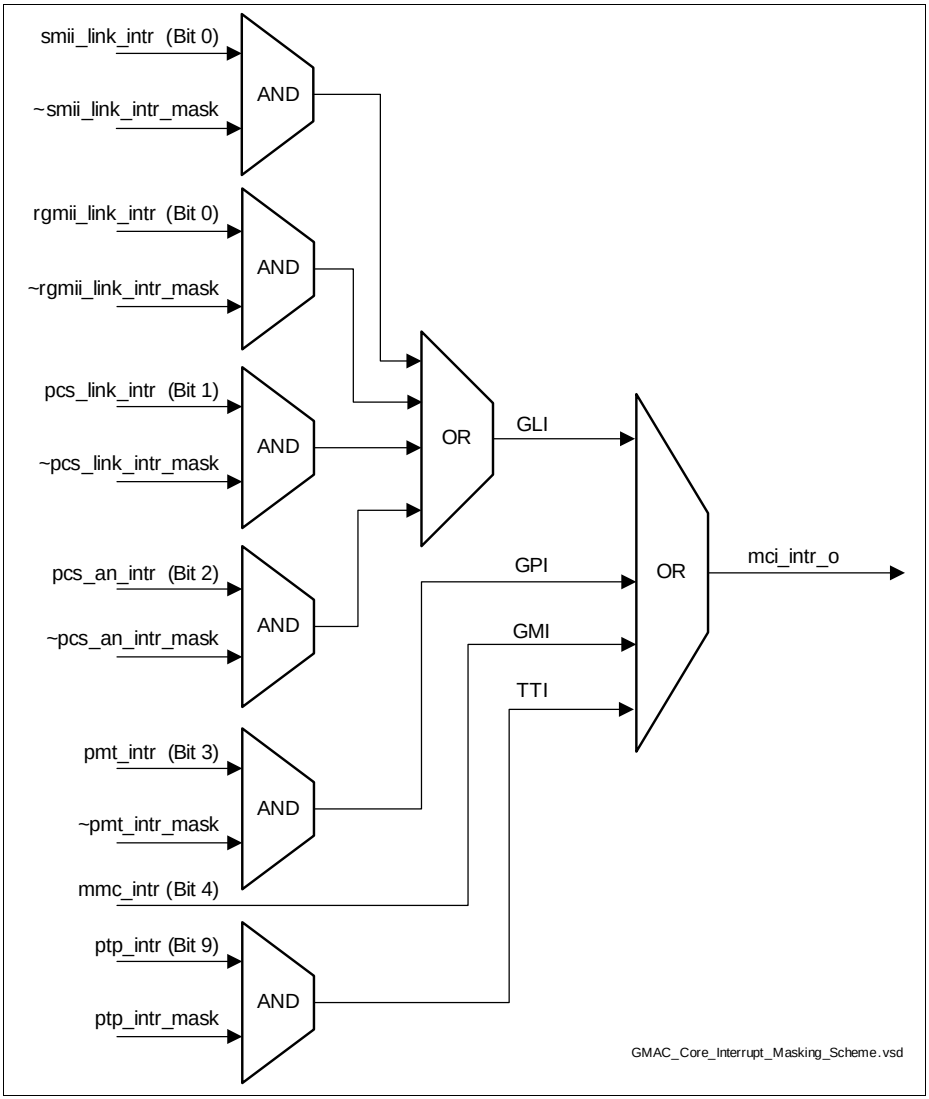

Figure 30-23 GMAC Core Interrupt Masking Scheme

30.3 Register

General notes on registers:

- All CSRs are implemented as 32-bit registers and can be accessed in 1 read/write cycle with a 32-bit MCI interface (or 32-bit AHB slave port). If you initiate a non-32-bit register access, the byte enable signals (mci_be_i[3:0]) qualify the corresponding register bytes. Only write operations are qualified with byte enables, while read operations are always 32-bit, unless the register is affected by a read operation. Byte enable signals qualify reads to such registers as, for example, the MMC counter registers.
- The transfer of particular register contents (e.g., MAC DA address register) to the Transmit or Receive clock domains are initiated when a particular byte is written. This is indicated in the register descriptions, where applicable.
- When any Register content is being transferred to a different clock domain after a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation will not get updated to the destination clock domain. Thus the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock or PHY transmit clock).

30.3.1 Register Maps

The register maps in this section provide high-level summaries of each register or group of registers. The detailed register descriptions in **“Register Description” on Page 1-292**.

Reserved address space (marked as “do not use”) will generate no bus error (nBE).

All registers in the DMA and MAC Registers map (1000_H - 2058_H) are P = ACCEN protected. The registers for additional Module Control are ACCEN protected according to **Figure 30-22**).

30.3.1.1 Register Overview

Table 30-19 Registers Address Space - ETH Module

Module	Base Address	End Address	Note
ETH	F001 $D000_H$	F001 $F0FF_H$	-

30.3.1.2 DMA Register Map

Table 30-20 DMA Register Map

DMA Register No.	Offset Address	Register Name and Description
0	2000_H	**DMA Register 0 (Bus Mode Register)** Controls the Host Interface Mode.
1	2004_H	**DMA Register 1 (Transmit Poll Demand Register)** Used by the host to instruct the DMA to poll the Transmit Descriptor List.
2	2008_H	**DMA Register 2 (Receive Poll Demand Register)** Used by the Host to instruct the DMA to poll the Receive Descriptor List.
3	$200C_H$	**DMA Register 3 (Receive Descriptor List Address Register)** Points the DMA to the start of the Receive Descriptor list.
4	2010_H	**DMA Register 4 (Transmit Descriptor List Address Register)** Points the DMA to the start of the Transmit Descriptor List.
5	2014_H	**DMA Register 5 (Status Register)** The Software driver (application) reads this register during interrupt service routine or polling to determine the status of the DMA.
6	2018_H	**DMA Register 6 (Operation Mode Register)** Establishes the Receive and Transmit operating modes and command.
7	$201C_H$	**DMA Register 7 (Interrupt Enable Register)** Enables the interrupts reported by the Status Register.
8	2020_H	**DMA Register 8 (Missed Frame and Buffer Overflow Counter Register)** Contains the counters for discarded frames because no host Receive Descriptor was available, and discarded frames because of Receive FIFO Overflow.
9	2024_H	**DMA Register 9 (Receive Interrupt Watchdog Timer Register)** Watchdog time-out for Receive Interrupt (RI) from DMA
12-17	2030_H-2044_H	Do not use

Table 30-20 DMA Register Map

DMA Register No.	Offset Address	Register Name and Description
18	2048_H	**DMA Register 18 (Current Host Transmit Descriptor Register)** Points to the start of current Transmit Descriptor read by the DMA.
19	$204C_H$	**DMA Register 19 (Current Host Receive Descriptor Register)** Points to the start of current Receive Descriptor read by the DMA.
20	2050_H	**DMA Register 20 (Current Host Transmit Buffer Address Register)** Points to the current Transmit Buffer address read by the DMA.
21	2054_H	**DMA Register 21 (Current Host Receive Buffer Address Register)** Points to the current Receive Buffer address read by the DMA.
22	2058_H	**DMA Register 22 (HW Feature Register)** Indicates the presence of the optional features of the core.
23-63	$205C_H$-$20FC_H$	Do not use

30.3.1.3 GMAC Register Map

Table 1-59 provides the address map of the GMAC core registers.

Table 30-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
0	1000_H	**GMAC Register 0 (MAC Configuration Register)** This is the operation mode register for the MAC.
1	1004_H	**GMAC Register 1 (MAC Frame Filter)** Contains the frame filtering controls.

Table 30-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
2	1008_H	**GMAC Register 2 (Hash Table High Register)** Contains the higher 32 bits of the Multicast Hash table.This register is present only when the Hash filter function is selected in coreConsultant. (See Table ??)
3	$100C_H$	**GMAC Register 3 (Hash Table Low Register)** Contains the lower 32 bits of the Multicast Hash table. This register is present only when the Hash filter function is selected in coreConsultant. (See Table ??)
4	1010_H	**GMAC Register 4 (GMII Address Register)** Controls the management cycles to an external PHY. This register is present only when the Station Management (MDIO) feature is selected in coreConsultant. (See Table ??)
5	1014_H	**GMAC Register 5 (GMII Data Register)** Contains the data to be written to or read from the PHY register. This register is present only when the Station Management (MDIO) feature is selected in coreConsultant. (See Table ??)
6	1018_H	**GMAC Register 6 (Flow Control Register)** Controls the generation of control frames.
7	$101C_H$	**GMAC Register 7 (VLAN Tag Register)** Identifies IEEE 802.1Q VLAN type frames.
8	1020_H	**GMAC Register 8 (Version Register)** Identifies the version of the Core
9	1024_H	**GMAC Register 9 (Debug Register)** Gives the status of various internal blocks for debugging

Table 30-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
10	1028_H	**Remote Wake-Up Frame Filter** This is the address through which the remote Wake-up Frame Filter registers (wkupfmfilter_reg) are written/read by the Application. wkupfmfilter_reg is actually a pointer to eight (not transparent) such wkupfmfilter_reg registers. Eight sequential Writes to this address (028) will write all wkupfmfilter_reg registers. Eight sequential Reads from this address (028) will read all wkupfmfilter_reg registers. This register contains the higher 16 bits of the 7th MAC address. This register is present only when the PMT module Remote Wake-up feature is selected in coreConsultant. (See Table ??) Refer to “Remote Wake-Up Frame Filter Register” on page ?? for additional information.
11	$102C_H$	**PMT Control and Status** This register is present only when the PMT module is selected in coreConsultant. (See Table ??) Refer to “PMT Control and Status Register” on page ?? for additional information.
12-13	1030_H - 1034_H	Do not use
14	1038_H	**GMAC Register 14 (Interrupt Status Register)** Contains the interrupt status.
15	$103C_H$	**GMAC Register 15 (Interrupt Mask Register)** Contains the masks for generating the interrupts.
16	1040_H	**GMAC Register 16 (MAC Address 0 High Register)** Contains the higher 16 bits of the first MAC address.
17	1044_H	**GMAC Register 17 (MAC Address 0 Low Register)** Contains the lower 32 bits of the first MAC address.
18	1048_H	**GMAC Register 18 (MAC Address 1 High Register)** Contains the higher 16 bits of the second MAC address. This register is present only when Enable MAC Address 1 is selected in coreConsultant. (See Table ??).

Table 30-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
19	$104C_H$	**GMAC Register 19 (MAC Address 1 Low Register)** Contains the lower 32 bits of the second MAC address. This register is present only when Enable MAC Address 1 is selected in coreConsultant. (See Table ??).
20	1050_H	**MAC Address 2 High Register** Contains the higher 32 bits of the third MAC address. This register is present only when Enable MAC Address 2 is selected in coreConsultant. (See Table ??).
21	1054_H	**MAC Address 2 Low Register** Contains the lower 32 bits of the third MAC address. This register is present only when Enable MAC Address 2 is selected in coreConsultant. (See Table ??).
22	1058_H	**MAC Address 3 High Register** Contains the higher 16 bits of the fourth MAC address. This register is present only when Enable MAC Address 3 is selected in coreConsultant. (See Table ??).
23	$105C_H$	**MAC Address 3 Low Register** Contains the lower 32 bits of the fourth MAC address. This register is present only when Enable MAC Address 3 is selected in coreConsultant. (See Table ??).
55-63	$10DC_H$ - $10FC_H$	Do not use
64-191	1100_H - $12FC_H$	MMC Register Map See **Table 1-17 “MMC Register Map” on Page 1-131**.
192-447	1300_H - $16FC_H$	Do not use
448	1700_H	**Register 448 (Time Stamp Control Register)** Controls the time stamp generation and update logic.
449	1704_H	**Register 449 (Sub-Second Increment Register)** Contains the 8-bit value by which the Sub-Second register is incremented.This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.

Table 30-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
450	1708_H	**Register 450 (System Time - Seconds Register)** Contains the lower 32 bits of the seconds field of the system time. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
451	$170C_H$	**Register 451 (System Time - Nanoseconds Register)** Contains 32 bits of the nanoseconds field of the system time. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
452	1710_H	**Register 452 (System Time - Seconds Update Register)** Contains the lower 32 bits of the seconds field to be written to, added to, or subtracted from the System Time value. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
453	1714_H	**Register 453 (System Time - Nanoseconds Update Register)** Contains 32 bits of the nanoseconds field to be written to, added to, or subtracted from the System Time value. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
454	1718_H	**Register 454 (Time Stamp Addend Register)** This register is used by the software to readjust the clock frequency linearly to match the master clock frequency. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
455	$171C_H$	**Register 455 (Target Time Seconds Register)** Contains the higher 32 bits of time to be compared with the system time for interrupt event generation. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
456	1720_H	**Register 456 (Target Time Nanoseconds Register)** Contains the lower 32 bits of time to be compared with the system time for interrupt event generation. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.

Table 30-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
457	1724_H	**Register 457 (System Time - Higher Word Seconds Register)** Contains the most significant 16-bits of the time stamp seconds value. This register is optional and can be selected using the coreKit parameter identified in “IEEE 1588 Time Stamp Block” on page ??.
458	1728_H	**Register 458 (Time Stamp Status Register)** Contains the PTP status. This register is available only when the advanced IEEE 1588 timestamp feature is selected.
459	$172C_H$	**Register 459 (PPS Control Register)** This register is used to control the interval of the PPS signal output, such that a duration of less than 1 second can be achieved between pulses.
460	1730_H	**Register 460 (Auxiliary Time Stamp - Nanoseconds Register)** Contains the lower 32 bits (nanoseconds field) of the auxiliary time stamp register.
461	1734_H	**Register 461 (Auxiliary Time Stamp - Seconds Register)** Contains the upper 32 bits (seconds field) of the auxiliary time stamp register.
462-511	1738_H - $17FC_H$	Do not use
512-511	1738_H - $17FC_H$	Do not use

30.3.1.4 Ethernet MAC Additional Module Control Registers

This section describes the additional module control registers of the Ethernet MAC module. All Ethernet MAC register names described in this section will be referenced in other parts of the TC21x/TC22x/TC23x User's Manual by the module name prefix "Ethernet MAC_" for the Ethernet MAC interface.

All registers in the Ethernet MAC address spaces are reset with the application reset (definition see SCU section "Reset Operation"). P = ACCEN protection

Table 30-22 Register Overview - ETH Add. Mod. Contr. Registers

Register Short Name	Register Long Name	Offset [1]	Access Mode		Description see
			Read	Write

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PS	FES	DO	LM	DM	IPC	DR	LUD	ACS	BL		DC	TE	RE	PRELEN	
r	rw	rw	rw	rw	rw	rw	r	rw	rw		rw	rw	rw	rw	

Field	Bits	Type	Description
PRELEN	[1:0]	rw	**Preamble Length for Transmit Frames** These bits control the number of preamble bytes that are added to the beginning of every Transmit frame. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. * 2'b00: 7 bytes of preamble * 2'b01: 5 byte of preamble * 2'b10: 3 bytes of preamble * 2'b11: reserved
RE	2	rw	**Receiver Enable** When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the GMII or MII. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames from the GMII or MII.

Field	Bits	Type	Description
TE	3	rw	**Transmitter Enable** When this bit is set, the transmit state machine of the MAC is enabled for transmission on the GMII or MII. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames.
DC	4	rw	**Deferral Check** When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times in the 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, or if the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on GMII or MII. Defer time is not cumulative. When the transmitter defers for 10,000 bit times, it transmits, collides, backs off, and then defers again after completion of back-off. The deferral timer resets to 0 and restarts. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration.

Field	Bits	Type	Description
BL	[6:5]	rw	**Back-Off Limit** The Back-Off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000 Mbps and 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration. * 00: k = min (n, 10) * 01: k = min (n, 8) * 10: k = min (n, 4) * 11: k = min (n, 1) where n = retransmission attempt. The random integer r takes the value in the range 0 <= r < kth power of 2
ACS	7	rw	**Automatic Pad or CRC Stripping** When this bit is set, the MAC strips the Pad or FCS field on the incoming frames only if the value of the length field is less than 1,536 bytes. All received frames with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming frames, without modifying them, to the Host.
LUD	8	r	**Link Up or Down** This bit indicates whether the link is up or down during the transmission of configuration in the RGMII, SGMII, or SMII interface: * 0: Link Down * 1: Link Up This bit is reserved (RO with default value) and is enabled when the RGMII, SGMII, or SMII interface is enabled during core configuration.

Field	Bits	Type	Description
DR	9	rw	**Disable Retry** When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status. When this bit is reset, the MAC attempts retries based on the settings of the BL field (Bits [6:5]). This bit is applicable only in the half-duplex mode and is reserved (RO with default value) in the full-duplex-only configuration.
IPC	10	rw	**Checksum Offload** When this bit is set, the MAC calculates the 16-bit one's complement of the one's complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 2526 or 2930 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The MAC also appends the 16-bit checksum calculated for the IP header datagram payload (bytes after the IPv4 header) and appends it to the Ethernet frame transferred to the application (when Type 2 COE is deselected). When this bit is reset, this function is disabled. When Type 2 COE is selected, this bit, when set, enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared. If the IP Checksum Offload feature is not enabled during core configuration, this bit is reserved (RO with default value).
DM	11	rw	**Duplex Mode** When this bit is set, the MAC operates in the full-duplex mode where it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configuration.

Field	Bits	Type	Description
LM	12	rw	**Loopback Mode** When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Receive clock input (clk_rx_i) is required for the loopback to work properly, because the Transmit clock is not looped-back internally.
DO	13	rw	**Disable Receive Own** When this bit is set, the MAC disables the reception of frames when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting. This bit is not applicable if the MAC is operating in the full-duplex mode. This bit is reserved (RO with default value) if the MAC is configured for the full-duplex-only operation.
FES	14	rw	**Speed** This bit selects the speed in the MII, RMII, SMII, RGMII, SGMII, or RevMII interface: * 0: 10 Mbps * 1: 100 Mbps This bit is reserved (RO) by default and is enabled only when the RMII, SMII, RGMII, SGMII, or RevMII interface is enabled during core configuration. This bit generates link speed encoding when TC (Bit 24) is set in the RGMII, SMII, or SGMII mode. This bit is always driven for RevMII. If the MAC is configured with an RMII, SMII, SGMII, or RGMII PHY interface, this bit can optionally be driven as an output signal (mac_speed_o[0]) to reflect the value of this bit in the mac_speed_o signal. In addition, this bit is reserved when RMII is enabled without enabling the Output Port for speed selection option during core configuration.

Field	Bits	Type	Description
PS	15	r	**Port Select** This bit selects between GMII and MII: * 0: GMII (1000 Mbps) * 1: MII (10/100 Mbps) In the 10 or 100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only with the appropriate value. In the default 10/100/1000 Mbps configurations, this bit is R_W. The mac_portselect_o signal reflects the value of this bit.
DCRS	16	rw	**Disable Carrier Sense During Transmission** When set high, this bit makes the MAC transmitter ignore the (G)MII CRS signal during frame transmission in the half-duplex mode. This request results in no errors generated because of Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors because of Carrier Sense and can even abort the transmissions. This bit is reserved (and RO) in the full-duplex-only configurations.
IFG	[19:17]	rw	**Inter-Frame Gap** These bits control the minimum IFG between frames during transmission. * 000: 96 bit times * 001: 88 bit times * 010: 80 bit times * ... * 111: 40 bit times In the half-duplex mode, the minimum IFG can be configured only for 64 bit times (IFG = 100). Lower values are not considered. In the 1000-Mbps mode, the minimum IFG supported is 64 bit times (and above) in the GMAC-CORE configuration and 80 bit times (and above) in other configurations.
JE	20	rw	**Jumbo Frame Enable** When this bit is set, the MAC allows Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status.

Field	Bits	Type	Description
BE	21	r	**Frame Burst Enable** When this bit is set, the MAC allows frame bursting during transmission in the GMII half-duplex mode. This bit is reserved (and RO) in the 10/100 Mbps only or full-duplex-only configurations.
JD	22	rw	**Jabber Disable** When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if JE is set high) during transmission.
WD	23	rw	**Watchdog Disable** When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive frames of up to 16,384 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the frame being received. The MAC cuts off any bytes received after 2,048 bytes.
TC	24	r	**Transmit Configuration in RGMII, SGMII, or SMII** When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII, SMII, or SGMII port. When this bit is reset, no such information is driven to the PHY. This bit is reserved (and RO) if the RGMII, SMII, or SGMII PHY port is not selected during core configuration.
CST	25	rw	**CRC Stripping of Type Frames** When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver.
SFTERR	26	r	**SMII Force Transmit Error** When set, this bit indicates to the PHY to force a transmit error in the SMII frame being transmitted. This bit is reserved if the SMII PHY port is not selected during core configuration.

Field	Bits	Type	Description
TWOKPE	27	rw	**IEEE 802.3as support for 2K packets Enable** When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames. When this bit is reset and Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames. When Bit 20 (Jumbo Enable) is set, setting this bit has no effect on Giant Frame status.

Field	Bits	Type	Description
SARC	[30:28]	r	**Source Address Insertion or Replacement Control** This field controls the source address insertion or replacement for all transmitted frames. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits [29:28]: * 2'b0x: The input signals mti_sa_ctrl_i and ati_sa_ctrl_i control the SA field generation. * 2'b10: - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers (registers 16 and 17) in the SA field of all transmitted frames. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected during core configuration, the MAC inserts the content of the MAC Address 1 registers (registers 18 and 19) in the SA field of all transmitted frames. * 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers (registers 16 and 17) in the SA field of all transmitted frames. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected during core configuration, the MAC replaces the content of the MAC Address 1 registers (registers 18 and 19) in the SA field of all transmitted frames. Note: - Changes to this field take effect only on the start of a frame. If you write this register field when a frame is being transmitted, only the subsequent frame can use the updated value, that is, the current frame does not use the updated value. - These bits are reserved and RO when the Enable SA, VLAN, and CRC Insertion on TX feature is not selected during core configuration.
RESERVED_31	31	r	**RESERVED_31**

32-bit Register - MAC_Frame_Filter

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

ETH_MAC_FRAME_FILTER
Register 1 - MAC Frame Filter **(1004_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RESERVED_15_11					HPF	SAF	SAIF	PCF		DBF	PM	DAIF	HMC	HUC	PR
r					rw	rw	rw	rw		rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
PR	0	rw	**Promiscuous Mode** When this bit is set, the Address Filter module passes all incoming frames regardless of its destination or source address. The SA or DA Filter Fails status bits of the Receive Status Word are always cleared when PR is set.
HUC	1	rw	**Hash Unicast** When set, MAC performs destination address filtering of unicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in DA registers. If Hash Filter is not selected during core configuration, this bit is reserved (and RO).

Field	Bits	Type	Description
HMC	2	rw	**Hash Multicast** When set, MAC performs destination address filtering of received multicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for multicast frames, that is, it compares the DA field with the values programmed in DA registers. If Hash Filter is not selected during core configuration, this bit is reserved (and RO).
DAIF	3	rw	**DA Inverse Filtering** When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast frames. When reset, normal filtering of frames is performed.
PM	4	rw	**Pass All Multicast** When set, this bit indicates that all received frames with a multicast destination address (first bit in the destination address field is '1') are passed. When reset, filtering of multicast frame depends on HMC bit.
DBF	5	rw	**Disable Broadcast Frames** When this bit is set, the AFM module filters all incoming broadcast frames. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast frames.

Field	Bits	Type	Description
PCF	[7:6]	rw	**Pass Control Frames** These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). * 00: MAC filters all control frames from reaching the application. * 01: MAC forwards all control frames except PAUSE control frames to application even if they fail the Address filter. * 10: MAC forwards all control frames to application even if they fail the Address Filter. * 11: MAC forwards control frames that pass the Address Filter. The following conditions should be true for the PAUSE control frames processing: * Condition 1: The MAC is in the full-duplex mode and flow control is enabled by setting Bit 2 (RFE) of Register 6 (Flow Control Register) to 1. * Condition 2: The destination address (DA) of the received frame matches the special multicast address or the MAC Address 0 when Bit 3 (UP) of the Register 6 (Flow Control Register) is set. * Condition 3: The Type field of the received frame is 0x8808 and the OPCODE field is 0x0001. Note: This field should be set to 01 only when the Condition 1 is true, that is, the MAC is programmed to operate in the full-duplex mode and the RFE bit is enabled. Otherwise, the PAUSE frame filtering may be inconsistent. When Condition 1 is false, the PAUSE frames are considered as generic control frames. Therefore, to pass all control frames (including PAUSE control frames) when the full-duplex mode and flow control is not enabled, you should set the PCF field to 10 or 11 (as required by the application).

Field	Bits	Type	Description
SAIF	8	rw	**SA Inverse Filtering** When this bit is set, the Address Check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA Address filter. When this bit is reset, frames whose SA does not match the SA registers are marked as failing the SA Address filter.
SAF	9	rw	**Source Address Filter Enable** When this bit is set, the MAC compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison matches, then the SA Match bit of RxStatus Word is set high. When this bit is set high and the SA filter fails, the MAC drops the frame. When this bit is reset, the MAC forwards the received frame to the application and with the updated SA Match bit of the RxStatus depending on the SA address comparison.
HPF	10	rw	**Hash or Perfect Filter** When this bit is set, it configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by the HMC or HUC bits. When this bit is low and the HUC or HMC bit is set, the frame is passed only if it matches the Hash filter. This bit is reserved (and RO) if the Hash filter is not selected during core configuration.
RESERVED_15_11	[15:11]	r	**RESERVED_15_11**
VTFE	16	rw	**VLAN Tag Filter Enable** When set, this bit enables the MAC to drop VLAN tagged frames that do not match the VLAN Tag comparison. When reset, the MAC forwards all frames irrespective of the match status of the VLAN Tag.
RESERVED_19_17	[19:17]	r	**RESERVED_19_17**

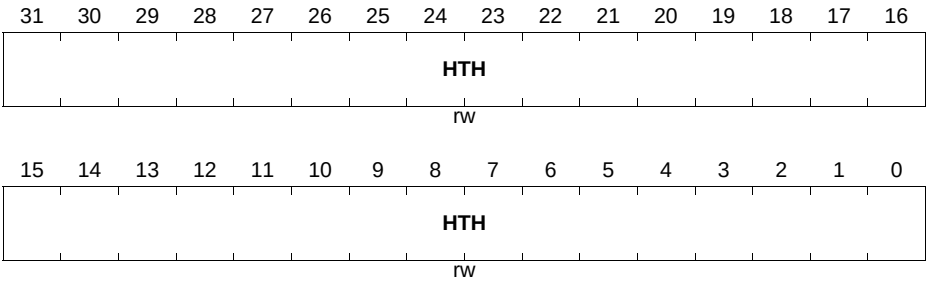
Field	Bits	Type	Description
IPFE	20	r	**Layer 3 and Layer 4 Filter Enable** When set, this bit enables the MAC to drop frames that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When reset, the MAC forwards all frames irrespective of the match status of the Layer 3 and Layer 4 fields. If the Layer 3 and Layer 4 Filtering feature is not selected during core configuration, this bit is reserved (RO with default value).
DNTU	21	r	**Drop non-TCP/UDP over IP Frames** When set, this bit enables the MAC to drop the non-TCP or UDP over IP frames. The MAC forward only those frames that are processed by the Layer 4 filter. When reset, this bit enables the MAC to forward all non-TCP or UDP over IP frames. If the Layer 3 and Layer 4 Filtering feature is not selected during core configuration, this bit is reserved (RO with default value).
RESERVED_30_22	[30:22]	r	**RESERVED_30_22**
RA	31	rw	**Receive All** When this bit is set, the MAC Receiver module passes all received frames, irrespective of whether they pass the address filter or not, to the Application. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bits in the Receive Status Word. When this bit is reset, the Receiver module passes only those frames to the Application that pass the SA or DA address filter.

32-bit Register - Hash_Table_High

The 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame is passed through the CRC logic, and the upper 6 bits of the CRC register are used to index the contents of the Hash table. The most significant bit determines the register to be used (Hash Table High or Hash Table Low), and the other 5 bits determine which bit within the register. A hash value of 5b'00000 selects Bit 0 of the selected register, and a value of 5b'11111 selects Bit 31 of the selected register. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
 2. Perform bitwise reversal for the value obtained in Step 1.
 3. Take the upper 6 bits from the value obtained in Step 2.
 For example, if the DA of the incoming frame is received as 0x1F52419CB6AF (0x1F is the first byte received on GMII interface), then the internally calculated 6-bit Hash value is 0x2C and Bit 12 of Hash Table High register is checked for filtering. If the DA of the incoming frame is received as 0xA00A98000045, then the calculated 6-bit Hash value is 0x07 and Bit 7 of Hash Table Low register is checked for filtering. Note: To help you program the hash table, a sample C routine that generates a DA's 6-bit hash is included in the /sample_codes/ directory of your workspace. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the PM (Pass All Multicast) bit is set in Register 1, then all multicast frames are accepted regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table High or Low registers are written. Consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain when double-synchronization is enabled. The Hash Table High register contains the higher 32 bits of the Hash table.

ETH_HASH_TABLE_HIGH

Register 2 - Hash Table High Register (1008_H) **Reset Value: 0000 0000_H**



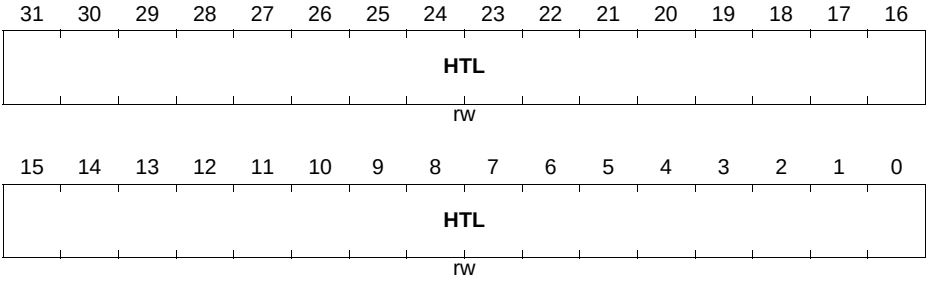
Field	Bits	Type	Description
HTH	[31:0]	rw	**Hash Table High** This field contains the upper 32 bits of the Hash table.

32-bit Register - Hash_Table_Low

The Hash Table Low register contains the lower 32 bits of the Hash table. Both Register 2 and Register 3 are reserved if the Hash Filter Function is disabled or the 128-bit or 256-bit Hash Table is selected during core configuration.

ETH_HASH_TABLE_LOW

Register 3 - Hash Table Low Register ($100C_H$) **Reset Value: $0000\ 0000_H$**

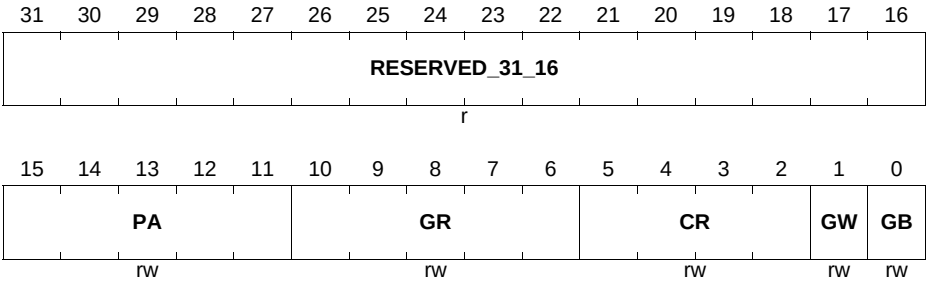


Field	Bits	Type	Description
HTL	[31:0]	rw	**Hash Table Low** This field contains the lower 32 bits of the Hash table.

32-bit Register - GMII_Address

The GMII Address register controls the management cycles to the external PHY through the management interface.

ETH_GMII_ADDRESS
Register 4 - GMII Address Register (1010$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
GB	0	rw	**GMII Busy** This bit should read logic 0 before writing to Register 4 and Register 5. During a PHY or RevMII register access, the software sets this bit to 1'b1 to indicate that a Read or Write access is in progress. The Register 5 is invalid until this bit is cleared by the MAC. Therefore, Register 5 (GMII Data) should be kept valid until the MAC clears this bit during a PHY Write operation. Similarly for a read operation, the contents of Register 5 are not valid until this bit is cleared. The subsequent read or write operation should happen only after the previous operation is complete. Because there is no acknowledgment from the PHY to MAC after a read or write operation is completed, there is no change in the functionality of this bit even when the PHY is not present.
GW	1	rw	**GMII Write** When set, this bit indicates to the PHY or RevMII that this is a Write operation using the GMII Data register. If this bit is not set, it indicates that this is a Read operation, that is, placing the data in the GMII Data register.

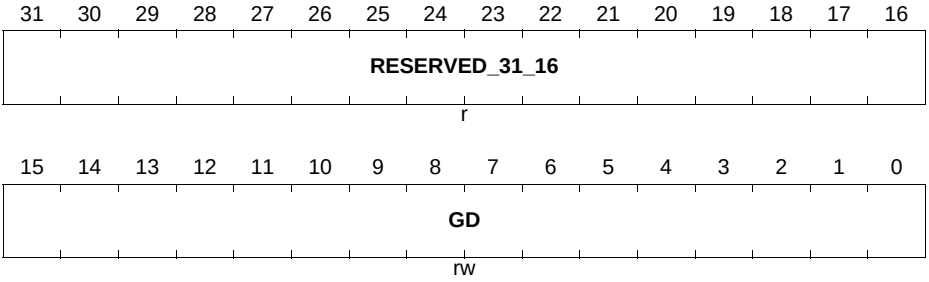
Field	Bits	Type	Description
CR	[5:2]	rw	**CSR Clock Range** The CSR Clock Range selection determines the frequency of the MDC clock according to the clk_csr_i frequency used in your design. The suggested range of clk_csr_i frequency applicable for each value (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. - 0000: The frequency of the clk_csr_i clock is 60-100 MHz and the MDC clock is clk_csr_i/42. - 0001: The frequency of the clk_csr_i clock is 100-150 MHz and the MDC clock is clk_csr_i/62. - 0010: The frequency of the clk_csr_i clock is 20-35 MHz and the MDC clock is clk_csr_i/16. - 0011: The frequency of the clk_csr_i clock is 35-60 MHz and the MDC clock is clk_csr_i/26. - 0100: The frequency of the clk_csr_i clock is 150-250 MHz and the MDC clock is clk_csr_i/102. - 0100: The frequency of the clk_csr_i clock is 250-300 MHz and the MDC clock is clk_csr_i/124. - 0110 and 0111: Reserved When Bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when clk_csr_i is of 100 MHz frequency and you program these bits as 1010, then the resultant MDC clock is of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Program the following values only if the interfacing chips support faster MDC clocks: - 1000: clk_csr_i/4 - 1001: clk_csr_i/6 - 1010: clk_csr_i/8 - 1011: clk_csr_i/10 - 1100: clk_csr_i/12 - 1101: clk_csr_i/14 - 1110: clk_csr_i/16 - 1111: clk_csr_i/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface.

Field	Bits	Type	Description
GR	[10:6]	rw	**GMII Register** These bits select the desired GMII register in the selected PHY device. For RevMII, these bits select the desired CSR register in the RevMII Registers set.
PA	[15:11]	rw	**Physical Layer Address** This field indicates which of the 32 possible PHY devices are being accessed. For RevMII, this field gives the PHY Address of the RevMII module.
RESERVED_31_16	[31:16]	r	**RESERVED_31_16**

32-bit Register - GMII_Data

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

ETH_GMII_DATA
Register 5 - GMII Data Register (1014_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
GD	[15:0]	rw	**GMII Data** This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.
RESERVED_31_16	[31:16]	r	**RESERVED_31_16**

32-bit Register - Flow_Control

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control module. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

ETH_FLOW_CONTROL
Register 6 - Flow Control Register (1018$_H$) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PT															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED_15_8								DZPQ	RESERVED_6	PLT		UP	RFE	TFE	FCA_BPA
r								rw	r	rw		rw	rw	rw	rw

Field	Bits	Type	Description
FCA_BPA	0	rw	**Flow Control Busy or Backpressure Activate** This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In the half-duplex mode, when this bit is set (and TFE is set), then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled.
TFE	1	rw	**Transmit Flow Control Enable** In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled.
RFE	2	rw	**Receive Flow Control Enable** When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled.

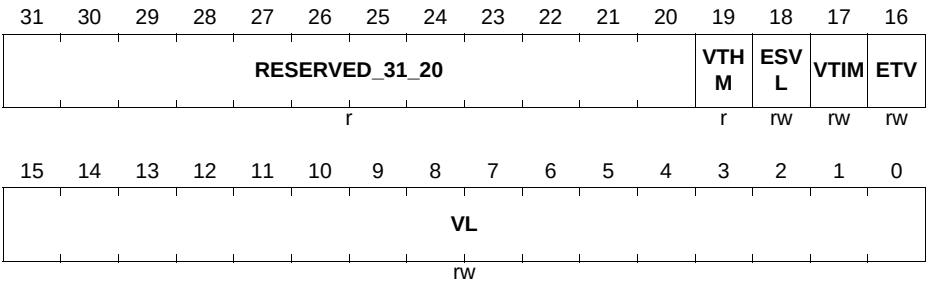
Field	Bits	Type	Description
UP	3	rw	**Unicast Pause Frame Detect** When this bit is set, then in addition to the detecting Pause frames with the unique multicast address, the MAC detects the Pause frames with the station's unicast address specified in the MAC Address0 High Register and MAC Address0 Low Register. When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard.
PLT	[5:4]	rw	**Pause Low Threshold** This field configures the threshold of the PAUSE timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of PAUSE Frame. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256 - 28) slot times after the first PAUSE frame is transmitted. The following list provides the threshold values for different values: - 00: The threshold is Pause time minus 4 slot times (PT - 4 slot times). - 01: The threshold is Pause time minus 28 slot times (PT - 28 slot times). - 10: The threshold is Pause time minus 144 slot times (PT - 144 slot times). - 11: The threshold is Pause time minus 256 slot times (PT - 256 slot times). The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface.
RESERVED_6	6	r	**RESERVED_6**

Field	Bits	Type	Description
DZPQ	7	rw	**Disable Zero-Quanta Pause** When this bit is set, it disables the automatic generation of the Zero-Quanta Pause Control frames on the de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i/mti_flowctrl_i). When this bit is reset, normal operation with automatic Zero-Quanta Pause Control frame generation is enabled.
RESERVED_15_8	[15:8]	r	**RESERVED_15_8**
PT	[31:16]	rw	**Pause Time** This field holds the value to be used in the Pause Time field in the transmit control frame. If the Pause Time bits is configured to be double-synchronized to the (G)MII clock domain, then consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.

32-bit Register - VLAN_Tag

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. If the VLAN Tag register is configured to be double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

ETH_VLAN_TAG
Register 7 - VLAN Tag Register (101C$_H$) Reset Value: 0000 0000$_H$



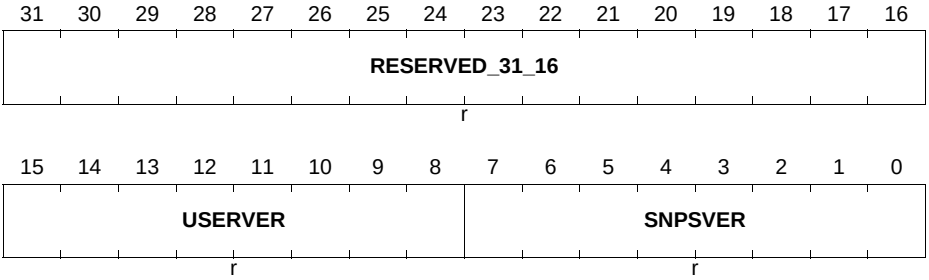
Field	Bits	Type	Description
VL	[15:0]	rw	**VLAN Tag Identifier for Receive Frames** This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.

Field	Bits	Type	Description
ETV	16	rw	**Enable 12-Bit VLAN Tag Comparison** When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering.
VTIM	17	rw	**VLAN Tag Inverse Match Enable** When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.
ESVL	18	rw	**Enable S-VLAN** When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.
VTHM	19	r	**VLAN Tag Hash Table Match Enable** When set, the most significant four bits of the VLAN tag¡Çs CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed. If the VLAN Hash feature is not enabled during core configuration, this bit is reserved (RO with default value).
RESERVED_31_20	[31:20]	r	**RESERVED_31_20**

32-bit Register - Version

The Version registers identifies the version of the DWC_gmac. This register contains two bytes: one that Synopsys uses to identify the core release number, and the other that you set during core configuration.

ETH_VERSION
Register 8 - Version Register (1020_H) Reset Value: $0000\ 5537_H$

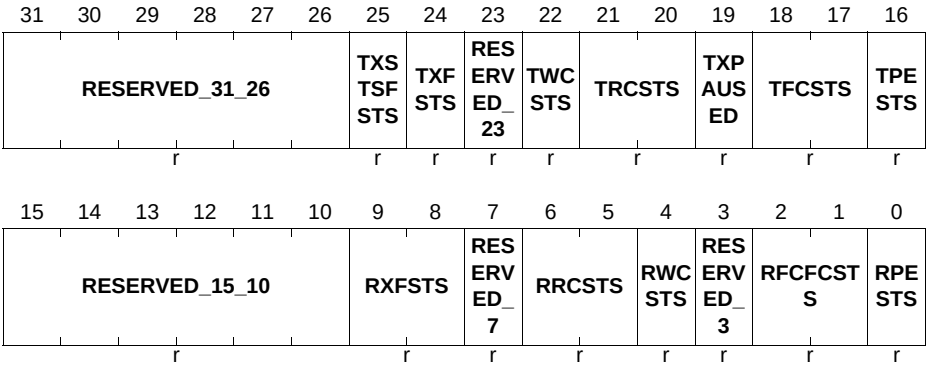


Field	Bits	Type	Description
SNPSVER	[7:0]	r	**SNPSVER** Synopsys-defined Version (3.7)
USERVER	[15:8]	r	**USERVER** User-defined Version (Configured with the coreConsultant)
RESERVED_31_16	[31:16]	r	**RESERVED_31_16**

32-bit Register - Debug

The Debug register gives the status of all main modules of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths. Note: The reset values, given for the Debug register, are valid only if the following clocks are present during the reset operation: * clk_csr_i, clk_app_i, hclk_i, or aclk_i * clk_tx_i * clk_rx_i

ETH_DEBUG
Register 9 - Debug Register (1024_H) Reset Value: $0000\ 0100_H$



Field	Bits	Type	Description
RPESTS	0	r	**MAC GMII or MII Receive Protocol Engine Status** When high, this bit indicates that the MAC GMII or MII receive protocol engine is actively receiving data and not in IDLE state.
RFCFCSTS	[2:1]	r	**MAC Receive Frame Controller FIFO Status** When high, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Frame Controller Module.
RESERVED_3	3	r	**RESERVED_3**
RWCSTS	4	r	**MTL Rx FIFO Write Controller Active Status** When high, this bit indicates that the MTL Rx FIFO Write Controller is active and is transferring a received frame to the FIFO.

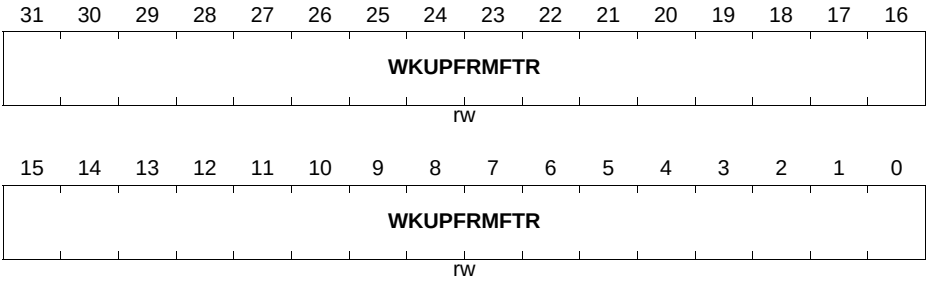
Field	Bits	Type	Description
RRCSTS	[6:5]	r	**MTL Rx FIFO Read Controller State** This field gives the state of the Rx FIFO read Controller: * 00: IDLE state * 01: Reading frame data * 10: Reading frame status (or timestamp) * 11: Flushing the frame data and status
RESERVED_7	7	r	**RESERVED_7**
RXFSTS	[9:8]	r	**MTL Rx FIFO Fill-level Status** This field gives the status of the fill-level of the Rx FIFO: * 00: Rx FIFO Empty * 01: Rx FIFO fill level is below the flow-control deactivate threshold * 10: Rx FIFO fill level is above the flow-control activate threshold * 11: Rx FIFO Full
RESERVED_15_10	[15:10]	r	**RESERVED_15_10**
TPESTS	16	r	**MAC GMII or MII Transmit Protocol Engine Status** When high, this bit indicates that the MAC GMII or MII transmit protocol engine is actively transmitting data and is not in the IDLE state.
TFCSTS	[18:17]	r	**MAC Transmit Frame Controller Status** This field indicates the state of the MAC Transmit Frame Controller module: * 00: IDLE state * 01: Waiting for Status of previous frame or IFG or backoff period to be over * 10: Generating and transmitting a PAUSE control frame (in the full-duplex mode) * 11: Transferring input frame for transmission
TXPAUSED	19	r	**MAC transmitter in PAUSE** When high, this bit indicates that the MAC transmitter is in the PAUSE condition (in the full-duplex only mode) and hence does not schedule any frame for transmission.

Field	Bits	Type	Description
TRCSTS	[21:20]	r	**MTL Tx FIFO Read Controller Status** This field indicates the state of the Tx FIFO Read Controller: * 00: IDLE state * 01: READ state (transferring data to MAC transmitter) * 10: Waiting for TxStatus from MAC transmitter * 11: Writing the received TxStatus or flushing the Tx FIFO
TWCSTS	22	r	**MTL Tx FIFO Write Controller Active Status** When high, this bit indicates that the MTL Tx FIFO Write Controller is active and transferring data to the Tx FIFO.
RESERVED_23	23	r	**RESERVED_23**
TXFSTS	24	r	**MTL Tx FIFO Not Empty Status** When high, this bit indicates that the MTL Tx FIFO is not empty and some data is left for transmission.
TXSTSFSTS	25	r	**MTL TxStatus FIFO Full Status** When high, this bit indicates that the MTL TxStatus FIFO is full. Therefore, the MTL cannot accept any more frames for transmission. This bit is reserved in the GMAC-AHB and GMAC-DMA configurations.
RESERVED_31_26	[31:26]	r	**RESERVED_31_26**

32-bit Register - Remote_Wake_Up_Frame_Filter

This is the address through which the application writes or reads the remote wake-up frame filter registers (wkupfmfilter_reg). The wkupfmfilter_reg register is a pointer to eight wkupfmfilter_reg registers. The wkupfmfilter_reg register is loaded by sequentially loading the eight register values. Eight sequential writes to this address (0x0028) writes all wkupfmfilter_reg registers. Similarly, eight sequential reads from this address (0x0028) read all wkupfmfilter_reg registers. This register contains the higher 16 bits of the seventh MAC address. This register is present only when you select the PMT module Remote Wake-up feature in coreConsultant.

ETH_REMOTE_WAKE_UP_FRAME_FILTER
Register 10 - Remote Wake-Up Frame Filter Register (1028_H) Reset Value: 0000 0000_H



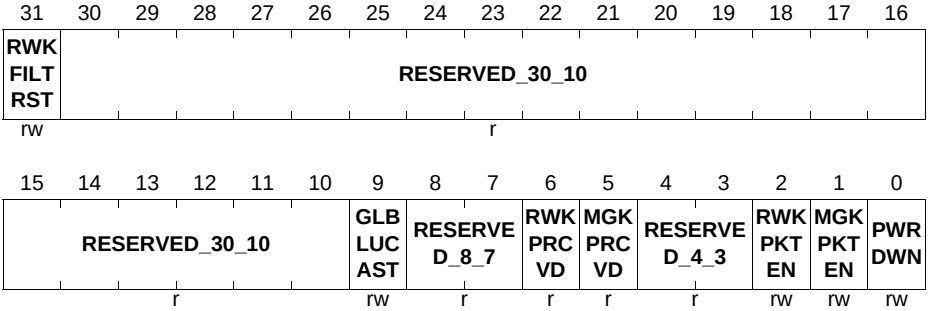
Field	Bits	Type	Description
WKUPFRMFTR	[31:0]	rw	**WKUPFRMFTR** Remote Wake-Up Frame Filter

32-bit Register - PMT_Control_Status

This register is present only when you select the PMT module in the coreConsultant.

ETH_PMT_CONTROL_STATUS

Register 11 - PMT Control and Status Register ($102C_H$) Reset Value: $0000\ 0000_H$



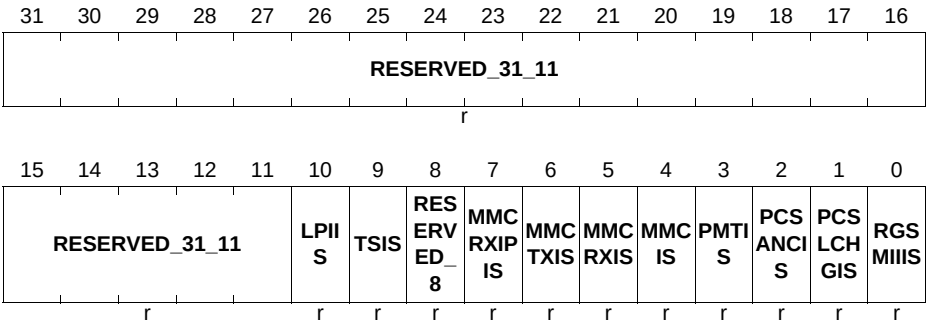
Field	Bits	Type	Description
PWRDWN	0	rw	**Power Down** When set, the MAC receiver drops all received frames until it receives the expected magic packet or wake-up frame. This bit is then self-cleared and the power-down mode is disabled. The Software can also clear this bit before the expected magic packet or wake-up frame is received. The frames, received by the MAC after this bit is cleared, are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Wake-Up Frame Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit.
MGKPKTEN	1	rw	**Magic Packet Enable** When set, enables generation of a power management event because of magic packet reception.
RWKPKTEN	2	rw	**Wake-Up Frame Enable** When set, enables generation of a power management event because of wake-up frame reception.

Field	Bits	Type	Description
RESERVED_4_3	[4:3]	r	**RESERVED_4_3**
MGKPRCVD	5	r	**Magic Packet Received** When set, this bit indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared by a Read into this register.
RWKPRCVD	6	r	**Wake-Up Frame Received** When set, this bit indicates the power management event is generated because of the reception of a wake-up frame. This bit is cleared by a Read into this register.
RESERVED_8_7	[8:7]	r	**RESERVED_8_7**
GLBLUCAST	9	rw	**Global Unicast** When set, enables any unicast packet filtered by the MAC (DAF) address recognition to be a wake-up frame.
RESERVED_30_10	[30:10]	r	**RESERVED_30_10**
RWKFILTRST	31	rw	**Wake-Up Frame Filter Register Pointer Reset** When set, resets the remote wake-up frame filter register pointer to 3¡Çb000. It is automatically cleared after 1 clock cycle.

32-bit Register - Interrupt_Status

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is selected during core configuration and enabled during operation. Therefore, these bits are reserved when the corresponding features are not present in the core.

ETH_INTERRUPT_STATUS
Register 14 - Interrupt Register **(1038_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RGSMIIIS	0	r	**RGMII or SMII Interrupt Status** This bit is set because of any change in value of the Link Status of RGMII or SMII interface (Bit 3 in Register 54 (SGMII/RGMII/SMII Status Register)). This bit is cleared when you perform a read operation on the SGMII/RGMII/SMII Status Register. This bit is valid only when you select the optional RGMII or SMII PHY interface during core configuration and operation.
PCSLCHGIS	1	r	**PCS Link Status Changed** This bit is set because of any change in Link Status in the TBI, RTBI, or SGMII PHY interface (Bit 2 in Register 49 (AN Status Register)). This bit is cleared when you perform a read operation on the AN Status register. This bit is valid only when you select the optional TBI, RTBI, or SGMII PHY interface during core configuration and operation.

Field	Bits	Type	Description
PCSANCIS	2	r	**PCS Auto-Negotiation Complete** This bit is set when the Auto-negotiation is completed in the TBI, RTBI, or SGMII PHY interface (Bit 5 in Register 49 (AN Status Register)). This bit is cleared when you perform a read operation to the AN Status register. This bit is valid only when you select the optional TBI, RTBI, or SGMII PHY interface during core configuration and operation.
PMTIS	3	r	**PMT Interrupt Status** This bit is set when a Magic packet or Wake-on-LAN frame is received in the power-down mode (see Bits 5 and 6 in the PMT Control and Status Register). This bit is cleared when both Bits[6:5] are cleared because of a read operation to the PMT Control and Status register. This bit is valid only when you select the optional PMT module during core configuration.
MMCIS	4	r	**MMC Interrupt Status** This bit is set high when any of the Bits [7:5] is set high and cleared only when all of these bits are low. This bit is valid only when you select the optional MMC module during core configuration.
MMCRXIS	5	r	**MMC Receive Interrupt Status** This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. This bit is valid only when you select the optional MMC module during core configuration.
MMCTXIS	6	r	**MMC Transmit Interrupt Status** This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. This bit is valid only when you select the optional MMC module during core configuration.

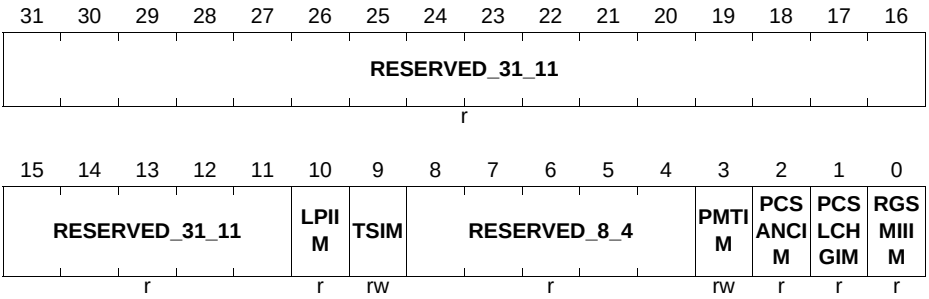
Field	Bits	Type	Description
MMCRXIPIS	7	r	**MMC Receive Checksum Offload Interrupt Status** This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. This bit is valid only when you select the optional MMC module and Checksum Offload Engine (Type 2) during core configuration.
RESERVED_8	8	r	**RESERVED_8**
TSIS	9	r	**Timestamp Interrupt Status** When the Advanced Timestamp feature is enabled, this bit is set when any of the following conditions is true: * The system time value equals or exceeds the value specified in the Target Time High and Low registers. * There is an overflow in the seconds register. * The Auxiliary snapshot trigger is asserted. This bit is cleared on reading Bit 0 of the Register 458 (Timestamp Status Register). If default Timestamping is enabled, when set, this bit indicates that the system time value is equal to or exceeds the value specified in the Target Time registers. In this mode, this bit is cleared after the completion of the read of this bit. In all other modes, this bit is reserved.
LPIIS	10	r	**LPI Interrupt Status** When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared on reading Bit 0 of Register 12 (LPI Control and Status Register). In all other modes, this bit is reserved.
RESERVED_31_11	[31:11]	r	**RESERVED_31_11**

32-bit Register - Interrupt_Mask

The Interrupt Mask Register bits enable you to mask the interrupt signal because of the corresponding event in the Interrupt Status Register. The interrupt signal is sbd_intr_o in the GMAC-AHB, GMAC-AXI, and GMAC-DMA configuration and mci_intr_o in the GMAC-MTL and GMAC-CORE configuration.

ETH_INTERRUPT_MASK

Register 15 - Interrupt Mask Register ($103C_H$) **Reset Value: $0000\ 0000_H$**



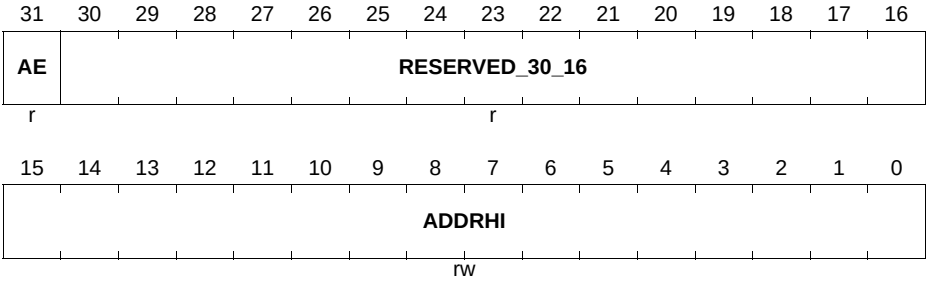
Field	Bits	Type	Description
RGSMIIIM	0	r	**RGMII or SMII Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of the RGMII or SMII Interrupt Status bit in Register 14 (Interrupt Status Register).
PCSLCHGIM	1	r	**PCS Link Status Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of the PCS Link-status changed bit in Register 14 (Interrupt Status Register).
PCSANCIM	2	r	**PCS AN Completion Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of PCS Auto-negotiation complete bit in Register 14 (Interrupt Status Register).
PMTIM	3	rw	**PMT Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of PMT Interrupt Status bit in Register 14 (Interrupt Status Register).
RESERVED_8_4	[8:4]	r	**RESERVED_8_4**

Field	Bits	Type	Description
TSIM	9	rw	**Timestamp Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of Timestamp Interrupt Status bit in Register 14 (Interrupt Status Register). This bit is valid only when IEEE1588 timestamping is enabled. In all other modes, this bit is reserved.
LPIIM	10	r	**LPI Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of the LPI Interrupt Status bit in Register 14 (Interrupt Status Register). This bit is valid only when you select the Energy Efficient Ethernet feature during core configuration. In all other modes, this bit is reserved.
RESERVED_31_11	[31:11]	r	**RESERVED_31_11**

32-bit Register - MAC_Address0_High

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS0_HIGH
Register 16 - MAC Address0 High Register (1040_H) **Reset Value: $8000\ FFFF_H$**



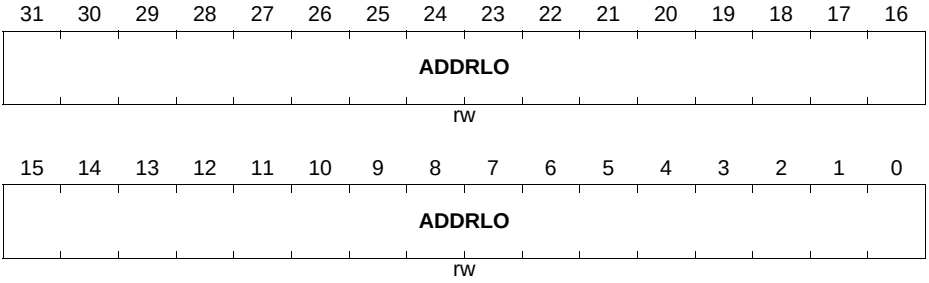
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address0 [47:32]** This field contains the upper 16 bits (47:32) of the first 6-byte MAC address. The MAC uses this field for filtering the received frames and inserting the MAC address in the Transmit Flow Control (PAUSE) Frames.
RESERVED_30_16	[30:16]	r	**RESERVED_30_16**
AE	31	r	**Address Enable** This bit is always set to 1.

32-bit Register - MAC_Address0_Low

The MAC Address0 Low register holds the lower 32 bits of the first 6-byte MAC address of the station.

ETH_MAC_ADDRESS0_LOW

Register 17 - MAC Address0 Low Register (1044_H) **Reset Value: $FFFF\ FFFF_H$**



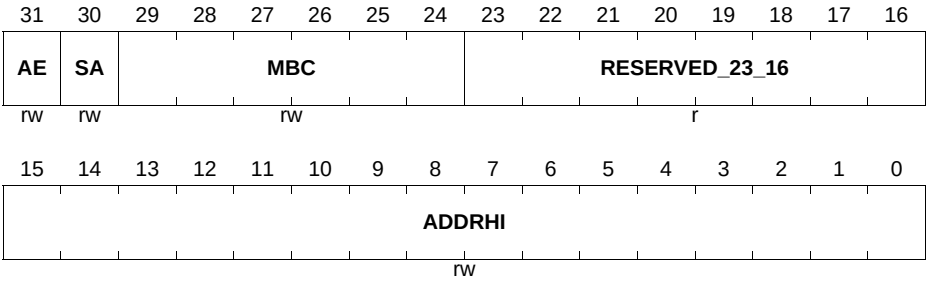
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address0 [31:0]** This field contains the lower 32 bits of the first 6-byte MAC address. This is used by the MAC for filtering the received frames and inserting the MAC address in the Transmit Flow Control (PAUSE) Frames.

32-bit Register - MAC_Address1_High

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS1_HIGH

Register 18 - MAC Address1 High Register (1048_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address1 [47:32]** This field contains the upper 16 bits (47:32) of the second 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**

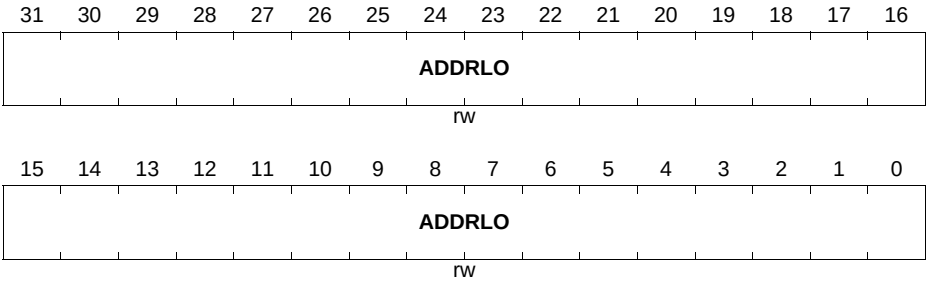
Field	Bits	Type	Description
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
SA	30	rw	**Source Address** When this bit is set, the MAC Address1[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address1[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address1_Low

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

ETH_MAC_ADDRESS1_LOW

Register 19 - MAC Address1 Low Register ($104C_H$) **Reset Value: $FFFF\ FFFF_H$**



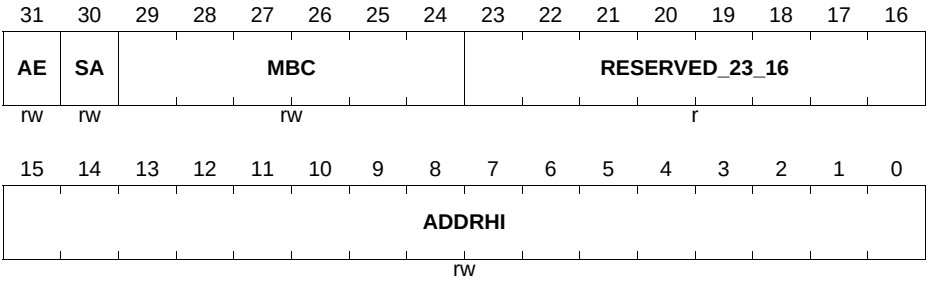
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address1 [31:0]** This field contains the lower 32 bits of the second 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address2_High

The MAC Address2 High register holds the upper 16 bits of the third 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address2 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address2 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS2_HIGH

Register 20 - MAC Address2 High Register (1050_H) **Reset Value: $0000\ FFFF_H$**



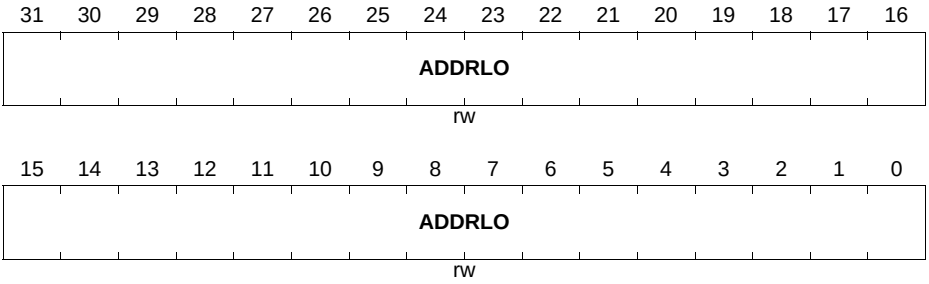
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address2 [47:32]** This field contains the upper 16 bits (47:32) of the third 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address2 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address2[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address2[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the third MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address2_Low

The MAC Address2 Low register holds the lower 32 bits of the third 6-byte MAC address of the station.

ETH_MAC_ADDRESS2_LOW
Register 21 - MAC Address2 Low Register (1054_H) **Reset Value: $FFFF\ FFFF_H$**



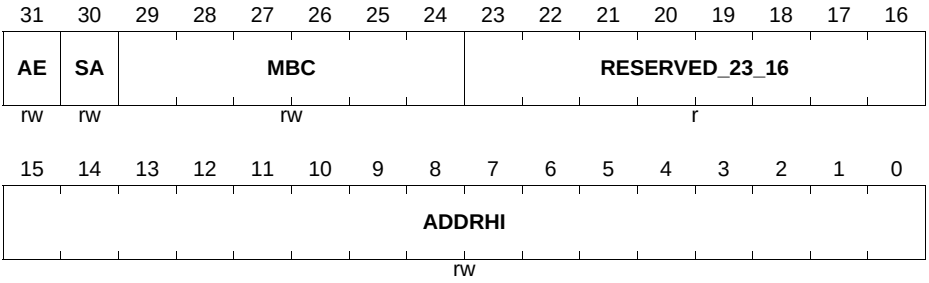
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address2 [31:0]** This field contains the lower 32 bits of the third 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address3_High

The MAC Address3 High register holds the upper 16 bits of the fourth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address3 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address3 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS3_HIGH

Register 22 - MAC Address3 High Register (1058_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address3 [47:32]** This field contains the upper 16 bits (47:32) of the fourth 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address3 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

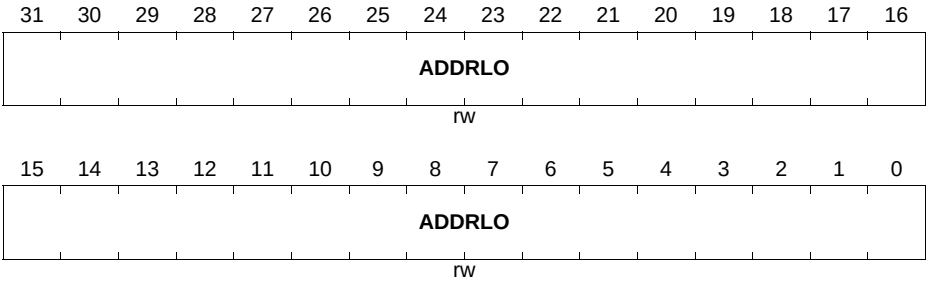
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address3[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address3[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the fourth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address3_Low

The MAC Address3 Low register holds the lower 32 bits of the fourth 6-byte MAC address of the station.

ETH_MAC_ADDRESS3_LOW

Register 23 - MAC Address3 Low Register ($105C_H$) **Reset Value: $FFFF\ FFFF_H$**



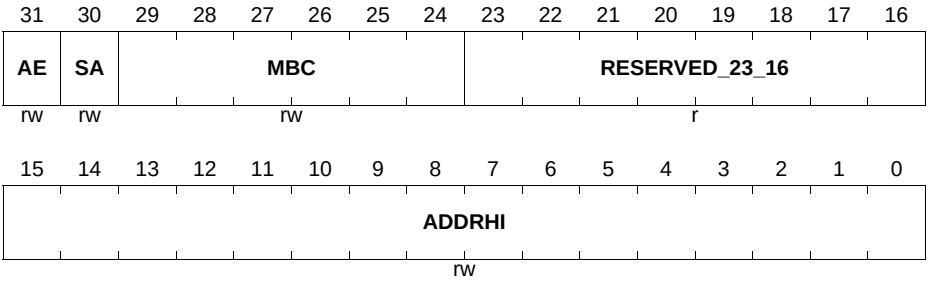
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address3 [31:0]** This field contains the lower 32 bits of the fourth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address4_High

The MAC Address4 High register holds the upper 16 bits of the fifth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address4 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address4 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS4_HIGH

Register 24 - MAC Address4 High Register (1060_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address4 [47:32]** This field contains the upper 16 bits (47:32) of the fifth 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address4 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

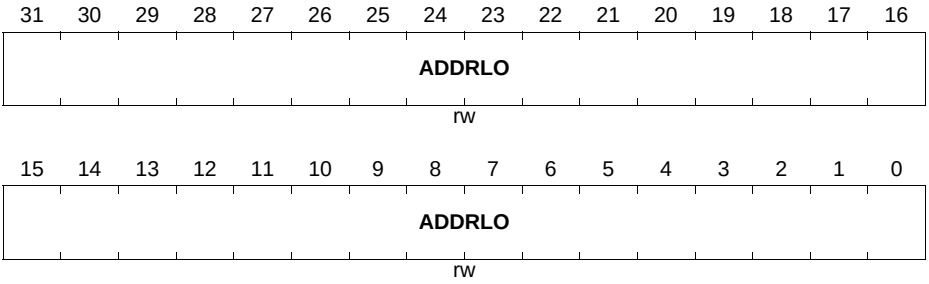
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address4[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address4[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the fifth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address4_Low

The MAC Address4 Low register holds the lower 32 bits of the fifth 6-byte MAC address of the station.

ETH_MAC_ADDRESS4_LOW

Register 25 - MAC Address4 Low Register (1064_H) **Reset Value: $FFFF\ FFFF_H$**



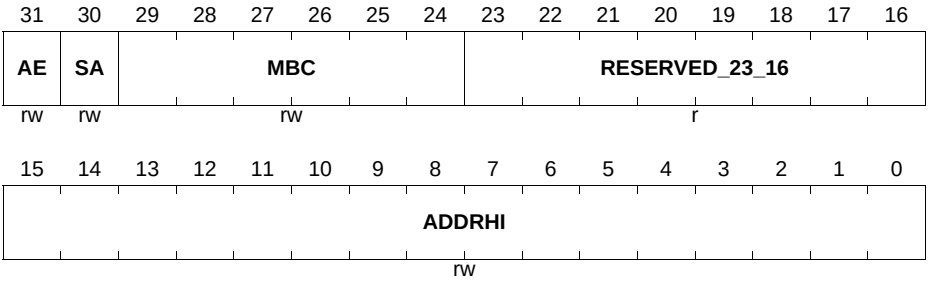
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address4 [31:0]** This field contains the lower 32 bits of the fifth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address5_High

The MAC Address5 High register holds the upper 16 bits of the sixth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address5 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address5 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS5_HIGH

Register 26 - MAC Address5 High Register (1068_H) **Reset Value: $0000\ FFFF_H$**



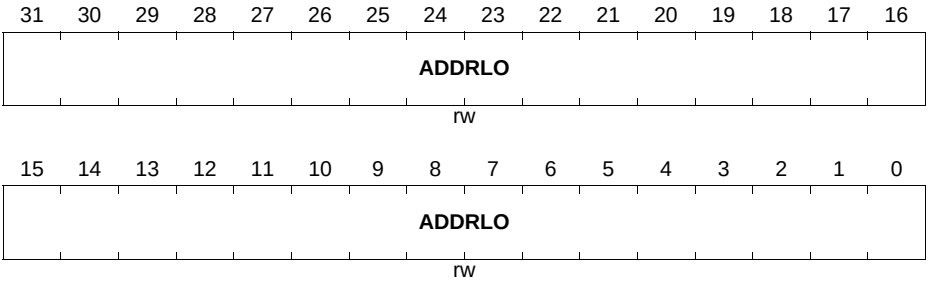
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address5 [47:32]** This field contains the upper 16 bits (47:32) of the sixth 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address5 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address5[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address5[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the sixth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address5_Low

The MAC Address5 Low register holds the lower 32 bits of the sixth 6-byte MAC address of the station.

ETH_MAC_ADDRESS5_LOW
Register 27 - MAC Address5 Low Register ($106C_H$) **Reset Value: $FFFF\ FFFF_H$**



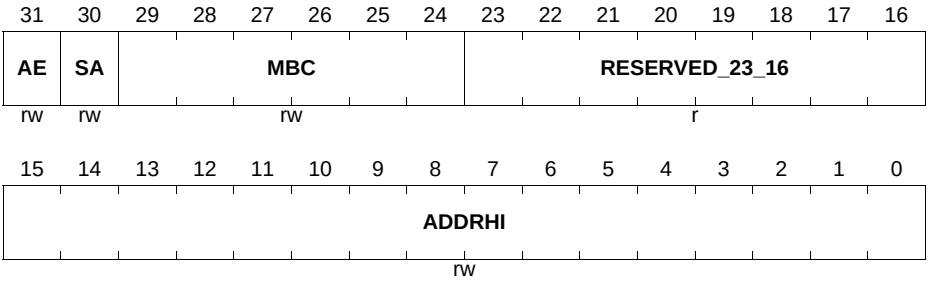
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address5 [31:0]** This field contains the lower 32 bits of the sixth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address6_High

The MAC Address6 High register holds the upper 16 bits of the seventh 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address6 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address6 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS6_HIGH

Register 28 - MAC Address6 High Register (1070_H) **Reset Value: $0000\ FFFF_H$**



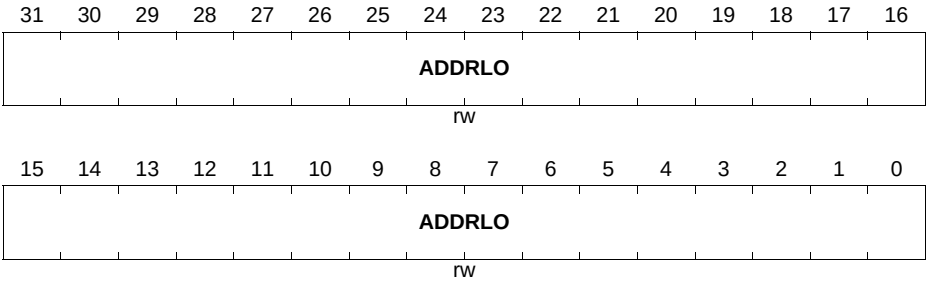
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address6 [47:32]** This field contains the upper 16 bits (47:32) of the seventh 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address6 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address6[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address6[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the seventh MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address6_Low

The MAC Address6 Low register holds the lower 32 bits of the seventh 6-byte MAC address of the station.

ETH_MAC_ADDRESS6_LOW
Register 29 - MAC Address6 Low Register (1074_H) **Reset Value: $FFFF\ FFFF_H$**



Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address6 [31:0]** This field contains the lower 32 bits of the seventh 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address7_High

The MAC Address7 High register holds the upper 16 bits of the eighth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address7 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address7 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS7_HIGH

Register 30 - MAC Address7 High Register (1078_H) **Reset Value: $0000\ FFFF_H$**

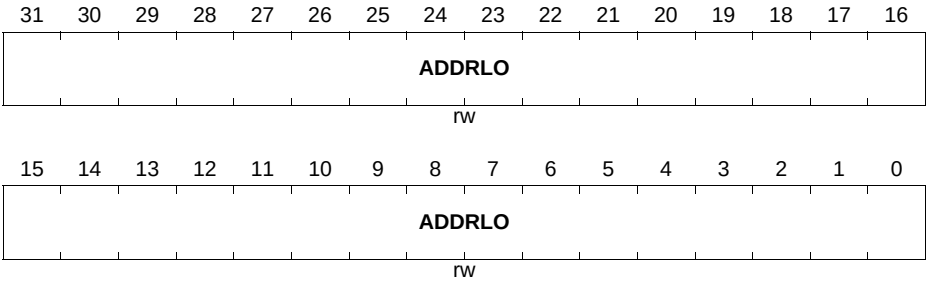
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 16th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address15_Low

The MAC Address15 Low register holds the lower 32 bits of the 16th 6-byte MAC address of the station.

ETH_MAC_ADDRESS15_LOW
Register 47 - MAC Address15 Low Register ($10BC_H$) **Reset Value: $FFFF\ FFFF_H$**



Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address15 [31:0]** This field contains the lower 32 bits of the 16th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MMC_Control

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

ETH_MMC_CONTROL
Register 64 - MMC Control Register (1100_H) **Reset Value: $0000\ 0000_H$**

RESERVED_31_9							UCDBC	RESERVED_7_6		CNTPRSTLVL	CNTPRST	CNTFREEZ	RSTONRD	CNTSTOPRO	CNTRST
r							rw	r		rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CNTRST	0	rw	**Counters Reset** When this bit is set, all counters are reset. This bit is cleared automatically after one clock cycle.
CNTSTOPRO	1	rw	**Counters Stop Rollover** When this bit is set, after reaching maximum value, the counter does not roll over to zero.
RSTONRD	2	rw	**Reset on Read** When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.
CNTFREEZ	3	rw	**MMC Counter Freeze** When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.

Field	Bits	Type	Description
CNTPRST	4	rw	**Counters Preset** When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.
CNTPRSTLVL	5	rw	**Full-Half Preset** When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0.
RESERVED_7_6	[7:6]	r	**RESERVED_7_6**
UCDBC	8	rw	**Update MMC Counters for Dropped Broadcast Frames** When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of DBF bit (Disable Broadcast Frames) of MAC Filter Register at offset 0x0004. When reset, MMC Counters are not updated for dropped Broadcast frames.
RESERVED_31_9	[31:9]	r	**RESERVED_31_9**

32-bit Register - MMC_Receive_Interrupt

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

TXSCOLGFIM	14	rw	**MMC Transmit Single Collision Good Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txsinglecol_g counter reaches half of the maximum value or the maximum value.
TXMCOLGFIM	15	rw	**MMC Transmit Multiple Collision Good Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txmulticol_g counter reaches half of the maximum value or the maximum value.
TXDEFFIM	16	rw	**MMC Transmit Deferred Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txdeferred counter reaches half of the maximum value or the maximum value.

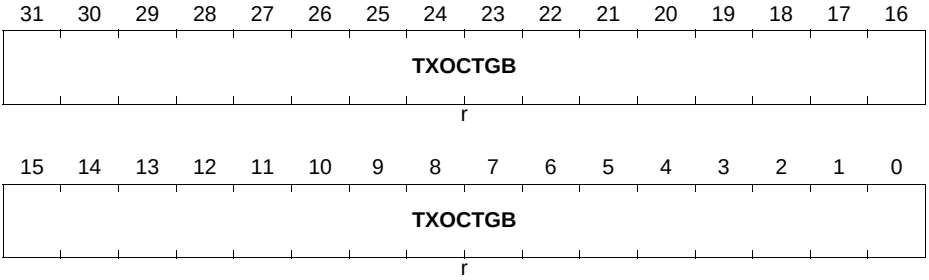
Field	Bits	Type	Description
TXLATCOLFIM	17	rw	**MMC Transmit Late Collision Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txlatecol counter reaches half of the maximum value or the maximum value.
TXEXCOLFIM	18	rw	**MMC Transmit Excessive Collision Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txexcesscol counter reaches half of the maximum value or the maximum value.
TXCARERFIM	19	rw	**MMC Transmit Carrier Error Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txcarriererror counter reaches half of the maximum value or the maximum value.
TXGOCTIM	20	rw	**MMC Transmit Good Octet Counter Interrupt Mask** Setting this bit masks the interrupt when the txoctetcount_g counter reaches half of the maximum value or the maximum value.
TXGFRMIM	21	rw	**MMC Transmit Good Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txframecount_g counter reaches half of the maximum value or the maximum value.
TXEXDEFFIM	22	rw	**MMC Transmit Excessive Deferral Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txexcessdef counter reaches half of the maximum value or the maximum value.
TXPAUSFIM	23	rw	**MMC Transmit Pause Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txpauseframes counter reaches half of the maximum value or the maximum value.
TXVLANGFIM	24	rw	**MMC Transmit VLAN Good Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txvlanframes_g counter reaches half of the maximum value or the maximum value.

Field	Bits	Type	Description
TXOSIZEGFIM	25	rw	**MMC Transmit Oversize Good Frame Counter Interrupt Mask** Setting this bit masks the interrupt when the txoversize_g counter reaches half of the maximum value or the maximum value.
RESERVED_31_26	[31:26]	r	**RESERVED_31_26**

32-bit Register - Tx_Octet_Count_Good_Bad

This register maintains the number of bytes transmitted in good and bad frames exclusive of preamble and retried bytes.

ETH_TX_OCTET_COUNT_GOOD_BAD
Register 69 - Transmit Octet Count for Good and Bad Frames (1114_H) Reset Value: $0000\ 0000_H$

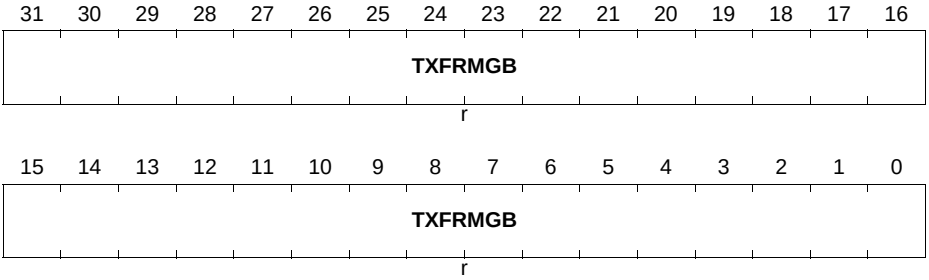


Field	Bits	Type	Description
TXOCTGB	[31:0]	r	**TXOCTGB** This field indicates the number of bytes transmitted in good and bad frames exclusive of preamble and retried bytes.

32-bit Register - Tx_Frame_Count_Good_Bad

This register maintains the number of good and bad frames transmitted, exclusive of retried frames.

ETH_TX_FRAME_COUNT_GOOD_BAD
Register 70 - Transmit Frame Count for Good and Bad Frames (1118_H) Reset Value: $0000\ 0000_H$

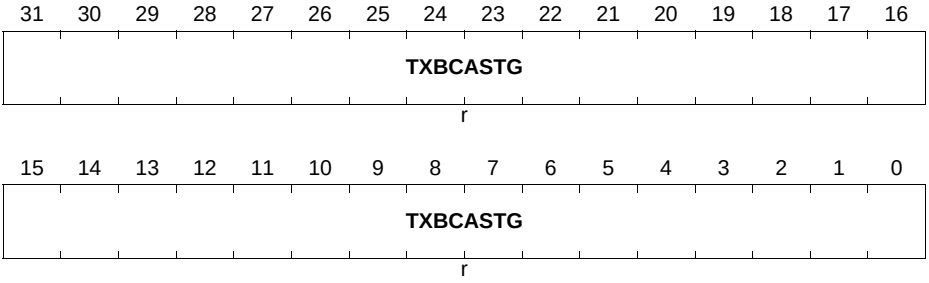


Field	Bits	Type	Description
TXFRMGB	[31:0]	r	**TXFRMGB** This field indicates the number of good and bad frames transmitted, exclusive of retried frames

32-bit Register - Tx_Broadcast_Frames_Good

This register maintains the number of transmitted good broadcast frames.

ETH_TX_BROADCAST_FRAMES_GOOD
Register 71 - Transmit Frame Count for Good Broadcast Frames ($111C_H$) Reset Value: $0000\ 0000_H$

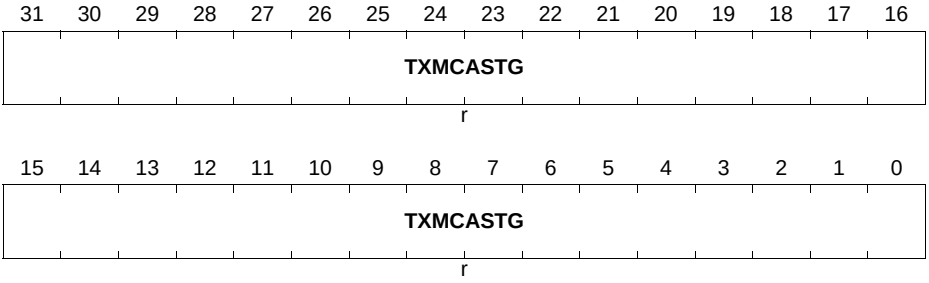


Field	Bits	Type	Description
TXBCASTG	[31:0]	r	**TXBCASTG** This field indicates the number of transmitted good broadcast frames.

32-bit Register - Tx_Multicast_Frames_Good

This register maintains the number of transmitted good multicast frames.

ETH_TX_MULTICAST_FRAMES_GOOD
Register 72 - Transmit Frame Count for Good Multicast Frames (1120_H) Reset Value: $0000\ 0000_H$

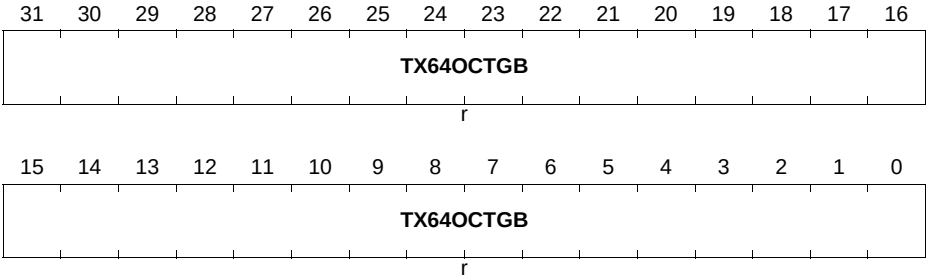


Field	Bits	Type	Description
TXMCASTG	[31:0]	r	**TXMCASTG** This field indicates the number of transmitted good multicast frames.

32-bit Register - Tx_64Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length of 64 bytes, exclusive of preamble and retried frames.

ETH_TX_64OCTETS_FRAMES_GOOD_BAD
Register 73 - Transmit Octet Count for Good and Bad 64 Byte Frames (1124_H)
Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
TX64OCTGB	[31:0]	r	**TX64OCTGB** This field indicates the number of transmitted good and bad frames with length of 64 bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_65To127Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_65TO127OCTETS_FRAMES_GOOD_BAD
Register 74 - Transmit Octet Count for Good and Bad 65 to 127 Bytes Frames (1128_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
TX65_127 OCTGB	[31:0]	r	**TX65_127OCTGB** This field indicates the number of transmitted good and bad frames with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_128To255Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_128TO255OCTETS_FRAMES_GOOD_BAD
Register 75 - Transmit Octet Count for Good and Bad 128 to 255 Bytes Frames ($112C_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
TX128_255OCTGB	[31:0]	r	**TX128_255OCTGB** This field indicates the number of transmitted good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_256To511Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_256TO511OCTETS_FRAMES_GOOD_BAD
Register 76 - Transmit Octet Count for Good and Bad 256 to 511 Bytes Frames (1130_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
TX256_511OCTGB	[31:0]	r	**TX256_511OCTGB** This field indicates the number of transmitted good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_512To1023Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames.

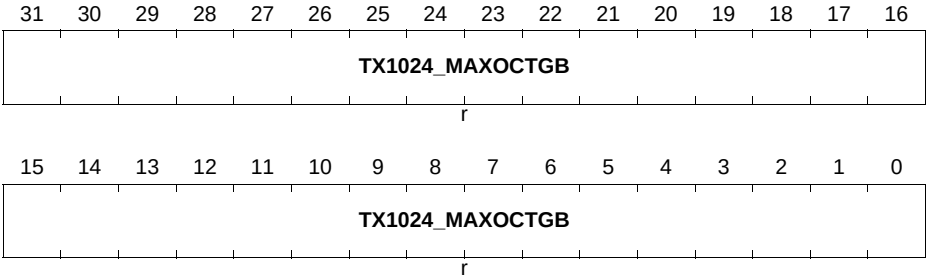
ETH_TX_512TO1023OCTETS_FRAMES_GOOD_BAD
Register 77 - Transmit Octet Count for Good and Bad 512 to 1023 Bytes Frames (1134_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
TX512_1023OCTGB	[31:0]	r	**TX512_1023OCTGB** This field indicates the number of transmitted good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_1024ToMaxOctets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_1024TOMAXOCTETS_FRAMES_GOOD_BAD
Register 78 - Transmit Octet Count for Good and Bad 1024 to Maxsize Bytes Frames (1138_H) Reset Value: $0000\ 0000_H$

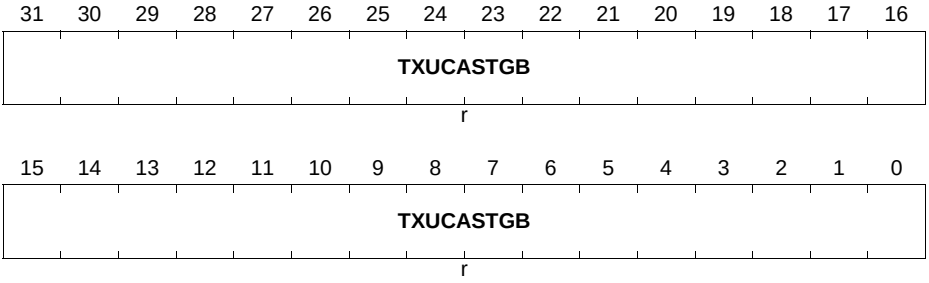


Field	Bits	Type	Description
TX1024_MAXOCTGB	[31:0]	r	**TX1024_MAXOCTGB** This field indicates the number of good and bad frames transmitted with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_Unicast_Frames_Good_Bad

This register maintains the number of transmitted good and bad unicast frames.

ETH_TX_UNICAST_FRAMES_GOOD_BAD
Register 79 - Transmit Frame Count for Good and Bad Unicast Frames ($113C_H$)
Reset Value: $0000\ 0000_H$

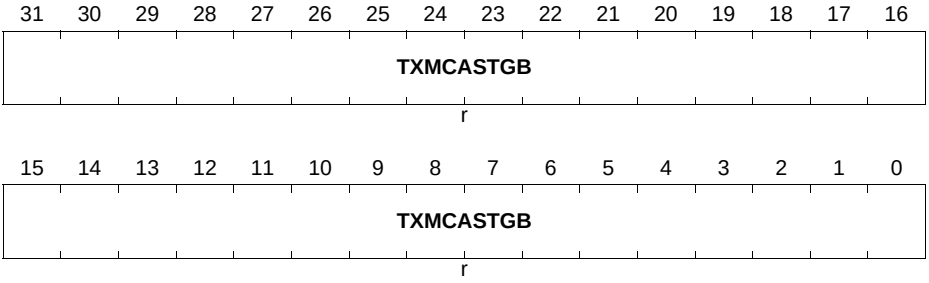


Field	Bits	Type	Description
TXUCASTGB	[31:0]	r	**TXUCASTGB** This field indicates the number of transmitted good and bad unicast frames.

32-bit Register - Tx_Multicast_Frames_Good_Bad

This register maintains the number of transmitted good and bad multicast frames.

ETH_TX_MULTICAST_FRAMES_GOOD_BAD
Register 80 - Transmit Frame Count for Good and Bad Multicast Frames (1140_H)
Reset Value: $0000\ 0000_H$

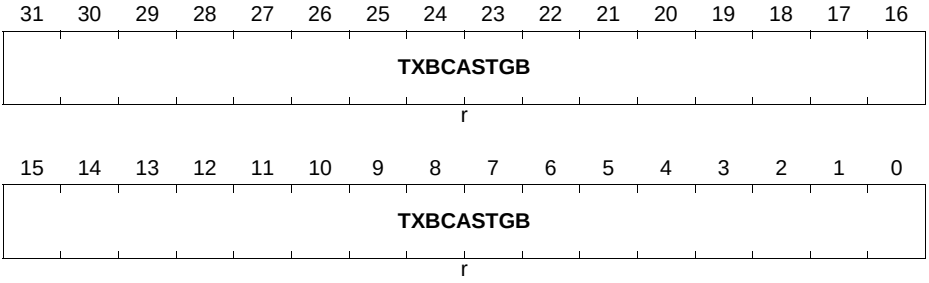


Field	Bits	Type	Description
TXMCASTGB	[31:0]	r	**TXMCASTGB** This field indicates the number of transmitted good and bad multicast frames.

32-bit Register - Tx_Broadcast_Frames_Good_Bad

This register maintains the number of transmitted good and bad broadcast frames.

ETH_TX_BROADCAST_FRAMES_GOOD_BAD
Register 81 - Transmit Frame Count for Good and Bad Broadcast Frames (1144_H)
Reset Value: $0000\ 0000_H$

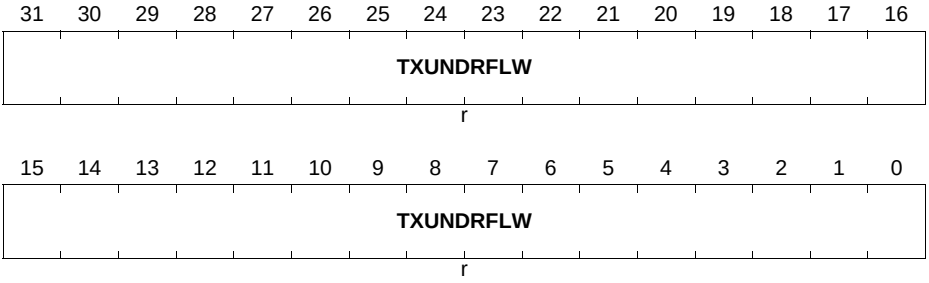


Field	Bits	Type	Description
TXBCASTGB	[31:0]	r	**TXBCASTGB** This field indicates the number of transmitted good and bad broadcast frames.

32-bit Register - Tx_Underflow_Error_Frames

This register maintains the number of frames aborted because of frame underflow error.

ETH_TX_UNDERFLOW_ERROR_FRAMES
Register 82 - Transmit Frame Count for Underflow Error Frames (1148_H) Reset Value: $0000\ 0000_H$

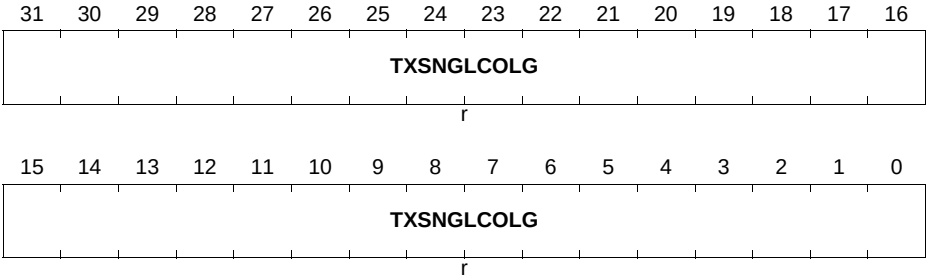


Field	Bits	Type	Description
TXUNDRFLW	[31:0]	r	**TXUNDRFLW** This field indicates the number of frames aborted because of frame underflow error.

32-bit Register - Tx_Single_Collision_Good_Frames

This register maintains the number of successfully transmitted frames after a single collision in the half-duplex mode.

ETH_TX_SINGLE_COLLISION_GOOD_FRAMES
Register 83 - Transmit Frame Count for Frames Transmitted after Single Collision ($114C_H$) **Reset Value: $0000\ 0000_H$**

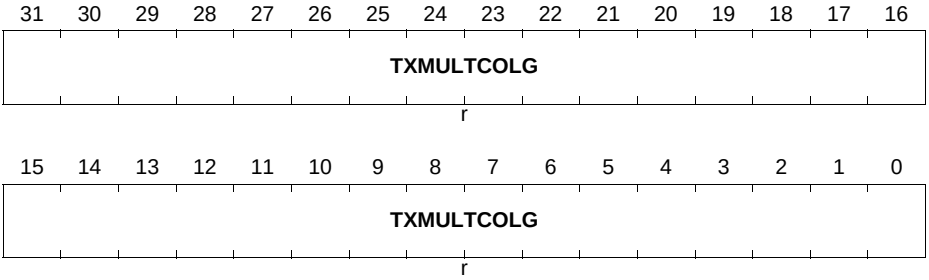


Field	Bits	Type	Description
TXSNGLCOLG	[31:0]	r	**TXSNGLCOLG** This field indicates the number of successfully transmitted frames after a single collision in the half-duplex mode.

32-bit Register - Tx_Multiple_Collision_Good_Frames

This register maintains the number of successfully transmitted frames after multiple collisions in the half-duplex mode.

ETH_TX_MULTIPLE_COLLISION_GOOD_FRAMES
Register 84 - Transmit Frame Count for Frames Transmitted after Multiple Collision (1150_H) Reset Value: $0000\ 0000_H$

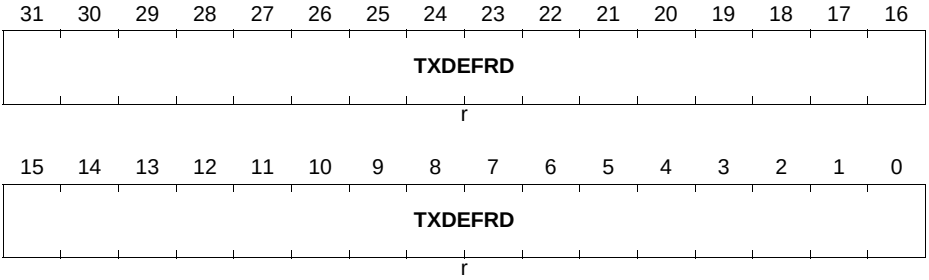


Field	Bits	Type	Description
TXMULTCOLG	[31:0]	r	**TXMULTCOLG** This field indicates the number of successfully transmitted frames after multiple collisions in the half-duplex mode.

32-bit Register - Tx_Deferred_Frames

This register maintains the number of successfully transmitted frames after a deferral in the half-duplex mode.

ETH_TX_DEFERRED_FRAMES
Register 85 - Transmit Frame Count for Deferred Frames (1154_H) Reset Value: $0000\ 0000_H$

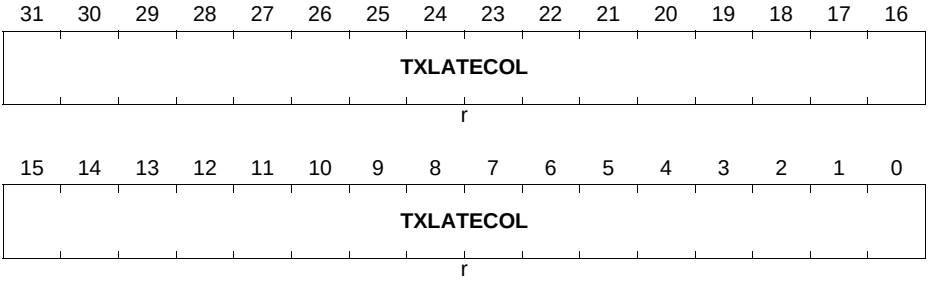


Field	Bits	Type	Description
TXDEFRD	[31:0]	r	**TXDEFRD** This field indicates the number of successfully transmitted frames after a deferral in the half-duplex mode.

32-bit Register - Tx_Late_Collision_Frames

This register maintains the number of frames aborted because of late collision error.

ETH_TX_LATE_COLLISION_FRAMES
Register 86 - Transmit Frame Count for Late Collision Error Frames (1158_H) Reset Value: $0000\ 0000_H$

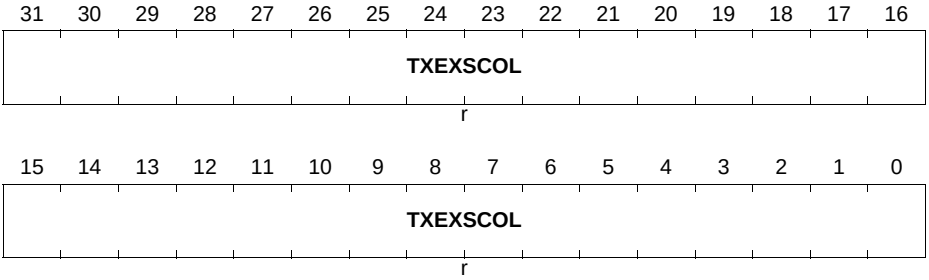


Field	Bits	Type	Description
TXLATECOL	[31:0]	r	**TXLATECOL** This field indicates the number of frames aborted because of late collision error.

32-bit Register - Tx_Excessive_Collision_Frames

This register maintains the number of frames aborted because of excessive (16) collision error.

ETH_TX_EXCESSIVE_COLLISION_FRAMES
Register 87 - Transmit Frame Count for Excessive Collision Error Frames ($115C_H$) **Reset Value: $0000\ 0000_H$**

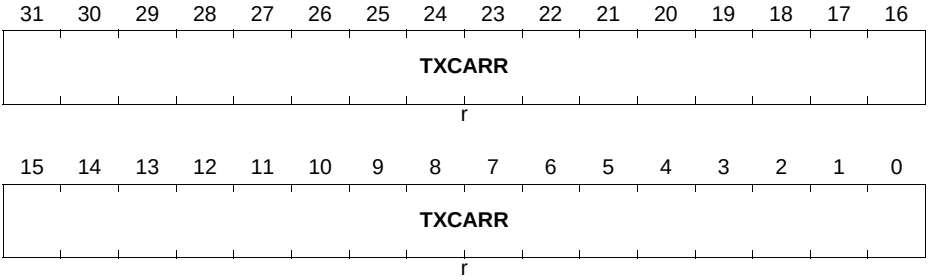


Field	Bits	Type	Description
TXEXSCOL	[31:0]	r	**TXEXSCOL** This field indicates the number of frames aborted because of excessive (16) collision error.

32-bit Register - Tx_Carrier_Error_Frames

This register maintains the number of frames aborted because of carrier sense error (no carrier or loss of carrier).

ETH_TX_CARRIER_ERROR_FRAMES
Register 88 - Transmit Frame Count for Carrier Sense Error Frames (1160_H) Reset Value: $0000\ 0000_H$

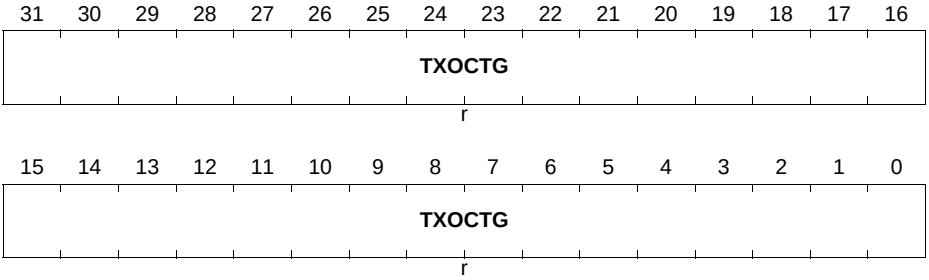


Field	Bits	Type	Description
TXCARR	[31:0]	r	**TXCARR** This field indicates the number of frames aborted because of carrier sense error (no carrier or loss of carrier).

32-bit Register - Tx_Octet_Count_Good

This register maintains the number of bytes transmitted, exclusive of preamble, in good frames.

ETH_TX_OCTET_COUNT_GOOD
Register 89 - Transmit Octet Count for Good Frames (1164_H) Reset Value: 0000 0000_H



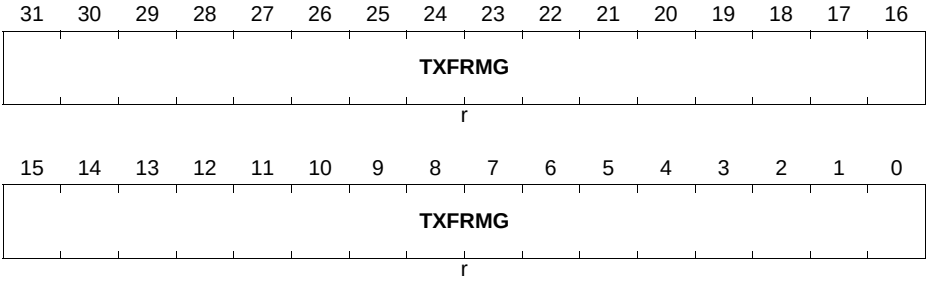
Field	Bits	Type	Description
TXOCTG	[31:0]	r	**TXOCTG** This field indicates the number of bytes transmitted, exclusive of preamble, in good frames.

32-bit Register - Tx_Frame_Count_Good

This register maintains the number of transmitted good frames, exclusive of preamble.

ETH_TX_FRAME_COUNT_GOOD

Register 90 - Transmit Frame Count for Good Frames (1168_H) Reset Value: 0000 0000_H

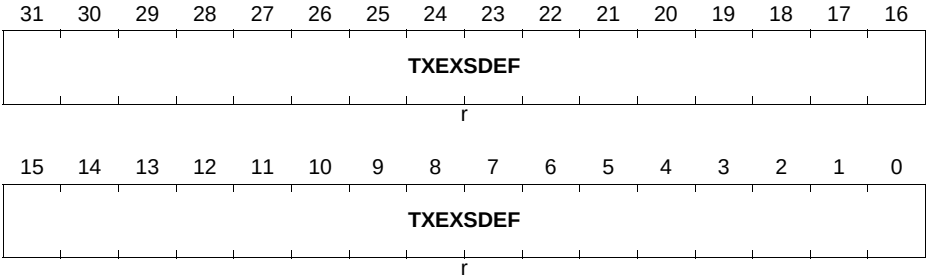


Field	Bits	Type	Description
TXFRMG	[31:0]	r	**TXFRMG** This field indicates the number of transmitted good frames, exclusive of preamble.

32-bit Register - Tx_Excessive_Deferral_Error

This register maintains the number of frames aborted because of excessive deferral error, that is, frames deferred for more than two max-sized frame times.

ETH_TX_EXCESSIVE_DEFERRAL_ERROR
Register 91 - Transmit Frame Count for Excessive Deferral Error Frames ($116C_H$)
Reset Value: $0000\ 0000_H$

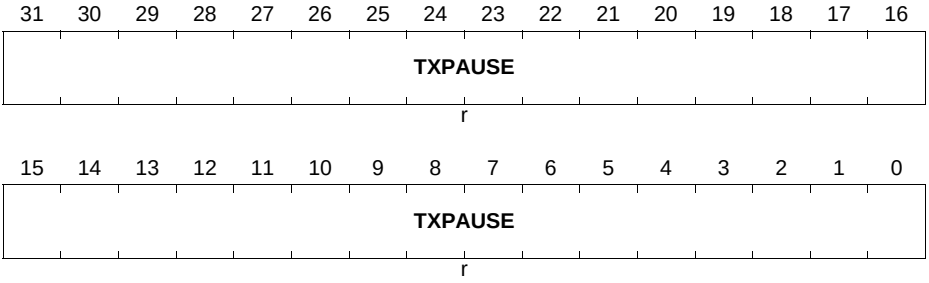


Field	Bits	Type	Description
TXEXSDEF	[31:0]	r	**TXEXSDEF** This field indicates the number of frames aborted because of excessive deferral error, that is, frames deferred for more than two max-sized frame times.

32-bit Register - Tx_Pause_Frames

This register maintains the number of transmitted good PAUSE frames.

ETH_TX_PAUSE_FRAMES
Register 92 - Transmit Frame Count for Good PAUSE Frames (1170_H) Reset Value: $0000\ 0000_H$

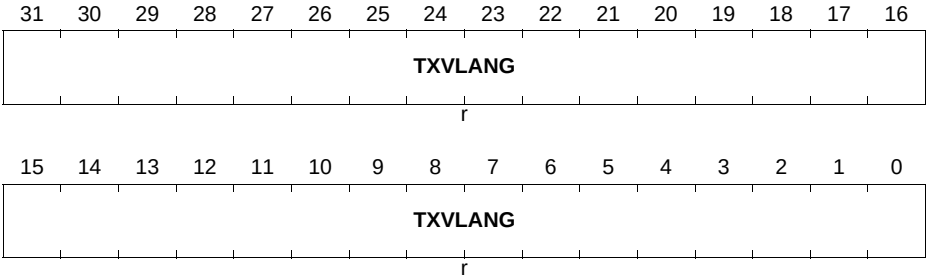


Field	Bits	Type	Description
TXPAUSE	[31:0]	r	**TXPAUSE** This field indicates the number of transmitted good PAUSE frames.

32-bit Register - Tx_VLAN_Frames_Good

This register maintains the number of transmitted good VLAN frames, exclusive of retried frames.

ETH_TX_VLAN_FRAMES_GOOD
Register 93 - Transmit Frame Count for Good VLAN Frames (1174_H) Reset Value: $0000\ 0000_H$

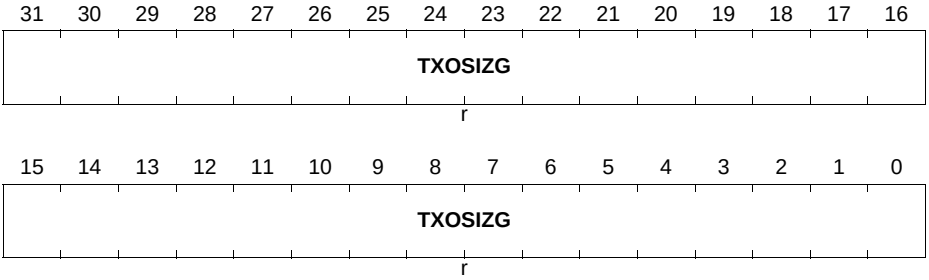


Field	Bits	Type	Description
TXVLANG	[31:0]	r	**TXVLANG** This register maintains the number of transmitted good VLAN frames, exclusive of retried frames.

32-bit Register - Tx_OSize_Frames_Good

This register maintains the number of transmitted good Oversize frames, exclusive of retried frames.

ETH_TX_OSIZE_FRAMES_GOOD
Register 94 - Transmit Frame Count for Good Oversize Frames (1178_H) Reset Value: $0000\ 0000_H$

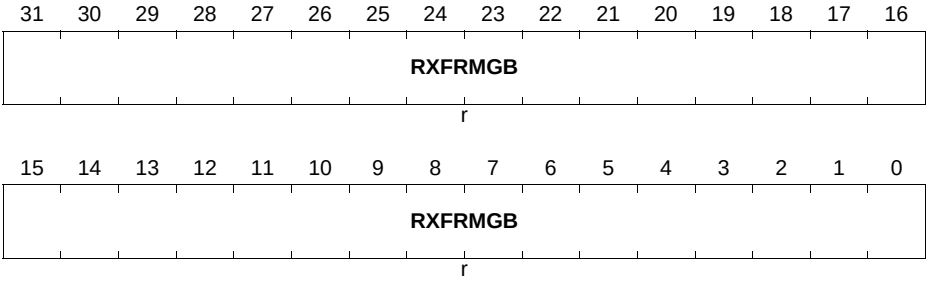


Field	Bits	Type	Description
TXOSIZG	[31:0]	r	**TXOSIZG** This field indicates the number of frames transmitted without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged frames; 2000 bytes if enabled in bit 27 of Register 0 (MAC Configuration Register)).

32-bit Register - Rx_Frames_Count_Good_Bad

This register maintains the number of received good and bad frames.

ETH_RX_FRAMES_COUNT_GOOD_BAD
Register 96 - Receive Frame Count for Good and Bad Frames (1180_H) Reset Value: $0000\ 0000_H$

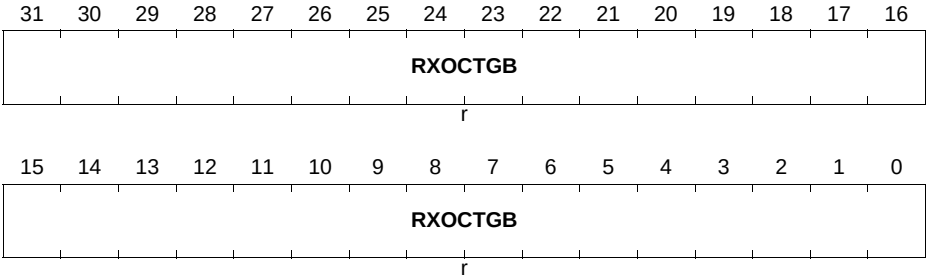


Field	Bits	Type	Description
RXFRMGB	[31:0]	r	**RXFRMGB** This field indicates the number of received good and bad frames.

32-bit Register - Rx_Octet_Count_Good_Bad

This register maintains the number of bytes received, exclusive of preamble, in good and bad frames.

ETH_RX_OCTET_COUNT_GOOD_BAD
Register 97 - Receive Octet Count for Good and Bad Frames (1184_H) Reset Value: $0000\ 0000_H$



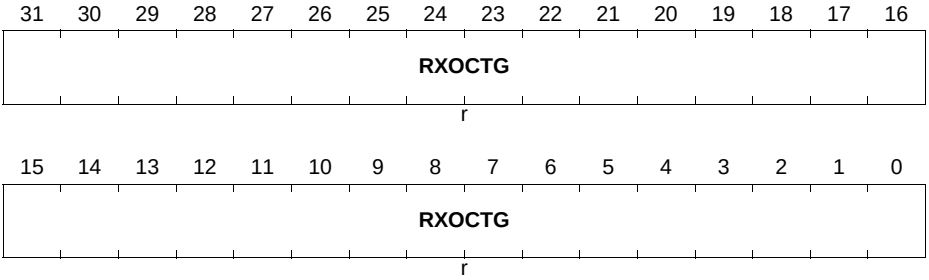
Field	Bits	Type	Description
RXOCTGB	[31:0]	r	**RXOCTGB** This field indicates the number of bytes received, exclusive of preamble, in good and bad frames.

32-bit Register - Rx_Octet_Count_Good

This register maintains the number of bytes received, exclusive of preamble, only in good frames.

ETH_RX_OCTET_COUNT_GOOD

Register 98 - Receive Octet Count for Good Frames (1188_H) Reset Value: $0000\ 0000_H$

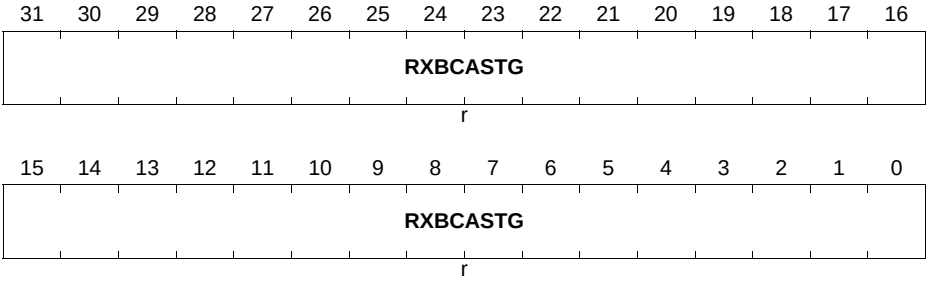


Field	Bits	Type	Description
RXOCTG	[31:0]	r	**RXOCTG** This field indicates the number of bytes received, exclusive of preamble, only in good frames.

32-bit Register - Rx_Broadcast_Frames_Good

This register maintains the number of received good broadcast frames.

ETH_RX_BROADCAST_FRAMES_GOOD
Register 99 - Receive Frame Count for Good Broadcast Frames ($118C_H$) Reset Value: $0000\ 0000_H$

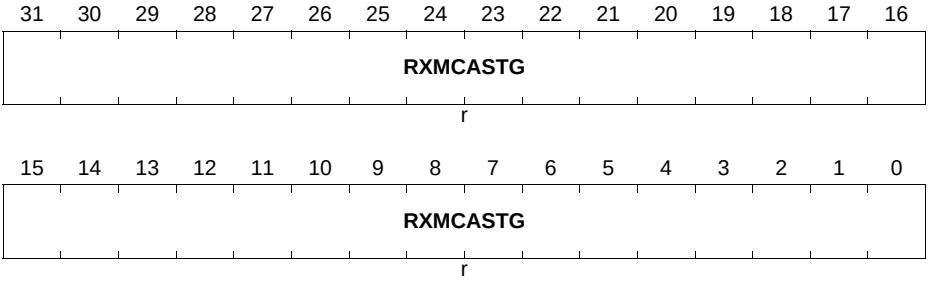


Field	Bits	Type	Description
RXBCASTG	[31:0]	r	**RXBCASTG** This field indicates the number of received good broadcast frames.

32-bit Register - Rx_Multicast_Frames_Good

This register maintains the number of received good multicast frames.

ETH_RX_MULTICAST_FRAMES_GOOD
Register 100 - Receive Frame Count for Good Multicast Frames (1190_H) Reset Value: $0000\ 0000_H$



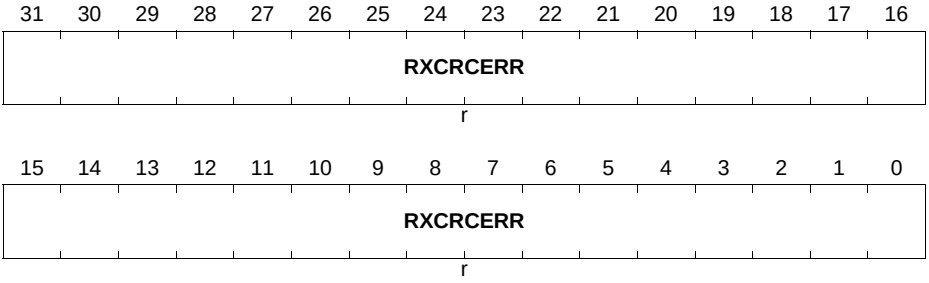
Field	Bits	Type	Description
RXMCASTG	[31:0]	r	**RXMCASTG** This field indicates the number of received good multicast frames.

32-bit Register - Rx_CRC_Error_Frames

This register maintains the number of frames received with CRC error.

ETH_RX_CRC_ERROR_FRAMES

Register 101 - Receive Frame Count for CRC Error Frames (1194_H) Reset Value: $0000\ 0000_H$

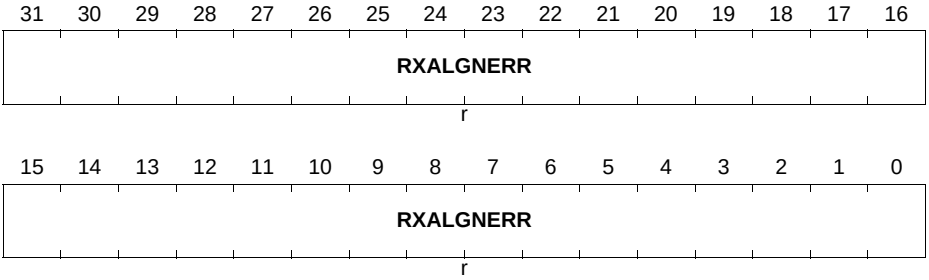


Field	Bits	Type	Description
RXCRCERR	[31:0]	r	**RXCRCERR** This field indicates the number of frames received with CRC error.

32-bit Register - Rx_Alignment_Error_Frames

This register maintains the number of frames received with alignment (dribble) error. This field is valid only in the 10 or 100 Mbps mode.

ETH_RX_ALIGNMENT_ERROR_FRAMES
Register 102 - Receive Frame Count for Alignment Error Frames (1198_H) Reset Value: $0000\ 0000_H$

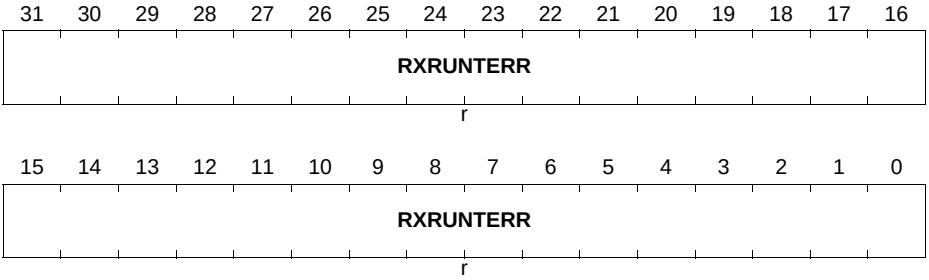


Field	Bits	Type	Description
RXALGNERR	[31:0]	r	**RXALGNERR** This field indicates the number of frames received with alignment (dribble) error. This field is valid only in the 10 or 100 Mbps mode.

32-bit Register - Rx_Runt_Error_Frames

This register maintains the number of frames received with runt error(<64 bytes and CRC error).

ETH_RX_RUNT_ERROR_FRAMES
Register 103 - Receive Frame Count for Runt Error Frames ($119C_H$) Reset Value: $0000\ 0000_H$



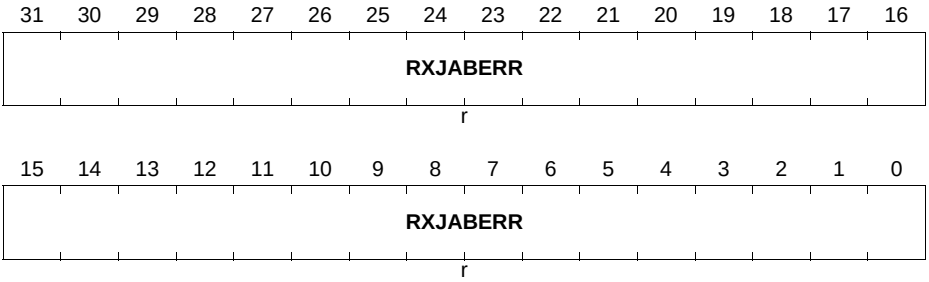
Field	Bits	Type	Description
RXRUNTERR	[31:0]	r	**RXRUNTERR** This field indicates the number of frames received with runt error(<64 bytes and CRC error).

32-bit Register - Rx_Jabber_Error_Frames

This register maintains the number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.

ETH_RX_JABBER_ERROR_FRAMES

Register 104 - Receive Frame Count for Jabber Error Frames ($11A0_H$) Reset Value: $0000\ 0000_H$

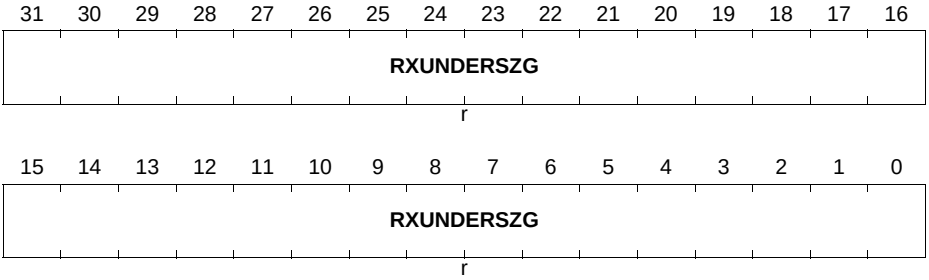


Field	Bits	Type	Description
RXJABERR	[31:0]	r	**RXJABERR** This field indicates the number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.

32-bit Register - Rx_Undersize_Frames_Good

This register maintains the number of frames received with length less than 64 bytes and without errors.

ETH_RX_UNDERSIZE_FRAMES_GOOD
Register 105 - Receive Frame Count for Undersize Frames ($11A4_H$) Reset Value: $0000\ 0000_H$

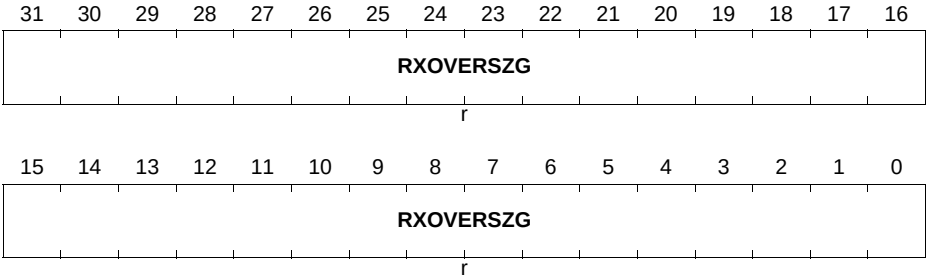


Field	Bits	Type	Description
RXUNDERSZG	[31:0]	r	**RXUNDERSZG** This field indicates the number of frames received with length less than 64 bytes and without errors.

32-bit Register - Rx_Oversize_Frames_Good

This register maintains the number of frames received with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames) and without errors.

ETH_RX_OVERSIZE_FRAMES_GOOD
Register 106 - Receive Frame Count for Oversize Frames ($11A8_H$) Reset Value: $0000\ 0000_H$

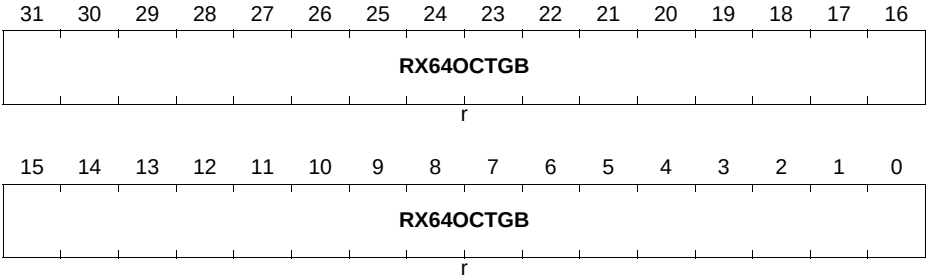


Field	Bits	Type	Description
RXOVERSZG	[31:0]	r	**RXOVERSZG** This field indicates the number of frames received without errors, with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames; 2,000 bytes if enabled in bit 27 of Register 0 (MAC Configuration Register)).

32-bit Register - Rx_64Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length 64 bytes, exclusive of preamble.

ETH_RX_64OCTETS_FRAMES_GOOD_BAD
Register 107 - Receive Frame Count for Good and Bad 64 Byte Frames ($11AC_H$)
Reset Value: $0000\ 0000_H$

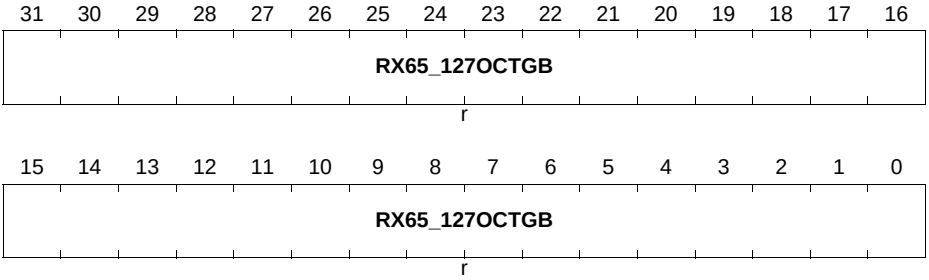


Field	Bits	Type	Description
RX64OCTGB	[31:0]	r	**RX64OCTGB** This field indicates the number of received good and bad frames with length 64 bytes, exclusive of preamble.

32-bit Register - Rx_65To127Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.

ETH_RX_65TO127OCTETS_FRAMES_GOOD_BAD
Register 108 - Receive Frame Count for Good and Bad 65 to 127 Bytes Frames ($11B0_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RX65_127 OCTGB	[31:0]	r	**RX65_127OCTGB** This field indicates the number of received good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.

32-bit Register - Rx_128To255Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble.

ETH_RX_128TO255OCTETS_FRAMES_GOOD_BAD
Register 109 - Receive Frame Count for Good and Bad 128 to 255 Bytes Frames ($11B4_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
RX128_255OCTGB	[31:0]	r	**RX128_255OCTGB** This field indicates the number of received good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble.

32-bit Register - Rx_256To511Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

ETH_RX_256TO511OCTETS_FRAMES_GOOD_BAD
Register 110 - Receive Frame Count for Good and Bad 256 to 511 Bytes Frames ($11B8_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
RX256_511OCTGB	[31:0]	r	**RX256_511OCTGB** This field indicates the number of received good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

32-bit Register - Rx_512To1023Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble.

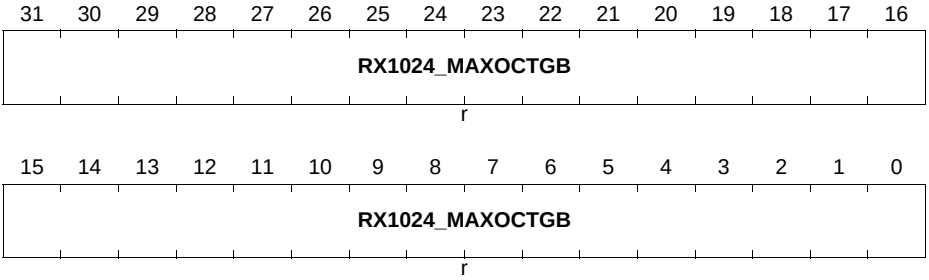
ETH_RX_512TO1023OCTETS_FRAMES_GOOD_BAD
Register 111 - Receive Frame Count for Good and Bad 512 to 1,023 Bytes Frames ($11BC_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
RX512_1023OCTGB	[31:0]	r	**RX512_1023OCTGB** This field indicates the number of received good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble.

32-bit Register - Rx_1024ToMaxOctets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble.

ETH_RX_1024TOMAXOCTETS_FRAMES_GOOD_BAD
Register 112 - Receive Frame Count for Good and Bad 1,024 to Maxsize Bytes Frames **($11C0_H$)** **Reset Value: $0000\ 0000_H$**

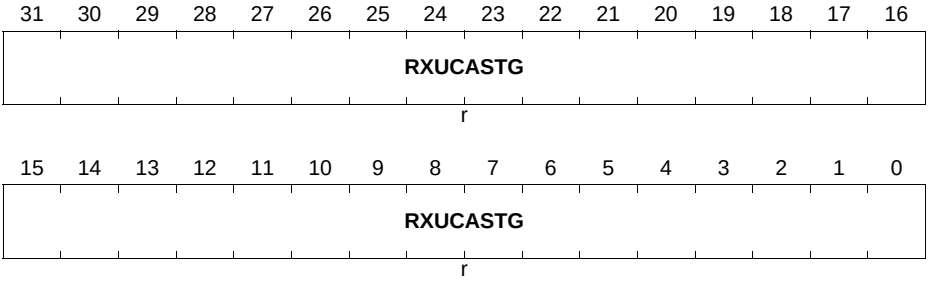


Field	Bits	Type	Description
RX1024_MAXOCTGB	[31:0]	r	**RX1024_MAXOCTGB** This field indicates the number of received good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Rx_Unicast_Frames_Good

This register maintains the number of received good unicast frames.

ETH_RX_UNICAST_FRAMES_GOOD
Register 113 - Receive Frame Count for Good Unicast Frames ($11C4_H$) Reset Value: $0000\ 0000_H$

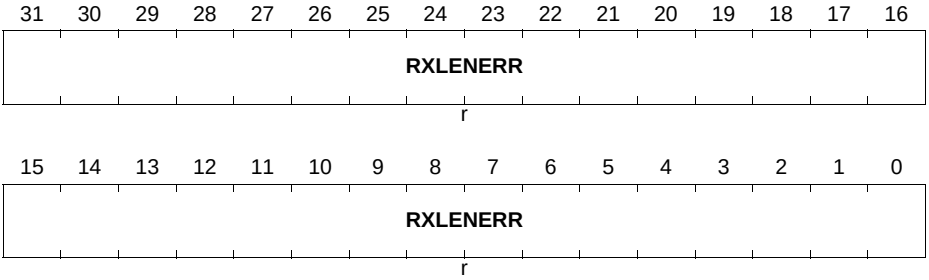


Field	Bits	Type	Description
RXUCASTG	[31:0]	r	**RXUCASTG** This field indicates the number of received good unicast frames.

32-bit Register - Rx_Length_Error_Frames

This register maintains the number of frames received with length error (Length type field not equal to frame size) for all frames with valid length field.

ETH_RX_LENGTH_ERROR_FRAMES
Register 114 - Receive Frame Count for Length Error Frames ($11C8_H$) Reset Value: $0000\ 0000_H$

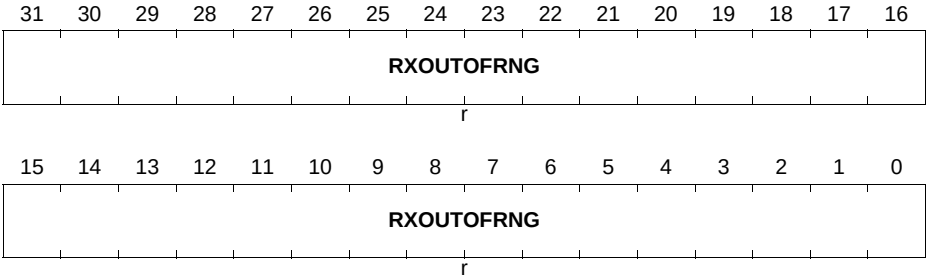


Field	Bits	Type	Description
RXLENERR	[31:0]	r	**RXLENERR** This field indicates the number of frames received with length error (Length type field not equal to frame size) for all frames with valid length field.

32-bit Register - Rx_Out_Of_Range_Type_Frames

This register maintains the number of received frames with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).

ETH_RX_OUT_OF_RANGE_TYPE_FRAMES
Register 115 - Receive Frame Count for Out of Range Frames ($11CC_H$) Reset Value: $0000\ 0000_H$



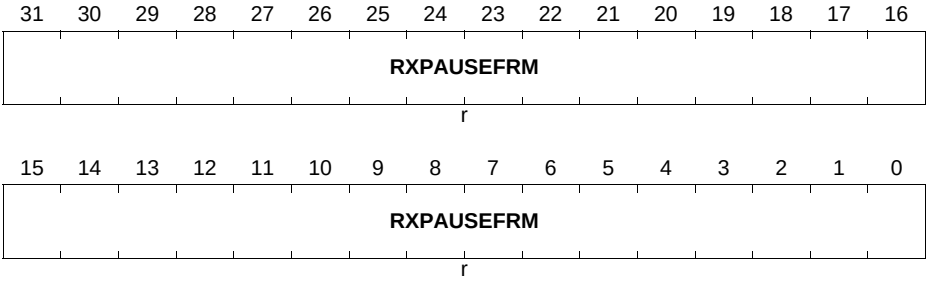
Field	Bits	Type	Description
RXOUTOFRNG	[31:0]	r	**RXOUTOFRNG** This field indicates the number of received frames with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).

32-bit Register - Rx_Pause_Frames

This register maintains the number of received good and valid PAUSE frames.

ETH_RX_PAUSE_FRAMES

Register 116 - Receive Frame Count for PAUSE Frames ($11D0_H$)Reset Value: $0000\ 0000_H$

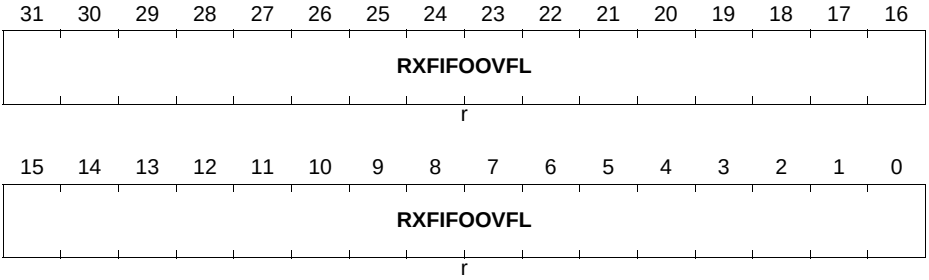


Field	Bits	Type	Description
RXPAUSEFRM	[31:0]	r	**RXPAUSEFRM** This field indicates the number of received good and valid PAUSE frames.

32-bit Register - Rx_FIFO_Overflow_Frames

This register maintains the number of received frames missed because of FIFO overflow.

ETH_RX_FIFO_OVERFLOW_FRAMES
Register 117 - Receive Frame Count for FIFO Overflow Frames ($11D4_H$) Reset Value: $0000\ 0000_H$

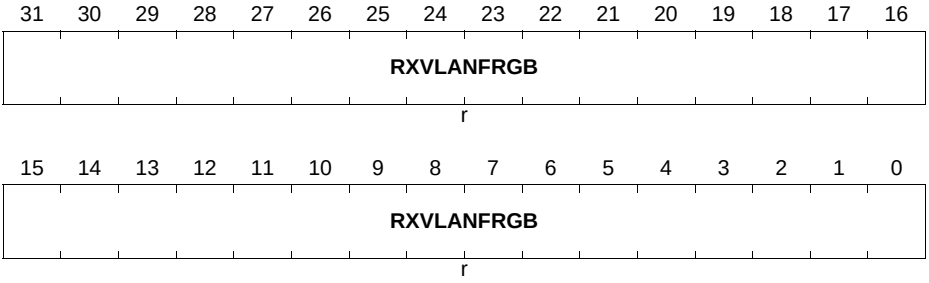


Field	Bits	Type	Description
RXFIFOOVFL	[31:0]	r	**RXFIFOOVFL** This field indicates the number of received frames missed because of FIFO overflow.

32-bit Register - Rx_VLAN_Frames_Good_Bad

This register maintains the number of received good and bad VLAN frames.

ETH_RX_VLAN_FRAMES_GOOD_BAD
Register 118 - Receive Frame Count for Good and Bad VLAN Frames ($11D8_H$)
Reset Value: $0000\ 0000_H$

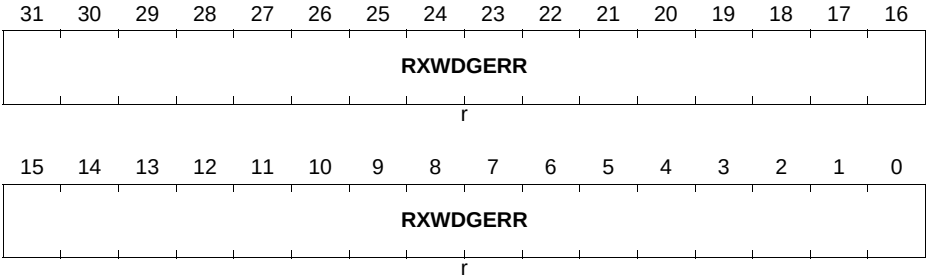


Field	Bits	Type	Description
RXVLANFRGB	[31:0]	r	**RXVLANFRGB** This field indicates the number of received good and bad VLAN frames.

32-bit Register - Rx_Watchdog_Error_Frames

This register maintains the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

ETH_RX_WATCHDOG_ERROR_FRAMES
Register 119 - Receive Frame Count for Watchdog Error Frames ($11DC_H$) Reset Value: $0000\ 0000_H$

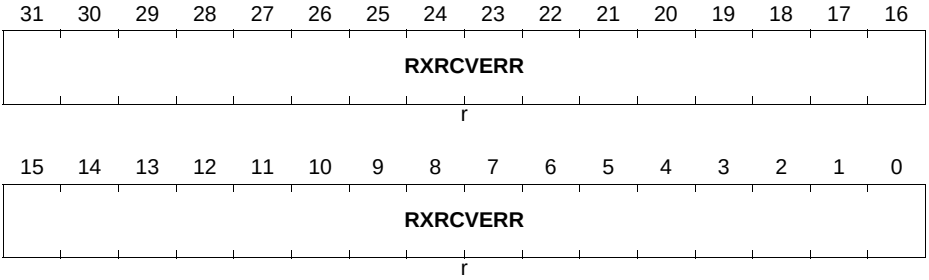


Field	Bits	Type	Description
RXWDGERR	[31:0]	r	**RXWDGERR** This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

32-bit Register - Rx_Receive_Error_Frames

This register maintains the number of frames received with error because of the GMII/MII RXER error.

ETH_RX_RECEIVE_ERROR_FRAMES
Register 120 - Receive Frame Count for Receive Error Frames ($11E0_H$) Reset Value: $0000\ 0000_H$

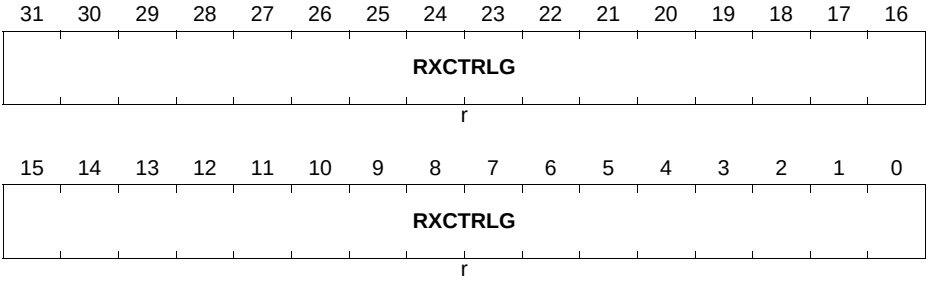


Field	Bits	Type	Description
RXRCVERR	[31:0]	r	**RXRCVERR** This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

32-bit Register - Rx_Control_Frames_Good

This register maintains the number of godd control frames received.

ETH_RX_CONTROL_FRAMES_GOOD
Register 121 - Receive Frame Count for Good Control Frames Frames ($11E4_H$)
Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RXCTRLG	[31:0]	r	**RXCTRLG** This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

32-bit Register - MMC_IPC_Receive_Interrupt_Mask

This register maintains the mask for the interrupt generated from the receive IPC statistic counters. This register is 32-bits wide. This register is present only when any one of the MMC Receive IPC Counters is selected during core configuration.

ETH_MMC_IPC_RECEIVE_INTERRUPT_MASK
Register 128 - MMC Receive Checksum Offload Interrupt Mask Register (1200_H)
Reset Value: $0000\ 0000_H$

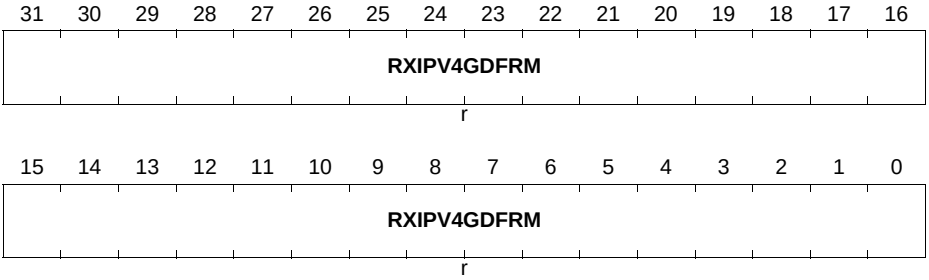
32-bit Register - RxIPv4_Good_Frames

This register maintains the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

ETH_RXIPV4_GOOD_FRAMES
Register 132 - Receive IPV4 Good Frame Counter Register (1210_H) Reset Value: $0000\ 0000_H$

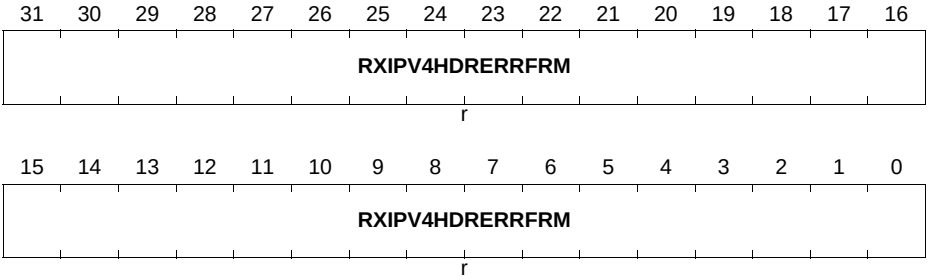


Field	Bits	Type	Description
RXIPV4GDFRM	[31:0]	r	**RXIPV4GDFRM** This field indicates the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

32-bit Register - RxIPv4_Header_Error_Frames

This register maintains the number of IPv4 datagrams received with header errors (checksum, length, or version mismatch).

ETH_RXIPV4_HEADER_ERROR_FRAMES
Register 133 - Receive IPV4 Header Error Frame Counter Register (1214_H) Reset Value: $0000\ 0000_H$

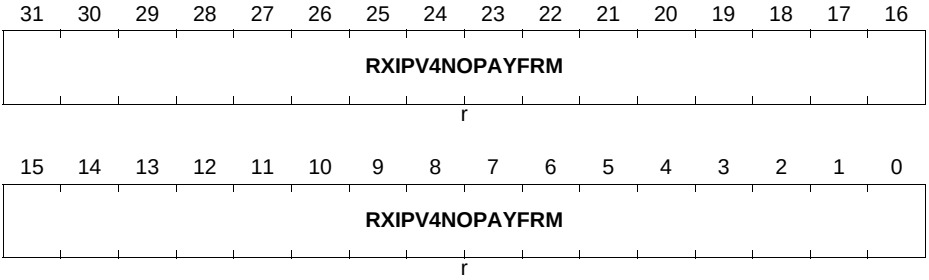


Field	Bits	Type	Description
RXIPV4HDRERRFRM	[31:0]	r	**RXIPV4HDRERRFRM** This field indicates the number of IPv4 datagrams received with header errors (checksum, length, or version mismatch).

32-bit Register - RxIPv4_No_Payload_Frames

This register maintains the number of received IPv4 datagram frames without a TCP, UDP, or ICMP payload processed by the Checksum engine.

ETH_RXIPV4_NO_PAYLOAD_FRAMES
Register 134 - Receive IPV4 No Payload Frame Counter Register (1218_H) Reset Value: $0000\ 0000_H$

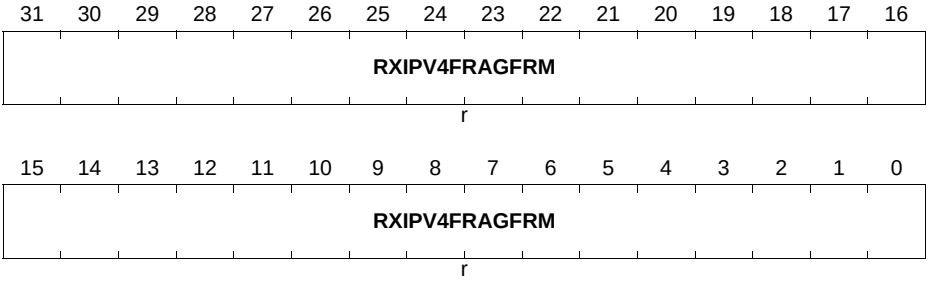


Field	Bits	Type	Description
RXIPV4NOPAYFRM	[31:0]	r	**RXIPV4NOPAYFRM** This field indicates the number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine.

32-bit Register - RxIPv4_Fragmented_Frames

This register maintains the number of good IPv4 datagrams received with fragmentation.

ETH_RXIPV4_FRAGMENTED_FRAMES
Register 135 - Receive IPV4 Fragmented Frame Counter Register ($121C_H$) Reset Value: $0000\ 0000_H$

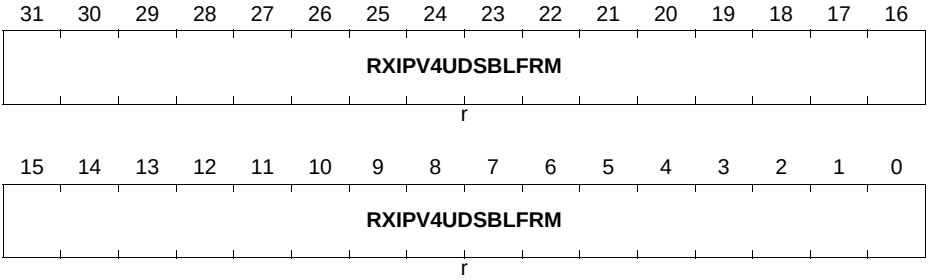


Field	Bits	Type	Description
RXIPV4FRAGFRM	[31:0]	r	**RXIPV4FRAGFRM** This field indicates the number of good IPv4 datagrams received with fragmentation.

32-bit Register - RxIPv4_UDP_Checksum_Disabled_Frames

This register maintains the number of received good IPv4 datagrams which have the UDP payload with checksum disabled.

ETH_RXIPV4_UDP_CHECKSUM_DISABLED_FRAMES
Register 136 - Receive IPV4 UDP Checksum Disabled Frame Counter Register (1220_H) **Reset Value: $0000\ 0000_H$**

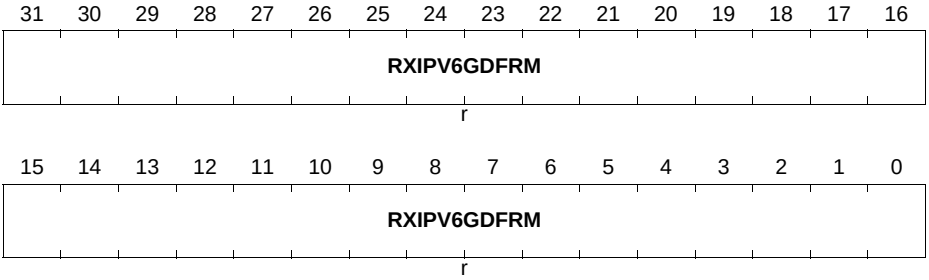


Field	Bits	Type	Description
RXIPV4UDSBLFRM	[31:0]	r	**RXIPV4UDSBLFRM** This field indicates the number of received good IPv4 datagrams which have the UDP payload with checksum disabled.

32-bit Register - RxIPv6_Good_Frames

This register maintains the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads.

ETH_RXIPV6_GOOD_FRAMES
Register 137 - Receive IPV6 Good Frame Counter Register (1224_H) Reset Value: $0000\ 0000_H$

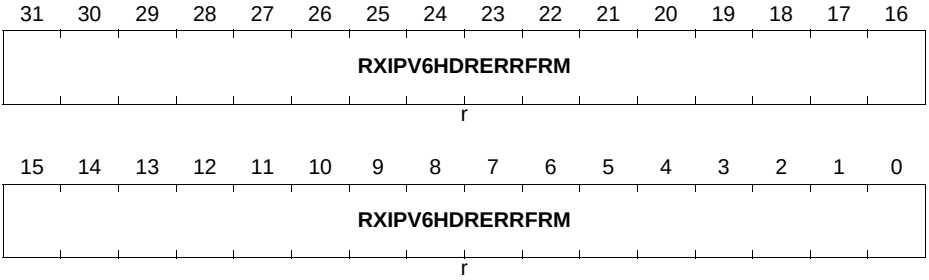


Field	Bits	Type	Description
RXIPV6GDFRM	[31:0]	r	**RXIPV6GDFRM** This field indicates the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads.

32-bit Register - RxIPv6_Header_Error_Frames

This register maintains the number of IPv6 datagrams received with header errors (length or version mismatch).

ETH_RXIPV6_HEADER_ERROR_FRAMES
Register 138 - Receive IPV6 Header Error Frame Counter Register (1228_H) Reset Value: $0000\ 0000_H$

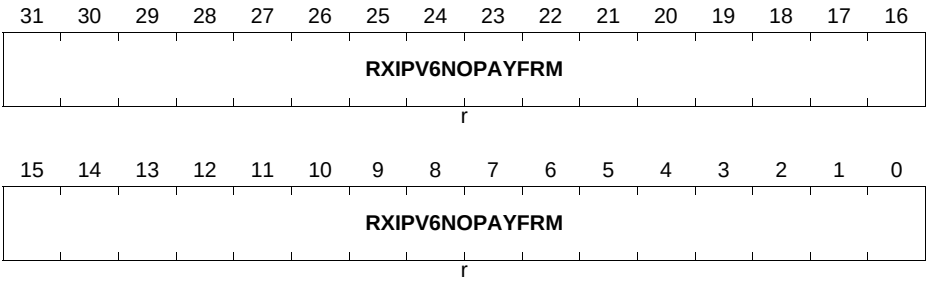


Field	Bits	Type	Description
RXIPV6HDRERRFRM	[31:0]	r	**RXIPV6HDRERRFRM** This field indicates the number of IPv6 datagrams received with header errors (length or version mismatch).

32-bit Register - RxIPv6_No_Payload_Frames

This register maintains the number of received IPv6 datagram frames without a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

ETH_RXIPV6_NO_PAYLOAD_FRAMES
Register 139 - Receive IPV6 No Payload Frame Counter Register ($122C_H$) Reset Value: $0000\ 0000_H$

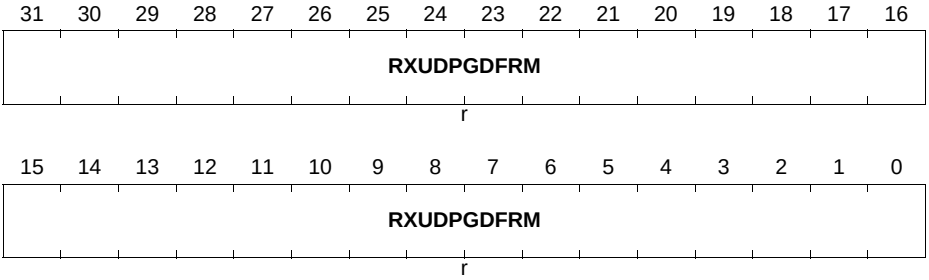


Field	Bits	Type	Description
RXIPV6NOPAYFRM	[31:0]	r	**RXIPV6NOPAYFRM** This field indicates the number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

32-bit Register - RxUDP_Good_Frames

This register maintains the number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented.

ETH_RXUDP_GOOD_FRAMES
Register 140 - Receive UDP Good Frame Counter Register (1230_H) Reset Value: $0000\ 0000_H$

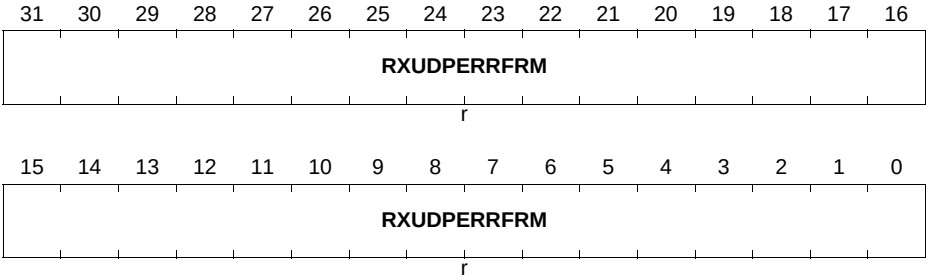


Field	Bits	Type	Description
RXUDPGDFRM	[31:0]	r	**RXUDPGDFRM** This field indicates the number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented.

32-bit Register - RxUDP_Error_Frames

This register maintains the number of good IP datagrams whose UDP payload has a checksum error.

ETH_RXUDP_ERROR_FRAMES
Register 141 - Receive UDP Error Frame Counter Register (1234_H) Reset Value: $0000\ 0000_H$

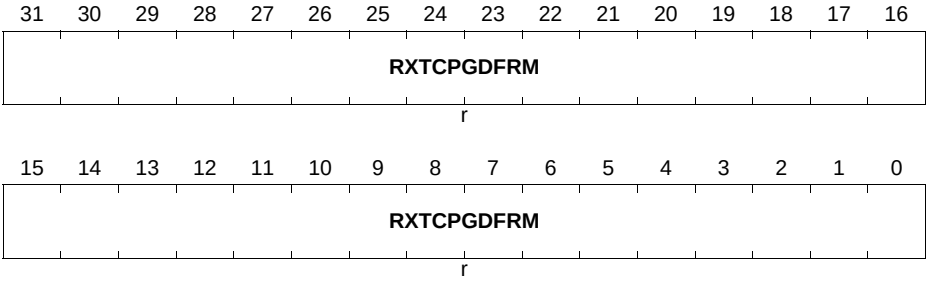


Field	Bits	Type	Description
RXUDPERRFRM	[31:0]	r	**RXUDPERRFRM** This field indicates the number of good IP datagrams whose UDP payload has a checksum error.

32-bit Register - RxTCP_Good_Frames

This register maintains the number of good IP datagrams with a good TCP payload.

ETH_RXTCP_GOOD_FRAMES
Register 142 - Receive TCP Good Frame Counter Register (1238_H) Reset Value: $0000\ 0000_H$

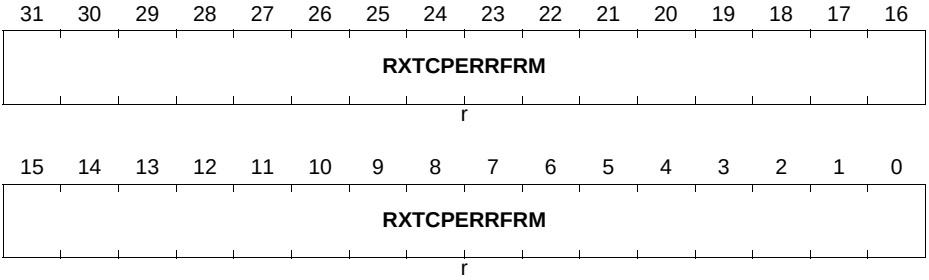


Field	Bits	Type	Description
RXTCPGDFRM	[31:0]	r	**RXTCPGDFRM** This field indicates the number of good IP datagrams with a good TCP payload.

32-bit Register - RxTCP_Error_Frames

This register maintains the number of good IP datagrams whose TCP payload has a checksum error.

ETH_RXTCP_ERROR_FRAMES
Register 143 - Receive TCP Error Frame Counter Register ($123C_H$) Reset Value: $0000\ 0000_H$

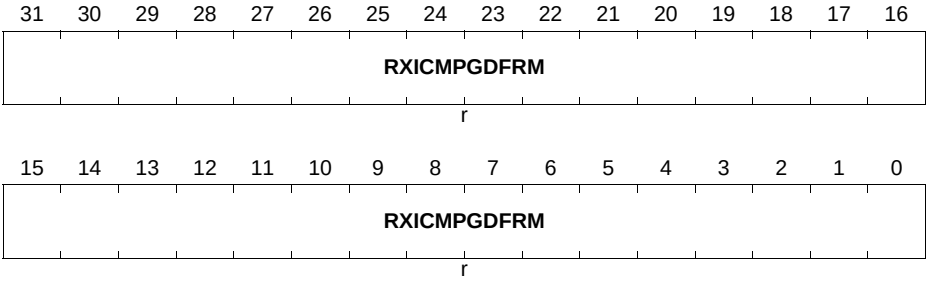


Field	Bits	Type	Description
RXTCPERRFRM	[31:0]	r	**RXTCPERRFRM** This field indicates the number of good IP datagrams whose TCP payload has a checksum error.

32-bit Register - RxICMP_Good_Frames

This register maintains the number of good IP datagrams with a good ICMP payload.

ETH_RXICMP_GOOD_FRAMES
Register 144 - Receive ICMP Good Frame Counter Register (1240_H) Reset Value: $0000\ 0000_H$

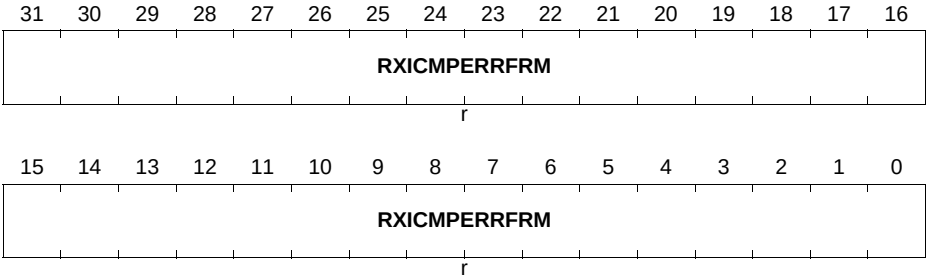


Field	Bits	Type	Description
RXICMPGDFRM	[31:0]	r	**RXICMPGDFRM** This field indicates the number of good IP datagrams with a good ICMP payload.

32-bit Register - RxICMP_Error_Frames

This register maintains the number of good IP datagrams whose ICMP payload has a checksum error.

ETH_RXICMP_ERROR_FRAMES
Register 145 - Receive ICMP Error Frame Counter Register (1244_H) Reset Value: $0000\ 0000_H$

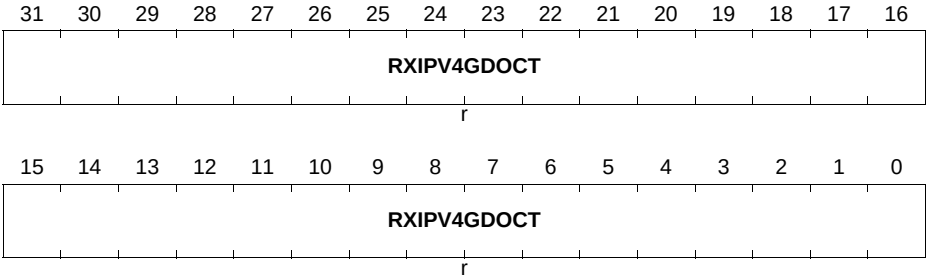


Field	Bits	Type	Description
RXICMPERRFRM	[31:0]	r	**RXICMPERRFRM** This field indicates the number of good IP datagrams whose ICMP payload has a checksum error.

32-bit Register - RxIPv4_Good_Octets

This register maintains the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data.

ETH_RXIPV4_GOOD_OCTETS
Register 148 - Receive IPV4 Good Octet Counter Register (1250_H) Reset Value: $0000\ 0000_H$

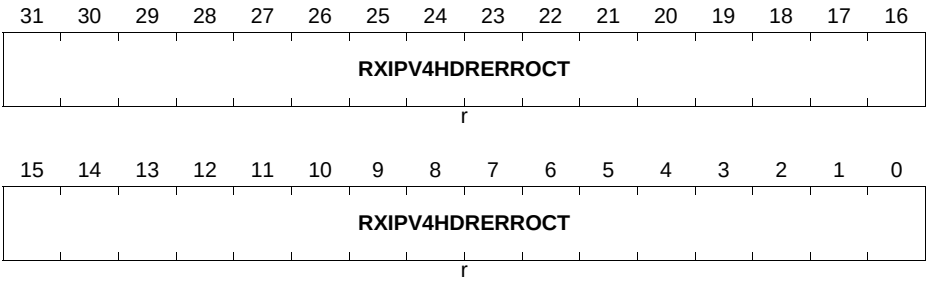


Field	Bits	Type	Description
RXIPV4GDOCT	[31:0]	r	**This field indicates the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. The Ethernet header, FCS, pad, or IP pad** bytes are not included in this counter.

32-bit Register - RxIPv4_Header_Error_Octets

This register maintains the number of bytes received in IPv4 datagrams with header errors (checksum, length, or version mismatch). The value in the Length field of the IPv4 header is used to update this counter.

ETH_RXIPV4_HEADER_ERROR_OCTETS
Register 149 - Receive IPV4 Header Error Octet Counter Register (1254_H) Reset Value: $0000\ 0000_H$

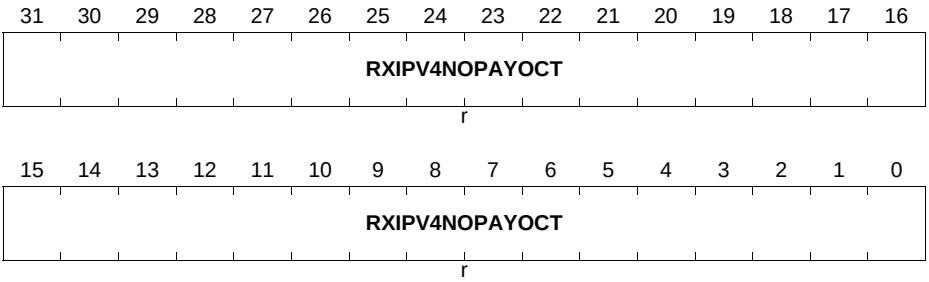


Field	Bits	Type	Description
RXIPV4HDRERROCT	[31:0]	r	**This field indicates the number of bytes received in the IPv4 datagrams with header errors (checksum, length, or version mismatch). The value in the Length field of IPv4 header is used to update this counter.** The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv4_No_Payload_Octets

This register maintains the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter.

ETH_RXIPV4_NO_PAYLOAD_OCTETS
Register 150 - Receive IPV4 No Payload Octet Counter Register (1258_H) Reset Value: $0000\ 0000_H$

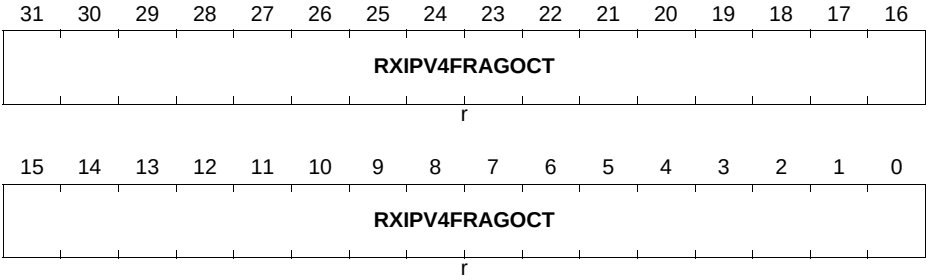


Field	Bits	Type	Description
RXIPV4NOPAYOCT	[31:0]	r	**This field indicates the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter.** The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv4_Fragmented_Octets

This register maintains the number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter.

ETH_RXIPV4_FRAGMENTED_OCTETS
Register 151 - Receive IPV4 Fragmented Octet Counter Register ($125C_H$) Reset Value: $0000\ 0000_H$

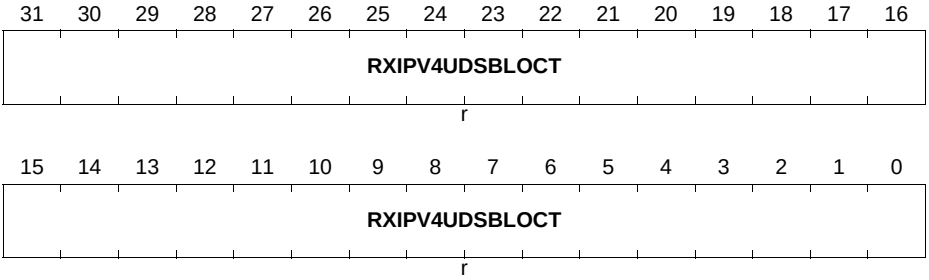


Field	Bits	Type	Description
RXIPV4FRAGOCT	[31:0]	r	**This field indicates the number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter.** The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv4_UDP_Checksum_Disable_Octets

This register maintains the number of bytes received in a UDP segment that had the UDP checksum disabled.

ETH_RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS
Register 152 - Receive IPV4 Fragmented Octet Counter Register (1260_H) Reset Value: $0000\ 0000_H$

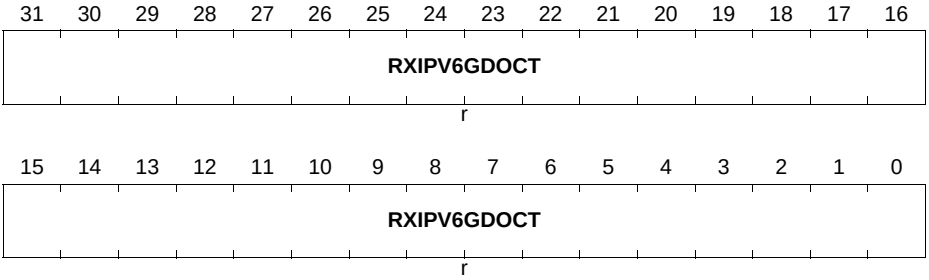


Field	Bits	Type	Description
RXIPV4UDSBLOCT	[31:0]	r	**RXIPV4UDSBLOCT** This field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv6_Good_Octets

This register maintains the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data.

ETH_RXIPV6_GOOD_OCTETS
Register 153 - Receive IPV6 Good Octet Counter Register (1264_H) Reset Value: $0000\ 0000_H$

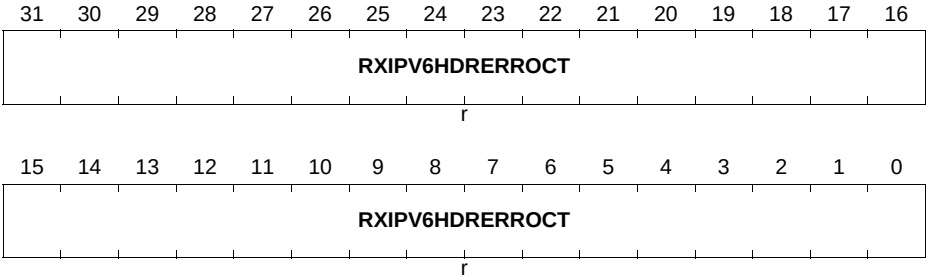


Field	Bits	Type	Description
RXIPV6GDOCT	[31:0]	r	**Thsi field indicates the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data.** This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv6_Header_Error_Octets

This register maintains the number of bytes received in IPv6 datagrams with header errors (length or version mismatch).

ETH_RXIPV6_HEADER_ERROR_OCTETS
Register 154 - Receive IPV6 Header Error Octet Counter Register (1268_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RXIPV6HDRERROCT	[31:0]	r	**This field indicates the number of bytes received in IPv6 datagrams with header errors (length or version mismatch). The value in the IPv6 headers Length field is used to update this counter.** This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv6_No_Payload_Octets

This register maintains the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload.

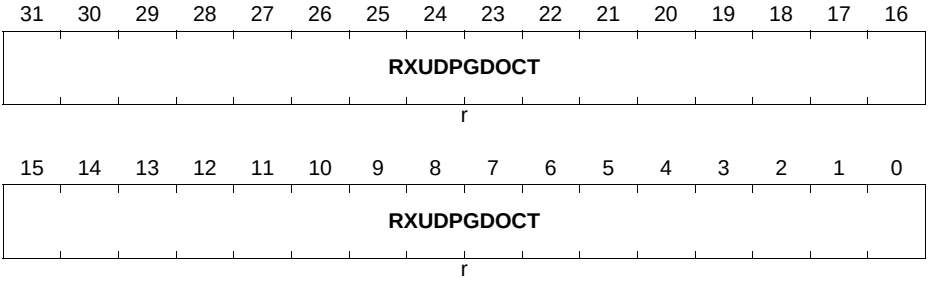
ETH_RXIPV6_NO_PAYLOAD_OCTETS
Register 155 - Receive IPV6 No Payload Octet Counter Register ($126C_H$) Reset Value: $0000\ 0000_H$

Field	Bits	Type	Description
RXIPV6NOPAYOCT	[31:0]	r	**This field indicates the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 headers Length field is used to update this counter.** This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxUDP_Good_Octets

This register maintains the number of bytes received in a good UDP segment.

ETH_RXUDP_GOOD_OCTETS
Register 156 - Receive UDP Good Octet Counter Register (1270_H) Reset Value: $0000\ 0000_H$

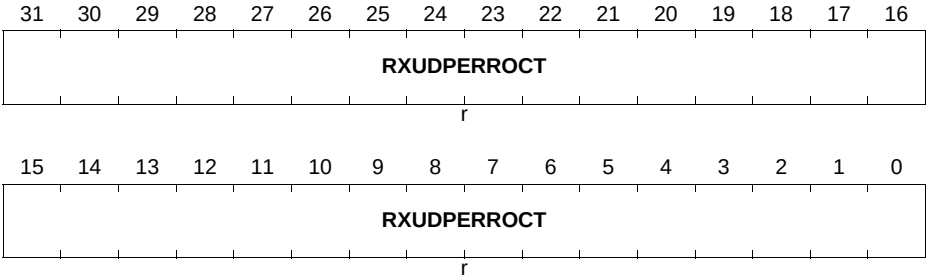


Field	Bits	Type	Description
RXUDPGDOCT	[31:0]	r	**RXUDPGDOCT** This field indicates the number of bytes received in a good UDP segment. This counter does not count IP header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxUDP_Error_Octets

This register maintains the number of bytes received in a UDP segment with checksum errors.

ETH_RXUDP_ERROR_OCTETS
Register 157 - Receive UDP Error Octet Counter Register (1274_H) Reset Value: $0000\ 0000_H$

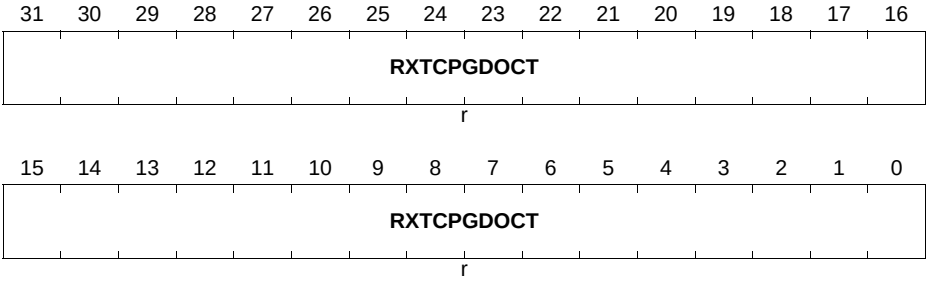


Field	Bits	Type	Description
RXUDPERROCT	[31:0]	r	**RXUDPERROCT** This field indicates the number of bytes received in a UDP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxTCP_Good_Octets

This register maintains the number of bytes received in a good TCP segment.

ETH_RXTCP_GOOD_OCTETS
Register 158 - Receive TCP Good Octet Counter Register (1278_H) Reset Value: $0000\ 0000_H$

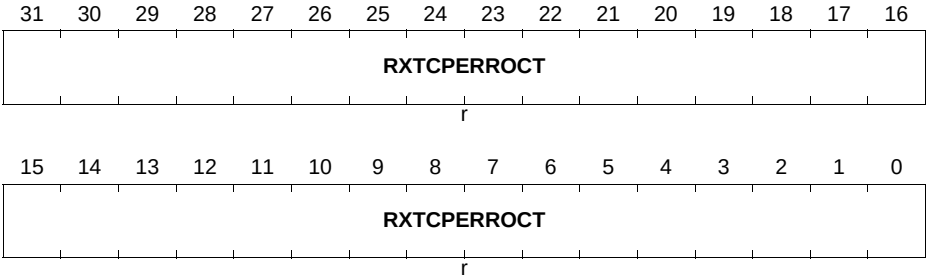


Field	Bits	Type	Description
RXTCPGDOCT	[31:0]	r	**RXTCPGDOCT** This field indicates the number of bytes received in a good TCP segment. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxTCP_Error_Octets

This register maintains the number of bytes received in a TCP segment with checksum errors.

ETH_RXTCP_ERROR_OCTETS
Register 159 - Receive TCP Error Octet Counter Register ($127C_H$) Reset Value: $0000\ 0000_H$

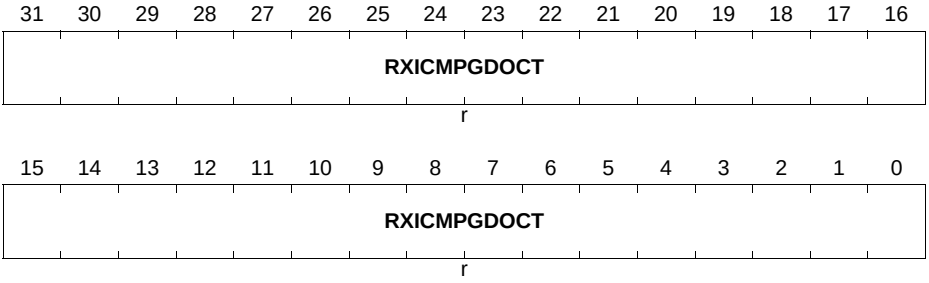


Field	Bits	Type	Description
RXTCPERROCT	[31:0]	r	**RXTCPERROCT** Thsi field indicates the number of bytes received in a TCP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxICMP_Good_Octets

This register maintains the number of bytes received in a good ICMP segment.

ETH_RXICMP_GOOD_OCTETS
Register 160 - Receive ICMP Good Octet Counter Register (1280_H) Reset Value: $0000\ 0000_H$

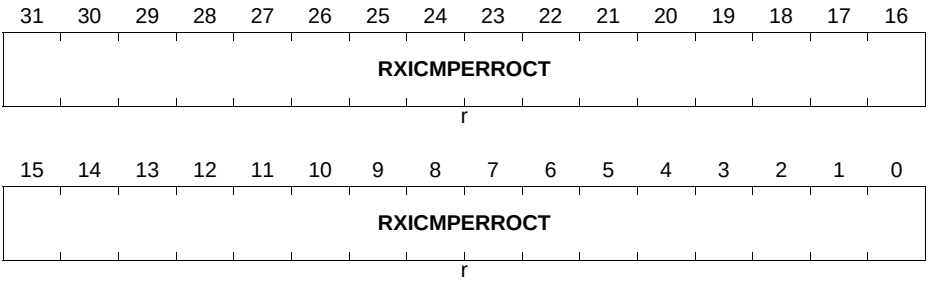


Field	Bits	Type	Description
RXICMPGDOCT	[31:0]	r	**RXICMPGDOCT** This field indicates the number of bytes received in a good ICMP segment. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxICMP_Error_Octets

This register maintains the number of bytes received in a ICMP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

ETH_RXICMP_ERROR_OCTETS
Register 161 - Receive ICMP Error Octet Counter Register (1284_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RXICMPERROCT	[31:0]	r	**RXICMPERROCT** Number of bytes received in an ICMP segment with checksum errors

32-bit Register - Timestamp_Control

This register controls the operation of the System Time generator and the processing of PTP packets for timestamping in the Receiver. Note: * Bits[5:1] are reserved when External Timestamp Input feature is enabled. * Bits[19:8] are reserved and read-only when Advanced Timestamp feature is not enabled. * Bits[28:24] are reserved and read-only when Auxiliary Snapshot feature is not enabled. * Release 3.60a onwards, the functions of Bits 17 and 16 (SNAPTYPSEL) have changed. These functions are not backward compatible with the functions described in release 3.50a.

ETH_TIMESTAMP_CONTROL

Register 448 - Timestamp Control Register (1700_H) **Reset Value: $0000\ 2000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESERVED_31_29			ATSEN3	ATSEN2	ATSEN1	ATSEN0	ATSFC	RESERVED_23_19					TSENMACADDR	SNAPTYPSEL	
r			r	r	r	r	r	r					rw	rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSMSTRENA	TSEVNTENA	TSIPV4ENA	TSIPV6ENA	TSIPENA	TSVER2ENA	TSCTRLSSR	TSENALL	RESERVED_7_6		TSADDREG	TSTRIG	TSUPDT	TSINIT	TSCFUPDT	TSENA
rw	rw	rw	rw	rw	rw	rw	rw	r		rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
TSENA	0	rw	**Timestamp Enable** When set, the timestamp is added for the transmit and receive frames. When disabled, timestamp is not added for the transmit and receive frames and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the receive side, the MAC processes the 1588 frames only if this bit is set.
TSCFUPDT	1	rw	**Timestamp Fine or Coarse Update** When set, this bit indicates that the system times update should be done using the fine update method. When reset, it indicates the system timestamp update should be done using the Coarse method.

Field	Bits	Type	Description
TSINIT	2	rw	**Timestamp Initialize** When set, the system time is initialized (overwritten) with the value specified in the Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized.
TSUPDT	3	rw	**Timestamp Update** When set, the system time is updated (added or subtracted) with the value specified in Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the update is completed in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated.
TSTRIG	4	rw	**Timestamp Interrupt Trigger Enable** When set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the generation of the Timestamp Trigger Interrupt.
TSADDREG	5	rw	**Addend Reg Update** When set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This is cleared when the update is completed. This register bit should be zero before setting it.
RESERVED_7_6	[7:6]	r	**RESERVED_7_6**
TSENALL	8	rw	**Enable Timestamp for All Frames** When set, the timestamp snapshot is enabled for all frames received by the MAC.

Field	Bits	Type	Description
TSCTRLSSR	9	rw	**Timestamp Digital or Binary Rollover Control** When set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment has to be programmed correctly depending on the PTP reference clock frequency and the value of this bit.
TSVER2ENA	10	rw	**Enable PTP packet Processing for Version 2 Format** When set, the PTP packets are processed using the 1588 version 2 format. Otherwise, the PTP packets are processed using the version 1 format.
TSIPENA	11	rw	**Enable Processing of PTP over Ethernet Frames** When set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores the PTP over Ethernet packets.
TSIPV6ENA	12	rw	**Enable Processing of PTP Frames Sent Over IPv6-UDP** When set, the MAC receiver processes PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets.
TSIPV4ENA	13	rw	**Enable Processing of PTP Frames Sent over IPv4-UDP** When set, the MAC receiver processes the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default.
TSEVNTENA	14	rw	**Enable Timestamp Snapshot for Event Messages** When set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all messages except Announce, Management, and Signaling.
TSMSTRENA	15	rw	**Enable Snapshot for Messages Relevant to Master** When set, the snapshot is taken only for the messages relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

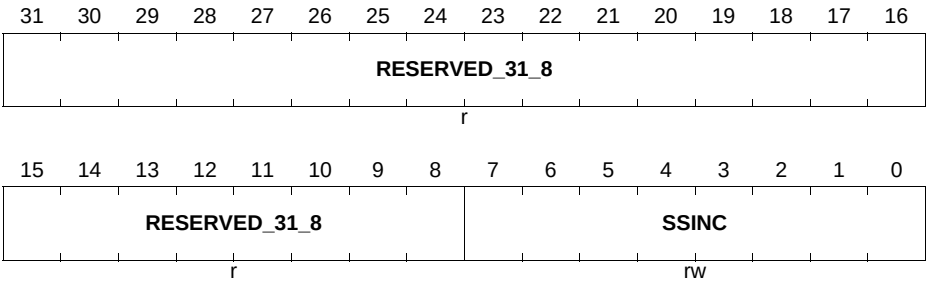
Field	Bits	Type	Description
SNAPTYPSEL	[17:16]	rw	**Select PTP packets for Taking Snapshots** These bits along with Bits 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken.
TSENMACADDR	18	rw	**Enable MAC address for PTP Frame Filtering** When set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP frames when PTP is directly sent over Ethernet.
RESERVED_23_19	[23:19]	r	**RESERVED_23_19**
ATSFC	24	r	**Auxiliary Snapshot FIFO Clear** When set, it resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, auxiliary snapshots get stored in the FIFO. This bit is reserved when the Add IEEE 1588 Auxiliary Snapshot option is not selected during core configuration.
ATSEN0	25	r	**Auxiliary Snapshot 0 Enable** This field controls capturing the Auxiliary Snapshot Trigger 0. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration.
ATSEN1	26	r	**Auxiliary Snapshot 1 Enable** This field controls capturing the Auxiliary Snapshot Trigger 1. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration or the selected number in the Number of IEEE 1588 Auxiliary Snapshot Inputs option is less than two.

Field	Bits	Type	Description
ATSEN2	27	r	**Auxiliary Snapshot 2 Enable** This field controls capturing the Auxiliary Snapshot Trigger 2. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[2] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration or the selected number in the Number of IEEE 1588 Auxiliary Snapshot Inputs option is less than three.
ATSEN3	28	r	**Auxiliary Snapshot 3 Enable** This field controls capturing the Auxiliary Snapshot Trigger 3. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[3] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration or the selected number in the Number of IEEE 1588 Auxiliary Snapshot Inputs option is less than four.
RESERVED_31_29	[31:29]	r	**RESERVED_31_29**

32-bit Register - Sub_Second_Increment

This register is present only when the IEEE 1588 timestamp feature is selected without an external timestamp input. In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

ETH_SUB_SECOND_INCREMENT
Register 449 - Sub-Second Increment Register (1704_H) Reset Value: $0000\ 0000_H$

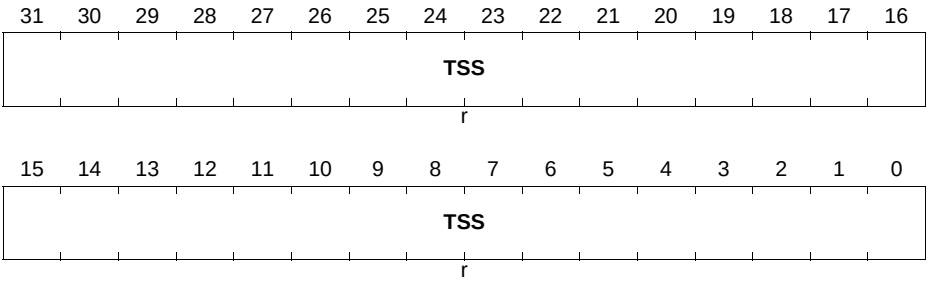


Field	Bits	Type	Description
SSINC	[7:0]	rw	**Sub-second Increment Value** The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.
RESERVED_31_8	[31:8]	r	**RESERVED_31_8**

32-bit Register - System_Time_Seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to clk_csr_i). These registers (450 and 451) are present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_SYSTEM_TIME_SECONDS
Register 450 - System Time - Seconds Register (1708_H) Reset Value: $0000\ 0000_H$

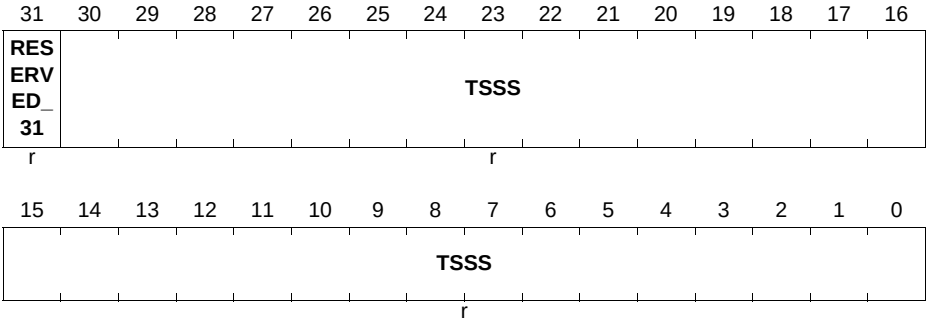


Field	Bits	Type	Description
TSS	[31:0]	r	**Timestamp Second** The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

32-bit Register - System_Time_Nanoseconds

The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When TSCTRLSSR is set, each bit represents 1 ns and the maximum value is 0x3B9A_C9FF, after which it rolls-over to zero.

ETH_SYSTEM_TIME_NANOSECONDS
Register 451 - System Time - Nanoseconds Register ($170C_H$) Reset Value: 0000 0000_H

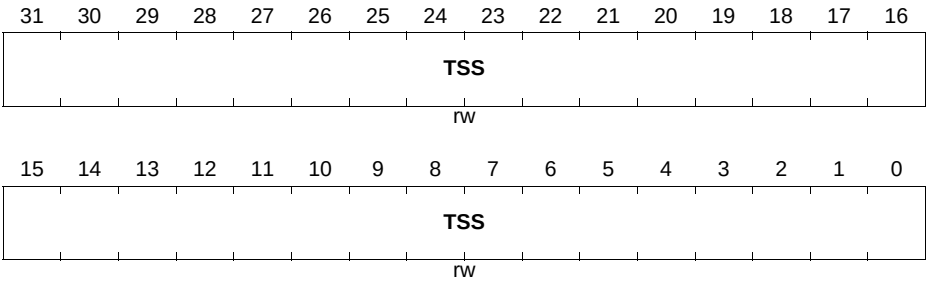


Field	Bits	Type	Description
TSSS	[30:0]	r	**Timestamp Sub Seconds** The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When bit 9 (TSCTRLSSR) is set in Register 448 (Timestamp Control Register), each bit represents 1 ns and the maximum value is 0x3B9A_C9FF, after which it rolls-over to zero.
RESERVED_31	31	r	**RESERVED_31**

32-bit Register - System_Time_Seconds_Update

The System Time - Seconds Update register, along with the System Time - Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both of these registers before setting the TSINIT or TSUPDT bits in the Timestamp Control register. This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_SYSTEM_TIME_SECONDS_UPDATE
Register 452 - System Time - Seconds Update Register (1710_H) Reset Value: 0000 0000_H

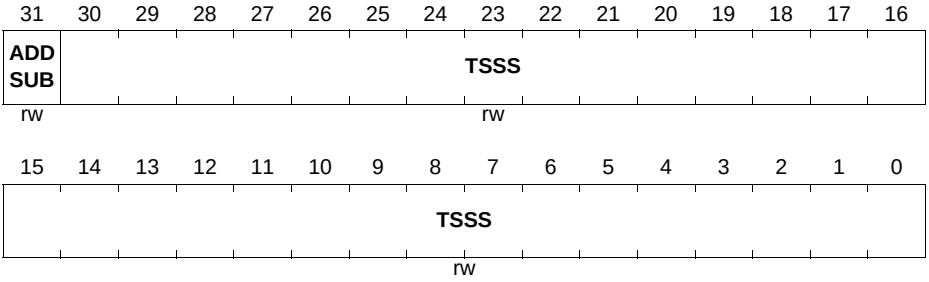


Field	Bits	Type	Description
TSS	[31:0]	rw	**Timestamp Second** The value in this field indicates the time in seconds to be initialized or added to the system time.

32-bit Register - System_Time_Nanoseconds_Update

This register is present only when IEEE 1588 timestamp feature is selected without external timestamp input.

ETH_SYSTEM_TIME_NANOSECONDS_UPDATE
Register 453 - System Time - Nanoseconds Update Register (1714_H) Reset Value: $0000\ 0000_H$

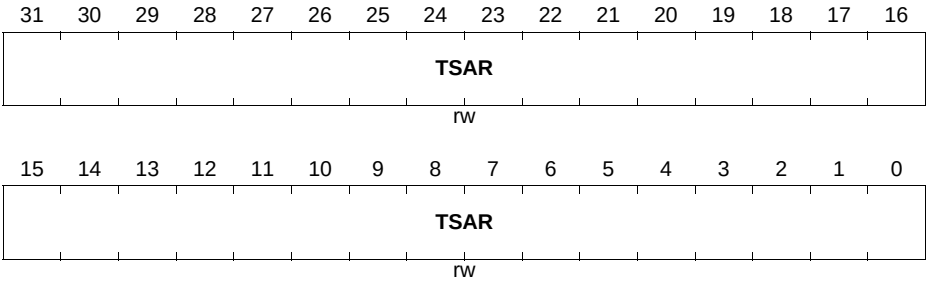


Field	Bits	Type	Description
TSSS	[30:0]	rw	**Timestamp Sub Second** The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When bit 9 (TSCTRLSSR) is set in Register 448 (Timestamp Control Register), each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF.
ADDSUB	31	rw	**Add or subtract time** When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.

32-bit Register - Timestamp_Addend

This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in Register 448). This register content is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

ETH_TIMESTAMP_ADDEND
Register 454 - Timestamp Addend Register (1718_H) **Reset Value: $0000\ 0000_H$**

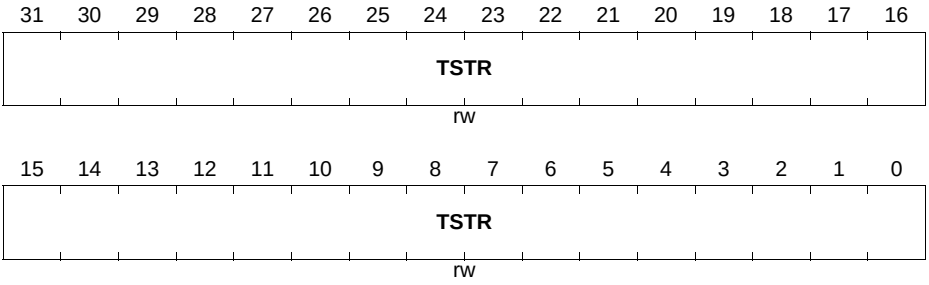


Field	Bits	Type	Description
TSAR	[31:0]	rw	**Timestamp Addend Register** This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

32-bit Register - Target_Time_Seconds

The Target Time Seconds register, along with Target Time Nanoseconds register, is used to schedule an interrupt event (Register 458[1] when Advanced Timestamping is enabled; otherwise, TS interrupt bit in Register14[9]) when the system time exceeds the value programmed in these registers. This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_TARGET_TIME_SECONDS
Register 455 - Target Time Seconds Register ($171C_H$) **Reset Value: $0000\ 0000_H$**

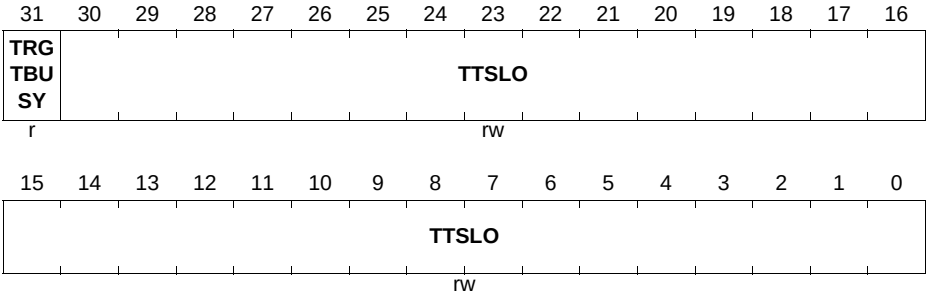


Field	Bits	Type	Description
TSTR	[31:0]	rw	**Target Time Seconds Register** This register stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, then based on Bits [6:5] of Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled).

32-bit Register - Target_Time_Nanoseconds

This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_TARGET_TIME_NANOSECONDS
Register 456 - Target Time Nanoseconds Register (1720_H) Reset Value: $0000\ 0000_H$



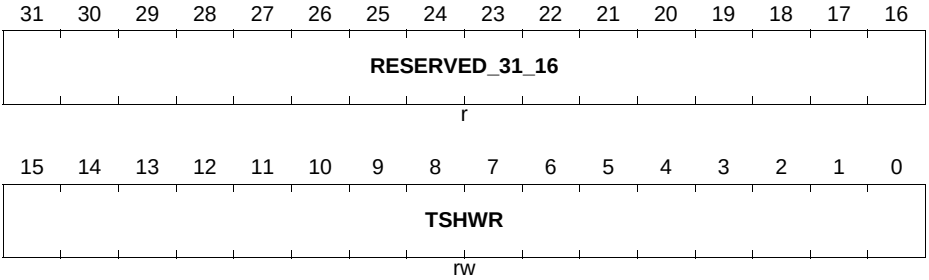
Field	Bits	Type	Description
TTSLO	[30:0]	rw	**Target Timestamp Low Register** This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the TRGTMODSEL0 field (Bits [6:5]) in Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.

Field	Bits	Type	Description
TRGTBUSY	31	r	**Target Time Register Busy** The MAC sets this bit when the PPSCMD field (Bits[3:0]) in Register 459 (PPS Control Register) is programmed to 010 or 011. Programming the PPSCMD field to 010 or 011, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.

32-bit Register - System_Time_Higher_Word_Seconds

This register is present only when the IEEE 1588 Advanced Timestamp feature is selected without an external timestamp input.

ETH_SYSTEM_TIME_HIGHER_WORD_SECONDS
Register 457 - System Time - Higher Word Seconds Register (1724_H) Reset Value: $0000\ 0000_H$

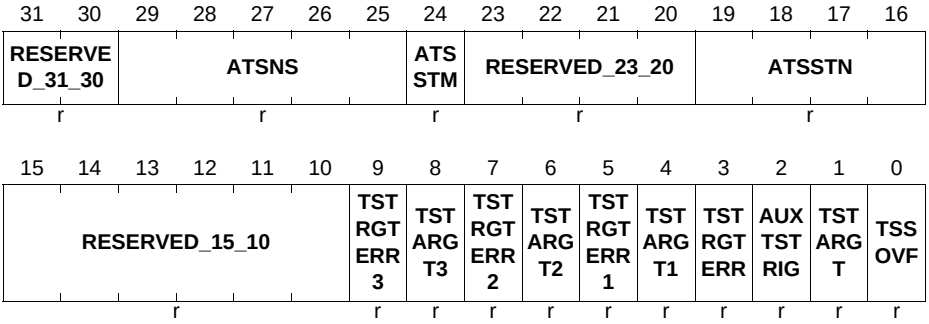


Field	Bits	Type	Description
TSHWR	[15:0]	rw	**Timestamp Higher Word Register** This field contains the most significant 16-bits of the timestamp seconds value. This register is optional and can be selected using the Enable IEEE 1588 Higher Word Register option during core configuration. The register is directly written to initialize the value. This register is incremented when there is an overflow from the 32-bits of the System Time - Seconds register.
RESERVED_31_16	[31:16]	r	**RESERVED_31_16**

32-bit Register - Timestamp_Status

This register is present only when Advanced IEEE 1588 Timestamp feature is selected. All bits except Bits[27:25] gets cleared when the host reads this register.

ETH_TIMESTAMP_STATUS
Register 458 - Timestamp Status Register (1728_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TSSOVF	0	r	**Timestamp Seconds Overflow** When set, this bit indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF.
TSTARGT	1	r	**Timestamp Target Time Reached** When set, this bit indicates that the value of system time is greater or equal to the value specified in the Register 455 (Target Time Seconds Register) and Register 456 (Target Time Nanoseconds Register).
AUXTSTRIG	2	r	**Auxiliary Timestamp Trigger Snapshot** This bit is set high when the auxiliary snapshot is written to the FIFO. This bit is valid only if the Enable IEEE 1588 Auxiliary Snapshot feature is selected.
TSTRGTERR	3	r	**Timestamp Target Time Error** This bit is set when the target time, being programmed in Target Time Registers, is already elapsed. This bit is cleared when read by the application.

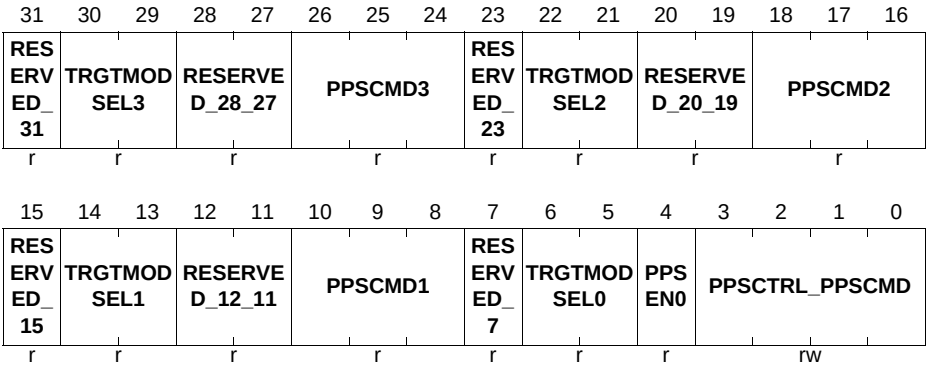
Field	Bits	Type	Description
TSTARGT1	4	r	**Timestamp Target Time Reached for Target Time PPS1** When set, this bit indicates that the value of system time is greater than or equal to the value specified in Register 480 (PPS1 Target Time High Register) and Register 481 (PPS1 Target Time Low Register).
TSTRGTERR1	5	r	**Timestamp Target Time Error** This bit is set when the target time, being programmed in Register 480 and Register 481, is already elapsed. This bit is cleared when read by the application.
TSTARGT2	6	r	**Timestamp Target Time Reached for Target Time PPS2** When set, this bit indicates that the value of system time is greater than or equal to the value specified in Register 488 (PPS2 Target Time High Register) and Register 489 (PPS2 Target Time Low Register).
TSTRGTERR2	7	r	**Timestamp Target Time Error** This bit is set when the target time, being programmed in Register 488 and Register 489, is already elapsed. This bit is cleared when read by the application.
TSTARGT3	8	r	**Timestamp Target Time Reached for Target Time PPS3** When set, this bit indicates that the value of system time is greater than or equal to the value specified in Register 496 (PPS3 Target Time High Register) and Register 497 (PPS3 Target Time Low Register).
TSTRGTERR3	9	r	**Timestamp Target Time Error** This bit is set when the target time, being programmed in Register 496 and Register 497, is already elapsed. This bit is cleared when read by the application.
RESERVED_15_10	[15:10]	r	**RESERVED_15_10**

Field	Bits	Type	Description
ATSSTN	[19:16]	r	**Auxiliary Timestamp Snapshot Trigger Identifier** These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list: * Bit 16: Auxiliary trigger 0 * Bit 17: Auxiliary trigger 1 * Bit 18: Auxiliary trigger 2 * Bit 19: Auxiliary trigger 3 The software can read this register to find the triggers that are set when the timestamp is taken.
RESERVED_23_20	[23:20]	r	**RESERVED_23_20**
ATSSTM	24	r	**Auxiliary Timestamp Snapshot Trigger Missed** This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected during core configuration.
ATSNS	[29:25]	r	**Number of Auxiliary Timestamp Snapshots** This field indicates the number of Snapshots available in the FIFO. A value equal to the selected depth of FIFO (4, 8, or 16) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected during core configuration.
RESERVED_31_30	[31:30]	r	**RESERVED_31_30**

32-bit Register - PPS_Control

This register is present only when the Advanced Timestamp feature is selected and External Timestamp is not enabled. Note: * Bits[30:24] are valid only when four Flexible PPS outputs are selected. * Bits[22:16] are valid only when three or more Flexible PPS outputs are selected. * Bits[14:8] are valid only when two or more Flexible PPS outputs are selected. * Bits[6:4] are valid only when Flexible PPS feature is selected.

ETH_PPS_CONTROL
Register 459 - PPS Control Register (172C$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
PPSCTRL_PPSCMD	[3:0]	rw	**PPSCTRL0 or PPSCMD0** PPSCTRL0: PPS0 Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: -0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. -0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. -0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. -0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. -... -1111: The binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: * When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms * When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of: - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high) * When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of: - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register). Flexible PPS0 Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. Once the command is

Field	Bits	Type	Description
PPSEN0	4	r	**Flexible PPS Output Mode Enable** When set low, Bits[3:0] function as PPSCTRL (backward compatible). When set high, Bits[3:0] function as PPSCMD.
TRGTMODSEL0	[6:5]	r	**Target Time Register Mode for PPS0 Output** This field indicates the Target Time registers (register 455 and 456) mode for PPS0 output signal: * 00: Indicates that the Target Time registers are programmed only for generating the interrupt event. * 01: Reserved * 10: Indicates that the Target Time registers are programmed for generating the interrupt event and starting or stopping the generation of the PPS0 output signal. * 11: Indicates that the Target Time registers are programmed only for starting or stopping the generation of the PPS0 output signal. No interrupt is asserted.
RESERVED_7	7	r	**RESERVED_7**
PPSCMD1	[10:8]	r	**Flexible PPS1 Output Control** This field controls the flexible PPS1 output (ptp_pps_o[1]) signal. This field is similar to PPSCMD0[2:0] in functionality.
RESERVED_12_11	[12:11]	r	**RESERVED_12_11**
TRGTMODSEL1	[14:13]	r	**Target Time Register Mode for PPS1 Output** This field indicates the Target Time registers (register 480 and 481) mode for PPS1 output signal. This field is similar to the TRGTMODSEL0 field.
RESERVED_15	15	r	**RESERVED_15**
PPSCMD2	[18:16]	r	**Flexible PPS2 Output Control** This field controls the flexible PPS2 output (ptp_pps_o[2]) signal. This field is similar to PPSCMD0[2:0] in functionality.

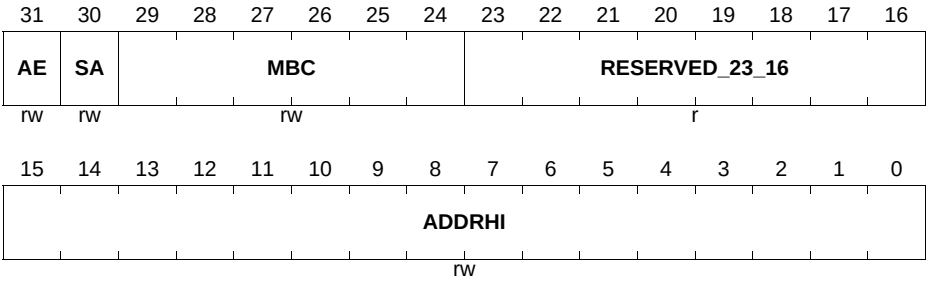
TRGTMODSEL3	[30:29]	r	**Target Time Register Mode for PPS3 Output** This field indicates the Target Time registers (register 496 and 497) mode for PPS3 output signal. This field is similar to the TRGTMODSEL0 field.
RESERVED_31	31	r	**RESERVED_31**

32-bit Register - MAC_Address16_High

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address16 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS16_HIGH

Register 512 - MAC Address16 High Register (1800_H) **Reset Value: $0000\ FFFF_H$**



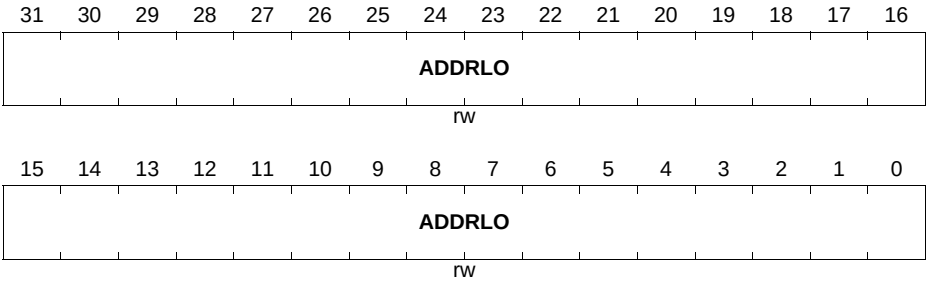
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address16 [47:32]** This field contains the upper 16 bits (47:32) of the 17th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address16 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address16[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address16[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 17th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address16_Low

The MAC Address16 Low register holds the lower 32 bits of the 17th 6-byte MAC address of the station.

ETH_MAC_ADDRESS16_LOW
Register 513 - MAC Address16 Low Register (1804_H) **Reset Value: $FFFF\ FFFF_H$**



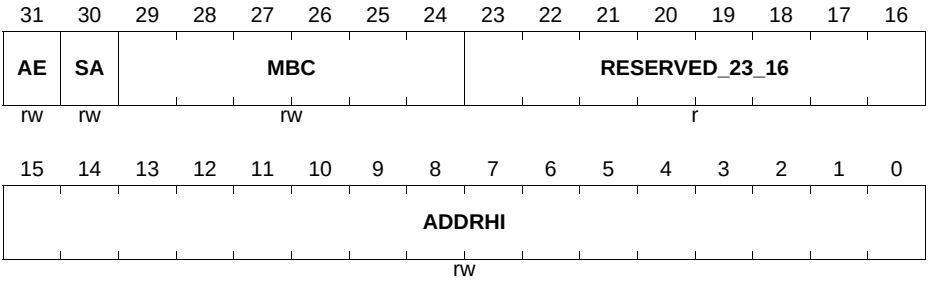
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address16 [31:0]** This field contains the lower 32 bits of the 17th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address17_High

The MAC Address17 High register holds the upper 16 bits of the 18th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address17 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address17 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS17_HIGH

Register 514 - MAC Address17 High Register (1808_H) **Reset Value: $0000\ FFFF_H$**



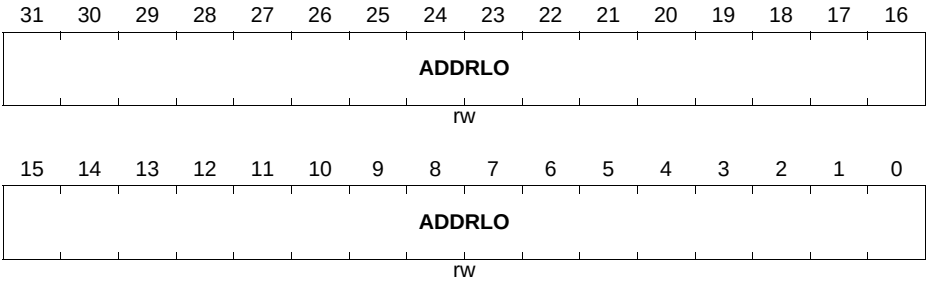
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address18 [47:32]** This field contains the upper 16 bits (47:32) of the 19th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address17 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address17[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address17[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 18th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address17_Low

The MAC Address17 Low register holds the lower 32 bits of the 18th 6-byte MAC address of the station.

ETH_MAC_ADDRESS17_LOW
Register 515 - MAC Address17 Low Register (180C$_H$) Reset Value: FFFF FFFF$_H$



Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address17 [31:0]** This field contains the lower 32 bits of the 18th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address18_High

The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address18 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS18_HIGH

32-bit Register - Bus_Mode

The Bus Mode register establishes the bus operating modes for the DMA.

ETH_BUS_MODE

Register 0 - Bus Mode Register (2000_H) Reset Value: $0002\ 0101_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESERVED_31_30		PRWG		TXPR	MB	AAL	PBLx8	USP	RPBL						FB
r		r		rw	rw	rw	rw	rw	rw						rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PR		PBL						ATDS	DSL					DA	SWR
rw		rw						rw	rw					rw	rw

Field	Bits	Type	Description
SWR	0	rw	**Software Reset** When this bit is set, the MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the DWC_gmac clock domains. Before reprogramming any register of the DWC_gmac, you should read a zero (0) value in this bit . Note: * The Software reset function is driven only by this bit. Bit 0 of Register 64 (Channel 1 Bus Mode Register) or Register 128 (Channel 2 Bus Mode Register) has no impact on the Software reset function. * The reset operation is completed only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for the software reset completion.

Field	Bits	Type	Description
DA	1	rw	**DMA Arbitration Scheme** This bit specifies the arbitration scheme between the transmit and receive paths of Channel 0. * 0: Weighted round-robin with Rx:Tx or Tx:Rx. The priority between the paths is according to the priority specified in bits 15:14 (PR) and priority weights specified in Bit 27 (TXPR). * 1: Fixed priority. The transmit path has priority over receive path when Bit 27 (TXPR) is set. Otherwise, receive path has priority over the transmit path. In the GMAC-AXI configuration, these bits are reserved and read-only (RO).
DSL	[6:2]	rw	**Descriptor Skip Length** This bit specifies the number of Word, Dword, or Lword (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When the DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA in Ring mode.

Field	Bits	Type	Description
ATDS	7	rw	**Alternate Descriptor Size** When set, the size of the alternate descriptor increases to 32 bytes (8 DWORDS). This is required when the Advanced Timestamp feature or the IPC Full Offload Engine (Type 2) is enabled in the receiver. The enhanced descriptor is not required if the Advanced Timestamp and IPC Full Checksum Offload (Type 2) features are not enabled. In such cases, you can use the 16 bytes descriptor to save 4 bytes of memory. This bit is present only when you select the Alternate Descriptor feature and any one of the following features during core configuration: * Advanced Timestamp feature * IPC Full Checksum Offload Engine (Type 2) feature Otherwise, this bit is reserved and read-only. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). This bit preserves the backward compatibility for the descriptor size. In versions prior to 3.50a, the descriptor size is 16 bytes for both normal and enhanced descriptor. In version 3.50a, descriptor size is increased to 32 bytes because of the Advanced Timestamp and IPC Full Checksum Offload Engine (Type 2) features.

Field	Bits	Type	Description
PBL	[13:8]	rw	**Programmable Burst Length** These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions. If the number of beats to be transferred is more than 32, then perform the following steps: 1. Set the PBLx8 mode. 2. Set the PBL. For example, if the maximum number of beats to be transferred is 64, then first set PBLx8 to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified. For different data bus widths and FIFO sizes, the valid PBL range (including x8 mode) is provided in the following list. If the PBL is common for both transmit and receive DMA, the minimum Rx FIFO and Tx FIFO depths must be considered. Note: In the half-duplex mode, the valid PBL range specified in the following list is applicable only for Tx FIFO. * 32-Bit Data Bus Width - 2 KB and Higher FIFO Depth: All PBL values are supported in the full-duplex mode and half-duplex modes.

Field	Bits	Type	Description
PR	[15:14]	rw	**Priority Ratio** These bits control the priority ratio in the weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when Bit 1 (DA) is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether Bit 27 (TXPR) is reset or set. * 00: The Priority Ratio is 1:1. * 01: The Priority Ratio is 2:1. * 10: The Priority Ratio is 3:1. * 11: The Priority Ratio is 4:1. In the GMAC-AXI configuration, these bits are reserved and read-only (RO).
FB	16	rw	**Fixed Burst** This bit controls whether the AHB or AXI Master interface performs fixed burst transfers or not. When set, the AHB interface uses only SINGLE, INCR4, INCR8, or INCR16 during start of the normal burst transfers. When reset, the AHB or AXI interface uses SINGLE and INCR burst transfer operations. For more information, see Bit 0 (UNDEF) of the AXI Bus Mode register in the GMAC-AXI configuration.
RPBL	[22:17]	rw	**Rx DMA PBL** This field indicates the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read or Write. The Rx DMA always attempts to burst as specified in the RPBL bit each time it starts a Burst transfer on the host bus. You can program RPBL with values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. This field is valid and applicable only when USP is set high.
USP	23	rw	**Use Seperate PBL** When set high, this bit configures the Rx DMA to use the value configured in Bits[22:17] as PBL. The PBL value in Bits[13:8] is applicable only to the Tx DMA operations. When reset to low, the PBL value in Bits[13:8] is applicable for both DMA engines.

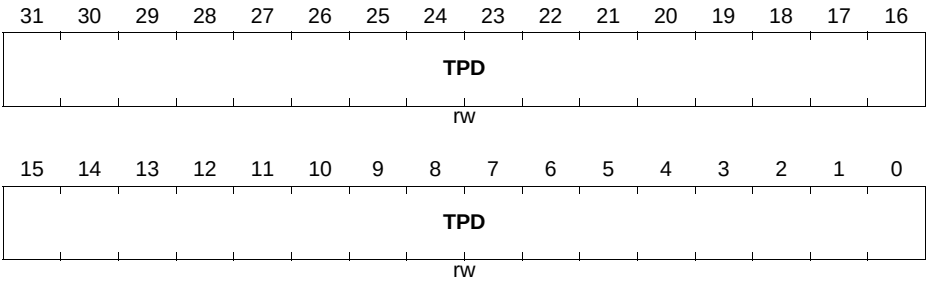
Field	Bits	Type	Description
PBLx8	24	rw	**PBLx8 Mode** When set high, this bit multiplies the programmed PBL value (Bits[22:17] and Bits[13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. Note: This bit function is not backward compatible. Before release 3.50a, this bit was 4xPBL.
AAL	25	rw	**Address Aligned Beats** When this bit is set high and the FB bit is equal to 1, the AHB or AXI interface generates all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address. This bit is valid only in the GMAC-AHB and GMAC-AXI configuration and is reserved (RO with default value 0) in all other configurations.
MB	26	rw	**Mixed Burst** When this bit is set high and the FB bit is low, the AHB Master interface starts all bursts of length more than 16 with INCR (undefined burst) whereas it reverts to fixed burst transfers (INCRx and SINGLE) for burst length of 16 and less. This bit is valid only in the GMAC-AHB configuration and reserved in all other configuration.
TXPR	27	rw	**Transmit Priority** When set, this bit indicates that the transmit DMA has higher priority than the receive DMA during arbitration for the system-side bus. In the GMAC-AXI configuration, this bit is reserved and read-only (RO).

Field	Bits	Type	Description
PRWG	[29:28]	r	**Channel Priority Weights** This field sets the priority weights for Channel 0 during the round-robin arbitration between the DMA channels for the system bus. * 00: The priority weight is 1. * 01: The priority weight is 2. * 10: The priority weight is 3. * 11: The priority weight is 4. This field is present in all DWC_gmac configurations except GMAC-AXI when you select the AV feature. Otherwise, this field is reserved and read-only (RO).
RESERVED_31_30	[31:30]	r	**RESERVED_31_30**

32-bit Register - Transmit_Poll_Demand

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

ETH_TRANSMIT_POLL_DEMAND
Register 1 - Transmit Poll Demand Register (2004_H) **Reset Value: $0000\ 0000_H$**



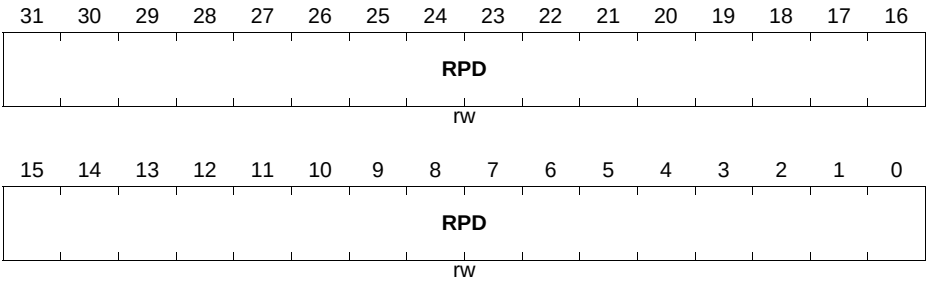
Field	Bits	Type	Description
TPD	[31:0]	rw	**Transmit Poll Demand** When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 18 (Current Host Transmit Descriptor Register). If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.

32-bit Register - Receive_Poll_Demand

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

ETH_RECEIVE_POLL_DEMAND

Register 2 - Receive Poll Demand Register (2008_H) **Reset Value: $0000\ 0000_H$**

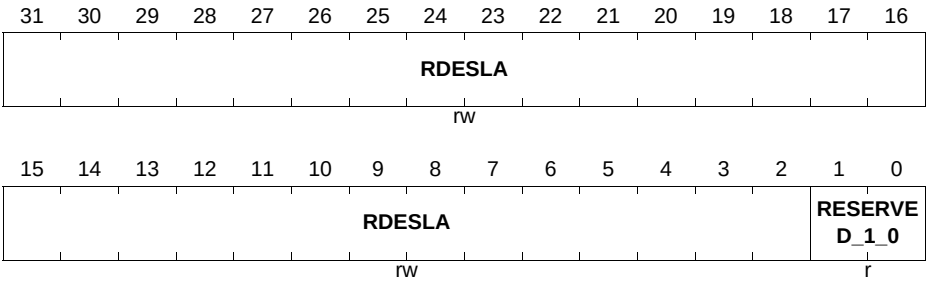


Field	Bits	Type	Description
RPD	[31:0]	rw	**Receive Poll Demand** When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.

32-bit Register - Receive_Descriptor_List_Address

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

ETH_RECEIVE_DESCRIPTOR_LIST_ADDRESS
Register 3 - Receive Descriptor List Address Register ($200C_H$) Reset Value: $0000\ 0000_H$

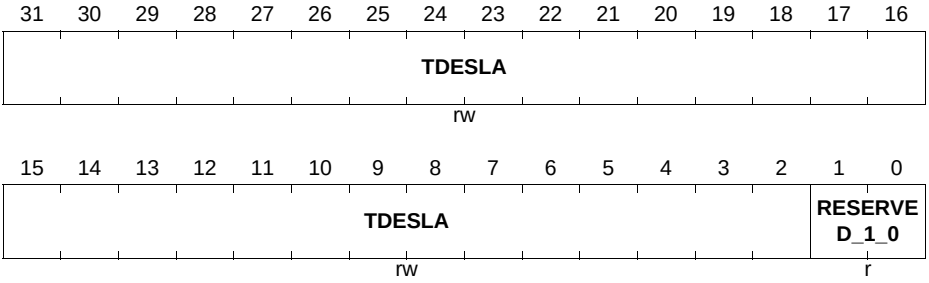


Field	Bits	Type	Description
RESERVED_1_0	[1:0]	r	**RESERVED_1_0**
RDESLA	[31:2]	rw	**Start of Receive List** This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) for 32-bit bus width are ignored and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).

32-bit Register - Transmit_Descriptor_List_Address

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

ETH_TRANSMIT_DESCRIPTOR_LIST_ADDRESS
Register 4 - Transmit Descriptor List Address Register (2010_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RESERVED_1_0	[1:0]	r	**RESERVED_1_0**
TDESLA	[31:2]	rw	**Start of Transmit List** This field contains the base address of the first descriptor in the Transmit Descriptor list. The LSB bits (1:0) for 32-bit bus width are ignored and are internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).

32-bit Register - Status

The Status register contains all status bits that the DMA reports to the host. The Software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

ETH_STATUS
Register 5 - Status Register **(2014_H)** **Reset Value: 0000 0000$_H$**

rw	rw	rw	r		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
TI	0	rw	**Transmit Interrupt** This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.
TPS	1	rw	**Transmit Process Stopped** This bit is set when the transmission is stopped.
TU	2	rw	**Transmit Buffer Unavailable** This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.

Field	Bits	Type	Description
TJT	3	rw	**Transmit Jabber Timeout** This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled). When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.
OVF	4	rw	**Receive Overflow** This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].
UNF	5	rw	**Transmit Underflow** This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.
RI	6	rw	**Receive Interrupt** This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.
RU	7	rw	**Receive Buffer Unavailable** This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.
RPS	8	rw	**Receive Process Stopped** This bit is asserted when the Receive Process enters the Stopped state.

Field	Bits	Type	Description
RWT	9	rw	**Receive Watchdog Timeout** This bit is asserted when a frame with length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).
ETI	10	rw	**Early Transmit Interrupt** This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.
RESERVED_12_11	[12:11]	r	**RESERVED_12_11**
FBI	13	rw	**Fatal Bus Error Interrupt** This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.
ERI	14	rw	**Early Receive Interrupt** This bit indicates that the DMA had filled the first data buffer of the packet. Bit 6 (RI) of this register automatically clears this bit.
AIS	15	rw	**Abnormal Interrupt Summary** Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[1]: Transmit Process Stopped * Register 5[3]: Transmit Jabber Timeout * Register 5[4]: Receive FIFO Overflow * Register 5[5]: Transmit Underflow * Register 5[7]: Receive Buffer Unavailable * Register 5[8]: Receive Process Stopped * Register 5[9]: Receive Watchdog Timeout * Register 5[10]: Early Transmit Interrupt * Register 5[13]: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared.

Field	Bits	Type	Description
NIS	16	rw	**Normal Interrupt Summary** Normal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[0]: Transmit Interrupt * Register 5[2]: Transmit Buffer Unavailable * Register 5[6]: Receive Interrupt * Register 5[14]: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in Register 7) affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing 1 to this bit) each time a corresponding bit, which causes NIS to be set, is cleared.
RS	[19:17]	r	**Received Process State** This field indicates the Receive DMA FSM state. This field does not generate an interrupt. * 3'b000: Stopped: Reset or Stop Receive Command issued * 3'b001: Running: Fetching Receive Transfer Descriptor * 3'b010: Reserved for future use * 3'b011: Running: Waiting for receive packet * 3'b100: Suspended: Receive Descriptor Unavailable * 3'b101: Running: Closing Receive Descriptor * 3'b110: TIME_STAMP write state * 3'b111: Running: Transferring the receive packet data from receive buffer to host memory

Field	Bits	Type	Description
TS	[22:20]	r	**Transmit Process State** This field indicates the Transmit DMA FSM state. This field does not generate an interrupt. * 3'b000: Stopped; Reset or Stop Transmit Command issued * 3'b001: Running; Fetching Transmit Transfer Descriptor * 3'b010: Running; Waiting for status * 3'b011: Running; Reading Data from host memory buffer and queuing it to transmit buffer (Tx FIFO) * 3'b100: TIME_STAMP write state * 3'b101: Reserved for future use * 3'b110: Suspended; Transmit Descriptor Unavailable or Transmit Buffer Underflow * 3'b111: Running; Closing Transmit Descriptor
EB	[25:23]	r	**Error Bits** This field indicates the type of error that caused a Bus Error, for example, error response on the AHB or AXI interface. This field is valid only when Bit 13 (FBI) is set. This field does not generate an interrupt. * Bit 23 - 1'b1: Error during data transfer by the Tx DMA - 1'b0: Error during data transfer by the Rx DMA * Bit 24 - 1'b1: Error during read transfer - 1'b0: Error during write transfer * Bit 25 - 1'b1: Error during descriptor access - 1'b0: Error during data buffer access
GLI	26	r	**GMAC Line interface Interrupt** This bit reflects an interrupt event in the PCS (link change and AN complete), SMII (link change), or RGMII (link change) interface block of the DWC_gmac. The software must read the corresponding registers (Register 49 for PCS or Register 54 for SMII or RGMII) in the DWC_gmac to get the exact cause of the interrupt and clear the source of interrupt to make this bit as 1'b0. The interrupt signal from the DWC_gmac subsystem (sbd_intr_o) is high when this bit is high.

Field	Bits	Type	Description
GMI	27	r	**GMAC MMC Interrupt** This bit reflects an interrupt event in the MMC module of the DWC_gmac. The software must read the corresponding registers in the DWC_gmac to get the exact cause of interrupt and clear the source of interrupt to make this bit as 1'b0. The interrupt signal from the DWC_gmac subsystem (sbd_intr_o) is high when this bit is high. This bit is applicable only when the MAC Management Counters (MMC) are enabled. Otherwise, this bit is reserved.
GPI	28	r	**GMAC PMT Interrupt** This bit indicates an interrupt event in the PMT module of the DWC_gmac. The software must read the PMT Control and Status Register in the MAC to get the exact cause of interrupt and clear its source to reset this bit to 1'b0. The interrupt signal from the DWC_gmac subsystem (sbd_intr_o) is high when this bit is high. This bit is applicable only when the Power Management feature is enabled. Otherwise, this bit is reserved. Note: This interrupt is different from the pmt_intr_o interrupt.
TTI	29	r	**Timestamp Trigger Interrupt** This bit indicates an interrupt event in the Timestamp Generator block of DWC_gmac. The software must read the corresponding registers in the DWC_gmac to get the exact cause of interrupt and clear its source to reset this bit to 1'b0. When this bit is high, the interrupt signal from the DWC_gmac subsystem (sbd_intr_o) is high. This bit is applicable only when the IEEE 1588 Timestamp feature is enabled. Otherwise, this bit is reserved.

Field	Bits	Type	Description
GLPII	30	r	**GMAC LPI Interrupt (for Channel 0)** This bit indicates an interrupt event in the LPI logic of the DWC_gmac. To reset this bit to 1'b0, the software must read the corresponding registers in the DWC_gmac to get the exact cause of the interrupt and clear its source. Note: GLPII status is given only in Channel 0 DMA register and is applicable only when the Energy Efficient Ethernet feature is enabled. Otherwise, this bit is reserved.When this bit is high, the interrupt signal from the MAC (sbd_intr_o) is high.
RESERVED_31	31	r	**RESERVED_31**

32-bit Register - Operation_Mode

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization. This register is also present in the GMAC-MTL configuration with unused and reserved bits 24, 13, 2, and 1.

ETH_OPERATION_MODE

Register 6 - Operation Mode Register (2018_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TTC		ST	RFD		RFA		EFC	FEF	FUF	RESERVED_5	RTC		OSF	SR	RESERVED_0
rw		rw	rw		rw		rw	rw	rw	r	rw		rw	rw	r

Field	Bits	Type	Description
RESERVED_0	0	r	**RESERVED_0**

Field	Bits	Type	Description
SR	1	rw	**Start or Stop Receive** When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by Register 3 (Receive Descriptor List Address Register) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting Register 3 (Receive Descriptor List Address Register), the DMA behavior is unpredictable. When this bit is cleared, the Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.
OSF	2	rw	**Operate on Second Frame** When this bit is set, it instructs the DMA to process the second frame of the Transmit data even before the status for the first frame is obtained.
RTC	[4:3]	rw	**Receive Threshold Control** These two bits control the threshold level of the MTL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MTL Receive FIFO is larger than the threshold. In addition, full frames with length less than the threshold are transferred automatically. The value of 11 is not applicable if the configured Receive FIFO size is 128 bytes. These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1. * 00: 64 * 01: 32 * 10 : 96 * 11: 128

Field	Bits	Type	Description
RESERVED_5	5	r	**RESERVED_5**
FUF	6	rw	**Forward Undersized Good Frames** When set, the Rx FIFO forwards Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC. When reset, the Rx FIFO drops all frames of less than 64 bytes, unless a frame is already transferred because of the lower value of Receive Threshold, for example, RTC = 01.
FEF	7	rw	**Forward Error Frames** When this bit is reset, the Rx FIFO drops frames with error status (CRC error, collision error, GMII_ER, giant frame, watchdog timeout, or overflow). However, if the start byte (write) pointer of a frame is already transferred to the read controller side (in Threshold mode), then the frame is not dropped. In the GMAC-MTL configuration in which the Frame Length FIFO is also enabled during core configuration, the Rx FIFO drops the error frames if that frame's start byte is not transferred (output) on the ARI bus. When the FEF bit is set, all frames except runt error frames are forwarded to the DMA. If the Bit 25 (RSF) is set and the Rx FIFO overflows when a partial frame is written, then the frame is dropped irrespective of the FEF bit setting. However, if the Bit 25 (RSF) is reset and the Rx FIFO overflows when a partial frame is written, then a partial frame may be forwarded to the DMA.
EFC	8	rw	**Enable HW Flow Control** When this bit is set, the flow control signal operation based on the fill-level of Rx FIFO is enabled. When reset, the flow control operation is disabled. This bit is not used (reserved and always reset) when the Rx FIFO is less than 4 KB.

Field	Bits	Type	Description
RFA	[10:9]	rw	**Threshold for Activating Flow Control (in half-duplex and full-duplex)** These bits control the threshold (Fill level of Rx FIFO) at which the flow control is activated. - 00: Full minus 1 KB, that is, FULL - 1KB - 01: Full minus 2 KB, that is, FULL - 2KB - 10: Full minus 3 KB, that is, FULL - 3KB - 11: Full minus 4 KB, that is, FULL - 4KB These values only apply to Rx FIFOs of 4 KB or more when the EFC bit is set high. If the Rx FIFO is 8 KB or more, an additional bit (RFA_2) is used for more threshold levels as described in Bit 23. These bits are reserved and read-only when the depth of Rx FIFO is less than 4 KB.
RFD	[12:11]	rw	**Threshold for Deactivating Flow Control (in half-duplex and full-duplex)** These bits control the threshold (Fill-level of Rx FIFO) at which the flow control is de-asserted after activation. - 00: Full minus 1 KB, that is, FULL - 1KB - 01: Full minus 2 KB, that is, FULL - 2KB - 10: Full minus 3 KB, that is, FULL - 3KB - 11: Full minus 4 KB, that is, FULL - 4KB The de-assertion is effective only after flow control is asserted. If the Rx FIFO is 8 KB or more, an additional bit (RFD_2) is used for more threshold levels as described in Bit 22. These bits are reserved and read-only when the Rx FIFO depth is less than 4 KB.

Field	Bits	Type	Description
ST	13	rw	**Start or Stop Transmission Command** When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 (Transmit Descriptor List Address Register), or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 (Transmit Descriptor List Address Register), then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 (Transmit Descriptor List Address Register) with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.

Field	Bits	Type	Description
TTC	[16:14]	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Transmit FIFO. Transmission starts when the frame size within the MTL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when Bit 21 (TSF) is reset. * 000: 64 * 001: 128 * 010: 192 * 011: 256 * 100: 40 * 101: 32 * 110: 24 * 111: 16
RESERVED_19_17	[19:17]	r	**RESERVED_19_17**
FTF	20	rw	**Flush Transmit FIFO** When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO is lost or flushed. This bit is cleared internally when the flushing operation is completed. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation is complete only when the Tx FIFO is emptied of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. To complete this flush operation, the PHY transmit clock (clk_tx_i) is required to be active.
TSF	21	rw	**Transmit Store and Forward** When this bit is set, transmission starts when a full frame resides in the MTL Transmit FIFO. When this bit is set, the TTC values specified in Bits[16:14] are ignored. This bit should be changed only when the transmission is stopped.

Field	Bits	Type	Description
RFD_2	22	r	**MSB of Threshold for Deactivating Flow Control** If the DWC_gmac is configured for Rx FIFO size of 8 KB or more, this bit (when set) provides additional threshold levels for deactivating the flow control in both half-duplex and full-duplex modes. This bit (as Most Significant Bit) along with the RFD (Bits[12:11]) gives the following thresholds for deactivating flow control: * 100: Full minus 5 KB, that is, FULL - 5KB * 101: Full minus 6 KB, that is, FULL - 6KB * 110: Full minus 7 KB, that is, FULL - 7KB * 111: Reserved This bit is reserved (and RO) if the Rx FIFO is 4 KB or less deep.
RFA_2	23	r	**MSB of Threshold for Activating Flow Control** If the DWC_gmac is configured for an Rx FIFO depth of 8 KB or more, this bit (when set) provides additional threshold levels for activating the flow control in both half-duplex and full-duplex modes. This bit (as Most Significant Bit) along with the RFA (Bits[10:9]) gives the following thresholds for activating flow control: * 100: Full minus 5 KB, that is, FULL - 5KB * 101: Full minus 6 KB, that is, FULL - 6KB * 110: Full minus 7 KB, that is, FULL - 7KB * 111: Reserved This bit is reserved (and RO) if the Rx FIFO is 4 KB or less deep.
DFF	24	rw	**Disable Flushing of Received Frames** When this bit is set, the Rx DMA does not flush any frames because of the unavailability of receive descriptors or buffers as it does normally when this bit is reset. This bit is reserved (and RO) in the GMAC-MTL configuration.

Field	Bits	Type	Description
RSF	25	rw	**Receive Store and Forward** When this bit is set, the MTL reads a frame from the Rx FIFO only after the complete frame has been written to it, ignoring the RTC bits. When this bit is reset, the Rx FIFO operates in the cut-through mode, subject to the threshold specified by the RTC bits.
DT	26	rw	**Disable Dropping of TCP/IP Checksum Error Frames** When this bit is set, the MAC does not drop the frames which only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors only in the encapsulated payload. When this bit is reset, all error frames are dropped if the FEF bit is reset. If the IPC Full Checksum Offload Engine (Type 2) is disabled, this bit is reserved (RO with value 1'b0).
RESERVED_31_27	[31:27]	r	**RESERVED_31_27**

32-bit Register - Interrupt_Enable

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

ETH_INTERRUPT_ENABLE
Register 7 - Interrupt Enable Register (201C$_H$) **Reset Value: 0000 0000$_H$**

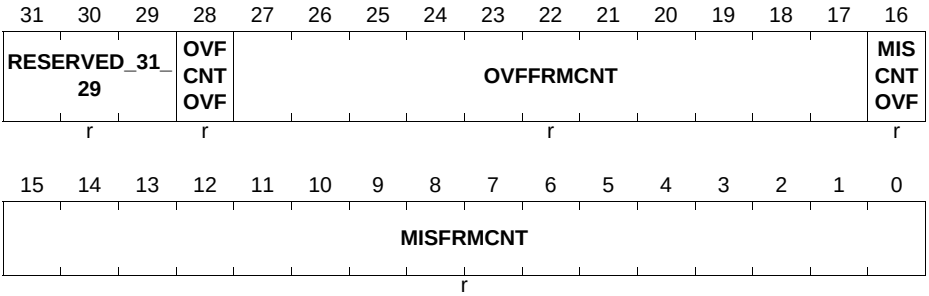
RESERVED_31_17	[31:17]	r	**RESERVED_31_17**

32-bit Register - Missed_Frame_And_Buffer_Overflow_Counter

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

ETH_MISSED_FRAME_AND_BUFFER_OVERFLOW_COUNTER
Register 8 - Missed Frame and Buffer Overflow Counter Register (2020_H) Reset Value: 0000 0000_H



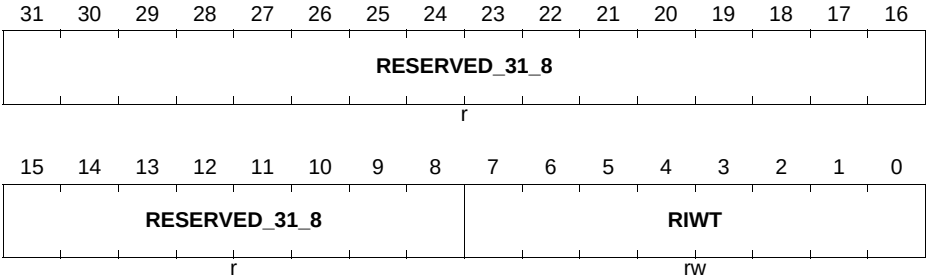
Field	Bits	Type	Description
MISFRMCNT	[15:0]	r	**MISFRMCNT** This field indicates the number of frames missed by the controller because of the Host Receive Buffer being unavailable. This counter is incremented each time the DMA discards an incoming frame. The counter is cleared when this register is read with mci_be_i[0] at 1'b1.
MISCNTOVF	16	r	**MISCNTOVF** Overflow bit for Missed Frame Counter
OVFFRMCNT	[27:17]	r	**OVFFRMCNT** This field indicates the number of frames missed by the application. This counter is incremented each time the MTL asserts the sideband signal mtl_rxoverflow_o. The counter is cleared when this register is read with mci_be_i[2] at 1'b1.

Field	Bits	Type	Description
OVFCNTOVF	28	r	**OVFCNTOVF** Overflow bit for FIFO Overflow Counter
RESERVED_31_29	[31:29]	r	**RESERVED_31_29**

32-bit Register - Receive_Interrupt_Watchdog_Timer

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

ETH_RECEIVE_INTERRUPT_WATCHDOG_TIMER
Register 9 - Receive Interrupt Watchdog Timer Register (2024_H)Reset Value: 0000 0000_H

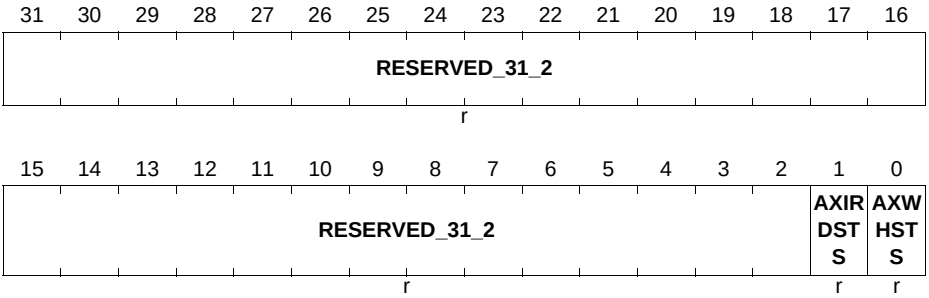


Field	Bits	Type	Description
RIWT	[7:0]	rw	**RI Watchdog Timer Count** This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.
RESERVED_31_8	[31:8]	r	**RESERVED_31_8**

32-bit Register - AHB_or_AXI_Status

This register provides the active status of the AHB master interface or AXI interface's read and write channels. This register is present and valid only in the GMAC-AHB and GMAC-AXI configurations. This register is useful for debugging purposes. In addition, this register is valid only in the Channel 0 DMA when multiple channels are present in the AV mode.

ETH_AHB_OR_AXI_STATUS
Register 11 - AHB or AXI Status Register ($202C_H$) **Reset Value: $0000\ 0000_H$**

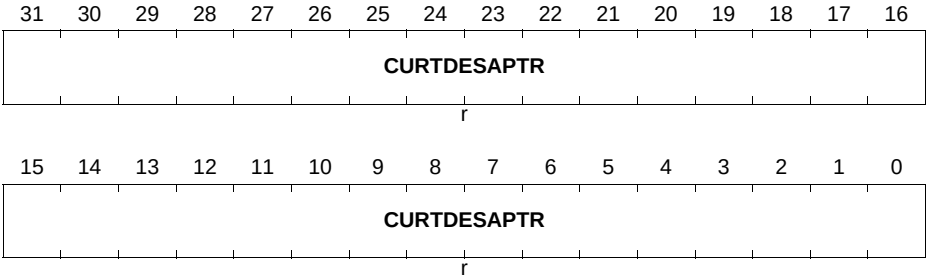


Field	Bits	Type	Description
AXWHSTS	0	r	**AXI Master Write Channel or AHB Master Status** When high, it indicates that AXI Master's write channel is active and transferring data in the GMAC-AXI configuration. In the GMAC-AHB configuration, it indicates that the AHB master interface FSMs are in the non-idle state.
AXIRDSTS	1	r	**AXI Master Read Channel Status** When high, it indicates that AXI Master's read channel is active and transferring data.
RESERVED_31_2	[31:2]	r	**RESERVED_31_2**

32-bit Register - Current_Host_Transmit_Descriptor

The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

ETH_CURRENT_HOST_TRANSMIT_DESCRIPTOR
Register 18 - Current Host Transmit Descriptor Register (2048_H)Reset Value: 0000 0000_H

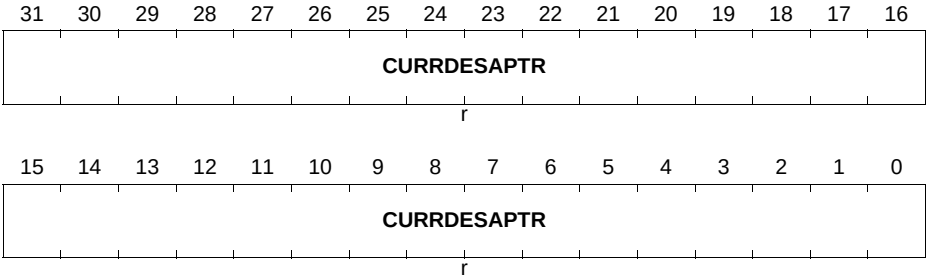


Field	Bits	Type	Description
CURTDESAPTR	[31:0]	r	**Host Transmit Descriptor Address Pointer** Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - Current_Host_Receive_Descriptor

The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.

ETH_CURRENT_HOST_RECEIVE_DESCRIPTOR
Register 19 - Current Host Receive Descriptor Register ($204C_H$) Reset Value: $0000\ 0000_H$

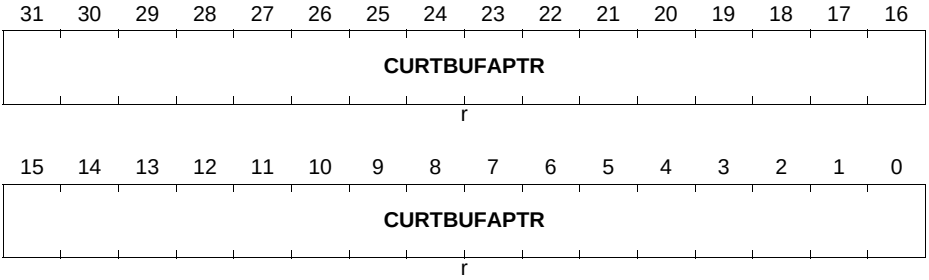


Field	Bits	Type	Description
CURRDESAPTR	[31:0]	r	**Host Receive Descriptor Address Pointer** Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - Current_Host_Transmit_Buffer_Address

The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.

ETH_CURRENT_HOST_TRANSMIT_BUFFER_ADDRESS
Register 20 - Current Host Transmit Buffer Address Register (2050_H) Reset Value: $0000\ 0000_H$

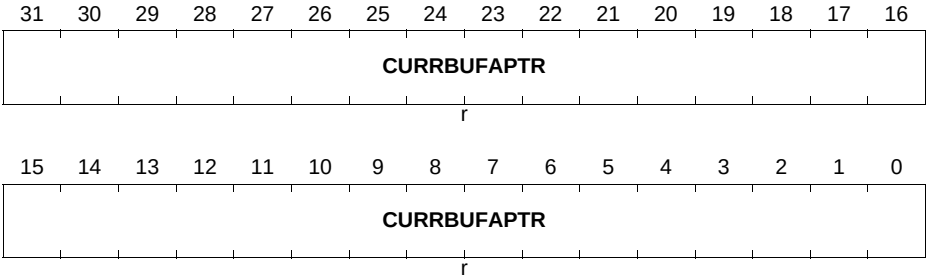


Field	Bits	Type	Description
CURTBUFAPTR	[31:0]	r	**Host Transmit Buffer Address Pointer** Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - Current_Host_Receive_Buffer_Address

The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

ETH_CURRENT_HOST_RECEIVE_BUFFER_ADDRESS
Register 21 - Current Host Receive Buffer Address Register (2054_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
CURRBUFAPTR	[31:0]	r	**Host Receive Buffer Address Pointer** Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - HW_Feature

This register indicates the presence of the optional features or functions of the DWC_gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks. Note: All bits are set or reset as per the selection of features during the DWC_gmac configuration.

ETH_HW_FEATURE

Register 22 - HW Feature Register (2058$_H$) **Reset Value:030D 2F35$_H$**

30.4 Descriptors

This chapter comprises the following subsections:

- **Normal Descriptor Formats**
- **Alternate or Enhanced Descriptors**

Note: The Ethernet MAC *in* TC21x/TC22x/TC23x *does not support Normal Descriptor Format as it is configured to support IEEE1588 PTP time stamping! Nevertheless parts of the explanations in the chapter* **Chapter 1.7.1** *are required for complete understanding.*

30.4.1 Normal Descriptor Formats

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors, as explained in **DMA Controller**. The default descriptor formats (common for both Receive and Transmit Descriptors) are shown in **Figure 30-24**, and field descriptions are provided in **Chapter 1.7.1.1** to **Chapter 1.7.1.2**.

Note:

14. *All descriptions in* ***Chapter 1.7.1.1*** *and* ***Chapter 1.7.1.2*** *correspond to the default descriptor format. The alternate enhanced descriptor format is discussed in* ***Chapter 1.7.2*** *"Alternate or Enhanced Descriptors" on* ***Page 1-680****.*
15. *Changes to the default descriptor format when IEEE1588 time stamping is enabled are described in* ***Chapter 1.7.1.3 "Descriptor Format With IEEE 1588 Time Stamping Enabled" on Page 1-676****".*

Each descriptor contains two buffers, two byte-count buffers, and two address pointers, which enable the adapter port to be compatible with various types of memory management schemes.

The descriptor addresses must be aligned to the bus width used (Word/Dword/Lword for 32-bit buses).

Figure 30-24 shows the descriptor format in a 32-bit data bus.

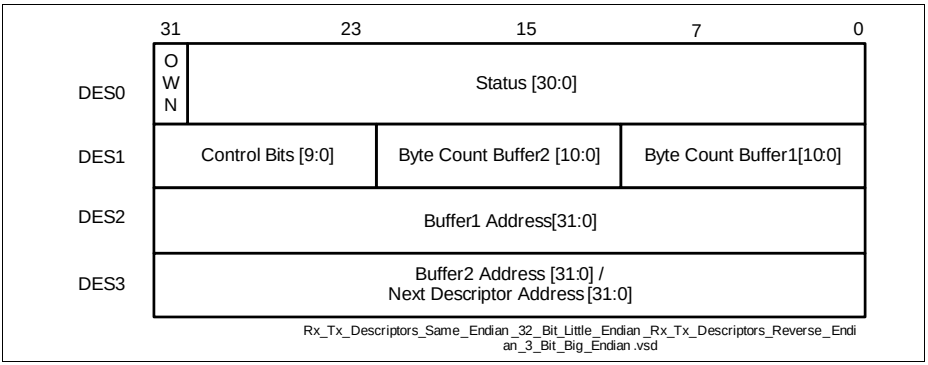

Figure 30-24 Rx/Tx Descriptors for 32-Bit Data Bus

30.4.1.1 Receive Descriptor

The GMAC Subsystem requires at least two descriptors when receiving a frame. The Receive state machine of the DMA (in the GMAC Subsystem) always attempts to acquire an extra descriptor in anticipation of an incoming frame. (The size of the incoming frame is unknown). Before the RxDMA closes a descriptor, it will attempt to acquire the next descriptor even if no frames are received.

In a single descriptor (receive) system, the subsystem will generate a descriptor error if the receive buffer is unable to accommodate the incoming frame and the next descriptor is not owned by the DMA. Thus, the Host is forced to increase either its descriptor pool or the buffer size. Otherwise, the subsystem starts dropping all incoming frames.

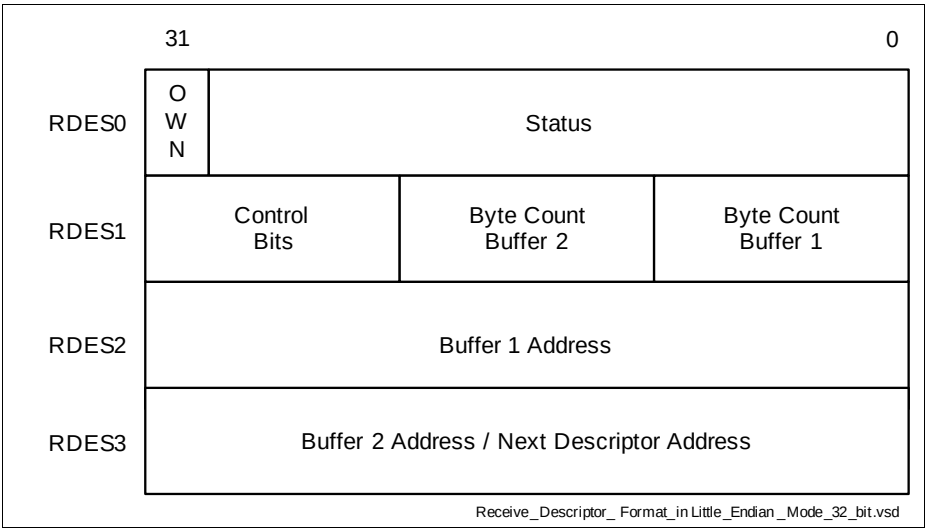

Figure 30-25 Receive Descriptor Format in Little-Endian Mode With a 32-bit Data Bus

Receive Descriptor 0 (RDES0)

RDES0 contains the received frame status, the frame length, and the descriptor ownership information. The descriptions in the following tables (**Table 1-83** through **Table 1-91**) are for the default mode of a Little-Endian 32-bit data bus with Same Endian descriptors, or Big-Endian data bus with Reverse-Endian descriptors. If the DUT is configured for Big-Endian mode, 32-bit data bus with Same Endian descriptors or Little-Endian data bus with Reverse Endian descriptors, then byte lanes 3 and 0 are swapped while byte lanes 1 and 2 are swapped, that is, bits [31:24] will be available on data bus [7:0], and vice-versa.

Table 30-23 Receive Descriptor 0

Bit	Description
31	**OWN: Own Bit** When set, this bit indicates that the descriptor is owned by the DMA of the GMAC Subsystem. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	**AFM: Destination Address Filter Fail** When set, this bit indicates a frame that failed in the DA Filter in the GMAC Core.

Table 30-23 Receive Descriptor 0 (cont'd)

Bit	Description
29:16	**FL: Frame Length** These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are are reset. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame. This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame.
15	**ES: Error Summary** Indicates the logical OR of the following bits: • RDES0[0]: Payload Checksum Error • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: IPC Checksum (Type 2) / Giant Frame • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error This field is valid only when the Last Descriptor (RDES0[8]) is set.
14	**DE: Descriptor Error** When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.
13	**SAF: Source Address Filter Fail** When set, this bit indicates that the SA field of frame failed the SA Filter in the GMAC Core.
12	**LE: Length Error** When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset. Length error status is not valid when CRC error is present.
11	**OE: Overflow Error** When set, this bit indicates that the received frame was damaged due to buffer overflow in MTL.

Table 30-23 Receive Descriptor 0 (cont'd)

Bit	Description
10	**VLAN: VLAN Tag** When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the GMAC Core.
9	**FS: First Descriptor** When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.
8	**LS: Last Descriptor** When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame
7	**IPC Checksum Error/Giant Frame** When IP Checksum Engine (Type 1) is enabled, this bit, when set, indicates that the 16-bit IPv4 Header checksum calculated by the core did not match the received checksum bytes. The Error Summary bit[15] is NOT set when this bit is set in this mode. If this bit is set when Full Checksum Offload Engine (Type 2) is enabled, it indicates an error in the IPv4 or IPv6 header. This error can be due to inconsistent Ethernet Type field and IP header Version field values, a header checksum mismatch in IPv4, or an Ethernet frame lacking the expected number of IP header bytes. Refer to **Table 1-84** for more details. If you do not select IP Checksum Module during core configuration, this bit, when set, indicates that the received frame was a Giant Frame. Giant frames are larger-than-1.518-byte (or 1.522-byte for VLAN) normal frames and larger-than-9,018-byte (9.022-byte for VLAN) frame when Jumbo Frame processing is enabled.
6	**LC: Late Collision** When set, this bit indicates that a late collision has occurred while receiving the frame in Half-Duplex mode.
5	**FT: Frame Type** When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes. Refer to **Table 1-84** for more details.
4	**RWT: Receive Watchdog Timeout** When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.

Table 30-23 Receive Descriptor 0 (cont'd)

Bit	Description
3	**RE: Receive Error** When set, this bit indicates that the gmii_rxer_i signal is asserted while gmii_rxdv_i is asserted during frame reception. This error also includes carrier extension error in GMII and Half-duplex mode. Error can be of less/no extension, or error (rxd ≠ 0f) during extension.
2	**DE: Dribble Bit Error** When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.
1	**CE: CRC Error** When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set.
0	**Rx MAC Address/Payload Checksum Error** When set, this bit indicates that the Rx MAC Address registers value (1 to 15) matched the frame's DA field. When reset, this bit indicates that the Rx MAC Address Register 0 value matched the DA field. If Full Checksum Offload Engine is enabled, this bit, when set, indicates the TCP, UDP, or ICMP checksum the core calculated does not match the received encapsulated TCP, UDP, or ICMP segment's Checksum field. This bit is also set when the received number of payload bytes does not match the value indicated in the Length field of the encapsulated IPv4 or IPv6 datagram in the received Ethernet frame. Refer to **Table 1-84** for more details.

When the Full Checksum Offload Engine (Type 2) is enabled, the permutations of bits 5, 7, and 0 reflect the conditions discussed in **Table 1-84**.

Table 30-24 Receive Descriptor 0 When COE (Type 2) Is Enabled

Bit 5: Frame Type	Bit 7: IPC Checksum Error	Bit 0: Payload Checksum Error	Frame Status
0	0	0	IEEE 802.3 Type frame (Length field value is less than 0600_H)
1	0	0	IPv4/IPv6 Type frame, no checksum error detected
1	0	1	IPv4/IPv6 Type frame with a payload checksum error (as described for PCE) detected

Table 30-24 Receive Descriptor 0 When COE (Type 2) Is Enabled (cont'd)

Bit 5: Frame Type	Bit 7: IPC Checksum Error	Bit 0: Payload Checksum Error	Frame Status
1	1	0	IPv4/IPv6 Type frame with an IP header checksum error (as described for IPC CE) detected
1	1	1	IPv4/IPv6 Type frame with both IP header and payload checksum errors detected
0	0	1	IPv4/IPv6 Type frame with no IP header checksum error and the payload check bypassed, due to an unsupported payload
0	1	1	A Type frame that is neither IPv4 or IPv6 (the Checksum Offload engine bypasses checksum completely.)
0	1	0	Reserved

Note: The first five conditions are backward-compatible to versions 3.30a and previous. The last two conditions (001, 011), which had been reserved, are not backward-compatible, because the Frame Type (FT) bit is reset during bypasses, even for valid Type frames.

Receive Descriptor 1 (RDES1)

RDES1 contains the buffer sizes and other bits that control the descriptor chain/ring.

*Note: See **Buffer Size Calculations** for further detail on calculating buffer sizes.*

Table 30-25 Receive Descriptor 1

Bit	Description
31	**Disable Interrupt on Completion** When set, this bit will prevent the setting of the RI (CSR5[6]) bit of the Status Register for the received frame that ends in the buffer pointed to by this descriptor. This, in turn, will disable the assertion of the interrupt to Host due to RI for that frame.
30:26	**Reserved**
25	**RER: Receive End of Ring** When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a Descriptor Ring.

Table 30-25 Receive Descriptor 1 (cont'd)

Bit	Description
24	**RCH: Second Address Chained** When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When RDES1[24] is set, RBS2 (RDES1[21-11]) is a "don't care" value. RDES1[25] takes precedence over RDES1[24].
23:22	**Reserved**
21:11	**RBS2: Receive Buffer 2 Size** These bits indicate the second data buffer size in bytes. The buffer size must be a multiple of 4/8/16 depending upon the bus widths (32/64/128), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. In the case where the buffer size is not a multiple of 4/8/16, the resulting behavior is undefined. This field is not valid if RDES1[24] is set.
10:0	**RBS1: Receive Buffer 1 Size** Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4/8/16 depending upon the bus widths (32/64/128), even if the value of RDES2 (buffer1 address pointer) is not aligned. In the case where the buffer size is not a multiple of 4/8/16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 24).

Receive Descriptor 2 (RDES2)

RDES2 contains the address pointer to the first data buffer in the descriptor.

*Note: See **Host Data Buffer Alignment** for further detail on buffer address alignment.*

Table 30-26 Receive Descriptor 2 (Default Operation)

Bit	Description
31:0	**Buffer 1 Address Pointer** These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3/2/1:0] (corresponding to bus width of 128/64/32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

Receive Descriptor 3 (RDES3)

RDES3 contains the address pointer either to the second data buffer in the descriptor or to the next descriptor.

Table 30-27 Receive Descriptor 3

Bit	Description
31:0	**Buffer 2 Address Pointer (Next Descriptor Address)** These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] = 0, corresponding to a bus width of 128, 64, or 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] (corresponding to a bus width of 128, 64, or 32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

30.4.1.2 Transmit Descriptor

The descriptor addresses must be aligned to the bus width used (32). **Figure 30-26** shows the transmit descriptor format in Little-Endian mode with a 32-bit data bus.

Each descriptor is provided with two buffers, two byte-count buffers, and two address pointers, which enable the adapter port to be compatible with various types of memory-management schemes.

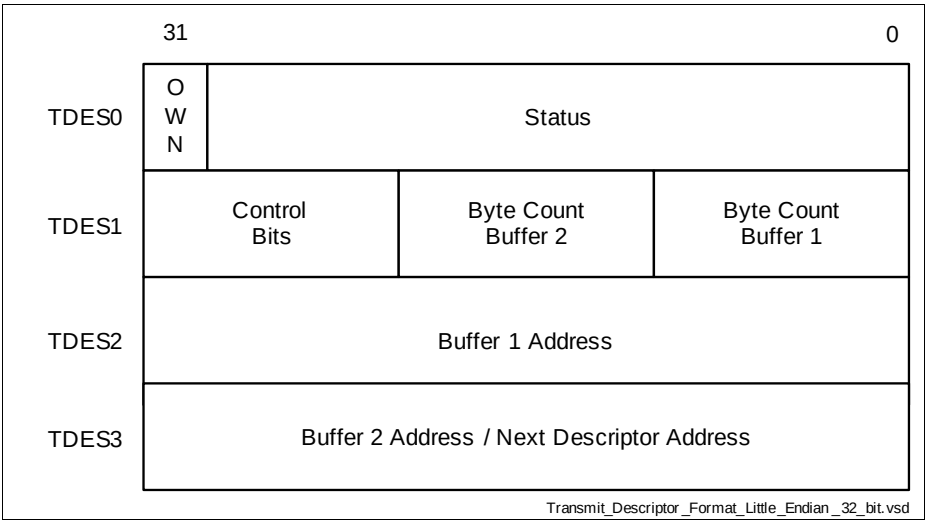

Figure 30-26 Transmit Descriptor Format in Little-Endian Mode With a 32-bit Data Bus

Transmit Descriptor 0 (TDES0)

TDES0 contains the transmitted frame status and the descriptor ownership information.

Table 30-28 Transmit Descriptor 0

Bit	Description
31	**OWN: Own Bit** When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are empty. The ownership bit of the First Descriptor of the frame should be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.
30:18	**Reserved**

Table 30-28 Transmit Descriptor 0 (cont'd)

Bit	Description
17	**TTSS: Tx Time Stamp Status** This status bit indicates that a time stamp has been captured for the corresponding transmit frame. When this bit is set, TDES2 and TDES3 have time stamp values that were captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30]) in a descriptor is set. This bit is valid only when IEEE1588 time stamping feature is enabled; otherwise, it is reserved.
16	**IHE: IP Header Error** When set, this bit indicates that the Checksum Offload engine detected an IP header error and consequently did not modify the transmitted frame for any checksum insertion. This bit is valid only when Full Checksum Offload is enabled; otherwise, it is reserved.
15	**ES: Error Summary** Indicates the logical OR of the following bits: • TDES0[14]: Jabber Timeout • TDES0[13]: Frame Flush • TDES0[11]: Loss of Carrier • TDES0[10]: No Carrier • TDES0[9]: Late Collision • TDES0[8]: Excessive Collision • TDES0[2]: Excessive Deferral • TDES0[1]: Underflow Error
14	**JT: Jabber Timeout** When set, this bit indicates the GMAC transmitter has experienced a jabber time-out. This bit is only set when the GMAC configuration register's JD bit is not set.
13	**FF: Frame Flushed** When set, this bit indicates that the DMA/MTL flushed the frame due to a SW flush command given by the CPU.

Table 30-28 Transmit Descriptor 0 (cont'd)

Bit	Description
12	**PCE: Payload Checksum Error** This bit, when set, indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either due to insufficient bytes, as indicated by the IP Header's Payload Length field, or the MTL starting to forward the frame to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet frame being transmitted: to avoid deadlock, the MTL starts forwarding the frame when the FIFO is full, even in Store-and-Forward mode. When the Full Checksum Offload engine is not enabled during configuration, this bit is reserved.
11	**LC: Loss of Carrier** When set, this bit indicates that Loss of Carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This is valid only for the frames transmitted without collision and when the GMAC operates in Half-Duplex Mode.
10	**NC: No Carrier** When set, this bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	**LC: Late Collision** When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times including Preamble in MII Mode and 512 byte times including Preamble and Carrier Extension in GMII Mode). Not valid if Underflow Error is set.
8	**EC: Excessive Collision** When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the DR (Disable Retry) bit in the GMAC Configuration Register is set, this bit is set after the first collision and the transmission of the frame is aborted.
7	**VF: VLAN Frame** When set, this bit indicates that the transmitted frame was a VLAN-type frame.
6:3	**CC: Collision Count** This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collisions bit (TDES0[8]) is set.

Table 30-28 Transmit Descriptor 0 (cont'd)

Bit	Description
2	**ED: Excessive Deferral** When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbit/s mode, or in Jumbo Frame enabled mode) if the Deferral Check (DC) bit is set high in the GMAC Control Register.
1	**UF: Underflow Error** When set, this bit indicates that the GMAC aborted the frame because data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty Transmit Buffer while transmitting the frame. The transmission process enters the suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]).
0	**DB: Deferred Bit** When set, this bit indicates that the GMAC defers before transmission because of the presence of carrier. This bit is valid only in Half-Duplex mode.

Transmit Descriptor 1 (TDES1)

TDES1 contains the buffer sizes and other bits which control the descriptor chain/ring and the frame being transferred.

*Note: See **Buffer Size Calculations** for further detail on calculating buffer sizes.*

Table 30-29 Transmit Descriptor 1

Bit	Description
31	**IC: Interrupt on Completion** When set, this bit sets Transmit Interrupt (Register 5[0]) after the present frame has been transmitted.
30	**LS: Last Segment** When set, this bit indicates that the buffer contains the last segment of the frame.
29	**FS: First Segment** When set, this bit indicates that the buffer contains the first segment of a frame.

Table 30-29 Transmit Descriptor 1 (cont'd)

Bit	Description
28:27	**CIC: Checksum Insertion Control** These bits control the insertion of checksums in Ethernet frames that encapsulate TCP, UDP, or ICMP over IPv4 or IPv6 as described below. • 2'b00: Do nothing. Checksum Engine is bypassed • 2'b01: Insert IPv4 header checksum. Use this value to insert IPv4 header checksum when the frame encapsulates an IPv4 datagram. • 2'b10: Insert TCP/UDP/ICMP checksum. The checksum is calculated over the TCP, UDP, or ICMP segment only and the TCP, UDP, or ICMP pseudo-header checksum is assumed to be present in the corresponding input frame's Checksum field. An IPv4 header checksum is also inserted if the encapsulated datagram conforms to IPv4. • 2'b11: Insert a TCP/UDP/ICMP checksum that is fully calculated in this engine. In other words, the TCP, UDP, or ICMP pseudo-header is included in the checksum calculation, and the input frame's corresponding Checksum field has an all-zero value. An IPv4 Header checksum is also inserted if the encapsulated datagram conforms to IPv4. The Checksum engine detects whether the TCP, UDP, or ICMP segment is encapsulated in IPv4 or IPv6 and processes its data accordingly.
26	**DC: Disable CRC** When set, the GMAC does not append the Cyclic Redundancy Check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES1[29]).
25	**TER: Transmit End of Ring** When set, this bit indicates that the descriptor list reached its final descriptor. The returns to the base address of the list, creating a descriptor ring.
24	**TCH: Second Address Chained** When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES1[24] is set, TBS2 (TDES1[21–11]) are "don't care" values. TDES1[25] takes precedence over TDES1[24].
23	**DP: Disable Padding** When set, the GMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes and the CRC field is added despite the state of the DC (TDES1[26]) bit. This is valid only when the first segment (TDES1[29]) is set.

Table 30-29 Transmit Descriptor 1 (cont'd)

Bit	Description
22	**TTSE: Transmit Time Stamp Enable** When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES1[29]) is set.
21:11	**TBS2: Transmit Buffer 2 Size** These bits indicate the Second Data Buffer in bytes. This field is not valid if TDES1[24] is set.
10:0	**TBS1: Transmit Buffer 1 Size** These bits indicate the First Data Buffer byte size. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of TCH (Bit 24).

Transmit Descriptor 2 (TDES2)

TDES2 contains the address pointer to the first buffer of the descriptor.

Table 30-30 Transmit Descriptor 2

Bit	Description
31:0	**Buffer 1 Address Pointer** These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See **Host Data Buffer Alignment** for further detail on buffer address alignment.

Transmit Descriptor 3 (TDES3)

TDES3 contains the address pointer either to the second buffer of the descriptor or the next descriptor.

Table 30-31 Transmit Descriptor 3

Bit	Description
31:0	**Buffer 2 Address Pointer (Next Descriptor Address)** Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.)

30.4.1.3 Descriptor Format With IEEE 1588 Time Stamping Enabled

The default descriptor format (as described in **"Receive Descriptor" on Page 1-677** and **"Transmit Descriptor" on Page 1-669**), and field descriptions remain unchanged when created by software (Own bit is set in DES0). However, if the software has enabled IEEE 1588 functionality, the DES2 and DES3 descriptor fields (see **Figure 30-27**) take on a different meaning when the DMA closes the descriptor (own bit in DES0 is cleared).

The DMA updates the DES2 and DES3 with the time stamp value before clearing the Own bit in DES0.

When the core is operating in 32-bit mode (**Figure 30-24**), DES2 is updated with the lower 32 time stamp bits (the Sub-Second field, called TSL in subsequent sections) and DES3 is updated with the upper 32 time stamp bits (the Seconds field, called TSH in subsequent sections).

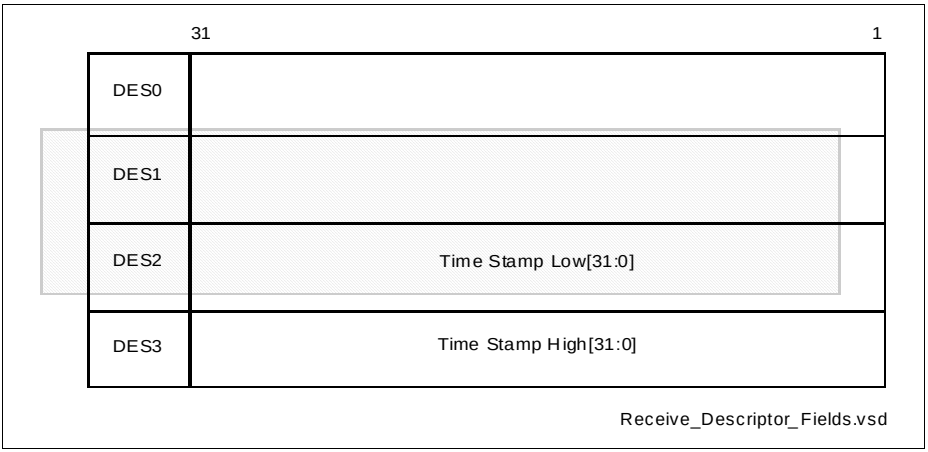

Figure 30-27 Receive Descriptor Fields When DMA Clears the Own Bit

The following sections describe the details specific to receive and transmit descriptors in this mode.

Receive Descriptor

Receive Time Stamp

The tables below describe the fields that have different meaning for RDES2 and RDES3 when the receive descriptor is closed and time stamping is enabled.

Note: When software disables the time stamping feature (the TSENA bit in Register 448 is low), the DMA does not update the descriptor's RDES2/RDES3 fields before closing the RDES0.

Table 30-32 Receive Descriptor Fields (RDES2)

Bit	Description
31:0	**RTSL: Receive Frame Time Stamp Low** The DMA updates this field with the least significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]). When this field and the RTSH field in RDES3 show an all-ones value, the time stamp must be treated as corrupt.

Table 30-33 Receive Descriptor Fields (RDES3)

Bit	Description
31:0	**RTSH: Receive Frame Time Stamp High** The DMA updates this field with the most significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]). When this field and RDES2's RTSL field show all-ones values, the time stamp must be treated as corrupt.

Transmit Descriptor

In addition to the changes described in **"Descriptor Format With IEEE 1588 Time Stamping Enabled" on Page 1-676**, the Transmit descriptor has additional control and status bits (TTSE and TTSS, respectively) for time stamping, as shown in **Figure 30-28**. Software sets the TTSE bit (when the Own bit is set), instructing the core to generate a time stamp for the corresponding Ethernet frame being transmitted. The DMA sets the TTSS bit if the time stamp has been updated in the TDES2 and TDES3 fields when the descriptor is closed (Own bit is cleared).

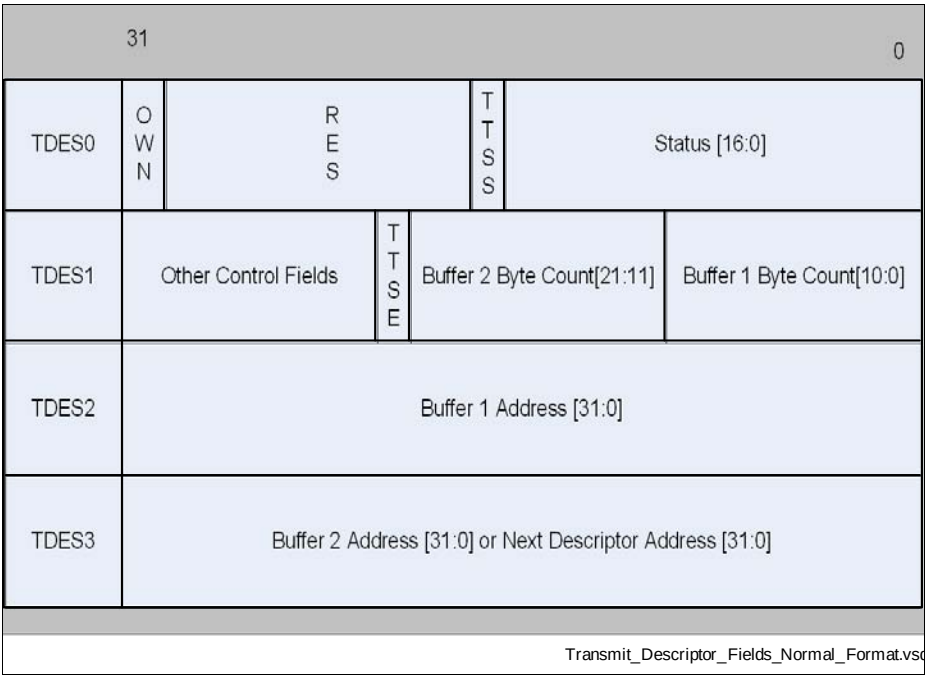

Figure 30-28 Transmit Descriptor Fields– Normal Format

Transmit Time Stamp Control and Status Fields

The position of these fields is different for normal transmit descriptor and enhanced format transmit descriptor. The value of this field in both the cases shall be preserved by the DMA at the time of closing the descriptor.

Updates to **Table 1-87** and **Table 1-88** for the default (normal) descriptor format are described below.

Table 30-34 Transmit Time Stamp Status – Normal Descriptor Format Case (TDES0)

Bit	Description
17	**TTSS: Transmit Time Stamp Status** This field is a status bit indicating that a time stamp was captured for the corresponding transmit frame. When this bit is set, both TDES2 and TDES3 have a time stamp value that was captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30] in the descriptor) is set.

Table 30-35 Transmit Time Stamp Control – Normal Descriptor Format Case (TDES1)

Bit	Description
22	**TTSE: Transmit Time Stamp Enable** When set, this field enables IEEE1588 hardware time stamping for the transmit frame described by the descriptor. This field is valid only when the First Segment control bit (TDES1[29] in the descriptor) is set.

Transmit Time Stamp Field

The transmit descriptor format and field descriptions remain unchanged when they are created by software (when the Own bit is set). However, when the DMA closes the last descriptor (marked, in the alternative descriptor format, by the LS bit in TDES1 or TDES0) and IEEE 1588 functionality is enabled (the Own bit is cleared), the TDES2 and TDES3 descriptor fields are updated with the time stamp, if taken, for that frame.

The fields in TDES2 and TDES3 are swapped when the core operates in 64- or 128-bit and with the descriptor in Reverse-Endian mode

Table 1-96 and **Table 1-97** describe the fields that have different meaning when the descriptor is closed.

Table 30-36 Transmit Descriptor Fields (TDES2)

Bit	Description
31:0	**TTSL: Transmit Frame Time Stamp Low** This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment control bit (LS) in the descriptor is set.

Table 30-37 Transmit Descriptor Fields (TDES3)

Bit	Description
31:0	**TTSH: Transmit Frame Time Stamp High** This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment control bit (LS) in the descriptor is set.

30.4.2 Alternate or Enhanced Descriptors

The alternate (or enhanced) descriptor structure can have 8 DWORDS (32-bytes) instead of the 4 DWORDS as in the case of normal descriptor format. The features of the alternate descriptor structure are

- The normal descriptor structure allows data buffers of up to 2.048 bytes. The alternative descriptor structure has been implemented to support buffers of up to 8 KB (useful for Jumbo frames).
- There is a re-assignment of control and status bits in TDES0, TDES1, RDES0 (Advanced time stamp or IPC full offload configuration), RDES1.
- The transmit descriptor stores the time stamp in TDES6 and TDES7 when advanced time stamp feature is selected.
- This receive descriptor structure is also used for storing the extended status (RDES4) and time stamp (RDES6 and RDES7) when advanced time stamp feature or IPC full offload is selected.
- When alternate descriptor mode is selected, and Time-stamping feature is enabled, the software needs to allocate 32-bytes (8 DWORDS) of memory for every descriptor. When Time-stamping or Receive IPC FullOffload engine are not enabled, the extended descriptors are not required and the SW can use alternate descriptors with the default size of 16 bytes. The core also needs to be configured for this change using the DMA Bus Mode Register[7].
- When alternate descriptor is chosen without Time Stamp or Full IPC Offload feature, the descriptor size is always 4 DWORDs (DES0-DES3).

The description or bit-mapping alternate descriptor structure (in Little Endian mode) is given below.

*Note: The effect of Big Endian mode (byte-swap) explained in **"Normal Descriptor Formats" on Page 1-658** apply to this descriptor structure as well.*
When alternate descriptor with only Full IPC Offload (Type 2) is selected, it is not backward compatible to the previous release 3.4x with respect to status bits[7,5,0] in RDES0. In this mode, you should enable the extended descriptor mode (8 DWORDS) to get the IPC checksum engine status in RDES4.

30.4.2.1 Transmit Descriptor

The transmit descriptor structure is shown in **Figure 30-29**. The application software must program the control bits TDES0[31:20] during descriptor initialization. When the DMA updates the descriptor, it write backs all the control bits except the OWN bit (which it clears) and updates the status bits[19:0]. The contents of the transmitter descriptor word 0 (TDES0) through word 3 (TDES3) are given in **Table 1-98** through **Table 1-101**, respectively.

With the advance time stamp support, the snapshot of the time stamp to be taken can be enabled for a given frame by setting the "TTSE: Transmit Time Stamp Enable" (bit-25 of TDES0). When the descriptor is closed (i.e. when the OWN bit is cleared), the time-

stamp is written into TDES6 and TDES7. This is indicated by the status bit “TTSS: Transmit Time Stamp Status” (bit-17 of TDES0). This is shown in **Figure 30-29**. The contents of TDES6 and TDES7 are mentioned in **Table 1-102** and **Table 1-103**.

Note: When either of Advanced Time Stamp or IPC Offload (Type 2) features is enabled, the SW should set the DMA Bus Mode register[7], so that the DMA operates with extended descriptor size. When this control bit is reset, the TDES4-TDES7 descriptor space are not valid.

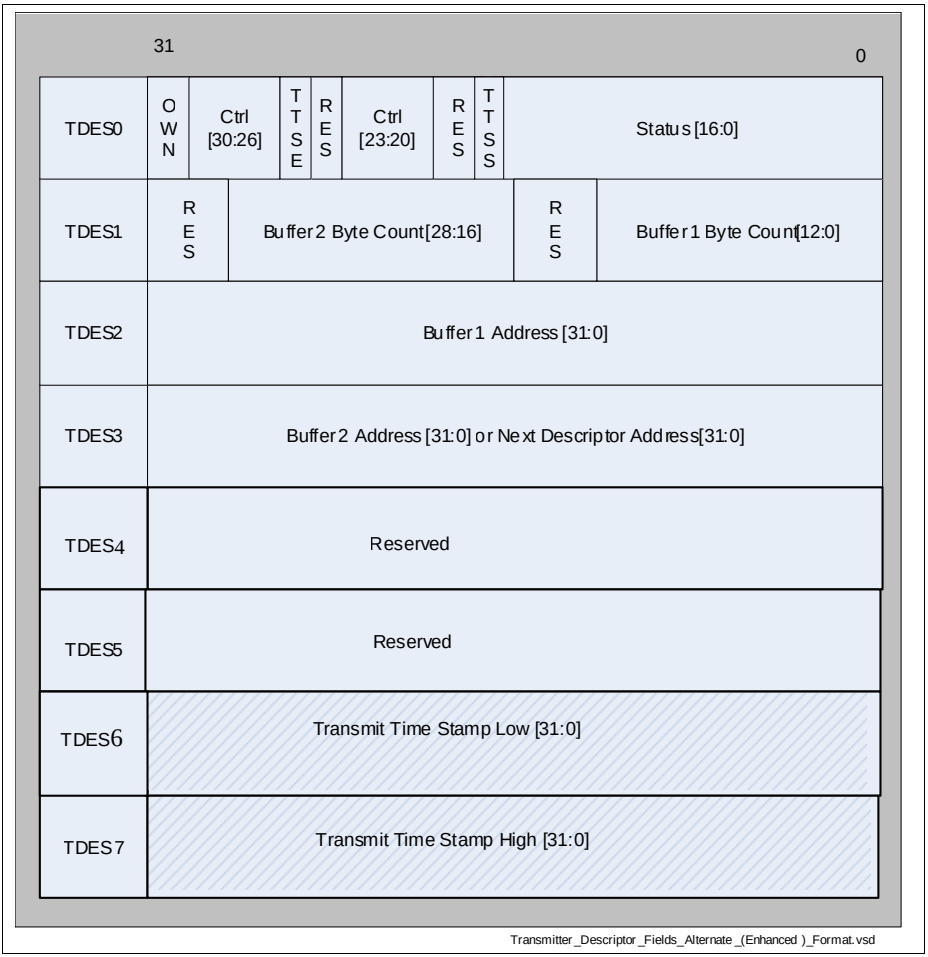

Figure 30-29 Transmitter Descriptor Fields - Alternate (Enhanced) Format

.

Table 30-38 Transmit Descriptor Word 0 (TDES0)

Bit	Description
31	**OWN: Own Bit** When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.
30	**IC: Interrupt on Completion** When set, this bit sets the Transmit Interrupt (Register 5[0]) after the present frame has been transmitted.
29	**LS: Last Segment** When set, this bit indicates that the buffer contains the last segment of the frame.
28	**FS: First Segment** When set, this bit indicates that the buffer contains the first segment of a frame.
27	**DC: Disable CRC** When this bit is set, the GMAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set.
26	**DP: Disable Pad** When set, the GMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set.
25	**TTSE: Transmit Time Stamp Enable** When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES0[28]) is set.
24	**Reserved**

Table 30-38 Transmit Descriptor Word 0 (TDES0) (cont'd)

Bit	Description
23:22	**CIC: Checksum Insertion Control** These bits control the checksum calculation and insertion. Bit encodings are as shown below. • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is reserved when the IPC_FULL_OFFLOAD configuration parameter is not selected.
21	**TER: Transmit End of Ring** When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.
20	**TCH: Second Address Chained** When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a "don't care" value. TDES0[21] takes precedence over TDES0[20].
19:18	**Reserved**
17	**TTSS: Transmit Time Stamp Status** This field is used as a status bit to indicate that a time stamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a time stamp value captured for the transmit frame. This field is only valid when the descriptor's Last Segment control bit (TDES0[29]) is set.
16	**IHE: IP Header Error** When set, this bit indicates that the GMAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet Length/Type field value for an IPv4 or IPv6 frame must match the IP header version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5.

Table 30-38 Transmit Descriptor Word 0 (TDES0) (cont'd)

Bit	Description
15	**ES: Error Summary** Indicates the logical OR of the following bits: • TDES0[14]: Jabber Timeout • TDES0[13]: Frame Flush • TDES0[11]: Loss of Carrier • TDES0[10]: No Carrier • TDES0[9]: Late Collision • TDES0[8]: Excessive Collision • TDES0[2]: Excessive Deferral • TDES0[1]: Underflow Error • TDES0[16]: IP Header Error • TDES0[12]: IP Payload Error
14	**JT: Jabber Timeout** When set, this bit indicates the GMAC transmitter has experienced a jabber time-out. This bit is only set when the GMAC configuration register's JD bit is not set.
13	**FF: Frame Flushed** When set, this bit indicates that the DMA/MTL flushed the frame due to a software Flush command given by the CPU.
12	**IPE: IP Payload Error** When set, this bit indicates that GMAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch.
11	**LC: Loss of Carrier** When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This is valid only for the frames transmitted without collision when the GMAC operates in Half-Duplex mode.
10	**NC: No Carrier** When set, this bit indicates that the Carrier Sense signal form the PHY was not asserted during transmission.
9	**LC: Late Collision** When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte-times, including preamble, in MII mode and 512 byte-times, including preamble and carrier extension, in GMII mode). This bit is not valid if the Underflow Error bit is set.

Table 30-38 Transmit Descriptor Word 0 (TDES0) (cont'd)

Bit	Description
8	**EC: Excessive Collision** When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the DR (Disable Retry) bit in the GMAC Configuration register is set, this bit is set after the first collision, and the transmission of the frame is aborted.
7	**VF: VLAN Frame** When set, this bit indicates that the transmitted frame was a VLAN-type frame.
6:3	**CC: Collision Count** This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collisions bit (TDES0[8]) is set.
2	**ED: Excessive Deferral** When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1,000-Mbit/s mode or if Jumbo Frame is enabled) if the Deferral Check (DC) bit in the GMAC Control register is set high.
1	**UF: Underflow Error** When set, this bit indicates that the GMAC aborted the frame because data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]).
0	**DB: Deferred Bit** When set, this bit indicates that the GMAC defers before transmission because of the presence of carrier. This bit is valid only in Half-Duplex mode.

Table 30-39 Transmit Descriptor Word 1 (TDES1)

Bit	Description
31:29	Reserved
28:16	**TBS2: Transmit Buffer 2 Size** These bits indicate the second data buffer size in bytes. This field is not valid if TDES0[20] is set. See **Buffer Size Calculations** for further detail on calculating buffer sizes.

Table 30-39 Transmit Descriptor Word 1 (TDES1) (cont'd)

Bit	Description
15:13	**Reserved**
12:0	**TBS1: Transmit Buffer 1 Size** These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]).

Table 30-40 Transmit Descriptor 2 (TDES2)

Bit	Description
31:0	**Buffer 1 Address Pointer** These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See **Host Data Buffer Alignment** for further detail on buffer address alignment.

Table 30-41 Transmit Descriptor 3 (TDES3)

Bit	Description
31:0	**Buffer 2 Address Pointer (Next Descriptor Address)** Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.)

Table 30-42 Transmit Descriptor 6 (TDES6)

Bit	Description
31:0	**TTSL: Transmit Frame Time Stamp Low** This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set.

Table 30-43 Transmit Descriptor 7 (TDES7)

Bit	Description
31:0	**TTSH: Transmit Frame Time Stamp High** This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set.

30.4.2.2 Receive Descriptor

The structure of the received descriptor is shown in **Figure 30-30**. This can have 32 bytes of descriptor data (8 DWORDs) when Advanced Time Stamping or IPC Full Offload feature is selected.

Note: When either of these features is enabled, the SW should set the DMA Bus Mode register[7] so that the DMA operates with extended descriptor size. When this control bit is reset, RDES0[7] and RDES0[0] will be always cleared and the RDES4-RDES7 descriptor space are not valid

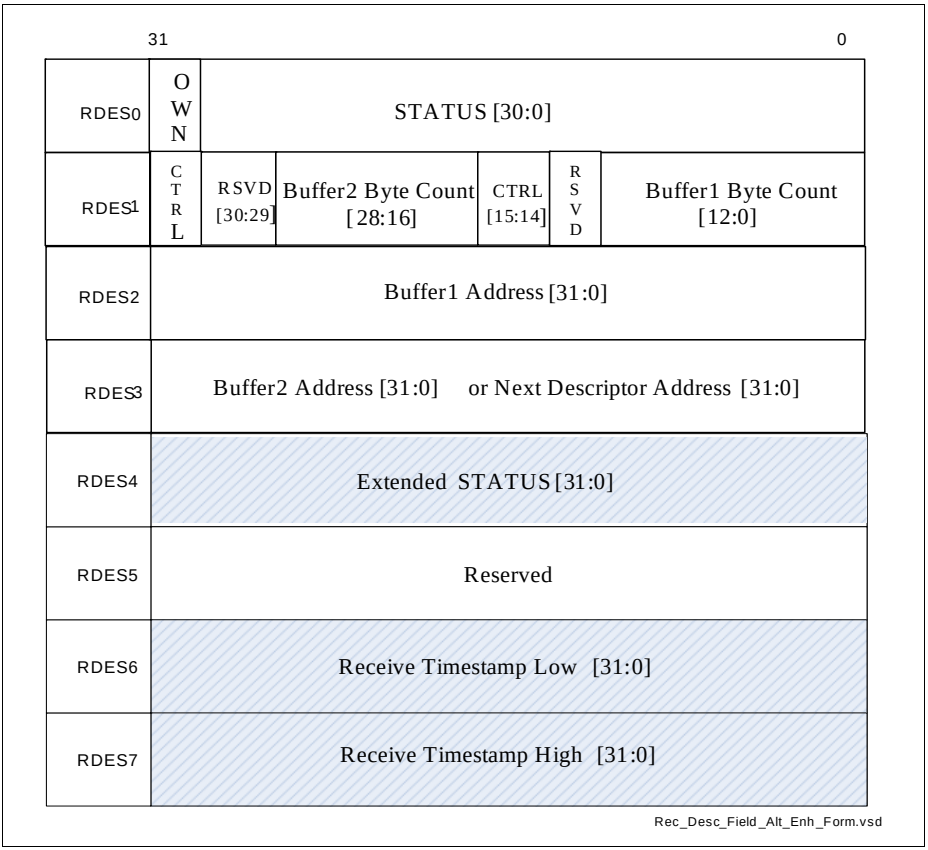

Figure 30-30 Receive Descriptor Fields - Alternate (Enhanced) Format

The contents of RDES0 are identified in **Table 1-104**. The contents of RDES1 through RDES3 are identified in **Table 1-105** through **Table 1-107**, respectively.

Note: Some of the bit functions of RDES0 are not backward compatible to Release 3.41a and previous versions. These bits are Bit[7], Bit[0] and Bit[5]. The function of Bit[5] is backward compatible to Release 3.30a and previous versions.

Table 30-44 Receive Descriptor Fields (RDES0)

Bit	Description
31	**OWN: Own Bit** When set, this bit indicates that the descriptor is owned by the DMA of the GMAC Subsystem. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	**AFM: Destination Address Filter Fail** When set, this bit indicates a frame that failed in the DA Filter in the GMAC Core.
29:16	**FL: Frame Length** These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are are reset. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame. This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame.
15	**ES: Error Summary** Indicates the logical OR of the following bits: • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: Giant Frame • RDES4[4:3]: IP Header/Payload Error • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error This field is valid only when the Last Descriptor (RDES0[8]) is set.
14	**DE: Descriptor Error** When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.
13	**SAF: Source Address Filter Fail** When set, this bit indicates that the SA field of frame failed the SA Filter in the GMAC Core.

Table 30-44 Receive Descriptor Fields (RDES0) (cont'd)

Bit	Description
12	**LE: Length Error** When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset.
11	**OE: Overflow Error** When set, this bit indicates that the received frame was damaged due to buffer overflow in MTL.
10	**VLAN: VLAN Tag** When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the GMAC Core.
9	**FS: First Descriptor** When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.
8	**LS: Last Descriptor** When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame
7	**Time Stamp Available/IP Checksum Error (Type1) /Giant Frame** When Advanced Time Stamp feature is present, this bit, when set, indicates that a snapshot of the timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set. When IP Checksum Engine (Type 1) is selected, this bit, when set, indicates that the 16-bit IPv4 Header checksum calculated by the core did not match the received checksum bytes. Otherwise, this bit, when set, indicates the Giant Frame Status. Giant frames are larger-than-1,518-byte (or 1,522-byte for VLAN) normal frames and larger-than-9,018-byte (9,022-byte for VLAN) frame when Jumbo Frame processing is enabled.
6	**LC: Late Collision** When set, this bit indicates that a late collision has occurred while receiving the frame in Half-Duplex mode.
5	FT: Frame Type When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes.

Table 30-44 Receive Descriptor Fields (RDES0) (cont'd)

Bit	Description
4	**RWT: Receive Watchdog Timeout** When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.
3	**RE: Receive Error** When set, this bit indicates that the gmii_rxer_i signal is asserted while gmii_rxdv_i is asserted during frame reception. This error also includes carrier extension error in GMII and Half-duplex mode. Error can be of less/no extension, or error (rxd ≠ 0f) during extension.
2	**DE: Dribble Bit Error** When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.
1	**CE: CRC Error** When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set.
0	**Extended Status Available/Rx MAC Address** When either Advanced Time Stamp or IP Checksum Offload (Type 2) is present, this bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This is valid only when the Last Descriptor bit (RDES0[8]) is set. When Advance Time Stamp Feature or IPC Full Offload is not selected, this bit indicates Rx MAC Address status. When set, this bit indicates that the Rx MAC Address registers value (1 to 31) matched the frame's DA field. When reset, this bit indicates that the Rx MAC Address Register 0 value matched the DA field.

Table 30-45 Receive Descriptor Fields 1 (RDES1)

Bit	Description
31	**DIC: Disable Interrupt on Completion** When set, this bit prevents setting the Status Register's RI bit (CSR5[6]) for the received frame ending in the buffer indicated by this descriptor. This, in turn, disables the assertion of the interrupt to Host due to RI for that frame.
30:29	**Reserved**

Table 30-45 Receive Descriptor Fields 1 (RDES1) (cont'd)

Bit	Description
28:16	**RBS2: Receive Buffer 2 Size** These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, 8, or 16, depending on the bus widths (32, 64, or 128, respectively), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. If the buffer size is not an appropriate multiple of 4, 8, or 16, the resulting behavior is undefined. This field is not valid if RDES1[14] is set. See **Buffer Size Calculations** for further details on calculating buffer sizes.
15	**RER: Receive End of Ring** When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.
14	**RCH: Second Address Chained** When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When this bit is cleared, RBS2 (RDES1[28:16]) is a "don't care" value. RDES1[15] takes precedence over RDES1[14].
13	**Reserved**
12:0	**RBS1: Receive Buffer 1 Size** Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, 8, or 16, depending upon the bus widths (32, 64, or 128), even if the value of RDES2 (buffer1 address pointer) is not aligned. When the buffer size is not a multiple of 4, 8, or 16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 14). See **Buffer Size Calculations** for further details on calculating buffer sizes.

Table 30-46 Receive Descriptor Fields 2 (RDES2)

Bit	Description
31:0	**Buffer 1 Address Pointer** These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3/2/1:0] (corresponding to bus width of 128/64/32) if the address pointer is to a buffer where the middle or last part of the frame is stored. See **Host Data Buffer Alignment** for further details on buffer address alignment.

Table 30-47 Receive Descriptor Fields 3 (RDES3)

Bit	Description
31:0	**Buffer 2 Address Pointer (Next Descriptor Address)** These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] = 0, corresponding to a bus width of 128, 64, or 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] (corresponding to a bus width of 128, 64, or 32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

The extended status written is as shown in **Table 1-108**. The extended status is written only when there is status related to IPC or Time Stamp available. The availability of extended status is indicated by bit-0 of RDES0. This status is available only when Advance Time Stamp or IPC Full Offload feature is selected.

Table 30-48 Receive Descriptor Fields 4 (RDES4)

Bit	Description
31:14	**Reserved**
13	**PTP Version** When set, indicates that the received PTP message is having the IEEE 1588 version 2 format. When reset, it has the version 1 format. This is valid only if the message type is non-zero. This bit is available only if Advance Time Stamp feature is selected else it is reserved
12	**PTP Frame Type** When set, this bit that the PTP message is sent directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information on IPv4 or IPv6 can be obtained from bits 6 and 7. This bit is available only if Advanced Time Stamp feature is selected

Table 30-48 Receive Descriptor Fields 4 (RDES4) (cont'd)

Bit	Description
11:8	**Message Type** These bits are encoded to give the type of the message received. • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011-1111: Reserved These bits are valid only when you select the Advance Time Stamp feature.
7	**IPv6 Packet Received** When set, this bit indicates that the received packet is an IPv6 packet.
6	**IPv4 Packet Received** When set, this bit indicates that the received packet is an IPv4 packet.
5	**IP Checksum Bypassed** When set, this bit indicates that the checksum offload engine is bypassed.
4	**IP Payload Error** When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the core calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field.

Table 30-48 Receive Descriptor Fields 4 (RDES4) (cont'd)

Bit	Description
3	**IP Header Error** When set, this bit indicates either that the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes, or that the IP datagram version is not consistent with the Ethernet Type value.
2:0	**IP Payload Type** These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE). The COE also sets these bits to 2'b00 if it does not process the IP datagram's payload due to an IP header error or fragmented IP. • 3'b000: Unknown or did not process IP payload • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b1xx: Reserved

RDES6 and RDES7 contain the snapshot of the time-stamp. The availability of the snapshot of the time-stamp in RDES6 and RDES7 is indicated by bit-7 in the RDES0 descriptor. The contents of RDES6 and RDES7 are identified in **Table 1-109** and **Table 1-110**, respectively.

Table 30-49 Receive Descriptor Fields 6 (RDES6)

Bit	Description
31:0	**RTSL: Receive Frame Time Stamp Low** This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).

Table 30-50 Receive Descriptor Fields 7 (RDES7)

Bit	Description
31:0	**RTSH: Receive Frame Time Stamp High** This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).

30.5 Ethernet MAC Module Implementation

This section describes the Ethernet MAC module interface as it is implemented in the TC21x/TC22x/TC23x. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

30.5.1 Interface Connections of the Ethernet MAC Module

The Ethernet MAC module is supplied with a separate clock control, address decoding, and interrupt control logic. The modules' service request outputs are connected with one interrupt node.

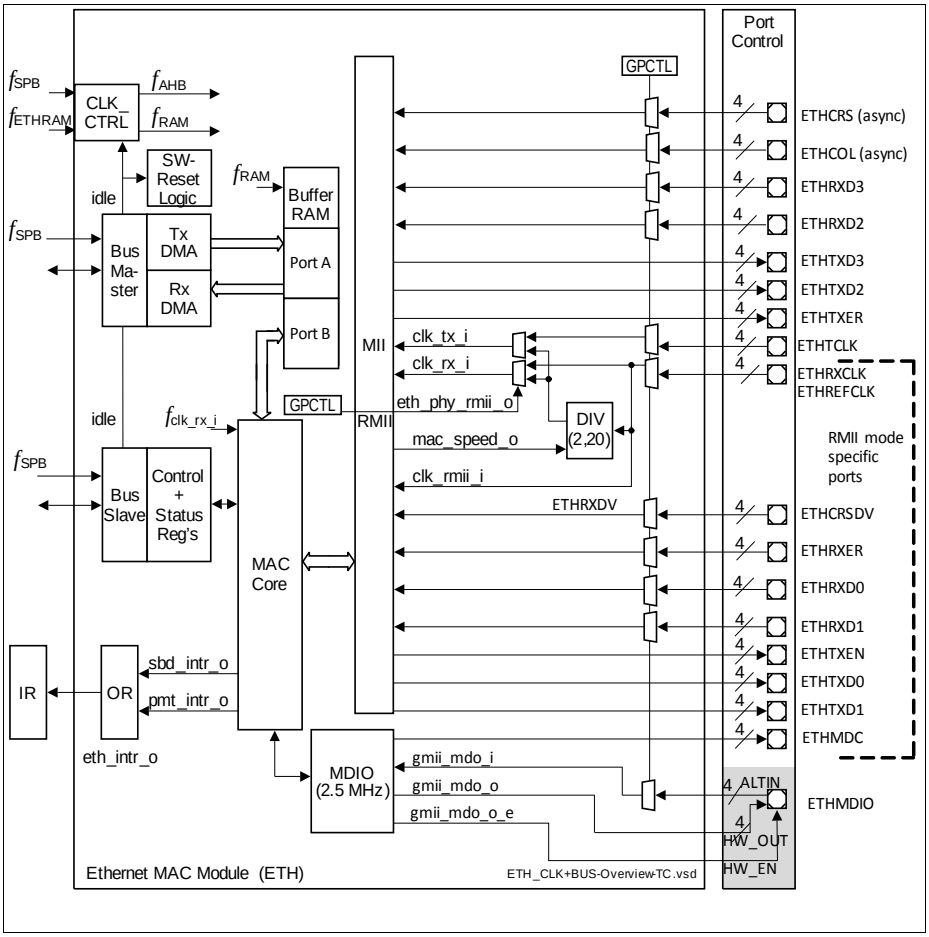

Figure 30-31 Ethernet MAC Module Implementation and Interconnections

30.5.1.1 On-Chip Connections

This section describes the on-chip connections of the Ethernet MAC module.

Interrupt Service Requests

The module has one Service Request Node connecting it to the interrupt system. The interrupt request line is connected to the interrupt controller as shown in **Table 1-112**.

Table 30-51 Service Request Lines of Ethernet MAC

Request Line	Connected to	Description
ETH_SRC0	eth_intr_o	DMA functions (sbd_intr_o), this internal line is connected via OR gate to ETH.SR0
ETH_SRC0	eth_intr_o	wake up on LAN (pmt_intr_o), this internal line is connected via OR gate to ETH.SR0

30.5.1.2 Clocks

The module has multiple clock inputs connecting it to the system. They are connected to the system as shown in **Table 1-113**.

Table 30-52 Clock Lines of Ethernet MAC

Clock Line	Connected to	Description
hclk_i / f_{AHB}	f_{SPB}	AHB Master Interface Clock, divided by 2 if GPCTL.DIV is set
clk_ram_i / f_{RAM}	f_{ETHRAM}	RAM Clock (separate clock from SCU.CGU) • it is by default 2 x f_{SPB} • must always be 2, 3, 4 ... (natural number) times higher than f_{SPB} • it must be ≥ 4 x clk_tx_i / clk_rx_i (Both are 25 MHz for 100 MBit/s and 2.5 MHz for 10 MBit/s) • divided by 2 if GPCTL.DIV is set
clk_csr_i	f_{SPB}	AHB Slave Interface Clock
clk_tx_i	ETHTXCLK (port pin)	Transmission Clock from Phy needs a clock input during SW reset (ETH_BUS_MODE.SWR)
clk_rx_i	ETHRXCLK (port pin)	Reception Clock from Phy needs a clock input during SW reset (ETH_BUS_MODE.SWR)

Table 30-52 Clock Lines of Ethernet MAC (cont'd)

Clock Line	Connected to	Description
clk_rmii_i	ETHREFCLK (port pin)	50-MHz clock used by the RMII from Phy needs a clock input during SW reset (ETH_BUS_MODE.SWR)
clk_ptp_ref_i	f_{SPB}	Reference Clock for the Time Stamp Update Logic

30.5.2 Ethernet MAC Module-Implementation Related Registers

The registers listed in **Figure 30-32** Ethernet MAC must be programmed for proper operation of the Ethernet MAC module.

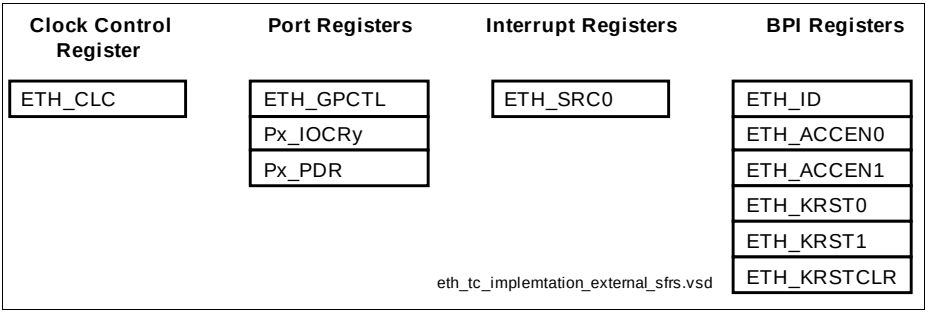

Figure 30-32 Ethernet MAC Implementation-specific Special Function Registers

30.5.2.1 Port Control

The Ethernet MAC is connected to general purpose I/O lines. Each line is connected to up to four different general purpose I/O lines that can be chosen alternatively. The selection from one of these alternatives is done by application SW by programming ETH_GPCTL.ALTIx respectively.

For MDIO, ALTIx selects the direction control signal (“HW_OUT control”) gmii_mdo_o_e_[x] as well. The signals gmii_mdo_o_e_[n] that are not selected are forced passive.

The following port control operations and selections must be executed for these I/O lines:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Table 30-53 shows an overview how bits and bit fields must be programmed for the required I/O functionality of the Ethernet MAC I/O lines.

Note: Some PHYs provide an interrupt output, signalling e.g. line activity. It might be useful to connect this to an interrupt input on system level. This signal is not connected to the Ethernet MAC*!*

Table 30-53 Ethernet MAC **I/O Control Selection and Setup**

Port	MAC signals	R/ Mii	Input Select Register	Input/Output Control Register Bits	I/ O
P02.8	ETHMDC		na	P02_IOCR8.PC8 = $1X110_B$	O

Table 30-53 Ethernet MAC **I/O Control Selection and Setup** (cont'd)

Port	MAC signals	R/ Mii	Input Select Register	Input/Output Control Register Bits	I/ O
P21.2	ETHMDC		na	P21_IOCR0.PC2 = $1X101_B$	O
P00.0	ETHMDIOA		ETH_GPCTL.ALTI0 = 00_B	P00_IOCR0.PC0 = $0XXX_B$	I/ O
	gmii_mdo_o_e_0 (I/O direction control of MDIO) connected to HW_DIR and HW_EN input of this port; choose Single EN - the pin is controlled by its own, dedicated, single HW_EN signal; gmii_mdo_o is connected to HW_OUT of the port, gmii_mdo_i is connected to ALTIN of the port (via input demultiplexer controlled by ALTI).				
P21.3	ETHMDIOD		ETH_GPCTL.ALTI0 = 11_B	P21_IOCR0.PC3 = $0XXX_B$	I/ O
	gmii_mdo_o_e_3 (I/O direction control of MDIO) connected to HW_DIR and HW_EN input of this port; choose Single EN - the pin is controlled by its own, dedicated, single HW_EN signal; gmii_mdo_o is connected to HW_OUT of the port, gmii_mdo_i is connected to ALTIN of the port (via input demultiplexer controlled by ALTI).				
P11.12	ETHRXCLKA / ETHREFCLKA	M / R	ETH_GPCTL.ALTI1 = 00_B	P11_IOCR12.PC12 = $0XXX_B$	I
	RMII: EXTCLK1 can be selected as output (P11_IOCR12.PC12 = $1X110_B$) while ETH_GPCTL.ALTI1 selects this pin as input. This setting supplies both: external PHY and this module with ETHREFCLK. Note that the jitter requirement of IEEE802.3 can not be met with this internal clock. If used as REFCLK, use fast input mode (P11_PDR1.PD12 = $X00_B$ and P11_IOCR12.PC12 = $0XXXX_B$)				
P11.12	ETHTXCLKB	R	ETH_GPCTL.ALTI10 =01_B	P11_IOCR12.PC12 = $0XXX_B$	I
	Not for application but for SW development and test. This allows to use MII loop back without external circuit if TXCLK and RXCLK are clocked with EXTCLK1.				
P11.11	ETHCRSB	M	ETH_GPCTL.ALTI2 = 01_B	P11_IOCR8.PC11 = $0XXX_B$	I
P10.1	ETHCRSC	M	ETH_GPCTL.ALTI2 = 10_B	P10_IOCR0.PC1 = $0XXX_B$	I
P10.2	ETHCOLB	M	ETH_GPCTL.ALTI3 = 01_B	P10_IOCR0.PC2 = $0XXX_B$	I

Table 30-53 Ethernet MAC **I/O Control Selection and Setup** (cont'd)

P11.9	ETHRXD1A	R	ETH_GPCTL.ALTI7 = 00_B	P11_IOCR8.PC9 = $0XXX_B$	I
P11.8	ETHRXD2A	M	ETH_GPCTL.ALTI8 = 00_B	P11_IOCR8.PC8 = $0XXX_B$	I
P10.5	ETHRXD3B	M	ETH_GPCTL.ALTI9 = 01_B	P10_IOCR4.PC5 = $0XXX_B$	I
P13.1	ETHTXCLKC	M	ETH_GPCTL.ALTI10 =10_B	P13_IOCR0.PC1 = $0XXX_B$	I
P13.0	ETHTXER	M	na	P13_IOCR0.PC0 = $1X110_B$	O
P11.6	ETHTXEN	R	na	P11_IOCR4.PC6 = $1X110_B$	O
P11.3	ETHTXD0	R	na	P11_IOCR0.PC3 = $1X110_B$	O
P11.2	ETHTXD1	R	na	P11_IOCR0.PC2 = $1X110_B$	O
P13.3	ETHTXD2	M	na	P13_IOCR0.PC3 = $1X110_B$	O
P13.2	ETHTXD3	M	na	P13_IOCR0.PC2 = $1X110_B$	O

30.5.2.2 Clock Control

The master interface (DMAs) of the Ethernet MAC is connected to f_{SPB}via a clock control in register GPCTL.

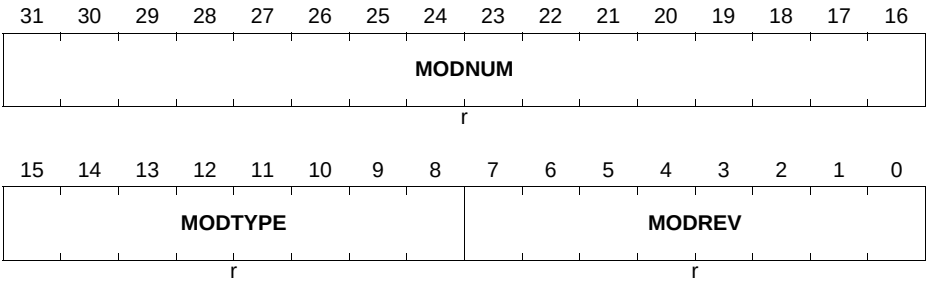
Note: The RAM frequency needs to run at double the application clock!

30.5.2.3 Additional Register

Module Identification Register

The Ethernet MAC Module Identification Register ID contains read-only information about the module version.

ETH_ID
Module Identification Register (0004$_H$) Reset Value: 00BF C0XX$_H$

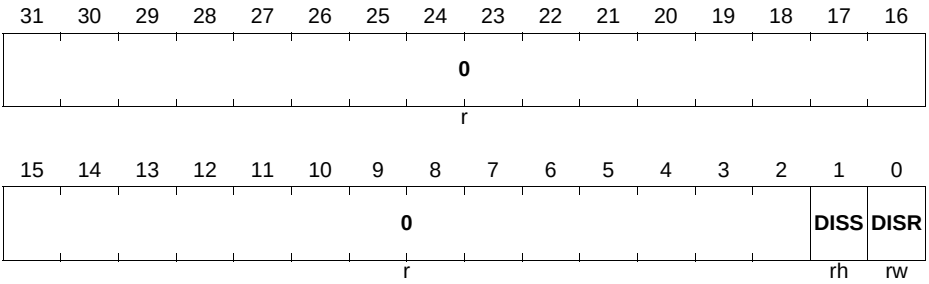


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: C0$_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the Ethernet MAC: 00BF$_H$

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock for the module.

ETH_CLC
Clock Control Register **(0000_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. The disable request is delayed internally until all pending transactions on the master and slave interface to the SPB are completed.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the $f_{Ethernet\ MAC}$ clock is switched off and the Ethernet MAC module is disabled (DISS set).

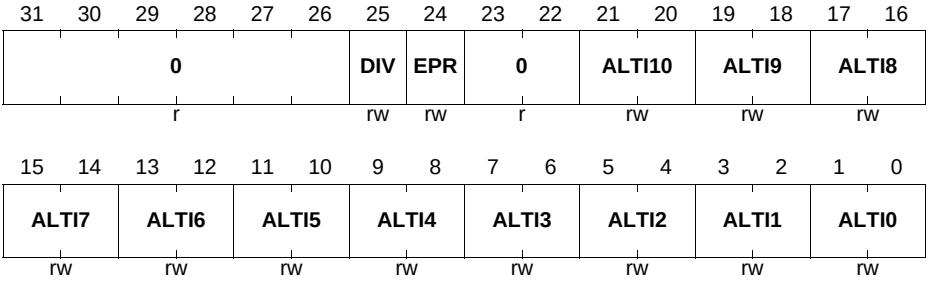
Input and Output Control Register Functions

The Input and Output Control Register GPCTLx determines for the Ethernet MAC which alternate input is to be used and selects the phy interface.

This register is reset by power on reset and hardware reset.

Note: This register is not affected by the local module reset!

ETH_GPCTL
Input and Output Control Register (0008_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
ALTIy **(y = 0-10)**	[2*y+1: 2*y]	rw	**Alternate Input Select** Selects the alternate input for channel y. If no signal is connected to an alternate input, it is connected to GND. 0000_B Alternate Input 0 selected 0001_B Alternate Input 1 selected $\ldots_B$ … 0011_B Alternate Input 3 selected

Field	Bits	Type	Description
EPR	24	rw	**External Phy Interface RMMI Mode Bit** Used to select the phy interface during module reset of MAC triggered by setting SWR bit of DMA Register 0. If set during this reset, RMII is selected and an internal predivider divides the clock clk_rmii_i from pin ETHRXC by 2 or 20 and provides it to the internal signals clk_tx_i and clk_rx_i. The division factor depends from the signal mac_speed_o, controlled by bit FES in Register 0 (MAC Configuration Register). If cleared during the module reset said above, MII is selected and the divider is not active but the clock signals clk_tx_i and clk_rx_i are connected directly to the referring port pins. Note that the status of this bit is latched in during module reset only.
DIV	25	rw	**Module Clock Divider Request Bit** If set, f_{AHB} and f_{RAM} will be divided by 2.
0	[31:26], [23:22]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset, all clocks are switched off and the Ethernet module is disabled (DISS set). In this case, only register CLC is accessible for configuration.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

ETH_ACCEN0

Access Enable Register 0 ($000C_H$) Reset Value: FFFF FFFF$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN31	EN30	EN29	EN28	EN27	EN26	EN25	EN24	EN23	EN22	EN21	EN20	EN19	EN18	EN17	EN16
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN15	EN14	EN13	EN12	EN11	EN10	EN9	EN8	EN7	EN6	EN5	EN4	EN3	EN2	EN1	EN0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

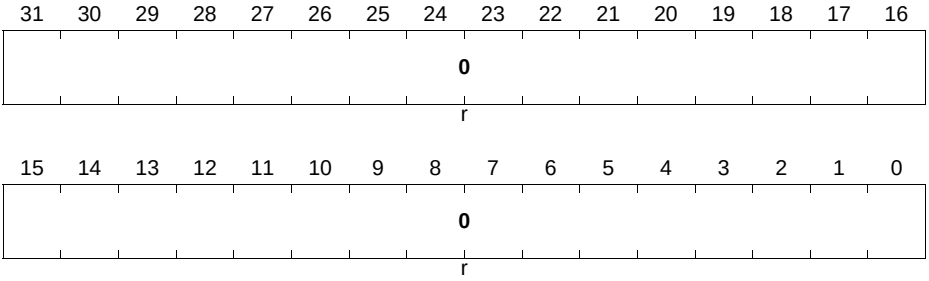
Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ETH_ACCEN1

Access Enable Register 1 **(0010_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

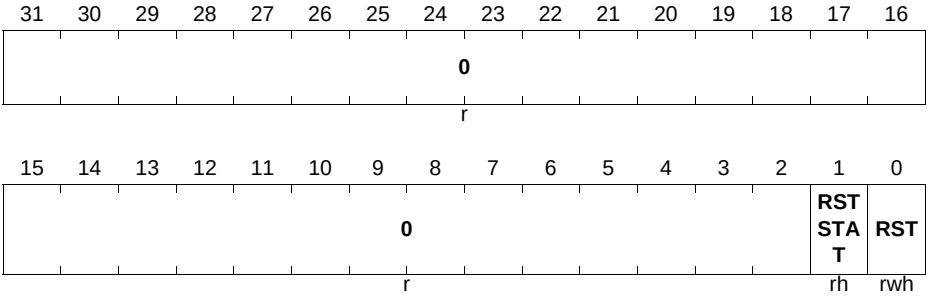
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

ETH_KRST0

Kernel Reset Register 0 **(0014_H)** **Reset Value: 0000 0000_H**



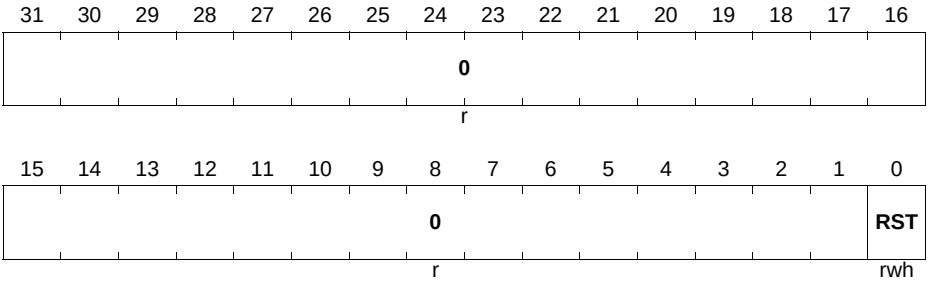
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set and both: master and slave interface are idle. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is

necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

ETH_KRST1
Kernel Reset Register 1 **(0018_H)** **Reset Value: $0000\ 0000_H$**

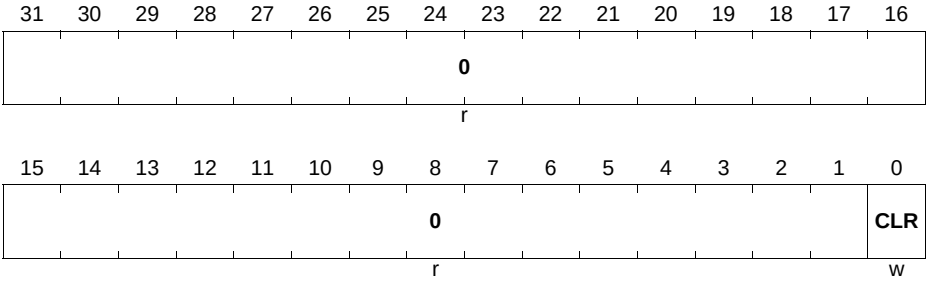


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set and both: master and slave interface are idle. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

ETH_KRSTCLR
Kernel Reset Status Clear Register (001C$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

30.6 Revision History

This User's Manual is based on: **Revision DWC Ether MAC 10/100/1000 Universal, V3.7a**".

Table 30-54 Revision History

Version Number	Changes to Previous Version
Rev_0.1	First Draft in IFX template
Rev_0.2	First configured version
Rev_0.3	First TS version
Rev_0.4	First ITS version
Rev_0.5	TS version
Rev_0.8	Removed unresolved cross references, Removed signal sbd_pwr_down_ack_o Added signals eth_phy_rmii_i and eth_rmii_speed_10_i
Rev_0.9	Updated Module Implementation Chapter
Rev_1.1	Expanded GMACREG19 headers for extraction
Rev_1.5	Removed non configured registers: GMACREG48 .. 54, DMAREG10 ..11 Updated reset values of registers GMACREG0, 8, 9, DMAREG22 Added clarification that normal descriptor format can not be supported
Rev_1.6	Updated Registers Chapter
Rev_1.7	Changed bit names to comply with compiler requirements - MAC_CONFIGURATION.2KPE -> TWOKPE - BUS_MODE.8xPBL -> PBLx8

Table 30-54 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.8	P21.1 ETHMDIO: No more support of I/O direction control by HW. P21.3: ETHMDIO mapping added Outputs remapped from O5 to O6 on all output ports P11.11 ETHCRSDV renamed to ETHCRSDVA P11.11 ETHCRSDVA: added ETHRXDVA and ETHCRSB P11.14 ETHCRS renamed to ETHCRSA P11.14 ETHCRSA: added ETHRXDVB and ETHCRSDVB P11.12: ETHTXCLKB mapping added P11.5 ETHTXCLK renamed ETHTXCLKA Fixed Synopsys issue: 9000522312 ("MAC inserts incorrect IP Payload Checksum at incorrect location for IPv6 packets with Authentication extension header") Fixed Synopsys issue: 9000522313 ("MAC provides incorrect IP Payload Checksum Error status when IPv6 packet with Authentication extension header is received") P21.2: ETHMDC added
Rev_1.9	Added port configuration hints for TXD0, TXD1, TXEN and REFCLK P11.13: ETHRXER renamed to ETHRXERA P21.7: ETHRXERB added
Rev_1.10	Port configuration changed for products with RMII only
Rev_1.11	Port configuration changed for TXD2 and TXD3 Added Port configuration for TC23x
